µR/hr	- microRoentgen per hour		
MV	- Magic Valley		
NIST	- National Institute of Standards and Technology		
nCi/L	- nanocuries per liter		

## Introduction

The State of Idaho, Department of Environmental Quality, Idaho National Laboratory Oversight Program (DEQ-INL OP) conducts an Environmental Surveillance Program (ESP) at locations on the INL, near the boundaries of the INL, and at distant locations to the INL in accordance with accepted monitoring procedures and management practices. This program is designed to provide the people of the state of Idaho with independently evaluated information about the impacts of the Department of Energy's (DOE) activities in Idaho.

The primary objective for DEQ-INL OP's ESP is to maintain an independent environmental monitoring and verification program designed to verify and supplement DOE's environmental data and programs. This program also provides the citizens of Idaho with information on current and proposed DOE programs that has been independently evaluated to enable them to reach informed conclusions about DOE activities in Idaho and potential impacts to public health and the environment.

Results of the ESP are published using two distinct reporting formats: quarterly data reports and an annual ESP report. The annual ESP report is designed for a broad audience and summarizes the results of the ESP for the previous four quarters. The annual report's primary emphasis is to focus on trends, ascertain the impacts of DOE operations on the environment, and confirm the validity of DOE monitoring programs. This quarterly report is designed to document the results of the ESP on a quarterly basis and provide detailed data to those who wish to "see the numbers." It is organized according to the media sampled and also provides a quality assurance assessment.

## Air and Precipitation Monitoring Results

The ESP operated eight air monitoring stations on and near the INL as well as two monitoring stations distant from the INL during the first quarter, 2016 (**Figure 1**). These stations employed instrumentation for collecting airborne particulate matter, gaseous radioiodine, precipitation, and water vapor for tritium analysis (**Table 1**). The Shoshone-Bannock Tribes operated an air monitoring station located at Fort Hall. The Fort Hall station uses identical instrumentation and sampling protocol as the ten stations operated by the ESP. The DEQ-INL OP reports the Fort Hall station data as an additional distant site.

Airborne particulate matter was sampled using high-volume total suspended particulate (TSP) air samplers. Starting in the first quarter of 2013 a new sampler (HVP 4304) is operating side by side at Idaho Falls air station with the current sampler (HVP 3804). The new sampler (HVP 4304) is being operated to test dependability and durability under field conditions. Weekly gross alpha and gross beta particulate radioactivity results for filters from the TSP samplers are presented in **Appendix A** and summarized as a range of results in **Table 2**. Results are within the expected historical range.

Composites of filters collected using TSP samplers during the course of a calendar quarter are analyzed using gamma spectroscopy. Typically, gamma spectroscopy results are only reported when exceeding a minimum detectable activity (MDA) or minimum detectable concentration (MDC). Gamma spectroscopy results for the first quarter of 2016 for TSP filters are presented in **Table 3**. The only reported gamma-emitting radionuclide was beryllium-7, a naturally occurring, cosmogenic radionuclide.

Annual composites of filters collected using TSP samplers are also analyzed using radiochemical separation techniques. Results from the annual composite analyses are typically presented in the following year's first quarter report. The samples are analyzed for Strontium-90, Plutonium-238,

Plutonium-239/240, and Americium-241 (**Table 6**). Measurable quantities of these radionuclides are expected in the environment due to historic above ground testing of nuclear weapons. DEQ-INL's action levels of 190 for Americium-241, 1900 for Strontium-90, 210 for Plutonium-238, and 200 for Plutonium-239/240 (in  $1 \times 10^{-6}$  pCi/m<sup>3</sup>) are 10 percent of the compliance values listed for the specific radionuclides in 40 CFR 61, Appendix E, Table 2. Field sample concentrations which exceed these amounts require further investigation. Results exceeding MDC for the 2015 annual composites are as follows: the Howe and Sand Dunes samples exceeded MDC for <sup>238</sup>Pu; and Atomic City, Howe, Rest Area, and Sand Dunes samples exceeded MDC for <sup>239/240</sup>Pu. Though minimally exceeding the MDC, the results are well under the specified regulatory limits and DEQ-INL OP's action levels.

Radioactive iodine samples are collected weekly. Samples are collected by drawing air through a canister filled with activated charcoal using a low-volume air pump. The activated charcoal contained in the canister traps the radioiodine by adsorption onto its porous surface. Each week, canisters are collected from all eleven air monitoring stations and analyzed together as a composite. If Iodine-131 is detected in this grouping, the canisters are individually analyzed. No radioactive isotopes of iodine, specifically Iodine-131, were detected on the weekly charcoal cartridges used to collect this nuclide during the first quarter.

Atmospheric moisture was collected by drawing air through hygroscopic media at each of the 11 monitoring stations. This moisture was stripped from the hygroscopic media and analyzed to calculate the atmospheric tritium concentration. Reported values are the result of either a single sample or a weighted mean based upon the volume of air sampled when more than one atmospheric moisture sample was collected during the calendar quarter. Atmospheric tritium was detected above the minimum detectable concentration (MDC) during the first quarter of 2016 at the Howe and Idaho Falls sampling stations. There is one individual sample within the weighted mean that exceeded MDC located at the Sand Dunes sampling site: 0.16 pCi/m<sup>3</sup> (MDC 0.10 pCi/m<sup>3</sup>). While the results are above MDC they are still well below the DEQ-INL OP action level of 150 pCi/m<sup>3</sup> (40 CFR 61). Average atmospheric tritium concentrations are presented in **Table 4**.

Precipitation samples were collected at six monitoring locations during the first quarter of 2016. Precipitation samples were analyzed for tritium and gamma-emitting radionuclides. Reported values were either the result of a single sample or a weighted mean when more than one precipitation sample was collected during the calendar quarter. Tritium and gamma-emitting radionuclides were below minimum detectable concentration in precipitation collected during the first quarter of 2016. Tritium and Cesium-137 analysis results are presented in **Table 5**.

Note: Concentrations are reported in  $1 \times 10^{-6}$  pCi/m<sup>3</sup> with associated uncertainty ( $\pm 2$  SD), minimum detectable concentration (MDC), and correspond to filter composites collected during the calendar year.

<sup>1</sup> Measurable quantities of these radionuclides are expected in the environment due to historic above-ground testing of nuclear weapons. DEQ-INL OP's action levels of 190 for americium-241, 1900 for strontium-90, 210 for plutonium-238, and 200 for plutonium-239/240 (in  $1 \times 10^{-6}$  pCi/m<sup>3</sup>) are 10 percent of the compliance values listed for the specific radionuclide in 40 CFR 61, Appendix E, Table 2.

<sup>2</sup> Operated by Shoshone-Bannock Tribes.

<sup>3</sup> Experimental Field Station.

## Environmental Radiation Monitoring Results

The ESP operated 14 environmental radiation stations during the first quarter of 2016 (**Figure 1**). To detect gamma radiation, each station is instrumented with triplicate electret ionization chambers (EIC), and 11 of the stations also are equipped with a high-pressure ion chamber (HPIC) (**Table 7**).

The Shoshone-Bannock Tribes operate an additional environmental radiation monitoring station at Fort Hall equipped with EICs and an HPIC, both of which are owned and operated by the DEQ-INL OP. The DEQ-INL OP reports these results as a distant site.

HPICs are instruments capable of real-time measurements, and are sensitive enough to detect small changes in gamma radiation levels. The real-time gamma radiation measurements collected by the HPICs at each location are radioed to DEQ-INL OP and presented graphically via the worldwide web at <http://www.deq.idaho.gov/inl-oversight/monitoring/gamma-radiation-measurements.aspx>.

EICs are a passive-integrating system that provides a cumulative measure of environmental gamma radiation exposure in the field. EICs are deployed, collected, and analyzed quarterly. EICs offer an inexpensive methodology to measure gamma radiation over a wide area, particularly in regions which do not have a power source. EICs can also provide valuable gamma radiation data in the event of an emergency. For this reason EICs are deployed at an additional 40 locations by DEQ-INL OP in a widespread network around the INL measuring external radiation. This information is tabulated in **Appendix B**.

These two systems are used by DEQ-INL OP to measure external gamma radiation for various radiological monitoring objectives. **Table 8** lists the average radiation exposure rates measured by the HPICs for first quarter 2016. **Table 9** lists the EIC monitoring results for first quarter 2016. Overall exposure rates were within the expected historical range of values observed by DEQ-INL OP for background radiation.

<sup>1</sup>Base of Howe, Big Southern Butte, and Howe Met Tower HPIC electronics had various electronic malfunctions or extreme temperature interference and the data was therefore unusable for determining exposure rates for first quarter 2016.

<sup>2</sup>Rover location was operational between 1/1/2016 and 1/31/2016, and the average shown in the table above for Rover is for this date range. Electronics have since been repaired or replaced and these locations are operating as of second quarter 2016.

**Table 9. Electret ionization chamber (EIC) cumulative average exposure rates, first quarter, 2016.**

Idaho Falls	11.9	2.0

Results are the average of triplicate exposure rate measurements with the associated sample variability ( $\pm 2$  SD), or the 2 measured exposure rates remaining after removal of an outlying value. One of the triplicate measurements is rejected if it is outside the average of the triplicate measurements  $\pm 2$  SD of the historical population variability. Typically, the two most consistent measurements are reported, based on judgment of the data analyst.

## Water Monitoring Results

Water monitoring sites are sampled for the purposes of examining trends of INL contaminants and other general ground water quality indicators and for verifying DOE monitoring results. Sites sampled include ground water locations (wells and springs), surface water locations (streams), and selected wastewater sites. Sample sites have been selected to aid in identifying INL impacts on the Eastern Snake River Plain Aquifer (ESRPA), and are categorized as up-gradient, facility, boundary, distant, surface water, and waste water, (**Figure 2 and Figure 3**). Up-gradient locations are not impacted by INL operations and are considered representative of background ground water quality conditions. Facility sites are sample locations on the INL near facilities, in areas of known contamination, or wells selected to illustrate trends for specific INL contaminants or indicators of ground water quality. Boundary locations are on or near the perimeter of the INL and are down-gradient of potential sources of INL contamination. Distant locations are monitored to provide trends in water quality down-gradient of the INL and include wells and springs used for irrigation, public water supply, livestock, domestic, and industrial purposes. During the first quarter of 2016, 1 facility location was sampled.

Most sites sampled by DEQ-INL OP are sampled with another agency or organization. Samples are collected at about the same time using the same collection equipment as the other agency or organization (co-sampled). DEQ-INL OP verifies work by these agencies monitoring on behalf of DOE by comparing results from co-sampled sites.

Gross alpha and gross beta analyses are conducted as a screening tool for alpha and beta emitting radionuclides potentially released from INL operations. Quantitative gamma analyses are conducted to

identify and determine concentrations of gamma emitting radionuclides. Selected sites are sampled for the man-made, alpha emitting isotopes of plutonium ( $^{238}\text{Pu}$ ,  $^{239/240}\text{Pu}$ ), uranium ( $^{234}\text{U}$ ,  $^{235}\text{U}$ , and  $^{238}\text{U}$ ), and americium ( $^{241}\text{Am}$ ); and beta emitting radionuclides technetium-99 ( $^{99}\text{Tc}$ ), strontium-90 ( $^{90}\text{Sr}$ ), and tritium ( $^3\text{H}$ ), based on historic INL contamination. In the event of suspect or unexpected levels of gross radioactivity, additional samples may also be analyzed for other specific radionuclides.

Gross alpha radioactivity was detected at the lone facility location sampled during the first quarter of 2016. The gross alpha concentration was within the range of concentrations observed for naturally-occurring radioactivity. The EPA maximum contaminant level (MCL) for alpha particles is 15 pCi/L.

Gross beta radioactivity was detected at the facility location sampled this quarter. The concentration observed is consistent with historic concentrations found at this location. The MCL for beta and gamma radioactivity is 4 mrem/year, equivalent to 8 pCi/L if the source is  $^{90}\text{Sr}$ ; 900 pCi/L if  $^{99}\text{Tc}$ ; 20,000 pCi/L if tritium ( $^3\text{H}$ ); or 200 pCi/L if  $^{137}\text{Cs}$ . Man-made, gamma emitting radioactivity was not detected at the sampled facility location. Results for gross alpha; gross beta; and man-made, gamma emitting  $^{137}\text{Cs}$  are shown in **Table 10**.

The facility site was sampled for isotopes of plutonium, with the result for  $^{238}\text{Pu}$  reporting as non-detectable (**Table 11**). The result for  $^{239/240}\text{Pu}$  was greater than the MDC; however, the value is less than three standard deviations and is considered a non-detection. Uranium isotopes were also sampled for at the facility site (**Table 12**), with  $^{234}\text{U}$  and  $^{238}\text{U}$  reporting in detectable concentrations. The result for  $^{235}\text{U}$  was greater than the MDC; however, the value is less than three standard deviations and is considered a non-detection. The results observed at the sample site cannot be distinguished from background values, which means the uranium found in the samples is likely to be naturally occurring. The facility site was also sampled for  $^{241}\text{Am}$  and  $^{90}\text{Sr}$  this quarter. Neither nuclide was detected (**Table 13 and Table 14**). Technetium-99 was sampled for and detected; however, the reported concentration is within the expected range for this site (**Table 15**).

Using the standard analytical method,  $^3\text{H}$  was detected at the facility location (**Table 16**). The tritium level found at this facility well is similar to historic concentrations for this site and is consistent with INL waste disposal influences at the INTEC facility. Selected water samples with tritium concentrations not measurable using the standard method (typically a MDC of 130 pCi/L) are analyzed using an electrolytic enrichment method with a much lower MDC of 10 to 14 pCi/L. There were no samples analyzed using the enrichment method for the current quarter; however, sample analyses from four sites collected during previous quarters were completed and presented this quarter (**Table 17**). A backlog of 52 samples remains.

Samples were also analyzed for metals and the results shown in **Table 18**. All results are within their expected ranges. Common ion results are shown in **Table 19** and nutrient results are shown in **Table 20**. All results are consistent with the expected values at each location. Samples were not analyzed for volatile organic compounds (VOC's) this quarter.

## Terrestrial Monitoring Results

The DEQ-INL OP conducts terrestrial (soil and milk) monitoring to characterize deposition and migration of contaminants, and provide independent verification of DOE's terrestrial monitoring programs. Physical soil sampling and *in-situ* gamma spectrometry are used to characterize actual deposition and accumulation of radioactive contaminants in soils. Milk samples are collected to evaluate the potential for ingestion of radioactivity by the population around the INL. No *in-situ* gamma spectroscopic measurements were performed, nor were any soil samples physically collected during the first calendar quarter of 2016.

### Milk

DEQ-INL OP monitors milk for the naturally occurring radionuclide potassium-40 ( $^{40}\text{K}$ ) and man-made iodine-131 ( $^{131}\text{I}$ ). Milk samples are collected on a monthly basis. Results for analyses of milk samples are presented in **Table 21**.  $^{40}\text{K}$  was detected in all samples within the expected range of concentration.  $^{131}\text{I}$  was not detected. Based on measurements of radionuclides in milk, there were no discernable impacts to the off-site environment from INL operations.

**Table 21. Gamma spectroscopy analysis data for milk samples, first quarter, 2016.**

Sample Location/Dairy	Sample Date	Naturally occurring Potassium-40		Man-made Iodine-131 <sup>1</sup>
		Concentration <sup>3</sup>	± 2 SD

<sup>1</sup> <MDC – Less than Minimum Detectable Concentration (approximately 4 pCi/L for iodine-131).

<sup>2</sup> DEQ-INL OP samples collected by the off-site INL environmental surveillance contractor.

<sup>3</sup> Concentrations with associated uncertainties (±2 SD) are expressed in pCi/L.

## Quality Assurance

The measurement of any physical quantity is subject to inaccuracy from errors that may be introduced during sample collection, storage, shipment, measurement, calibration, and the reading and reporting of results. While all of these inaccuracies cannot be quantified with certainty for each analytical result, a quality assurance program can evaluate the overall quality of a data set and, in many cases, identify and address errors or inaccuracies. The DEQ-INL OP quality assurance program is designed to (1) ensure sample integrity, (2) ensure precision and accuracy in the analytical results, and (3) ensure that the environmental data are representative and complete.

This section summarizes the results of the quality assurance (QA) assessment of the data collected for the first quarter of 2016 for the DEQ-INL OP's ESP. It also summarizes the quality control (QC) samples (spikes, blanks, and duplicates) submitted to the Idaho Bureau of Laboratories-Boise (IBL) for non-radiological analyses and to Idaho State University's Environmental Monitoring Laboratory (ISU-EML) for radiological analyses during the quarter. All analyses and QC measures at the analytical laboratories used by the ESP are performed in accordance with approved written procedures maintained by each respective analytical laboratory. Sample collection is performed in accordance with written procedures maintained by the DEQ-INL OP.

Analytical results for blanks, duplicates, and spikes are used to assess the precision, accuracy, and representativeness of results from analyzing laboratories. During the first quarter of 2016, the DEQ-INL OP submitted 50 QC samples for various radiological and non-radiological analyses (**Table 22**).

### Blank Samples

Blank samples consist of matrices that have negligible, acceptably low, or immeasurable amounts of the analyte(s) of interest in them. They are designed to determine if an analysis will yield a "zero" result when no contaminant is present, or a sufficiently low result to serve as an acceptable measure of "background." Blank samples are used to monitor for bias introduced during sample collection, storage, shipment, and analysis. Blank sample results submitted for gross alpha and gross beta screening in air for the first quarter of 2016 are presented in **Table 23**.

Blank sample results for select gamma emitters in air from composited air filters are presented in **Table 24**. Data for blank analyses used to assess data quality for tritium in water vapor in air are presented in **Table 25**. Blank analysis results for radiochemical separation analyses for TSP particulate filters collected during 2015 are presented in **Table 26**. Blank analyses results for radiological and non-radiological analytes in ground and surface water are presented in **Table 27**, **Table 28**, and **Table 29**.

There was one anomaly observed from the assessment of field blank water samples as measured by the analytical laboratories used by DEQ-INL OP for the first quarter of 2016. The anomaly includes a result for Total Alkalinity found at 1 mg/L, which is above the MDC. There was one sample result reported for Total Alkalinity this quarter of 130 mg/L (**Table 19**), which is significantly above the blank value of 1 mg/L; no qualifiers or flags will be attached with any Total Alkalinity results this quarter.

### Duplicate Samples

A laboratory's analytical precision capability, i.e., its ability to reproduce results, is assessed by comparing duplicate sample results. Duplicate samples are samples collected from the same location at approximately the same time and are considered to be essentially identical in composition. The difference between duplicate sample results is expressed as the relative percent difference (RPD), calculated from the following equation:

$$RPD = (R_1 - R_2) / ((R_1 + R_2) / 2) * 100$$

Where:

$R_1$  = First sample result.

$R_2$  = Second sample result.

A relative percent difference of up to  $\pm 20$  percent is acceptable. For non-radiological analysis, the RPD is used to compare each set of duplicate samples in which both of the results exceed five times the detection level. If one or both of the duplicate sample results are less than five times the detection level, the absolute difference between the two results is acceptable if it is less than or equal to the method detection limit.

For radiological analysis, the RPD is calculated (using the above equation) to compare duplicate samples if both duplicate results are greater than the sample-specific minimum detectable concentration (MDC). DEQ-INL OP also considers duplicate sample results that have an absolute difference of no more than three times the pooled error (or “3 sigma”) to be in acceptable agreement. This is accomplished using the following equation:

$$|R_1 - R_2| \leq 3(S_1^2 + S_2^2)^{1/2}$$

Where:

$R_1$  = First sample result.

$R_2$  = Second sample result.

$S_1$  = Uncertainty (one standard deviation) associated with the laboratory measurement of the first sample.

$S_2$  = Uncertainty (one standard deviation) associated with the laboratory measurement of the second sample.

Radiological duplicate sample results satisfying either the RPD or pooled error test are considered acceptable.

One duplicate water sample comparison was completed for ground water; results are presented in **Table 30** for radiological analyses. The duplicate comparison passed DEQ-INL criteria for the first quarter of 2016.

## Spiked Samples

Spiked samples are samples to which known concentrations of specific analytes have been added (spiked) in order to assess the bias a laboratory may have in accurately measuring these analytes. To determine agreement after laboratory analysis, DEQ-INL OP calculates the ratio of the spike concentration determined from the laboratory measurement to the known spike concentration in the sample. This result is known as percent recovery (%R) and the acceptable range used by DEQ-INL OP is  $100 \pm 25$  percent. Additionally, all results were qualified as “estimates (J)” if the associated quality control spike sample had a recovery of 50 – 74% or 126 – 150%, provided that each result was greater than the instrument detection limit (IDL). All results were qualified as “rejected (R)” if the associated quality control spike sample had a recovery of  $< 50\%$  or  $> 150\%$ , provided each result was also greater than the IDL.

Spike samples were not used during the first quarter of 2016.

DEQ-INL OP also prepares additional “spike-like” quality control samples to assess ambient radiation measurement bias. Once per quarter, DEQ-INL OP irradiates a number of electret ionization chambers (EICs) to verify EIC response. Irradiations of EICs are conducted in a repeatable geometry to a known exposure of near 30 mR and two additional higher and lower exposures, ranging from 15 to 60 mR. EIC responses are compared directly with the exposure received from the NIST traceable cesium-137 source provided by ISU-EML. EIC response is considered acceptable if each measurement has a percent recovery of  $100 \pm 25\%$  when compared to the known irradiated quantity. The irradiation results for first quarter 2016 are presented in **Table 31**. Real-time pressure correction is used to calculate the net exposure measured by these EIC control sets. All EIC spiked samples passed the DEQ-INL OP criteria.

### **Analytical QA/QC Assessment**

Other than those listed above, no issues involving sample chain of custody, sample holding times, and the analysis of blank, duplicate, and spiked samples were observed during the first quarter of 2016, which significantly affected data quality. Methodologies and data reports issued by the contracting laboratories generally conformed to the requirements of DEQ-INL OP during the first quarter of 2016.

Data usability is the measure of data that is not rejected compared to the amount that was expected to be obtained. The overall data usability rate for the first quarter of 2016 met the minimum criteria of the DEQ-INL OP ESP and is summarized in **Table 22**.

### **Preventative Maintenance and Equipment Reliability**

All equipment was calibrated and checked according to prescribed periodicity. During the first quarter of 2016, the radioiodine pump was replaced at the Montevue and Experimental Field Station sampling stations. Service reliability for air sampling equipment for the first quarter of 2016 is summarized in **Table 32**.

### **Conclusion**

All data collected for the first quarter of 2016 have been assigned the applicable qualifiers to designate the appropriate use of the data. In addition, all data have been verified and deemed complete meeting the requirements and data quality objectives established by DEQ-INL OP.

**Table 22. Summary of the analytical performance and usability of the analyses performed for the DEQ-INL OP ESP, first quarter, 2016.**

**Table B.1. continued. Results for all electret ionization chamber (EIC) locations, first quarter, 2016.**

Sample Location	Net Corrected Exposure Rate ( $\mu\text{R/hr}$ ) <sup>1</sup>	$\pm 2$ SD ( $\mu\text{R/h}$ )
Rover	12.9	0.2
Hamer	15.7	3.1
Sugar City	16.1	1.4
Roberts	12.4	1.1
Big Southern Butte	10.9	0.4
<sup>1</sup> Results are the average of triplicate exposure rate measurements with the associated sample variability ( $\pm 2$ SD), or the 2 measured exposure rates remaining after removal of an outlying value. One of the triplicate measurements is rejected if it is outside the average of the triplicate measurements $\pm 2$ SD of the historical population variability. Typically, the two most consistent measurements are reported, based on judgment of the data analyst.
