P R O C E E D I N G S

HEARING OFFICER LAWRENCE: This is In The Matter of Air Quality Permit to Construct P-2019.0047. It is BEQ Case No. 0101-22-01 and the OA -- the Office of Administrative Hearings Case No. 23-245-01.

And before we get any farther, I just got to say, I do have serious imposter syndrome being in the room like this and up here. I was going to really freak out if I had to be up here, but thankfully Vanessa is able to set up shop over here.

So why don't we start off with some introductions and appearances. My name is Dylan Lawrence. I am the appointed hearings officer in this matter on behalf of the Office of Administrative Hearings. Also present is Leslie Hayes.

And I have a disclaimer that I am going to read about that in a second, but why don't we also take appearances with the parties starting with the petitioners.

MS. THROWER: Yeah. Julia Thrower for Save the South Fork Salmon.

MR. HURLBUTT: Bryan Hurlbutt for the Nez Perce Tribe and Idaho Conservation League.

HEARING OFFICER LAWRENCE: How about the DEQ?

MR. SHACKELFORD: I am John Shackelford with the attorney general's office representing the Department of Environmental Quality.

MS. FLOYD: Tiffany Floyd, I'm the air quality commission administrator for the DEQ.

MR. POOSER: Christopher Pooser with Stoel Rives representing the intervenor, Perpetua.

MS. MCINTYRE: Krista McIntyre, Stole Rives, also representing Perpetua.

MR. FOSTER: Wade Foster with Stole Rives also representing Perpetua.

HEARING OFFICER LAWRENCE: All right. Thank you everybody. So the disclaimer that I'm going to read here, bear with me, it is a little formal. This has to do with Leslie's presence here.

You will note that Lesley Hayes is in attendance at this hearing today. The Office of Administrative Hearings is statutorily charged with the duty to implement the system for monitoring the quality of contested case proceedings and such other proceedings as are conducted by the Office of

Administrative Hearings in accordance with Section 67-5280(2)(a) and (b) Idaho Code.

Ms. Hayes is here as part of that monitoring process and will not be participating in these proceedings, instead only observing the proceedings. Ms. Hayes will not be participating in the decision in this case or the outcome of these proceedings in any way as I am the hearing officer specifically appointed to make the independent and unbiased decision pursuant to Idaho Code Section 67-5282(1)(f).

If a process question arises during this hearing I have discretion to determine whether it is necessary to resolve in order for the hearing to proceed and to clarify for the parties what the process is for purposes of these proceedings only. If necessary, I may then confer with the Office of Administrative Hearings for purposes of determining how that process question should be resolved in future proceedings.

Before I begin, are there any questions?

No. Okay. Hopefully that is as much as you need to hear from me today at one time, at least.

So we're here on a hearing for pending

motions for summary judgment. The hearing is being recorded by Vanessa Gosney, our court reporter. So just if you could, make sure to project towards her direction, that would be helpful, because she does have a microphone over there as well.

Before we get started are there any stipulations among the parties that I need to be aware of that affects today's proceedings? You guys haven't settled the case, huh? Okay. I can check that one off the list.

So as you guys know, on Friday I issued a notice to try and put some side boards on the hearing today. I feel like there has been a lot of briefing, it has all been very good. To me it would seem like a waste of your time and resources to make you regurgitate everything to me that was in those. So my goal was to identify issues that I'm still sort of struggling with or can use some more sort of input on. And even since Friday I have reviewed stuff -- stuff, I shouldn't use that word on the record -- materials in more detail and feel even stronger that for my purposes today I'd like to focus on the exclusion of the access road from ambient air.

I know in that notice I also mentioned

potentially walking through the language of the -- the air rule was the 210-14 about T-RACT and the evaluation of economic and environmental factors. But I spent the better part of Tuesday morning going through all that and I feel much more up to speed on it now. So the list of questions that I issued on Friday dealing with the exclusion of the access road from ambient air is what I would like to focus on today.

But just for planning purposes before we get into that, do any of the parties feel like there's any other issues that we need to talk about here today? And I'll start with the petitioners.

MR. HURLBUTT: I was planning to hit on three of the sub-issues in the outline, just to clarify a few points quickly, if that's okay.

HEARING OFFICER LAWRENCE: Can you tell me which ones?

MR. HURLBUTT: Yep. So 2 -- 2B, the 93.3 percent of PM emissions. And then three parts, B and C, the T-RACTs and averaging of arsenic.

HEARING OFFICER LAWRENCE: Okay. How about DEQ? I mean, obviously, if they are going to present on that you will want an opportunity to

respond. But is there anything else that you want to cover today?

MR. SHACKELFORD: My thought had been to cover the standard of review, although I don't even think that was listed in your requested -- or suggested topic, so if there's nothing else that needs to be said on that, then no, no other talking points.

HEARING OFFICER LAWRENCE: Okay. Personally I feel like I am good on the standard of review. Early on in this case, and especially, as I mentioned, given my experience ten years ago or so in another case, I feel like I'm on top of it. But if you want -- if there's any last minute things you want to say or to put a finer point, that's great. But we'll leave that for the end if we have time remaining, how about that?

MR. SHACKELFORD: That would be fine.

HEARING OFFICER LAWRENCE: Okay. And Perpetua Resources?

MR. POOSER: There's nothing specific. We wanted to be here to be responsive to your questions as well as the issues that the petitioners raise.

HEARING OFFICER LAWRENCE: Okay. So why

don't we -- why don't we focus, to begin, on the exclusion from ambient air. My cognition peaks mid-morning after my second cup of coffee and then steadily declines as the day goes on. So we could really start with that one. I'd say let's really start with that and then take a break. And then I may even think about time limits on some of these other issues, but want to give you the opportunity to at least, if there are things that you think have flown under the radar or need to be highlighted, to do that.

So let's go ahead and proceed on the ambient air issue. I don't -- in terms of time limits, I'm inclined to just put everybody on the honor system. And if I feel that somebody is getting off track or repeating themselves, then I will jump in, but -- because to me, it is one I want to make sure we cover -- I kind of want to let that one have some room to breathe.

So I'd like to start with petitioners. Obviously it's your guys' petition that determines the scope of this and you ultimately have the burden.

After petitioners I would like to hear from DEQ because they are, of course, the

respondent and I think they have the most sort of substantive declarations in the record that deal with these issues.

And then once DEQ finishes, go to Perpetua Resources to see if there's anything you think anything DEQ has missed or you would like to emphasize.

And then briefly back to petitioners just to, you know, if there is anything you want to highlight or emphasize before we wrap up the discussion.

Does that sound like a reasonable procedure?

MR. SHACKELFORD: Yes.

HEARING OFFICER LAWRENCE: Okay. For the record, I'm taking -- any time I ask a question and there's silence, I am taking that as an affirmative answer.

Okay. Well, so -- and by the way, just to clarify. With those questions that I -- you issued about exclusion from ambient air, we don't have to go in that order, that was kind of a little bit of a brain dump and I definitely don't foresee us like walking through each one of those individually. When I'm talking about going to the

parties, it's like this is your time to tell me anything you want about exclusion from ambient air and then we move on.

So with that, the floor is yours, petitioners.

MS. THROWER: All right. Good morning, Mr. Hearing Officer. My name is Julie Thrower here for Save the South Fork Salmon and also Idaho Conservation League and Nez Perce Tribe.

HEARING OFFICER LAWRENCE: Can you speak up just a tad bit? There is some sort of background noise.

MS. THROWER: Sure. I am going to just follow the questions that we have in Attachment A, so obviously I'm sure you will jump in if there are other issues you want covered. I'll just start by reading the question and then I will go ahead and answer.

So the first question was, "Petitioners appear to assert two separate bases of error, one, Perpetua lacks the legal authority to complete access, claim number 11, and two, the permit provisions regarding access control are inadequate, number 12. Is that an accurate characterization?"

Generally, yes. I'll just start with a

little bit of background.

As you know, the Clean Air Act seeks to protect human health and the environment from emissions that pollute ambient air. The regulatory definition of ambient air, which is incorporated in DEQ's air rule, is that portion of the atmosphere external to buildings to which the general public has access. Accordingly, an applicant must establish an ambient air boundary and include modeling demonstrating that the proposed potential emissions from the facility will maintain ambient air quality standards at the point of compliance, or essentially outside that ambient air boundary.

It's been EPA's long-standing policy, as we discussed in our briefs, that the facility must have both legal authority and practical ability to preclude public access to areas that are not ambient air.

This permit, DEQ and Perpetua, have not claimed that the air along the Stibnite Road access route is ambient air. They never have. They have not tried to model the air above that access route as ambient air during this entire approval -- permit approval process. Yet, this permit does not preclude public access to that route. That's a

fundamental requirement under EPA's long-standing ambient air policy and the Clean Air Act, and this permit did not demonstrate that that is being done.

So one of the issues is, as you stated in your question, that Perpetua has not demonstrated it has a legal authority to preclude public access and therefore it cannot exclude the road from ambient air protections.

The second issue, you asked, "Is the permit provisions regarding access control inadequate?"

In a nutshell, yes, that -- that is our claim. Perpetua's plan to require the public to sign a waiver before traveling through this access road is insufficient to practically preclude access, particularly when they don't have legal authority to do so. The practical ability to preclude access -- the public's access is hampered by that lack of legal authority.

So in order to get around this problem, what DEQ decided is that they'll have the public sign a waiver. They've created a new class of people called "guests of the facility" that is not anywhere in EPA's air policy nor in DEQ guidance and, in fact, conflicts with that policy and

guidance.

So our claim is, is that based on that characterization and allowing people to go through this area, the road that is not ambient air, it is not monitored for public health protections in compliance with ambient air quality standards, that it was arbitrary and capricious for them to do so.

So question two. "Is there anything in the record regarding the general public's need to utilize the road through the SGP, or Stibnite Gold Project, for example, to access trails, campgrounds and other communities, et cetera?"

Yes. There are several statements in the record that document the public's interest on traveling through this road.

And if I may approach, I have a couple of maps that I think will help, because they're in color, help explain or understand some of the statements from the record that I'd like to pull out.

HEARING OFFICER LAWRENCE: So these documents are in the record already?

MS. THROWER: The first map, it is record number PET532. This is in Appendix E of the statement of basis, which is the draft access

management plan.

HEARING OFFICER LAWRENCE: I have a good color copy over here.

MS. THROWER: Okay. If I may approach, I will still give you this, because I do have another map for illustrative purposes only.

The second map is from the recreation specialist report for the Stibnite Gold Project supplemental draft environmental impact statement. And as I said, it just provides a little bit more detail compared to the first map from the statement of basis. And I just want to use it for illustrative purposes so that when I read these statements from the record, you'll be able to kind of place them on the map. And also, I'm directionally challenged. So if I say "east" I might mean west, so obviously you'll have some visual to realize the area in that respect.

So looking at the first map, I'm sure everyone is well-oriented with these maps, but the cross-hatched area on the top right-hand corner is the project operations boundary or the air -- ambient air boundary. West of that to the northwest is Yellow Pine, the community of Yellow Pine. And to the east of that cross-hatch there is

a black line going through the cross-hatched area and going out east into the Payette National Forest and Frank Church Wilderness -- Frank Church River of No Return Wilderness. That line represents a road that is open to the public, it's a forest service road, and that does access several important recreation areas.

What I would like to point out on this map is there's an intersection on the east side of the cross-hatch area, and that road, which is a red road, going south along the border of the operations boundary or the ambient air boundary, that road -- this is a map of the proposed project. That road, which is, if you follow it down, is later labeled Brent Law Road. Most of that road around the operations boundary does not exist; that is what is proposed to be built.

So currently people going to Yellow Pine -- and you can see on the left-hand side, the lake in the upper left-hand corner is where McCall is. Going down to the lake on the lower left-hand corner is where Cascade is. Those are the two major population centers in this area.

So access, a lot of people access Yellow Pine through the road going from north and

northeast from McCall, go through Yellow Pine, and then they go through the project area and out east on that road to other recreational areas.

So I will just point out a few statements in the record that establish that there are areas that are of important access to the community.

So on record number PET310, this is from the statement of basis. It says, "In response to comments from local community citizens" --

HEARING OFFICER LAWRENCE: Sorry to interrupt. Can you repeat that reference?

MS. THROWER: Yeah. It is PET310, from the statement of basis.

And it says, "In response to the comments from local community citizens, PRI," Perpetua, "will manage an access route to provide the general public with limited access through the SGP site between Stibnite Road and Sugar Creek and Thunder Mountain Road at Meadow Creek."

Continues down a sentence later, "The proposed Stibnite Road access route through the SGP site is meant to provide control through site access that is safe, provides travel time comparable to current conditions, and is consistent

with the United States Forest Service Travel Management Plan."

Also from the statement of basis, Appendix E, which is called the access management plan, on PET527, in the first -- excuse me, in the second paragraph it says, "The United States Forest Service system road that passes through Stibnite extends from the village of Yellow Pine eastward along the East Fork of the South Fork of the Salmon River approximately 14 miles. Stibnite Road then continues south through the historic mine site and connects with Thunder Mountain Road on the eastern portion of the proposed SGP. This route also allows for access to Meadow Creek Lookout Road."

And so if you look at that second map I handed out from the recreation specialist report, you can see in sort of the lower half of the map, there's the Stibnite Road on the left-hand side and kind of the third -- two-thirds of the way down there's Yellow Pine. And if you follow that out, that's Stibnite Road, which follows the East Fork of the South Fork of the Salmon River into the Stibnite mining district.

And it is a little hard to see, it's not -- it's not very prominent, but there is a gray

line that goes out east into that area where there's purple bubbles around it, and that is trailheads from Monumental Summit and Lookout Mountain and Thunder Mountain. So those are established trailheads in US Forest Service land.

And then again, on that same page, it says, "Following the representation" -- "Following the presentation of the proposed public access routes described above in Midas Gold's PRO, an alternative public access route has been proposed by Midas Gold and would pass through the SPG mine site."

So there is another statement, there's several others, but I'll just give you those cites. I don't want to take up time reading these.

Another one, also from the access management plan, at PET529. The first full paragraph talks about different points, Thunder Mountain Road and beyond, that are important recreational areas for the community to access.

Also, I haven't -- this is the community access. I haven't talked about access for the Nez Perce Tribe. They use the area for their hunting, fishing and gathering, and their access and their interest to a lot of the area and the recreation --

these areas around the Stibnite Gold Mine is vast and is --

HEARING OFFICER LAWRENCE: Right. And they went into a fair amount of detail on that in the declarations on the standing issue, right?

MS. THROWER: Right. Yes.

HEARING OFFICER LAWRENCE: I have read those pretty extensively.

MS. THROWER: And as you pointed out, on the standing declaration for Save the South Fork Salmon, in particular Zack Seres's declaration, talks about how he goes through that road to access that Monumental Summit area.

HEARING OFFICER LAWRENCE: Right.

MS. THROWER: So number three -- I think that will be the longest one. Number three, "Is there anything in the record regarding the nature of Perpetua's property interest in the Stibnite Gold Project and its legal ability to control access?"

Yes. Some of the statements are in that draft access management plan, Appendix E of the statement of basis. They provide some understanding of both Perpetua's property interest in the road and their legal ability to control or

preclude access.

HEARING OFFICER LAWRENCE: Was that back on 529?

MS. THROWER: 527, PET527. That talks about the US Forest system road that passes through -- passes through Stibnite and extends from the village of Yellow Pine. That's a statement I read for the other question. So that provides us with an indication that that is not a private road, that is a US Forest Service system road and therefore it is a public road. And it is managed in accordance with the forest service's travel management plan, which is also one of the statements I read before from the Appendix E.

So any legal ability for Perpetua to control access comes from the forest service once it approves the final record of decision. That decision, whether to open this road or to close this road, needs to be consistent with the forest service's access management plan for the Payette National Forest. That's the governing document that tells people what types of uses are allowed on different roads. And currently, that Stibnite Road is open to public use and public travel by motorized use.

The access management plan at PET528 through 529, Section 2.2, discusses or has a section that is labeled the "SGP NEPA." That discusses the whole process and provides insight into what authority Perpetua or DEQ have to keep this road open or closed. And basically it says this is what the forest service is trying to decide, not quite whether it is going to be open or closed, but the alternatives that are being proposed in the NEPA process are two different alternatives for a road that would remain open and go through the Stibnite Gold Project area.

So it is only the forest service that can give legal authority to Perpetua to be able to preclude public access. In other words, they could say the road can stay closed. It may potentially need to modify its travel management plan. They would do that in the NEPA process. But that road needs to -- it will remain open until the forest service makes that decision to close it. And as I said, right now, during that NEPA process, the two alternatives that are on the table leave that road open.

To the contrary, there's no documentation that I am aware of in the record that

validates Perpetua's claim that it does have legal authority to preclude access. And in fact, DEQ's response to comments also indicates that the agency did not review any documents to confirm that Perpetua has legal authority to close the road down or to preclude public access.

So on PET570, response to comments, it says, "PRI has asserted they have complete and sole authority to control access to or through the facility, granting or excluding access at their discretion to anyone wishing to visit the site or pass through the site." That statement indicates -- it is a response to a comment. So it's not even -- you know, this is a response of someone saying we don't -- this isn't right. EPS's response to comments didn't say, hey, we've documentation here, here or there. They have clearly just taken Perpetua's word for it, you know, trust but not verify, right?

HEARING OFFICER LAWRENCE: On that point, do you have -- are there legal authorities that talk about how far DEQ is supposed to go in verifying that sort of thing versus relying on -- relying on an application that you are certifying under penalty of perjury what you are saying is true? So

what -- what is out there that tells us how far DEQ has to go down that road --

MS. THROWER: Right. And that touches on question four --

HEARING OFFICER LAWRENCE: -- no pun intended.

MS. THROWER: -- question four. Well, you know, just one thing under the Idaho Administrative Procedures Act, you know, petitioners can bring a claim for that an agency made a decision without substantial evidence. So if there's nothing in the record and the agency, you know, just made a decision based on that, you know, there's just authority just in the process or in the claims in the Administrative Procedure Act that indicate that an agency when making a decision should base that decision on substantial evidence.

This is from the Ninth Circuit. But there is a recent case called the Rosemont decision that touches on that issue as well.

So in the Rosemont case, this is a copper company that had a valid mining claim for land work proposed to locate a mine, however, its mining plan of operations proposed to dump waste rock onto adjacent National Forest Service land.

The United States Forest Service argued that they approved the mining operation because dumping of waste rock was a use of reasonably incident to mining operations and it assumed that Rosemont had valid mining claims on the national forest where it proposed to dump the waste.

The district court found, and the Ninth Circuit affirmed, that the forest service could not proceed with just the assumption that those mining claims were valid. It didn't find that the forest service had any basis for concluding that. And thus its decision to allow the mine to dump its waste on national forest land was arbitrary and capricious. And that citation to that Ninth Circuit case is 33 F.4th 1202. And that's a 2022 decision.

HEARING OFFICER LAWRENCE: When did we get to the 4th of the federal reporters? That's news to me.

MS. THROWER: I don't know.

HEARING OFFICER LAWRENCE: Okay.

MS. THROWER: So question number 235, "To what extent are DEQ's enforcement authorities relevant to these issues?"

You know, I think they're relevant at

basically the permitting level. It must require an applicant to include modeling to demonstrate that a proposed potential emissions from the facility will maintain ambient air quality standards in areas of where the public is allowed to access. It can, as part of the permit, require that Perpetua monitor that route to ensure that the ambient air quality standard is maintained. However, once this permit is approved, as the permit now stands, there are no air quality standards that DEQ can enforce or do anything about over that road.

HEARING OFFICER LAWRENCE: But if -- if Perpetua wasn't doing the things that the permit says in terms of controlling access, is there ability to then redo anything of the permit and say, well, no, you're not doing -- you're not doing what you said you would do in terms of maintaining access so now we need to remodel and do everything over again?

MS. THROWER: I will leave that answer to Mr. Shackelford. I'm, you know, sure that they can go back and try and do some enforcement, I suppose. That's at the discretion of the -- of the agency. I'll let him answer that question and see if he has any -- any sense of whether DEQ can do that.

But with respect to whether this road stays open or closed, that stands with the forest service and not DEQ.

So, for example, DEQ or the State couldn't go back and say, no, you have to close this road because we realize that, you know, you're not following your access management plan, people are going through here, it's not -- it should have been ambient air, it's not ambient air. There's no controls over this. That would be a change in the plan of operations that is authorized by the forest service, again a change in travel management plan that manages use of that road. So they -- they could not do that.

Question number six, "Is there anything in the record discussing the difference between guests to the facility and members of the general public and how Perpetua will determine who is allowed to access and who is not?"

There's EPA's ambient air policy document that discusses the difference between persons that have legal and practical access to a source of property but are not considered members of the public. That is at PET776. It talks about things such as an employee of the owner or operator

who works at the site is not a member of the public, and business invitees such as contractors or delivery persons. IDEQ's guidance also discusses some situations of other persons can be considered the public and require ambient air protections. Here are some statements from DEQ's guidance, which are -- I think those are on PET743 and 744.

HEARING OFFICER LAWRENCE: And I don't mean to interrupt. I mean, I'm pretty familiar with the guidance document. With this question I was more trying to get at like nuts and bolts how that's actually going to happen in real life outside of the, you know, the EPA document.

MS. THROWER: Right. So, you know, the thing if you look at EPA's policy in the guidance documents, there's no mention of what this guest of the facility is. I mean, there's -- there's people invited as a normal part of business conducted at the facility, but guest of the facility is not mentioned in the statement of basis either. It wasn't until the response to comments that I see that DEQ added this term and defined it as though seeking access for a specific purpose.

So how this is going to work

practically, it's unclear because they basically subsumed everybody into this guest of the facility. So I don't see how they would preclude anyone from accessing that site. Everybody that's going there is going to be seeking access for a specific purpose, whether it's a legitimate purpose or not.

I suppose the practical aspect of it is they will have a gate and presumably, if someone doesn't sign their health protections away and signs their paper saying they are now a guest of the facility and not the general public, then, you know, if they sign it they're allowed to go through. And if not, then presumably they would say you can't go through.

But, you know, this -- this definition, as I said, it sort of -- it's everybody. I mean, there's no distinction. It's not consistent with the distinctions made in EPA's policy and DEQ's guidance. No one needs to be excluded in this case. And no one's afforded ambient air protections in this case. I mean, you know, this definition basically guts the entire ambient air protections that are there to protect public health.

Does that answer your question?

HEARING OFFICER LAWRENCE: Yes. Thank you.

MS. THROWER: And let's see, question seven. I believe this is the last question. "How did DEQ guidance documents in the record at PET743 through 744 and EPA e-mail attached to the Shilling declaration affect the determination of ambient air?"

You know, we believe DEQ's guidance is consistent with the EPA's ambient air protection policy. You know, it states that it shall be assumed that the air within facility boundaries is ambient air unless the facility can demonstrate that public access is precluded. It talks about right-of-way access, for instance, if the general public is allowed on the site as part of a right-of-way easement or common service road, then the right of way is determined to be ambient air. I think, you know, that is -- is pretty close to what we have here with the public road. I mean, there's a right of way for the public to go over forest service roads, yet this was not determined to be ambient air.

The e-mail from the EPA regional modeler, Jay Emmett Alpine, doesn't really change our assessment that -- that DEQ's decision to treat

everyone as guests of the facility is wrong. His e-mail states -- you know, it's based on a limited number of facts in the prior e-mail that was sent to him from someone from DEQ, so he clearly wasn't looking at the entire record. And it states it's just his understanding of the roadway, it's just his opinion and not an approval, and it directs the e-mail sender, Kevin Shilling, to get formal review by EPA's ambient air review team.

So the value of his opinion on this road is not very valuable, and it's undermined by EPA's official comment on the draft permit at PET672 where the EPA says, "the State needs to provide sufficient justification to demonstrate the measures and requirements to preclude public access and ensure members of the public to presume the road can be classified as guests of the mine sufficiently complies with the national ambient air policy.

"Given the uniqueness and ambiguity of the situation, a petition to the EPA national ambient air policy team for review and concurrence with the State's findings could be warranted."

And again, I think we can see from the August 10th, 2023, EPA letter that it confirmed

that comment in its official position that it still has legal access concerns whether the general public has a right or permission to enter a specific property.

So in short, we don't believe that e-mail has any -- any value in terms of -- or shouldn't really be given any weight in terms of it being an official EPA declaration that it is okay to leave this road open and not preclude access.

So that concludes the questions that you had listed in your notice.

HEARING OFFICER LAWRENCE: I have one question. To backtrack, I probably should have interjected this on number six. This is going to seem like kind of a mundane, like on-the-ground question, but it's something I have been wondering. To your knowledge, is there anything in the record that talks about once within the project area, so if someone is on the access road and they're a guest, are there any destinations within the SGP that somebody would be stopping at or allowed to stop at or is it literally they are going straight through from the north to the south and vice versa and that's it? If there's anything in the record on that, that's all I'm asking.

MS. THROWER: Right. Yeah. There are draft access management plan and there are statements in the record. Again, there's not a finalized access management plan like a lot of the other plans. The stuff is not finalized prior to issuing the permit. But there are statements about how the road is being built to be separate from mining activities. That people will not be able to stop or go off of that road. There might be a pilot car that they will have to follow.

So no, as far as I understand that, they would not allow people to go off of that road to go check out the blasting activities or even go to -- you know, there's not going do be any interpretive signs open.

HEARING OFFICER LAWRENCE: Okay. Thank you.

For the petitioners, we have, what, three petitioner entities, right? I just want to make sure I'm not overlooking --

MR. HURLBUTT: Yeah, I just want to make one last point before moving on.

THE COURT: Okay.

MR. HURLBUTT: And I think a number of the questions that you've asked about whether Perpetua can have or will have the authority to control the

road, whether DEQ could take enforcement action to make sure that indeed happens, I think those miss one of the larger points, which is that whatever authority Perpetua does have or is granted, they've been stating throughout this process that they will be letting people access the site as long as they go through the check point and sign the waiver. So whatever authority they have, the plan, and what DEQ has approved in the permit process is this situation where people will be allowed to use the access road through the site.

HEARING OFFICER LAWRENCE: Okay.

MR. HURLBUTT: Thank you.

HEARING OFFICER LAWRENCE: Okay. DEQ, Mr. Shackelford.

I avoided calling you "Shackleton." I've always been into Ernest Shackelton so I always feel like I'm about to say that name instead of you.

MR. SHACKELFORD: I would just start, before getting to the questions, I will probably skip down to number four anyway, start by saying that this is an unusual situation regarding access management plans. I think the declaration of Kevin Shilling, which is probably our most extensive explanation of

the decision-making behind this problem, illustrates that this is not a normal thing for us to do, to do an access management plan for facilities. Since -- and my assignment also indicates we do approximately 100 or so air permits per year in the air quality program. So since this issue, this permit was issued, we have probably done 100 more.

Given that, and I think that you alluded to this earlier, as to number four, DEQ is reasonable in relying on the certification of documents that IDAPA 58.01.01.23, what I think you were alluding to earlier, which essentially requires sworn statements in the application so that we can reasonably rely on those. We can't go and fact check all 100 applicants every year for every little detail that they provide for us. This is also why we have the guidance documents that has also been referred to here. Because for all the different parts of the state and all the different activities, whether it be some sort of metal mining or sand mining or asphalt production, whatever it is, whatever the emissions are, we have to have some sort of flexibility in determining what will actually work on the ground.

So that's in my view the relevance both of the evidence that we relied upon and the guidance documents that are referred to as well.

HEARING OFFICER LAWRENCE: Before you move on, can I just ask a couple of follow-up questions? So is there -- and I have gone through the record, I mean, I've read the briefs and then when people would cite to things I would see if I could lay eyes on that myself. But is there some place in the record where -- that you're aware of that Perpetua has actually made that representation about the ability to control access?

Because what I recall is, when I would go back to documents in the record based on the citations and the briefs, I'd see what looked to me like sort of descriptions of a prior representation that had been made, but I don't know that I've actually seen where that representation is. So I was wondering if that is somewhere in the record, if that question makes sense.

MR. SHACKELFORD: No, that does make sense and I can't recall one either. I suspect it is in the actual permit application. All I know is I'm referencing Kevin Shilling's declaration, which in turn refers back to what representations that were

made to him in the modeling team.

HEARING OFFICER LAWRENCE: Right.

MR. SHACKELFORD: But further than that, I'm not sure.

HEARING OFFICER LAWRENCE: Okay. Thank you.

MR. SHACKELFORD: And I think, to put a finer point on one of your earlier questions, I'm not -- I'm not aware of any existing authorities, I think you asked about legal authorities addressing the extent to which DEQ is responsible for verifying any of that information.

HEARING OFFICER LAWRENCE: Right.

MR. SHACKELFORD: I'm not aware of any law that was violated here that says, well, DEQ needs to go and fact check all the different parts of the application that have been certified.

HEARING OFFICER LAWRENCE: So when I asked Mrs. Thrower that question, her answer was, well, it's an issue of evidence in the record.

Do you have any particular thoughts on that point?

MR. SHACKELFORD: No. I think that's fairly put. It's what's relied upon by -- by the permit writers in the modeling team.

HEARING OFFICER LAWRENCE: So DEQ would say,

well, the reliance on the representation, that's the sufficient record evidence or under the standards that govern --

MR. SHACKELFORD: Yeah. This isn't just for the air quality program. I mean, if you -- there's all kinds of permits that require maybe legal descriptions of land that we don't get into. So most -- most facilities are going to be a normal parcel. We don't ask who owns it? What are your leasehold rights? Does your lease specifically indicate that you can exclude people? Does it require you to allow anybody on that may not be directly associated with the facility?

If you were applying for reapplication of recycled water, for example, you need a place to put that recycled water. Maybe you have a lease with a farmer who then decides, well, I don't like the way that you're spraying my fields, you no longer have that. What does that mean for our permit that was reliant on some place where we can put it? Well, it means you can't really use it anymore. So that's how it would happen in the practical world.

So to what extent of DEQ's enforcement authority is relevant to the issues, they -- they

are very relevant. In my time with the air program, I've seen that their enforcement typically is commensurate with the level of the -- of the violation. So if it's a very minor violation it may be simply a letter or a small fine. And for larger violations, consent orders, consent decrees, CASAs, and larger fines.

I don't know how deep into hypotheticals we should really get, but I think if this were just somebody crossing over the boundary far away from the mine and that were to be found out by DEQ, that would probably be seen as a minor violation. But if they were just -- if Perpetua were to decide to just let everybody in, we are not really doing the whole escort vehicle, we are not putting up any trespassing signs, anybody who wants to come in and go through that's fine, that would be a major violation of the permit.

To the extent that the forest service, if that is true, somehow reneges or doesn't give Perpetua the right over some portions of this land, although my understanding is that a lot of these are fee simple parcels with patented mining claims, then that would require a permit modification. But at this point we don't have that evidence, which is

why DEQ's decision was reasonable with the record before it.

That said, as Kevin Shilling mentioned, there is an option. I think on Page 5 and 6 it discusses the other option, which would be to include the road and ambient air, and that compliance could have been demonstrated. It would have required considerable analytical scenarios and extensive number of permit conditions to make such scenarios enforceable, which is why option two is preferred by the team.

As for number six, I think the answer is likely no, whether there's anything in the record discussing the difference between guests of the facility. From DEQ's point of view, that's not its responsibility to dictate who gets to enter, enter different facilities. Lots of places do provide tours. So it's not really up to us to decide how that -- how that works.

What is up to us is to ensure that it's not the general public that has access, that they are reasonably precluded, that they are discouraged from entering the property.

For number seven, I would say I touched briefly on the guidance document. And it's

important because it provides a lot of flexibility for all different kinds of stationary sources throughout the state and it requires reasonable preclusion. I think on the second page, on PET744, there's essentially a series of questions, and you answer yes or no. And based on the answers to those questions, you can decide whether the general public is reasonably precluded from gaining access to the facility. And based on the permit application, we could see that the general public was reasonably precluded based on the number of parameters that they provided as well as permit conditions that would be required. And then, of course, the more specific access management plan, which would be their -- incorporated thereafter.

As to e-mail attached to Kevin Shilling's declaration. It is an opinion by one of EPA's PhD-prepared staff members. I don't think it is fair to say it's not relevant. I think it's fair to say that this is a nuanced and difficult issue, that DEQ -- DEQ took considerable time and paid considerable attention to figuring out a scenario that could work for the permit applicant while protecting the public's health. And I think that opinion helps go to show DEQ's effort in

trying to bring in more support for its decision and trying to bounce this idea off of others to make sure that they got it right.

HEARING OFFICER LAWRENCE: All right. Actually, I have a question that relates to that and I think something you said at the beginning, which is this is kind of -- this is not a typical situation for DEQ. What makes this unusual?

And the reason I ask is obviously we all know Idaho has -- we have so much federal land within our borders. So what -- why is it that this is sort of such a unique type of situation? And that may not be relevant to anything at all, but I'm curious.

MR. SHACKELFORD: Well, I think for the most part, stationary sources aren't places people want to go, right? So if you see a big stack emitting things, it's probably not a fun place to recreate in the first place.

But you're right, there are other mines in very rural places in Idaho where there might be nearby lakes or forests to visit that could be somewhat similar, but maybe the topography are such that there aren't any kinds of roads for people to get in and out and there they're even more rural

and rugged.

So I can't really speak beyond that because I haven't had in-depth conversations with the permitting team on all the different permits that they've seen.

HEARING OFFICER LAWRENCE: Right.

MR. SHACKELFORD: All I know is that from their perspective, and I think there was a discovery request on this, any other type of scenario they could come up with when there was some sort of public right of way. The closest they could come up with, a place down in Owyhee County, when there was an actual road, like a public road, and that could not be permitted because the permit applicant had no authority and it was beyond question, didn't represent that they had the authority to close it down. That's what DEQ considered a right of way. Literally you have the right to go through, you cannot possibly preclude it, and so you can't represent such.

HEARING OFFICER LAWRENCE: All right. Like you mentioned, other mines, like Thompson Creek Mine or the Cobalt project up near Salmon, it seems like this might replicate itself. It's funny to me that it is so unusual. But anyway, so that was my

last question.

MR. SHACKELFORD: Great. I don't have anything further.

HEARING OFFICER LAWRENCE: Okay. Thank you.

Mr. Pooser.

MR. POOSER: Thank you, Mr. Hearing officer, Counsel.

I think I will probably just go through these questions as the parties have already done. And with respect to the first question, I do want to address kind of this idea of legal authority to preclude access. And I want to make sure we're actually looking at that with the right perspective, and that's what the actual allegations are by the petitioners. And it's quite limited when you actually look at their -- at their briefing.

Their opening brief doesn't actually address legal control at all. In their reply, it is at Pages 14 and 16, they talk about legal control, but it's only within a very specific allegation and assumption, and that is, that the forest service is requiring that Perpetua include this road and that then allows public access across the road. And that is an assumption that is flawed

and it's also not -- is unsupported by the record.

So I want to just make sure when we're talking about legal authority that we're looking at it as the issue has been presented and the issue has been kind of briefed and discussed already. It is very limited to just simply the assumption that the forest service here is -- is mandating that this access road exist, is mandating that the public be pro- -- the general public be provided access across the site, and that is just simply not the case.

HEARING OFFICER LAWRENCE: So you're saying that there's nothing in the record where the forest service is saying that access has to be allowed through the project site?

MR. POOSER: Yeah. And this kind of -- this kind of goes back to some of the other questions about, you know, the questions too about the public's need to access it, also kind of what Perpetua's interests are.

So, I mean, there's simultaneous permit -- permit actions going on here, and so one is with the forest service. And so Perpetua has submitted a plan of operation, and that plan of operation is seeking to establish an operational

boundary for the project. That operational boundary is also being used as the ambient air boundary. So there's a fundamental assumption in the operation -- in the plan of operation that there will be an ambient air boundary around the site, that Perpetua has legal -- full legal control over and can exclude the public for operational reasons, for safety reasons, and also for air quality permitting. So that process is ongoing.

At the same time, we're here in front of DEQ saying, hey, can you confirm what our air -- air ambient boundary is? And that is what we're kind of talking -- that's ultimately what we're talking about here, which is the operational boundary of the facility.

And so when we're -- when we're looking at these two permit processes actually kind of go hand in hand and they're going -- they're coming together kind of simultaneously. And so when you look at the assumptions that are kind of being made and the representations of legal -- of legal authority, those are being made because that is what is -- that is what the plan of operation actually calls for. So that's when we kind of talk about this legal control.

Now the other aspect of the plan of operation is that there is going to be this access road. And I think it's kind of important to kind of look at the timeline and you've kind of asked where in the record is some of this information available in and in particular, it is in the application materials and it is in -- some of those are supplied as part of the statement of basis, some of those were supplied in the application that we submitted as part of our summary judgment briefing.

And so if you look at the draft access management plan, I mean, it does kind of sort of, you know, give this background as far as, hey, we're going in front of the forest service, we have this plan of operation and this plan of operation includes our operational boundary, which is our air -- ambient air boundary and it also includes this -- this access road that we would also control. And so that is all -- so that is all in the record.

And I think in looking at kind of the timeline of this, it is kind of important just to understand how this kind of came about and that's in the access management plan.

And so in September 2016, that's when the plan of operation was submitted to the forest service. And again, as proposed, it is creating this operational boundary. And at that time the public access through the mine site was completely prohibited under the plan of operation. And in public comments, particularly the Yellow Pine residents, expressed concerns about that and Perpetua was asked to consider, are there other options? So it came up with this option. And so now that is -- that is -- the plan of operation was refined and so now that option is in there as far as having this access and this controlled access that Perpetua would have full control of this road, they would protect its ambient air boundary, and that is kind of, again, part of this plan of operations.

And so you can -- you can see this, you know, in the application materials. Perpetua applied August 2019. It submitted a final application in June of 2020. In December of 2020 it submitted another refined plan of operation. And then it updated its modeling at that time with DEQ.

HEARING OFFICER LAWRENCE: Are those in the

record?

MR. POOSER: Yes, they are.

So when I'm talking about the timeline that is largely set forth in the access management plan, which we've already talked about, which is petition 527 through 533. That has a lot of the background. You know, the application itself kind of indicates that there's a record of decision that is still required from -- from the forest service, that's at PRI382. And then you have the application itself with respect to kind of the air quality modeling report, and then there's also kind of an addendum to that report. And those reports are at PRI411 through 419. And also at PRI818 through 825. And those talk about -- what the situation here is as far as how Perpetua is having to go through this forest service process and present a plan of operation.

So you asked specifically like where did Perpetua make the representations that it has control? There's a couple, and one is just the permit and the air quality analysis. Again, it is assuming that we have this operational boundary and the operational boundary is the -- is the ambient air boundary. And so that is a fundamental

assumption that is in the permit application. It is a fundamental assumption that goes into the air quality analysis, the NAAQS analysis, et cetera, et cetera.

And the statements are made again, kind of pointing to the access management plan, that we will have full control over this road, and that we have the legal authority to exclude the general public. And so those representations were made and, again, kind of where that -- where that is in the access management plan.

Kind of see, perhaps move to question five. And you're kind of asking sort of about DEQ's enforcement authorities relative to this.

And I think enforcement authority is kind of relevant, but also the sequencing of events here is also kind of relevant because there is, as I mentioned earlier, there is sort of this challenge in sequencing because Perpetua has to get forest service approval for its operational boundary. At the same time, Perpetua needs DEQ to recognize what the actual ambient air boundary is, you know, based on that operational boundary. So, you know, we can't commence construction -- if we don't have a project, we've got no air permit. So,

you know, this is fundamentally sort of based on that -- that, you know, we can't commence construction unless we have a project.

So I want to kind of turn just real quick back -- well, actually, maybe I will just kind of move forward and get to that later.

So question six, as far as kind of you're asking whether or not there's anything in the record that kind of discusses this sort of difference between guests of the facility and members of the general public, and Mr. Shackelford said there's really not, but I think there is and that's in the permit -- that's in the permit. And that's in permit condition 2.7, which makes that distinction between the general public and people -- and the folks that are actually allowed to cross the site. And so that kind of distinction between the general public and, you know, guests to the site, that is how that is defined. That is how the DEQ chose to address the situation. And that's where you find that fundamental distinction.

HEARING OFFICER LAWRENCE: As I recall, is there anything that says what the difference between a guest and a member of the general public actually is?

MR. POOSER: Yes. Yes. I mean, so a member of general public would be somebody that can just come through the site unrestricted, right? They could just pass through it like a county road. They could just kind of pass through the site without any obligation whatsoever. It is just the general public has access to go through there. And that's not what we have here.

This is a controlled -- this is a controlled road. It is monitored, it is -- there is surveillance provided, there are barriers put up. When people come to this site, they know they are not the general public. They know that they are going to be a guest. They know they don't have a right to be there other than as allowed to go through -- to pass through on the road. And so those conditions are very clear and that is what kind of makes that distinction between the general public and the guest.

On number seven, as far as the DEQ guidance document, I thought Kevin Shilling addressed that very well in his -- in his declaration about how he kind of sort of -- how the DEQ guidance and EPA guidance are the same and how they kind of sort of went through this analysis.

As far as the EPA e-mail goes, I think it is, you know, important because it does show that DEQ actually consulted with -- with EPA on this issue. It is not like DEQ just kind of made a mandate and just said, this is how we're going to do it. It actually consulted with the EPA to try to get its thoughts and those are the thoughts that they got back.

And that kind of gets me back to sort of the original point as far as kind of the legal -- the idea of legal authority and the specific challenge here, again, which is that the forest service requires public access. And the only proof that they provide, that the petitioners provided in the record, are two memos. One is a Stantec memo, which I understand is kind of like a -- I suppose a consultant of the forest service that's kind of consulting on air quality issues. And then there is also a much lengthier document that is an actual air quality analysis.

And both of those documents do what DEQ does, they're assuming that there is a plan of operation that includes an operational boundary and an ambient air boundary. And so their analysis is based on there being an ambient air boundary.

Their analysis is also based on the fact that Perpetua is going to have legal control of this access road.

So all of those are assumed in these two documents. And those documents in no way show that the forest service is requiring public access. Frankly, it is the opposite because those documents, again, are kind of reporting what is in the plan of operation and what is -- what is going to happen with this project when it gets off the ground.

The other aspect of those two -- of those two documents, which I think are quite interesting, is that they also refer to EPA's response to this question on whether or not the road should be excluded from the ambient air.

And so if you look at Petition 964, and this is the -- this is kind of that larger air quality analysis -- yes, this is the large air quality analysis. On Petition 964 it specifically talks about that there was a November 18th, 2020, response to comments letter authored by EPA that is accepting DEQ's findings on the -- on the road. And on Page 25 of the letter it states that EPA are recognizing that this control access road would not

be ambient air. It also -- and so that's that air quality analysis.

When you turn to the Stantec memo, which is at Petition 838 and 839, if you look specifically at Page 839, you will see there it says, "EPA approach" -- "EPA approach to the access road." And it talks specifically about that same November 18th, 2020, response to comments that EPA did where it acknowledges and accepts DEQ's findings.

And then in addition, they talk about an April 15th, 2021, conference call with Stantec and the forest service. And what this says is "EPA representatives affirm that control public access road is consistent with the December 2nd, 2019 revised policy on exclusions from ambient air memorandum."

So it's not just that -- that e-mail that was attached to Mr. Shilling's declaration. There's other -- there's other evidence in the record as far as EPA's approval -- approval of the ambient air boundary and specifically with respect to that access road.

So I'm happy to address any additional questions you may have.

HEARING OFFICER LAWRENCE: No, I don't have anything else.

Thank you.

Petitioners, do you want to follow up?

MS. THROWER: Just a couple quick points. As DEQ mentioned, you know, that they should be able to rely on sworn statements of an applicant, you know, I would just like to point out that these were comments that were brought up to the agency indicating that there was potential issue about, you know, whether -- whether they could preclude access, whether they have the control to preclude access. So, you know, to that extent, the agency should have had a little bit of more heightened awareness and should have -- it would have been reasonable for them to look into that and respond to comments with that information saying, yes, they've looked at it.

You know, I -- like I said, I mean, you know, in the Rosemont case, that was the same issue. The mining company said, hey, we have valid mining claims, but there was never any indication that the forest service looked to see if those really were valid mining claims. Having a valid mining claim there are certain -- certain things

that you have to meet, for instance, that you have valuable minerals underground. They never checked that. And the Ninth Circuit said you can't make those assumptions. You need to have some basis for -- you know, if you are going to make a decision based on those assumptions, you need to have looked at those and have made a reasonable assessment if those claims are true.

You know, this issue with guests versus the general public, you know, the guests of the facility is, as I said, this is a category of people that was made up for this permit. It's based -- it's not based -- like EPA policy and IDEQ guidance. If you look at the people that are either not the general public or the general public, they are -- those situations or those classes of people are based on what people are doing at that site or trying -- or why they are trying to access that site. They are not based on someone signing a paper. And so by doing this, they really, like I've said, there is no general public anymore. And it's completely gutted any protections that the general public has by, you know, this new class of people.

So, you know, just for instance, DEQ

decided that the general public is considered anyone not directly associated with the facility. You know, people trying to access the road to get to the public land are not directly associated with the facility. Most people are probably not going to want to, you know, hang out there. Someone not subject to worker exposure regulation or someone not onsite. It is probably going to be someone who is trying to drive their car through there. People invited as part of a normal business conducted on the facility site like a commercial establishment or service provider, those are people of the general public. They need ambient air protections.

You know, I don't think it is consistent with this guidance to say, oh, okay, well, if you walk on to -- maybe the facility has a taco shop, right? If you walk on there to get a taco and they have you sign a piece of paper that you're not the general public, is that okay? I mean, that just seems to completely, like I said, gut the whole -- whole purpose of this ambient air policy and precluding the public from areas that are not ambient air.

You know, there's other, as I mentioned, general public allowed as part of a right-of-way

easement or common service road. Even if the facility is under common ownership but there's a different facility and the employees have to pass through the one source to get to where -- to where they work, they are still considered the general public. You know, can they sign a waiver every time they have to go to work to say, okay, well, if we pass through this facility we get to breathe all the pollution that the facility is emitting and we don't get ambient air protections?

You know, I don't think there's a case, I haven't seen anything that says that's okay. But like I said, I mean, this whole new guest of the facility thing, there isn't any general public anymore. Anybody can just sign they are a guest of the facility and it's done.

I get the -- I get the whole, you know, the permits, there's a lot of permits that Perpetua has to get. There's a lot of assumptions they need to make, you know, about the project because the forest service has not permitted the project. We don't know exactly what the plan of operations or what the final approval is going to look like.

What we do know is that the two options are to keep that road open just the alignment is a

little bit different. But both of those options would be going through the mine site, and both of those options would allow the public to access these recreational sites that are really important to the community.

So, you know, you talk about a larger air -- ambient air boundary and giving Perpetua complete control over that, you know, that's -- you know, that's what the forest service's approval gives them in terms of blocking people out from using the rivers there, blocking trails, that kind of thing. If they -- if the forest service gives them that authority to do that, that's fine. But to the extent that they don't have the authority to preclude people from accessing this road to go through to other public lands, I just -- you know, I don't see how Perpetua can claim they have legal authority to preclude access that's required under EPA's policy.

And about other comment letters, about other statements from EPA about, you know, that the ambient -- the excluding the road from ambient air protections is okay and other things, you know, I'm sure you'll be going through all the citations and all the documents to see, but we do know that the

last -- on the last draft permit EPA's comment letter was not -- was -- basically said that this doesn't seem right. You need to, you know, check this out more, that there's -- the public is going to be going through there.

Same thing with the August 10th, 2023, letter. EPA clearly made a point there that the assumptions that Perpetua's making in terms of being able to preclude access to the public are not substantiated and they had issues there.

We don't have a final determination as the EPA letters, both of them said, you know, get an EPA determination, get an EPA determination. DEQ hasn't done that.

So, you know, as far as EPA's official policy on this road, I suppose that we don't have that official policy from the ambient air team. It's not something EPA is going to impose on the State. The State has delegated authority to issue these permits. So I understand that EPA's not going to mandate that, but that is available and that hasn't been done. And so, you know, the latest official policy, I suppose, or the official opinion that we have from EPA is the latest they have submitted on the last draft permit on the 2022

and 2023 letter that we have been talking about.

And, you know, I think that concludes my comments. You know, currently that road is being used, you can drive up there, you can go through there and have fun. It is a rough road, but, you know, it's a public road. As -- as far as the forest service is reviewing the plan of operations and reviewing the environmental impact statement, that road will stay open to the public. And if it's not excluded from -- or if it is not included in the ambient air and people are going to be driving through there. A lot of those cars are these Razors and everything --

HEARING OFFICER LAWRENCE: I'm having trouble hearing you now.

MS. THROWER: A lot of those cars are these Razors and stuff that are open air. People are going to be, you know, enclosed in their cars with air-conditioner and they are going to be breathing all of that dust, all of that particulate matter, all of that arsenic, which, you know, as we've argued, is also been underestimated to begin with. And I don't think people are going to make that distinction of, oh, I signed a paper so I'm no longer the general public so I'm protected, you

know, I'm protected now from this pollution. Nobody is going to understand that. And the truth is that they're not.

HEARING OFFICER LAWRENCE: All right. Thank you.

MS. THROWER: Thank you.

HEARING OFFICER LAWRENCE: Okay. Well, that was helpful for me, and that concludes the exclusion from ambient air argument.

Do you guys still want to present argument on those few issues you mentioned in the beginning, Petitioners?

MR. HURLBUTT: If that's okay with you, Mr. Hearing officer, and I don't -- I don't want to take up too much time, but yes.

HEARING OFFICER LAWRENCE: Do you have an idea how much time? I'm kind of inclined to take a break just to give my brain a chance to recover a little bit, unless you're going to tell me it's going to be super short.

MR. HURLBUTT: I mean, I think ten to 15 minutes.

HEARING OFFICER LAWRENCE: Let's go ahead and take a ten-minute break because obviously these folks need time to respond too. So that would be

helpful for me. So I have we are at 10:49, so why don't we make it that we reconvene at 11 a.m. even.

(Break taken from 10:49 a.m. to 11:00 a.m.)

HEARING OFFICER LAWRENCE: We're back on the record in the matter of air quality permit to construct P-2019.0047.

So we have concluded the argument about the exclusion of the access road from ambient air and now the petitioners would like to present argument on a few other issues. Given it's only three of them, I would be inclined to just go party by party on this one and not issue by issue so that everyone is getting up three different times and all that.

Is that okay with you?

MR. HURLBUTT: Yes.

HEARING OFFICER LAWRENCE: Okay. And disclaimer. I did my best during the ten-minute break to refresh my recollection of a couple of these issues. My attention more recently has been focused on the ambient air and the second issue you raised, the T-RACT analysis, so that one I'm pretty up to speed on. It's been a while since I have looked at the other two, so you may want to talk to me like you are explaining the issue to a fifth

grader, is all I am trying to say, if you want it to land.

So Petitioners, you are free to go.

Oh, is someone trying to come in?

MR. HURLBUTT: Yeah.

So I wanted to hit on just three of these sub-issues which I think are really important and require a little bit of clarification after -- after all the briefing.

So first on issue 2B, the assumption of 93.3 percent dust control. I'd like to point out that this is a big deal, the 93.3 percent. They're operating on a razor thin margin to comply with the national ambient air quality standards for particulate matter. This is in the statement of basis attachments at PET325 through 326 where DEQ modeled a slightly different scenario. Instead of what's been approved, which is 180,000 tons per day of mining operations and 93.3 percent dust control, what if instead they cut the operations by a third and only did 120,000 tons per day of mining operations, but also were only able to achieve 90 percent dust control. So just a little bump down in the dust control efficiency and a one-third drop in the amount of mining that would occur.

And in that modeling, DEQ found that that would violate the PM10 daily standards for the NAAQS. Again, that's in the record. I think that's at five receptors around the site, those would be exceeded. So even with a huge reduction in mining but just a small reduction in control efficiency we had violations of the air quality standards. And that's why DEQ says this throughout the statement of basis, 93.3 percent is critical for NAAQS compliance. It is an aggressive level of control. It is challenging to consistently and continuously achieve 93.3 percent control. And the permit therefore requires aggressive implementation measures to achieve that.

HEARING OFFICER LAWRENCE: So sorry to interrupt. So am I correct in the ultimate alleged error is that because this is such an important issue and maybe -- if that's accurate, that it's a razor-thin margin, but the ultimate alleged error is that it was error not to include an enforceable limitation on that.

Am I accurately describing what the alleged error is?

MR. HURLBUTT: The error is that there is -- there is no 93.3 percent enforceable limitation or

there is no other limitations that reasonably assure that that 93.3 percent would be left. So, yeah, it's true there's no, you know, limitation that you shall achieve 93.3 percent. All there is is this future fugitive dust control plan, not yet been submitted, that DEQ and Perpetua claim will help achieve that 93.3 percent.

But really DEQ is hiding the ball here. We don't know how Perpetua plans to use magnesium chloride and water to actually achieve 93.3 percent control at this particular site. They've not yet identified the frequencies and rates of spraying that are going to be used and when and where that's all going to happen. They're hiding the ball, shielding it from public scrutiny. EPA in its comments have not been able to comment on the actual plan that Perpetua is going to employ. Neither is Save the South Fork, neither is the Nez Perce Tribe air division, neither has ICL or any other member of the public. DEQ is shielding that view.

The super important issue is to whether the plan Perpetua comes up with can actually achieve 93.3 percent, and we have no idea yet what that plan is going to be. And the requirements in

the facility -- the fugitive dust control plan, though they do require Perpetua to set specific tasks that it's going to perform and monitoring to make sure it performs those tasks, none of that is actually in any way tied to specifically achieving 93.3 percent.

And these points are backed up by EPA's original comments where they thought that an 80 percent air control was a more appropriate thing to assume, and also by EPA's recent letter from August 10th. And I would just like to point out that in that enclosure to the EPA letter at Page 14, after EPA raises concerns about the lack of information to support that 93.3 percent could be achieved specifically at this project site, EPA then warns, "ultimately IDEQ appears to have back-calculated the control efficiency necessary to demonstrate NAAQS compliance rather than determine a control efficiency that's achievable in practice."

And if you don't have any further questions on the 93.3 percent I'll move on.

HEARING OFFICER LAWRENCE: I -- can you -- well, this may be more of a question for Mr. Shackelford. But do you recall -- and I'm

asking just because, again, I haven't looked at this particular issue recently. Do you remember what the Simon and Shilling declarations say on this issue in terms of how they explained the 93.3?

MR. HURLBUTT: I don't. Sorry.

HEARING OFFICER LAWRENCE: Okay. No questions.

So we'll move on to -- the next one was the T-RACT issue, right?

MR. HURLBUTT: Yeah, 3B, T-RACT. Perpetua doesn't have a right to be granted a T-RACT adjustment, which lets the acceptable levels of carcinogenic arsenic be ten times higher than what's normally acceptable. They have to follow the rules and go through a T-RACT process. And I realize you now said you have gone through those rules, but with the air rules at 210.14 say that on a case-by-case basis DEQ has to decide whether to grant T-RACT. It then says the applicant shall submit and what DEQ shall consider when making its determination and that includes both environmental information about the environmental impacts of the control technology that is going to be used, here this spraying the roads with magnesium chloride and water, and the economic feasibility of doing that.

The case-by-case thing is important, and this is a unique case that a lot of Perpetua's reply brief focused on the fact that magnesium chloride has been used in other situations so why do they need to, you know, consider it here. But again, the rules say case by case.

Nothing in the T-RACT analysis that's in the record talks about the environmental impacts of using magnesium chloride. This is a unique project site. It's up in the mountains in narrow valleys. Most of the roads are near live water. And to achieve this super high 93.3 percent control efficiency, presumably they're going to be spraying a lot of magnesium chloride. So the idea that because maybe this has been used out in the phosphate patch or at a gravel mine on the Snake River plain, that somehow shows DEQ knows what the environmental impacts of using this high amount of magnesium chloride at this particular site, that's just not -- not accurate and needs to be considered here.

And the same goes with economic feasibility. Again, maybe other projects have used these types of controls before, but what's the feasibility of doing it here where they're trying

to achieve such a high and aggressive level of control?

Any questions on T-RACT?

HEARING OFFICER LAWRENCE: No.

MR. HURLBUTT: And so moving to -- this is issue 3C.

HEARING OFFICER LAWRENCE: Averaging?

MR. HURLBUTT: Averaging of projected arsenic emissions. Again, DEQ needs to follow the air rules as they're written, which require meeting ambient arsenic concentrations. Those concentrations are laid out in the rules and they provide for two specific instances in which those standards can be adjusted. That's the T-RACT which we've already talked about. So with the T-RACT demonstration, ten times as much arsenic can be found in the ambient air during the project than would otherwise be able to.

The other exemption in the rule that allows for adjusting the arsenic, AAC, is for a short-term project. This is in the air rules at 210.15. And then the definition for a short-term project is in the air rules at Section 007.08 in the definitions. Those are five-year sources or less.

Even if the Stibnite Project is granted the T-RACT adjustment, so allowing ten times as much arsenic to be found in the air, the project would not comply with the arsenic ambient air levels, and that's why DEQ came up with this 16/70ths adjustment. Multiplying the annual arsenic that can be actually found in the air when the project's underway as well, multiplying it by the 16 years of the life of the mine and dividing by a 70-year lifetime, effectively cutting 77 percent of what's actually modeled to be in the air for arsenic each year down to just about 23 percent by spreading it out over this longer period.

That's not in the rules. That's not one of the exceptions of the rules. If DEQ's allowed to just come up with other things like that, I mean, why is there an actual arsenic number rule? Why are these two specific ways to adjust that, the T-RACT and the short-term source? This is just a third exception that DEQ made up. It's not found in the rules. And without it this project would not comply with the ambient arsenic standards.

Any questions on that?

HEARING OFFICER LAWRENCE: No.

MR. HURLBUTT: Thank you.

HEARING OFFICER LAWRENCE: Thank you.

All right. Mr. Shackelford.

MR. SHACKELFORD: Well, I'd like to start, given that it's been mentioned several times throughout this hearing, with the EPA's recent letter, which has now found its way into this administrative record, there's something important in the attachment, there's an incomplete citation to a reference document. And that document was issued by the environmental appeals board, and I think that document can help put some of these arguments into context. That document is called the Order Denying Relief, and that is dated February 18th, 2005. And it was issued in the case In re: Peabody Western Coal. So you'll see footnotes throughout that attachment to the letter, which is now in our administrative record.

In that case, the board denied the coal company's petition to review the EPA's decision declining to impose a potential to emit on the coal company's operations. And that was because the board found, and I will quote it, "in light of the considerable deference that the board typically affords the permit issuer in questions on technical judgment, the board concludes that the regent

adequately explained the basis for its decision and that the regent's rationale was reasonable based on the information in the administrative record."

And then in reaching that conclusion, the board highlighted the particularly heavy burden that petitioner -- that is assigned to the petitioner that seeks review of a permit that is based on issues that are fundamentally technical in nature.

So technical judgment, deference, heavy burden, reasonable basis, these are the themes prevailing in this order that was provided by EPA to DEQ.

HEARING OFFICER LAWRENCE: So just to clarify. So we are talking about sort of general standards that apply. This -- this Peabody, this isn't relevant to one of these three specific issues.

MR. SHACKELFORD: Yes, it is.

HEARING OFFICER LAWRENCE: Oh, it is. Sorry to interrupt.

MR. SHACKELFORD: No, that's all right. No, I can see. It's a long lead up, I guess.

The point is that when a matter is open to interpretation or subject to many variables

you're inevitably going to see a rise in multiplicity opinions. And the petitioner's arguments are opinions, and these opinions are not favored by our law which grants great deference to the agencies tasked with making the complex technical judgments that are at issue today.

So coming to things like the 93.3 control efficiency, okay. To make these arguments that it's razor thin means you have to ignore the entire declaration of Kevin Shilling and Mike Simon as well, bureau chief Mike Simon, who together have a combined relative experience of 60 years doing this.

Built into all of their engineering, all their modeling are conservative values. That's what gives them the confidence to say within a reasonable degree of engineering certainty we can have a high assurance the NAAQS won't be violated over any of the time periods. It's ignoring all the conservative principles that are going into this. It is not razor thin. Modeling was based on worst case scenarios. That's found throughout the declaration of Kevin Shilling about Pages 16 through 18.

Regarding hiding the ball, I'm not sure

what ball is being hidden. It sounds like the idea is that the actual operations, the specific timetables for sprays, the combination mixtures of water to magnesium chloride or some other chemical dust suppressant, that is the ball being hidden.

DEQ issues permits all the time requiring fugitive dust control plans. Unlike the access management plan, this is a much more typical thing that DEQ does all the time. And DEQ enforces when there's permit violations.

Now, typically that will require neighbors complaining. And it is my understanding that this site, although I haven't visited it, doesn't have much in the way of neighbors to complain about dust. But the fact is that DEQ has experienced controlling those fugitive dusts based on plans that it approves.

And there's nothing in the record to suggest that DEQ is somehow now going to approve a plan that doesn't meet its level of expectation for control. And in fact, overriding all of this is there's a ten percent opacity, instantaneous opacity test, that needs to be conducted such that anything is beyond ten percent, operations shut down.

The permit requires daily inspections of all fugitive dust sources. So there's all kinds of protections built in here that precludes all of the various hideous scenarios that are being alleged.

Regarding T-RACT, that's a misstatement of the law -- of the rule. Never does it say DEQ shall do anything. That is wishful thinking. The rule literally says, "will on a case-by-case basis consider factors to determine whether technological feasibility of any particular proposed control technology."

If you see the declaration of Mike Simon, it talks about how paving was one of the controls that was proposed and that was eliminated because it was not found technologically feasible based on the very first prong. So that was based on the process and operations. There was no need to go further.

The next one, that's what's remaining. DEQ has essentially no choices at this point, other than to say we have chemical dust suppressants combined with water. PRI, or Perpetua, provides us with studies indicating a control efficiency of 90 to 99 percent. We go ahead and take the most conservative one at 90 percent and applied that to

our modeling. Then when we do non-bulk RN process meteorological data there are no 24-hour NAAQS exceedences. Only when you use the bulk RN is there then NAAQS exceedences and only then at only five receptors, at only five of the receptors. And then later the company decides to eliminate those facilities with where the exceedences were found. That is all on Page 17 of Kevin Shilling's declaration.

If DEQ were to find that Perpetua's permit application were incomplete, why would DEQ then go on to, well, it says we have to or we will consider all these factors. We found it incomplete for some other reason, maybe they didn't certify it, but let's go ahead and look at all these other factors. It would be an exercise in futility.

And in this case it's the same. We have one control technology that is proven in the field that there's really no reason to look into at this point since there's no other control technologies available at this site.

So for these reasons, there's no basis to question DEQ's technical judgments in this case on those issues. Thank you.

HEARING OFFICER LAWRENCE: Thank you. Did

you want to say anything about the averaging?

MR. SHACKELFORD: So regarding the averaging, again, I think that's -- that's fairly well explained also by the declarations about how they applied the five-year rule by analog and extending it to a 16-year projected mine site. This is -- it is different because most stationary sources don't have projected life frames. We're going to set up a potato processing plant and it is going to be there until we run out of potatoes or whatever the case may be.

So this is unique, and DEQ didn't have any rules indicating that this would be inappropriate and would fit with health concerns given that the standard is a lifetime exposure rate.

So again, I think that's -- I don't need to get too into the weeds in that one because it is explained by both Mr. Shilling and Mr. Simon.

HEARING OFFICER LAWRENCE: Okay.

Okay. Thank you.

Mr. Pooser.

MR. POOSER: Just one question. Will we have a chance to kind of provide final thoughts or are we done after this?

HEARING OFFICER LAWRENCE: We can do -- we can do some final thoughts. I may do a time limit on those.

MR. POOSER: Okay. Completely fine with me. I was just kind of wondering.

So let me first start with the 93.3 percent and -- and the reference to, you know, the model analysis that DEQ did. DEQ did multiple model analyses. I think Kevin Shilling's declaration at Pages 14 to 18 does a really good job of sort of kind of explaining all the different angles that DEQ was -- was looking at, trying to make sure that it reached the best decision in this permit in determining whether or not the NAAQS were protected. And so it did multiple, multiple analyses looking at -- at this from a lot of different perspectives.

And when we get to the 93.3 percent and you ask the question, you know, where was -- what did -- what did DEQ base that on, and that's explained in our -- in our briefing. And specifically we talked about how, you know, DEQ is very deliberate in looking at this 93.3 percent. And in particular, it considered there was a review that Perpetua had done of AP42, Section 13.2.2,

which addresses unpaved roads. And it actually looked at the underlying test studies to see what was the actual control efficiency on with the use of chemical dust suppressant and water, what was it -- what was it just for chemical dust suppressant, what was it for water and what was it combined, and it provided that information.

And that showed very specifically that the chemical dust suppressants was 90 to 99 percent. And so that is also in the record.

They also relied upon -- there was kind of an analysis of the RACT/BACT/LAER Clearinghouse, and that looked at these different projects that were using chemical dust suppressant with and without water. And that, again, came to 90 to 98 percent control for chemical dust suppressant. AP42 also indicates that the control for water can be between 75 and 100 percent depending on the moisture content. So that is what DEQ relied upon that is in the record.

The question is here is whether or not DEQ's decision to choose 93.3 percent was arbitrary and capricious. And there's a rational basis for this. It looked at these different studies, it made its determination.

As far as a lack of enforcement, I think we've kind of -- we've hit this very hard in our briefing. The control efficiencies for chemical dust suppressant and water has many, many different variables, and so, you know, DEQ sort of built this permit based on numerous conditions and limits, you know, particularly with respect to the fugitive dust control plan.

But not just that. There was monitoring, there's daily inspections, all these different control measures. And then that kind of leads to some of the comments that were -- that were made about the plans.

And to kind of follow up on Mr. Shackelford's points. The con- -- the contents of the plans were very detailed in the permits themselves and that went out to public comment. Petitioners had an opportunity to get public comment on what those minimum requirements were. And these work plans, as is explained in Mike Simon's declaration, are common in DEQ permits and there's a good reason for them. They're typically -- and they're all, they're all prepared kind of post permit. And there's kind of a balance between --

HEARING OFFICER LAWRENCE: Can I jump in for a second? Which of the three issues -- I'm aware of the whole concept of the future plans, but if you could ground me in terms of which of the three particular issues we're --

MR. POOSER: This is responding to Mr. Hurlbutt's comments with respect to that there was -- they didn't have a chance -- there was kind of no review as far as what the plans are going to be and that, you know, DEQ's kind of hiding the ball on what these plans are going to be. And I think this is specifically responsive to that.

HEARING OFFICER LAWRENCE: Okay.

MR. POOSER: And so -- I mean, because these work plans are common and it makes complete sense from DEQ's perspective. Mr. Simon kind of addresses that in -- in his -- in his declaration. And I think that is owed -- that is owed discretion, particularly the comments about public comment. These did go to public comment. The minimum requirements are in there.

So turning to the T-RACT analysis. So very -- very briefly. I think Mr. Simon addresses that in his declaration as well. And, you know, there were three -- for the haul roads there were

three options, there was paving, there was chemical suppressants and water. And looking at the technical feasibility, they said paving is not -- not feasible. And because trucks are heavy and you're also having to reroute the roads as -- as the mining operation evolves.

And so what we're left with is chemical suppressants and water. And it's obviously widely recognized and actually required in -- in DEQ's rules. So we don't believe there is really any issue with that.

With respect to the arsenic averaging, I think enough has been said about that. I think Mr. Shilling's declaration, Mr. Shackelford kind of pointed out at Pages 10 through 11 kind of talks about that very clearly.

And then let me very quickly just sort of -- I want to provide you a cite with respect to the 93 percent findings just so I don't lose that. And that is specifically with respect to the study of AP4213.2.2. That is at PRI2.9. And then with respect to sort of the T-RACT analysis and consideration of the clearinghouse, that is at Petition 544 through 548, PET544 to 548.

HEARING OFFICER LAWRENCE: Okay.

All right. Thank you.

So Petitioners, how about five minutes to both rebut anything that they said and if you want to have sort of final comments to high level wrap things up.

MR. HURLBUTT: I'm just going to focus on rebuttal and no final comments from us.

HEARING OFFICER LAWRENCE: Okay.

MR. HURLBUTT: So on the 93.3 percent issue, Mr. Shackelford pointed out that the issue and, you know, practice of deferring to an agency's technical judgment, and I would ask you here what are they asking you to defer to? What technical judgment? There is no specific plan yet as to how Perpetua is going to spray magnesium chloride and water on the roads. They are asking you to defer to their judgment that some future plan that has not yet been developed that we don't know the actual parameters to will somehow be at 93.3 percent. Everyone knows this case this is from, I think it's a famous federal court case saying that courts don't have to defer to a void when it comes to deferring to agency expertise. They're just asking you to defer to their hope that they can cross their fingers that this will

hopefully work.

On the -- also on the 93.3 percent, one of the conditions for the plan is to have a ten percent opacity test which was mentioned. And I would just like to point out that this is a visual opacity test. If it looks too dusty you need to shut down operations. That all may be well and good in general, but there is nothing in the record that specifically ties that to somehow meeting 93.3 percent dust control efficiency as is necessary here. EPA hammers on that in their enclosure to their August 10th letter. This is on Pages 16 and 17 of that. "Finally, IDEQ's response to EPA's comment on the basis for the ten percent opacity limit in condition 2.5 does not provide additional basis for correlation between opacity and the 93.3 percent control."

Moving on to T-RACT. I was a little surprised to hear it stated that the T-RACT does not say "shall." And just in the first few sections of air rule Section 210.14 on T-RACT, "shall" is used many times. First, opening part it says, "T-RACT shall be determined on a case-by-case basis by the department as follows." In the "as follows," part B, "the department shall review the

information submitted by the applicant and determine whether the applicant has T-RACT." Part C, "the technological feasibility of the control technology or other requirements of a particular source shall be considered in several factors then listed below which includes environmental impact factors. Part D, economic feasibility also shall be considered. "Shall" is used a lot. These factors were not considered in the T-RACT analysis ignoring all those "shalls."

And then on the arsenic averaging, the 16 out of 70 issue, DEQ's counsel admitted this is not in the rules. And that's our key point here. This is not in the rules. This is a made-up adjustment. They might be able to explain why they think it's a good idea, but it's not in the rules. Permits need to be issued based on what is in the air rules. DEQ can go through a rule making and change the rules and adjust what counts as a short-term source or come up with any other thing it wants to through the rule-making process. This is not in the rules, it's a made-up exception to the ambient air concentrations for arsenic. Thank you.

HEARING OFFICER LAWRENCE: Okay. Thank you.

DEQ, they declined their opportunity to have a wrap-up comment.

Do you -- is there anything you want to say briefly in order to wrap things up?

MR. SHACKELFORD: No. Thank you.

HEARING OFFICER LAWRENCE: Okay. Petitioners, how about you guys -- I'm sorry, Perpetua.

MR. POOSER: Just a few things, some things that I can't get a chance to sort of respond to.

Just to kind of clean things up. With respect to kind of the Rosemont decision that's addressed, we understand that's -- that has not been, you know, that has not been briefed. However, it is resolving. The issue, I understand, is whether the mining claims are valid. We're on an air quality permit. I don't know how that -- how that case has any bearing here.

With respect to kind of the control of the access road, you know, there's an example of control that's just right down the hall and the general public can't access this room. I had to get permission to be here. I know I'm a guest. And that is the exact same conditions that are in the permit with respect to the access road.

With respect to the 93.3 percent, again, you can't look at just one condition and say, oh, ten percent opacity, how does that relate? You have to look at the entire suite of control and limits that are in the permit. And that's what we tried to emphasize in our briefing, and that is what DEQ emphasized in its response to comments and statement of basis. There's a whole suite of -- of limitations and controls that are seeking to enforce this 93.3 percent. That's what's important and I think kind of gets lost in some of the petitioners' arguments.

HEARING OFFICER LAWRENCE: Can you be a little bit more specific on that? What -- what specific instances are you talking about?

MR. POOSER: Well, when we were talking about control he mentioned, like, opacity, ten percent, how does that control 93.3 percent? I think you have to consider that that's part of an entire suite of permit conditions and limits that are in the permit as far as daily inspections, the record keeping and reporting, the monitoring that's involved, all of it. You know, the conditions in that Section 2 of the permit, there's a whole suite of things. There's a fugitive dust control plan as

far as minimum requirements, what has to be in there. So I think you have to look at all of those things as a whole, not just one single permit condition.

HEARING OFFICER LAWRENCE: Okay.

MR. POOSER: And then finally, I just -- to reiterate DEQ's comments about -- these are technical determinations. DEQ was using its technical judgment here. And I think when you -- when you look at the petition you look at the arguments that are in the brief, you will see that DEQ adequately explained the basis for its decisions and that its rationale was reasonable. There is support for it in the record. And it was using its technical judgment and that requires some deference from the board. Thank you.

HEARING OFFICER LAWRENCE: Okay.

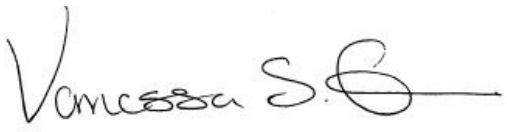
All right. Thank you all. As far as I'm concerned, this is all fully submitted and I'm on the clock now to issue a decision. Just so you guys know, the Office of Administrative Hearings goes by the judicial guideline of once a motion is fully submitted the goal is to get a decision issued by the end of the following month. So that's my goal.

Thank you all. I appreciate it. This was very helpful for me. Thank you for all the time and preparation. As I've said before, all of the briefing has been topnotch and I appreciate all the work that has gone into that. I don't have an easy job, but you guys have at least helped take the edge off of it a little bit with all that. So thank you.

We can adjourn.

(Proceedings concluded at 11:35 a.m.)

REPORTER'S CERTIFICATE



STATE OF IDAHO)
) ss.
COUNTY OF ADA)

I, VANESSA S. GOSNEY, Certified Shorthand Reporter and Notary Public in and for the State of Idaho, do hereby certify:

That I am the reporter who took the proceedings had in the above-entitled action in machine shorthand and thereafter the same was reduced into typewriting under my direct supervision; and

That the foregoing reporter's transcript contains a full, true, and accurate record of the proceedings had in the above and foregoing cause, which was heard in Boise, Idaho.

WITNESS my hand and seal this 9th day of October, 2023.

VANESSA S. GOSNEY
RPR and Notary
Public in and for the
State of Idaho.

MARCH 14, 2024 9:00 AM

P R O C E E D I N G S

BOARD CHAIR BOWEN: I call to order the meeting of the Idaho Board of Environmental Quality. In addition to being a public meeting, we are also on the record in the matter of the air quality permit to construct issued to Perpetua Resources Idaho, Inc., agency case number 0101-22-01, OAH case number 23-245-01. This meeting is being held in the state office of the Department of Environmental Quality.

For those present in the meeting room, please sign in on the sheet provided by the entrance. There won't be an opportunity for public comment today.

Elaine, could you please take the roll?

BOARD CLERK GANINO: Yes, Mr. Chairman.

Mark Bowen.

BOARD CHAIR BOWEN: Here.

BOARD CLERK GANINO: Dr. Randy MacMillan.

VICE CHAIR MACMILLAN: Here.

BOARD CLERK GANINO: Carol Mascarenas. Carol?

BOARD MEMBER MASCARENAS: Here. I'm here.

BOARD CLERK GANINO: Beth Elroy.

BOARD MEMBER ELROY: Present.

BOARD CLERK GANINO: John Sigler.

BOARD MEMBER SIGLER: Present.

BOARD CLERK GANINO: Clayton Steele.

BOARD MEMBER STEELE: Here.

BOARD CLERK GANINO: Pat Purdy.

BOARD MEMBER PURDY: Here.

BOARD CHAIR BOWEN: Before we get started, I'd like to take a moment to introduce the parties and talk about some of the logistics for today.

You will notice that unlike normal DEQ Board meetings we have a court reporter here today. The reporter will be on the record throughout the proceeding today, so please speak slowly and clearly, try not to talk over one another, and use yes or no instead of uh-huh or nodding your head, please. That will make the court reporter's job easier today.

I'd also like to take a moment to introduce the parties and get everyone's names and spellings down for the record so the reporter has those going forward.

Let's begin with the parties.

The petitioners in this matter are the Nez Perce Tribe, the Idaho Conservation League, and Save the South Fork of the Salmon. Would you all take a moment and please identify yourselves, the attorney representing each party.

Let's begin with the South Fork of the Salmon attorney.

MS. THROWER: Julia Thrower, T-h-r-o-w-e-r.

BOARD CHAIR BOWEN: Thank you.

Nez Perce Tribe and ICL. I assume they have the same attorney?

MR. HURLBUTT: Bryan Hurlbutt, H-u-r-l-b-u-t-t.

BOARD CHAIR BOWEN: Thank you.

The respondents in this matter are the Department of Environmental Quality and Perpetua Resources. Would you please identify yourselves for the record?

DEQ attorney.

MS. YOUNG: Hannah Young, Y-o-u-n-g.

BOARD CHAIR BOWEN: Thank you. Perpetua attorney?

MR. POOSER: Good morning. Christopher Pooser, P-o-o-s-e-r.

BOARD CHAIR BOWEN: Thank you.

Also in the courtroom today we have Deputy Attorney General Ann Yribar. She's representing the Board.

And we have DEQ board staff Paula Wilson and Elaine Ganino here to help with logistics.

Is there anyone else that I missed who wants their attendance put on the record?

(No response.)

BOARD CHAIR BOWEN: Thank you. So we have a joint motion to supplement the record with a March 12th, 2024 letter from EPA to DEQ. This is not on the agenda so we need a motion to add it to the agenda.

VICE CHAIR MACMILLAN: Mr. Chairman.

BOARD CHAIR BOWEN: Yes, Randy.

VICE CHAIR MACMILLAN: I make a motion to amend the agenda to include and to supplement the record with the letter received yesterday.

BOARD CHAIR BOWEN: Thank you.

VICE CHAIR MACMILLAN: Or the 12th, whichever day that was.

BOARD CHAIR BOWEN: Okay. Do I have a second?

BOARD MEMBER MCELROY: I have a second.

BOARD CHAIR BOWEN: Thank you.

Elaine, would you call roll?

BOARD CLERK GANINO: Yes, Mr. Chairman.

Mark Bowen.

BOARD CHAIR BOWEN: Just a minute.

Randy, could you state the reason clearly why it was not added to the agenda initially?

VICE CHAIR MACMILLAN: Yes, Mr. Chairman. The supplement to -- the joint motion to supplement the record was received by the Board anyway yesterday, so it

had not been added to the -- or included in the agenda for today.

BOARD CHAIR BOWEN: Right. Thank you, Randy.

Elaine, would you call the roll on the motion, please?

BOARD CLERK GANINO: Yes, Mr. Chairman.

Mark Bowen.

BOARD CHAIR BOWEN: Aye.

BOARD CLERK GANINO: Dr. Randy MacMillan.

VICE CHAIR MACMILLAN: Aye.

BOARD CLERK GANINO: Carol Mascarenas.

BOARD MEMBER MASCARENAS: Aye.

BOARD CLERK GANINO: Beth Elroy.

BOARD MEMBER ELROY: Aye.

BOARD CLERK GANINO: John Sigler.

BOARD MEMBER SIGLER: Aye.

BOARD CLERK GANINO: Clayton Steele.

BOARD MEMBER STEELE: Aye.

BOARD CLERK GANINO: Pat Purdy.

BOARD MEMBER PURDY: Aye.

BOARD CHAIR BOWEN: Thank you. Motion carried.

Is it the desire of the Board to enter into executive session to discuss this matter? I'll entertain a motion.

VICE CHAIR MACMILLAN: Mr. Chairman, I move the

Board enter into executive session pursuant to Idaho Code 74-206(1)(f) to communicate with legal counsel for the public agency to discuss the legal ramifications of and legal options for pending litigation for controversies not yet being litigated but imminently likely to be litigated.

I request that a roll call vote be taken and that vote be recorded in the minutes of this meeting.

BOARD MEMBER PURDY: I second that motion.

BOARD CHAIR BOWEN: Thank you. Any discussion?

(No response.)

Elaine, will you take roll, please?

BOARD CLERK GANINO: Yes, Mr. Chairman.

Mark Bowen.

BOARD CHAIR BOWEN: Aye.

BOARD CLERK GANINO: Dr. Randy MacMillan.

VICE CHAIR MACMILLAN: Aye.

BOARD CLERK GANINO: Carol Mascarenas.

BOARD MEMBER MASCARENAS: Aye.

BOARD CLERK GANINO: Beth Elroy.

BOARD MEMBER ELROY: Aye.

BOARD CLERK GANINO: John Sigler.

BOARD MEMBER SIGLER: Aye.

BOARD CLERK GANINO: Clayton Steele.

BOARD MEMBER STEELE: Aye.

BOARD CLERK GANINO: Pat Purdy.
BOARD MEMBER PURDY: Aye.
BOARD CHAIR BOWEN: Thank you. Motion carried.
We'll now enter executive session. So we have to clear the room. Sorry.
(Thereupon the Board convened into executive session off the record.)
BOARD CHAIR BOWEN: I'll entertain a motion.
VICE CHAIR MACMILLAN: Mr. Chairman, I move that the Board resolve off of executive session, and that the minutes of the meeting reflect that no action was taken during executive session.
BOARD CHAIR BOWEN: Thank you.
Do I hear a second?
BOARD MEMBER SIGLER: Second.
BOARD CHAIR BOWEN: Thank you.
Elaine, can you take a roll call?
BOARD CLERK GANINO: Yes, Mr. Chairman.
Mark Bowen.
BOARD CHAIR BOWEN: Aye.
BOARD CLERK GANINO: Dr. Randy MacMillan.
VICE CHAIR MACMILLAN: Aye.
BOARD CLERK GANINO: Carol Mascarenas.
BOARD MEMBER MASCARENAS: Aye.
BOARD CLERK GANINO: Beth Elroy.

BOARD MEMBER ELROY: Aye.
BOARD CLERK GANINO: John Sigler.
BOARD MEMBER SIGLER: Aye.
BOARD CLERK GANINO: Clayton Steele.
BOARD MEMBER STEELE: Aye.
BOARD CLERK GANINO: Pat Purdy.
BOARD MEMBER PURDY: Aye.
BOARD CHAIR BOWEN: Motion carries.
We're back in general session. The Board is going to take a five-minute break, a bathroom break, and we will readjourn. Thank you.
(Thereupon there was a brief recess.)
BOARD CHAIR BOWEN: All right. Call back into order the general session.
We're under the amended agenda item Joint Motion to Supplement the Record with a March 12th, 2024 letter from EPA to DEQ.
As a Board we're a little bit concerned that we haven't had a chance to review this letter. I'd be interested in other Board members, what your thoughts are receiving the letter, where we are on that? Any discussion?
Dr. MacMillan.
VICE CHAIR MACMILLAN: Mr. Chairman, I have considerable reservation discussing very much of the

substance of the -- of that letter, simply because I've hardly had an opportunity to look at the letter, and surely others would be in the same boat.

So in the interest of fairness, I think that's something that we should allow the parties to fully digest that letter and provide response to that letter.

BOARD CHAIR BOWEN: Okay.

BOARD MEMBER STEELE: I agree.

BOARD CHAIR BOWEN: Any other thoughts?

BOARD MEMBER MCELROY: Mr. Chairman.

BOARD CHAIR BOWEN: Yes.

BOARD MEMBER MCELROY: I would like to share the disappointment that this letter was received at the last minute. And I'm not sure how we message that back to EPA, but I'm assuming that they were well aware of the dates and what's been happening with this issue. And to have a last minute letter submitted to the department, they need the feedback that it makes this whole process more challenging to receive that type of information very last minute.

BOARD CHAIR BOWEN: Okay. Any other thoughts?

I think at this point the Board would like to hear from the parties. We'd like to give the parties a five minute opportunity just to give us your position on this current agenda item.

Let's start with DEQ. Five minutes, please.

MS. YOUNG: May I approach and sit at the table?

BOARD CHAIR BOWEN: Please, yeah.

MS. YOUNG: Thank you for this opportunity. I'd love to have the five minutes to speak to you about this. And again, my name is Hannah Young. I represent the Department of Environmental Quality in this matter.

And I did want to note that I understand that you have two motions truly before the Board to supplement the record, and if I may, I'd like to talk about both of them because they're obviously interrelated as they relate to the same subject matter ultimately.

BOARD CHAIR BOWEN: Excuse me.

MS. YOUNG: Yeah.

BOARD CHAIR BOWEN: Could you stick to the one agenda item at this point?

MS. YOUNG: Oh, absolutely.

BOARD CHAIR BOWEN: You'll have an opportunity to talk about the other one later.

MS. YOUNG: Oh, okay. Sure. I wasn't clear on that, so thank you for that clarification, chairman.

As Ms. Elroy just pointed out, we only received this letter two days ago late in the afternoon, and so the parties, Perpetua and DEQ, made the motion to supplement the record with this March 12th letter

yesterday.

And the reason that we are moving to put this in front of the Board today is because in the underlying contested case proceeding, the petitioners in this case moved to enter EPA's original letter, which was issued in 2023 of August. And at that time DEQ and Perpetua objected to the inclusion of that letter, primarily because EPA is not a party to this case -- although they could be if they wanted to be, they are not.

And because the letter was being introduced at a very late juncture during the contested case proceeding, over a year after the contested case proceeding had been initiated, and so the parties objected to the inclusion.

However, the hearing officer did allow that original EPA letter to be introduced into the record. And because of that -- well, and I should back up.

He allowed it to be introduced in the record, but only for limited purposes. It wasn't a carte blanche, you know, it wasn't allowed in for you to read anything you wanted into it, he had three limitations: One was that the letter could not add new allegations of error; it could not add factual information that was not already part of the record, or the proxy for expert testimony to the Board.

And so under those limitations, the hearing

officer allowed that original EPA letter to be introduced. Since the hearing officer made his decision, two more letters have been issued between the parties, between DEQ and EPA.

DEQ responded, that is the first motion which we will take up later.

And then EPA finally responded to us two days ago, about four months after DEQ issued its letter.

And so now here we are in a bit of an uncomfortable position putting something, you know, before the Board at a very late hour.

But the only reason that we're doing that is because we'd like the Board to have the complete story. If you were just left with what the record entails today, which is just that initial EPA letter, you would have a false impression of the story. It may lead you to believe that the conversation ended there, but that's absolutely not the case.

In reality, DEQ responded to that letter, continued to defend the permit, provided a lot of helpful information that EPA as the agency not writing the permit didn't know, and ultimately this final letter -- which we received two days ago, which now in our minds we consider the matter closed based on this letter -- is another very critical part of that story which is that DEQ essentially

was able to come to a common understanding with EPA and find that the letter does meet the Clean Air Act and that it's -- the matter is closed.

And so, again, we did not start this process of putting these letters into the record, but now that it's here, out of fairness and to not prejudice any of the parties, we would strongly argue that all of the letters be allowed in.

And the final point I'd like to make is that just because you allow the letter into the record today doesn't mean that you don't have time to study it, consider it, think about the merits of what's being raised, you know, under those limitations set by the hearing officer, of course, and analyze it in your own time, and decide what weight to give it.

By allowing it to be introduced into the record today though, it's at least something that you can do, you can consider it and make your judgment when you're ready and when you have time to review it fully.

And to that end I did bring courtesy copies of our motion and declaration that was filed yesterday. I don't know if that would be helpful to pass around, because I do realize and apologize for its very late filing.

If you want a copy you can certainly take one

and pass it around, but there's both the declaration of Ms. Floyd with the letter attached as well as our motion. So provide that.

So with that, I would absolutely stand for any questions, but that's all I have to say.

BOARD CHAIR BOWEN: Could I ask you a question?

MS. YOUNG: Yeah.

BOARD CHAIR BOWEN: I think one of the concerns the Board has is what about the opportunity to fair response to this letter? Do you have an opinion on whether the parties should be given a chance to have fair time to respond to this letter before it's considered entered into the record?

MS. YOUNG: Mr. Chairman, if I may ask a clarifying question? Who do you mean by parties? Do you mean the petitioners?

BOARD CHAIR BOWEN: To them and the respondents to this motion.

MS. YOUNG: I don't think that that's necessary.

If the Board did want to allow the petitioners to write an objection or write some sort of response to our motion, that would certainly, you know, be fine.

They were allowed that opportunity to file an objection to our first motion to supplement the record and have their voices heard.

But again, the substance of the EPA letter is really not incredibly relevant to the issues today, because EPA is not a party to this case, and because we see this dialogue with EPA as sort of a separate matter. They're talking about issues that don't completely overlap with what is in front of the Board today. As we'll talk about later, of course, the petitioners have sort of narrowed down their issues as this process has gone on, and so we don't have that same overlap.

I don't think we're really here to discuss or debate the merits of what EPA said, it's more just for the Board to understand from a high-level perspective that when we received that letter from EPA in August of 2023, it didn't end there; the story didn't end there, and we continue to defend the permit just like we are today.

BOARD CHAIR BOWEN: Okay. Thank you.

Any other questions from the Board?

BOARD MEMBER STEELE: So in the letter from EPA, there's no new facts in that letter for us to consider?

MS. YOUNG: No, I would say there are no new facts. From the most recent EPA letter?

BOARD MEMBER STEELE: Yes.

MS. YOUNG: Sorry, Mr. Steele.

No, there's really no new facts. There are --

and I hesitate because I don't want to get into the first two separate. But, you know, it's really --

There's been a dialogue between DEQ and EPA since that letter, and there are things that have transpired, there's information that's been shared. Again, that is all information that, you know, has been vetted during the public comment process, during the dialogue with EPA. As far as the response to comments documents and things like that, the EPA has raised some of these same issues, has raised the same issues during the permit development as they did in their letter, so there's really no new facts.

Again, we are just hoping to put it in front of the Board. Because petitioners moved to enter the August 2023 letter, we don't want the Board to have a false impression that DEQ didn't respond and take, you know, serious, take it very seriously the statements and, quite frankly, accusations made in that letter from EPA.

BOARD MEMBER STEELE: Thank you.

BOARD CHAIR BOWEN: All right. Thank you.

MS. YOUNG: Thank you.

BOARD CHAIR BOWEN: Does Perpetua's attorney want to make a statement?

MR. POOSER: Yeah. Thank you. Christopher Pooser for Perpetua.

Only to say that we join in the motion and we concur with Ms. Young's remarks. We don't really have anything to add to what she said. I'd be happy to stand for any questions.

BOARD CHAIR BOWEN: Thank you.

Let's give the respondents an opportunity. Let's begin with -- go ahead. Decide. Tell us who you are.

MR. HURLBUTT: Bryan Hurlbutt representing the Nez Perce Tribe and the Idaho Conservation League.

We do not oppose adding the new EPA letter to the record.

And relatedly, in interest of completing the record, we are willing to withdraw our opposition to the motion to add DEQ's previous letter to the record. It seemed fairly incomplete before without EPA's response, but now with that, we do not oppose having both of these documents before the Board to consider.

And as far as whether there should be an opportunity to respond to that letter, we're prepared to talk about the letter today to the extent that the Board wants to, and how it relates to the merits of our claims, and we are happy to provide supplemental briefing or something like that if the Board thinks that would be helpful for considering the EPA letter. Yeah.

BOARD CHAIR BOWEN: Okay. Questions?

BOARD MEMBER STEELE: So with that statement, I mean, would you formally want to provide written comments? Or you said you'd be happy to provide written comments?

MR. HURLBUTT: We are happy to if the Board thinks that that would be helpful to reach a decision. And if not, we're happy to just say some things about it today during our argument.

BOARD MEMBER PURDY: So I guess an additional follow-up then. If you had the opportunity to provide oral argument today, then do you feel like you need to still have the time frame in statute to respond in writing? Or do you feel like just today's would be -- you don't have an opposition, so it seems like you're saying that today would be enough; is that what I'm hearing?

MR. HURLBUTT: Correct. As far as responding to the actual motion that was filed yesterday.

BOARD MEMBER PURDY: Okay.

MR. HURLBUTT: Yeah.

BOARD CHAIR BOWEN: Okay. Thank you.

Any other parties want to speak to that?

MS. THROWER: No. Thank you.

(Reporter clarification.)

MS. THROWER: Julia Thrower for Save the South Fork Salmon.

BOARD CHAIR BOWEN: Any other discussion?

Yeah, I, for one, after that new information would like to entertain -- if the Board would like to entertain moving to executive session?

Randy, do you want to make a motion?

VICE CHAIR MACMILLAN: Yes, sir. I move that the Board enter into an executive session pursuant to Idaho Code 74-206(1)(f) to communicate with legal counsel and the public agency to discuss the ramifications of and legal options or controversies not yet being litigated but imminently likely to be litigated.

I request that a roll call vote be taken and that vote be recorded in the minutes of this meeting.

BOARD CHAIR BOWEN: Do I hear a second?

BOARD MEMBER MCELROY: Second.

BOARD CHAIR BOWEN: Thank you.

Elaine, let's take a roll call, please.

BOARD CLERK GANINO: All right, Mr. Chairman.

Mark Bowen.

BOARD CHAIR BOWEN: Aye.

BOARD CLERK GANINO: Dr. Randy MacMillan.

VICE CHAIR MACMILLAN: Aye.

BOARD CLERK GANINO: Carol Mascarenas.

BOARD MEMBER MASCARENAS: Aye.
BOARD CLERK GANINO: Beth Elroy.
BOARD MEMBER ELROY: Aye.
BOARD CLERK GANINO: John Sigler.
BOARD MEMBER SIGLER: Aye.
BOARD CLERK GANINO: Clayton Steele.
BOARD MEMBER STEELE: Aye.
BOARD CLERK GANINO: Pat Purdy.
BOARD MEMBER PURDY: Aye.
VICE CHAIR MACMILLAN: So motion passes?
BOARD CHAIR BOWEN: Motion passes.
Moving to executive session. Thank you.
(Thereupon the Board convened into executive session off the record.)
BOARD CHAIR BOWEN: Okay. I'll entertain a motion.
VICE CHAIR MACMILLAN: Mr. Chairman, I move that the Board resolve out of the executive session, and that the meeting of the minutes reflect that no action was taken during the executive session.
BOARD MEMBER PURDY: Second.
(Unreportable simultaneous cross-talk.)
BOARD CHAIR BOWEN: Carol, can you hear us?
BOARD SECRETARY MASCARENAS: Yes, I can.
BOARD CHAIR BOWEN: Okay.

BOARD MEMBER MASCARENAS: Thank you.
BOARD CHAIR BOWEN: All right. We have a motion and a second.
Elaine, will you take the roll?
BOARD CLERK GANINO: Yes, Mr. Chairman.
Mark Bowen.
BOARD CHAIR BOWEN: Aye.
BOARD CLERK GANINO: Dr. Randy MacMillan.
VICE CHAIR MACMILLAN: Aye.
BOARD CLERK GANINO: Carol Mascarenas.
BOARD MEMBER MASCARENAS: Aye.
BOARD CLERK GANINO: Beth Elroy.
BOARD MEMBER ELROY: Aye.
BOARD CLERK GANINO: John Sigler.
BOARD MEMBER SIGLER: Aye.
BOARD CLERK GANINO: Clayton Steele.
BOARD MEMBER STEELE: Aye.
BOARD CLERK GANINO: Pat Purdy.
BOARD MEMBER PURDY: Aye.
BOARD CHAIR BOWEN: Okay. We're back in general session here. I'd like to thank the audience for indulging the Board. I think with this new information we've received -- any discussion from the Board?
VICE CHAIR MACMILLAN: Mr. Chairman.
BOARD CHAIR BOWEN: Yes.

VICE CHAIR MACMILLAN: It would seem that all the parties have agreed that the correspondence between DEQ and EPA is appropriate to include in the record, and that resolves our concern about making sure that this whole process is fair and open.

BOARD CHAIR BOWEN: Okay. Any other comments?

(No response.)

BOARD CHAIR BOWEN: I think the Board would like to hear from the parties that they agree to stipulate bringing these two letters into the record under the stipulation that -- under the same conditions as found by the previous hearing officer:

That the EPA letter cannot be used, one, to add new allegations of error.

Two, to add factual information that was not already part of the record.

Or three, as a proxy for expert testimony to the petitioners.

Do the parties stipulate? DEQ?

MS. YOUNG: Yes, Mr. Chairman, we would stipulate to that. Thank you.

BOARD CHAIR BOWEN: Perpetua?

MR. POOSER: Yes, Mr. Chairman, we stipulate.

BOARD CHAIR BOWEN: ICL?

MR. HURLBUTT: Yes, we stipulate.

BOARD CHAIR BOWEN: And does that include the other parties?

MS. THROWER: Yes, it does. Thank you.

BOARD CHAIR BOWEN: Okay. Nez Perce.

MR. HURLBUTT: Yes, for the Nez Perce as well.

BOARD CHAIR BOWEN: Thank you. Okay. With that I'll hear -- I'll entertain a motion.

VICE CHAIR MACMILLAN: Mr. Chairman, I move that the Board accept into the record, under the same conditions as identified by the hearing officer with regard to the August 10th, 2023 letter, the November 22nd, 2023, and the March 12th, 2024 correspondence between DEQ and EPA.

BOARD CHAIR BOWEN: Do I have a second?

BOARD MEMBER STEELE: Second.

BOARD CHAIR BOWEN: Any discussion?

(No response.)

BOARD CHAIR BOWEN: We'll entertain a vote. Elaine, will you call roll?

BOARD CLERK GANINO: Yes, Mr. Chairman.

Mark Bowen.

BOARD CHAIR BOWEN: Aye.

BOARD CLERK GANINO: Dr. Randy MacMillan.

VICE CHAIR MACMILLAN: Aye.

BOARD CLERK GANINO: Carol Mascarenas.

BOARD MEMBER MASCARENAS: Aye.
BOARD CLERK GANINO: Beth Elroy.
BOARD MEMBER ELROY: Aye.
BOARD CLERK GANINO: John Sigler.
BOARD MEMBER SIGLER: Aye.
BOARD CLERK GANINO: Clayton Steele.
BOARD MEMBER STEELE: Aye.
BOARD CLERK GANINO: Pat Purdy.
BOARD MEMBER PURDY: Aye.
BOARD CHAIR BOWEN: Motion carried. Thank you.
So that was essentially amended agenda item number 1.
Item number two was the second letter which we've just handled.
Any further comment on those two agenda items?
(No response.)
BOARD CHAIR BOWEN: If not, we'll move to the last agenda item. This next item on the agenda is oral argument on the amended petition for review of the preliminary orders that was filed by the petitioners, the Nez Perce Tribe, ICL, and Save the South Fork of the Salmon on December 15th, 2023, in the matter for Air Quality Permit to Construct P-2019.0047, case docket number 0101-22-01, OAH case number 23-245-01.
The amended petition asked this Board to review

the amended preliminary order issued by the hearing officer on December 5, 2023. The matter has been fully briefed.

We'd like to provide 30 minutes to each party to argue the amended petition. In addition, there will be 10 minutes allotted to the petitioners for rebuttal.

Let's begin with the petitioners first, the Nez Perce Tribe, then ICL, then Save the South Fork Salmon.

MR. HURLBUTT: And if it's okay with you, we planned to sort of do this together instead of dividing, you know, by parties.

Ms. Thrower is going to handle two of the four issues that we raised, and I was going to handle the other two, if that's okay.

BOARD CHAIR BOWEN: Okay. Are you okay with 30 minutes between you?

MS. THROWER: Yes.

BOARD CHAIR BOWEN: Okay. Thank you. Begin.

MS. THROWER: Thank you, Mr. Chairman.

And just as a technical question, are we able to put up some of the record documents?

MS. WILSON: Uh-huh.

MS. THROWER: Okay. Can I have you please go to REC 0145?

MS. WILSON: Do you know which number it is? Or

REC which again?

MS. THROWER: 415. So yeah, you have to scroll up quite a bit.

VICE CHAIR MACMILLAN: Carol, can you hear us?

BOARD SECRETARY MASCARENAS: If the respondents can talk a little louder, that would be great.

VICE CHAIR MACMILLAN: There is a chair up here if you'd like.

BOARD CHAIR BOWEN: Move the microphones back there.

MS. WILSON: Can you repeat the REC number?

MS. THROWER: It's document 36 REC 145.

MS. WILSON: Okay.

BOARD MEMBER STEELE: Which two were you going to talk about? Is it ambient air or --

MS. THROWER: I'm going to talk about ambient air, the access road issue, and also the fourth issue in our brief, the arsenic issue.

BOARD MEMBER STEELE: Okay. Thank you.

MS. WILSON: Do you know what page number other than the --

MS. THROWER: It's REC 415 on the bottom.

MS. WILSON: I'll just do math, I'll figure it out

MS. THROWER: Sorry, I don't have the PDF page

number.

MS. WILSON: That's okay.

MS. THROWER: Well, I can go ahead and start, Mr. Chairman, while that comes up.

BOARD CHAIR BOWEN: Thank you.

MS. THROWER: So, you know, we've heard, and I'm sure we'll hear more today, but we've read in petitioners' and Perpetua's brief about this pioneering approach for this proposed mining project to access some minerals. But what we're talking about here is an age-old problem of dust from roads that are created by vehicles traveling on unpaved roads.

There's no pioneering approach here to controlling dust. We at times will call that fugitive dust. There's no technological advances for controlling fugitive dust like there are for controlling pollution like out of a smoke stack, something that's more of a point source.

The pollution that we're concerned about here is creating a public health risk for those traveling and recreating through and around the proposed mine site. Some of that will be created, that dust will be created by blasting and crushing ore, but most of it is going to be caused by heavy trucks hauling ore up from blasting sites to ore processing facility and traveling on 55

miles of unpaved roads that are within the proposed mine site. And that's been the problem, most of the problems that petitioners have focused on.

All through the versions of the various draft permits, Perpetua and DEQ have had trouble on figuring out how to deal with this dust. It's not just a problem with compliance with the National Air Quality Ambient Air Quality Standards or NAAQS which in this case does involve, in particular, particulate matter, but it is also an issue with the state's Toxic Air Pollutant rules or TAPs, and in this case we're talking about arsenic which is a carcinogenic pollutant.

The approved permit and records supporting its decision demonstrates that DEQ still cannot comply with the NAAQS for particulate matter and for the TAPs for arsenic emissions.

Rather, the record demonstrates that DEQ took unprecedented, unsupported, and groundless measures to make it appear that the permit will comply with the law and the regulation.

As I said at the beginning, and Mr. Hurlbutt said, I'll talk about the Stibnite Road access route, and how we feel that that, including their excluding that route from ambient air protections violates the Clean Air Act and creates a public health risk for those using that

road.

I'll also talk about the arsenic emissions.

And as Mr. Hurlbutt says, he'll talk about the other two issues, the fugitive dust control efficiency, and also the plans that were not developed -- that are supposed to contain the enforceable permit conditions that were not developed in time for public review.

So indeed, if this permit is approved and this mine continues or is allowed to operate under the guise of the state's approval, this suggests that it complies with the Clean Air Act and Idaho state rules. And this creates a grave risk to public health for those who travel, recreate, and use the area to support their livelihood.

That's why we ask the Board to carefully consider the evidence before it and vacate this permit and remand it back to DEQ for reconsideration.

So I had an exhibit pulled up because there's a lot going on in this area. And I know it can be a little confusing if you're not -- if you haven't studied this map and aren't really familiar with the area.

So what this map shows is the ambient air boundary, sometimes it's called the operations boundary as well. And that's that blue line that encircles the entire mine site and several other thousand acres. That

ambient air boundary is, you can think of it sort of as a bubble.

Inside that ambient air boundary, the air quality does not meet -- does not need to meet the NAAQS, and it does not need to meet the state's toxic air pollutant standards.

Outside that ambient air boundary, and that is where the public is allowed to recreate, it will be open for public use, there's a lot of important recreational sites, important sites that the Nez Perce Tribe uses, and those sites and those uses were established in our standing declarations that were submitted before the Office of Administrative Hearings.

Outside that, again, like I said, the public is allowed to recreate, to use the public lands, and outside that ambient air boundary the air quality must be consistent with the NAAQS or it must meet the NAAQS, and it must meet the state's toxic air pollution standards.

So we're concerned -- so going through -- let me back up.

So looking inside that ambient air boundary, the gray color is -- are the proposed mining sites, some of the pits that will be mined. And I want to draw your attention to that green line that kind of goes from the north, where it says north entry, all the way through the

mine site and to -- if we can scroll down a little bit, there's -- that road goes to the south entry where it exits the mine site and exits the ambient air boundary. So that is called the Stibnite Road access route. It is a proposed route.

Currently there is a route called the Stibnite Road that is being used by the public to go through this area. That road, as I said, exists. Under the proposed mine plan, that road will be reconstructed so that it can be separated a little bit more from mining activities and provide a safer route to the public.

As I said, the public access is important for recreation sites on public land, both from the north entry and the south entry.

Currently the only way to get from -- to recreational sites at the south entry is to go through this road from the north entry to the south entry. And there's some sites, Thunder Mountain, Monumental Summit that you'll see that we referenced, both in our standing declarations and also in our briefing. And those are all recreational sites that are on Forest Service land.

The road that appears there at the south entry is a proposed road called the Burntlog Road. If you scroll down a little bit, I think you can see the name of it there. But that -- it says main access road to the

Cascade log route. That currently does not exist. That is a road that is proposed as one of the alternatives under the mine plan that the Forest Service is considering in its National Environmental Policy Act or NEPA analysis.

So I just wanted to give you kind of a lay of the land. Hopefully that will make it a little more -- make a little more sense of what our issue is here.

So as I said, inside the ambient air boundary there aren't -- the air doesn't need to meet the NAAQS or the state's caps criteria outside of the, we might call that the point of compliance, the air needs to meet both of those standards.

So in this issue when I'm talking about the access road, we are mainly concerned about access through the mine inside of that ambient air boundary.

Now, we raised two issues, one that sort of goes to the same problem here.

One is the legal control of the road. So under the Clean Air Act -- and the Idaho state rules have adopted the regulatory definition of ambient air -- the issue is whether that road can be excluded from ambient air protections, meaning that it can have polluted air that exceeds healthy standards set by the EPA and set by the state for toxic air pollutants. The threshold

question in whether a facility, an applicant can exclude any portions of the facility, outside of the building, can exclude that from ambient air protection is whether it has legal control and practical control.

So if we look at EPA's policy on ambient air -- and just for your reference, that is REC 1138, and we don't need to go to that up on the screen.

But EPA says that in order to exclude an area from ambient air, you have to have two things: You have to have the legal power to control, and exclude the public. Not just control the public, but exclude the public, and the physical ability to exclude the public. So think about fences, maybe surveillance, that kind of thing.

The issue here is that DEQ is arguing -- and the hearing officer accepted this argument -- that they were reasonable in relying on the single statement and certification provided by Perpetua in the application that Perpetua has the legal control to exclude the public. And the reason this is important is because they're allowing the public through there.

So, you know, one of the problems is -- and, you know, if you look at the record, is there is evidence that Perpetua does have legal control to control access to a certain extent, but not to preclude public access.

So legal control can be just, you know, from their plain old simple ownership of land and they can keep people out. It can also be controlled as given to them through a different entity, from, for instance, the Forest Service. So there's a mix of land ownership patterns here, some of it on patented lands Perpetua owns, the rest of it, most of that ambient air boundary, inside that ambient air boundary the Forest Service owns, and that's public land.

The Forest Service, under the current mine plan -- which is not approved yet by the Forest Service, they're still going through the NEPA process. The Forest Service will give Perpetua the legal ability to control access to the extent that they can control the public's access for safety reasons. But there's evidence in the record that shows that Perpetua does not have the legal access to preclude the public. And some of those statements are related to the Forest Service's process here.

That process, the mine plan, currently there was a proposal to close that road, but comments from the public to the Forest Service had made it clear that that is an important road for the public to have open to access these recreational sites. And so the Forest Service, under both alternatives that are being

considered for the mine plan, that road is going to be open to public access. Perpetua cannot, if those two -- if one of those two alternatives -- it doesn't matter which one, as I said, it's the same thing.

If one of those two alternatives gets approved, Perpetua will have the ability to control access to the extent that it needs to to make sure that people can travel safely through there, but it will not be able to close the road to public access.

And so based on that, we don't believe that Perpetua can exclude this road from ambient air protection. It just doesn't meet the two requirements under EPA's policy on ambient air to be able to do that. Again, that's the legal power to exclude the public and the physical ability to also do so.

BOARD MEMBER STEELE: So real quick on that. I mean, we're talking about controlling access or excluding access?

MS. THROWER: Right.

BOARD MEMBER STEELE: I mean, that's what the argument is here?

MS. THROWER: Right. And, I mean, in order to be able to exclude an area from ambient air protections, meaning you don't have -- basically this is -- the whole idea of ambient air is to protect public health; right?

I mean, you have standards, the NAAQS standards, how much particulate matter can be in the air, the state standards for toxic air pollutants, how much can be in the air; that does not create a public risk, a public risk large enough for us to really worry about.

Particulate matters or respiratory irritants particularly, you know, affecting children, older people, people that have pre-existing conditions, but also it does affect, you know, healthy people if there's enough in the air. Same thing with arsenic, it's a carcinogen.

BOARD MEMBER PURDY: But isn't exposure time -- excuse me.

But exposure time is a critical part of that; right? If an individual is allowed to go into the area and camp for two or three days versus only allowed to pass through, and they only spend a half an hour or an hour inside of that bubble, that makes a big difference, doesn't it, the amount of the exposure time?

MS. THROWER: Well, yes and no.

BOARD MEMBER PURDUE: Okay.

MS. THROWER: Under the National Ambient Air Quality Standards which, you know, the state needs to meet, there's criteria set, levels of pollution that you can't go above --

BOARD MEMBER PURDY: Period?

MS. THROWER: -- to the ambient air. Yeah. It doesn't matter if, you know, people are just passing through or if they're going to be camping or if they're living there, you know. You just can't -- it's just a threshold. You're either meeting ambient air qualities standards or you're not.

BOARD MEMBER PURDY: So you don't -- obviously you don't accept Perpetua's guest of the mine --

MS. THROWER: Yes. Right.

BOARD MEMBER PURDY: -- process where it would either escort or control or monitor that access to make sure the people were moving through and not stopping and hanging out in that area, that they would move through the mine area safely as an escorted guest or a monitored guest.

MS. THROWER: That's right. Yeah. And it makes sense in terms of safety. Obviously they don't want people straying off the path, you know.

But in terms of air quality, it -- yeah, that doesn't matter. And it, you know, this is, you know, on paper it's a recreation area; a lot of people are traveling there, are going to travel there in the summer in open air vehicles, like Razors, ATV's or whatever, you know, people who pass in cars and supposedly they can close up their windows and turn their air off and

everything like that. But that still doesn't matter in terms of compliance with the National Ambient Air Quality Standards.

And that's really the threshold that we're talking about here. The state caps that we talk a lot about that, that kind of comes into the arsenic air issue and outside the ambient air boundary, but really for the access road it's the NAAQS and the particulate matter.

And so yeah -- oh, go ahead.

BOARD MEMBER STEELE: I've got a follow-up. So right now is the general public going from the north through the south, or is that whole area controlled right now?

MS. THROWER: It is open to public use. I think that I'll defer that question to Perpetua in terms of whether they have any, you know, if they're doing any activities. There are exploration activities out there. Whether -- they probably do have the ability to control access, maybe even temporarily shut down if they're going to be doing something that would create too much of a safety hazard for the public to pass through. But those are temporary closures, not a complete closure for 16 years, you know, the life of the mine.

BOARD MEMBER STEELE: Okay.

MS. THROWER: If you -- and yeah, if you enter

that south -- if you exit on that south entry, there are Forest Service roads that continue on into, as I said, the important recreational areas --

BOARD MEMBER STEELE: Okay. Thanks.

MS. THROWER: -- that are pretty heavily accessed through summer. Yeah.

So I do want to -- I'm taking a lot of time on this issue, and I do want to go ahead and move to the issue that you mentioned in terms of the guest of the mine.

We don't think that this --

We don't believe that that is consistent with EPA's policy, and it's not consistent with DEQ's guidance on ambient air boundaries.

I think I'll just, in the interest of time, I will just point out one of the glaring inconsistencies is with DEQ's guidance. And I'm going to note a typographical error in our motion in terms of the number, the record number. So I talked --

In our brief we talked about how the guest of the mine issue, which is really the public going through, they don't want to visit the mine, they just want to get to public land. So to call them guests of the mine to take away these ambient air protections is really inconsistent and really against the law and the purpose

and intent of the Clean Air Act.

But even DEQ's guidance says, and I quote,

"For the purpose of defining ambient air, the general public is considered anyone not directly associated with the facility. In general, if someone present at the site would not be subject to OSHA or other worker exposure regulations, then they are considered as the general public."

And that is at REC 1109.

I don't think anybody here can credibly claim that people traveling on this road to access public lands are going to be covered under OSHA or worker exposure laws.

So, you know, allowing people to do this and calling them guests of the mine because they sign a waiver I think is inconsistent with this DEQ guidance, it is against EPA's ambient air policy, and it creates a huge public health risk for the public traveling that, you know, isn't going to understand that when they sign this waiver that they're necessarily going to be exposed to air quality that doesn't meet EPA's standards for public to be able to breathe.

I want to move on to the second issue with

arsenic unless there are any further questions on that?

BOARD MEMBER STEELE: Well, I guess, you know, you talk about DEQ basically not using their guidance appropriately and same with EPA. But DEQ has had correspondence with EPA on that.

MS. THROWER: Right.

BOARD MEMBER STEELE: And they have decided that the road is likely exempt from ambient air protection.

MS. THROWER: Yeah.

BOARD MEMBER STEELE: So would you talk a little bit about that?

MS. THROWER: Yeah. We can go to this recent EPA letter that was just submitted into the record this morning.

And in that case EPA does still have concerns about the road and whether Perpetua has -- has the legal right to exclude the public. So at the top of page 2 it says,

> "With respect to ambient air boundary designation, the EPA continues to have concerns with IDEQ's acceptance of Perpetua's assertion that members of the general public do not have the legal rights of access to areas within the operations area boundary."

So I wouldn't say that that is completely resolved.

There were other issues that EPA had brought up about general access around the ambient air boundary in terms of there being a lot of trails, rivers going through there and everything like that.

But the EPA goes on in that letter, and I think there they are saying that, okay, we are okay with that. The access management plan provides those physical barriers for other areas around the ambient air boundary, and they believe that that is consistent with the policy.

But I think that this road access is still an issue, even after all these communications with EPA.

Okay. So I'll move on to arsenic. So we're moving outside of the ambient air boundary. There's still a lot of dust that's going to be flying around, and what I'm going to go through is the state's rules on this.

Because I think what is clear here is that there's certain prescribed ways to assess toxic air pollutants -- and now I'm shifting to arsenic and more away from particulate matter.

But there are specific state rules on how you calculate your toxic air pollutant emissions, and there's specific thresholds that you have to be under. There are

ways to -- different ways to calculate that and everything and, but this isn't a free-for-all, there's no availability to do project specific adjustments as Perpetua and DEQ have suggested.

So if you look at the state's rule, Section 203 says that,

> "No permit to construct shall be granted unless an applicant can show that emissions of TAPs will not injure or unreasonably affect human health or animal life or vegetation as required by Section 161."

So 161 basically says that toxic air pollutant must not be admitted in quantities or concentrations up to, alone or with other contaminants, injure or unreasonably affect human life -- excuse me -- human health or animal life or vegetation.

Section 203 also states that you can -- that,

> "An applicant can demonstrate compliance with Section 161 by meeting the emission increments in section 586."

Don't you love regulations, right? I'm sure you'll be pulling all of these up at some point.

Section 586 is basically a table of toxic air pollutants emission limits. The one that we're focused

on here is the called the Acceptable Ambient Air Concentrations for carcinogen or AACC. And arsenic has a number, an AACC number.

The regulations also state that AACC's are annual averages. So you figure, like with the mine, 16 years, maybe emissions aren't exactly the same every year. You add up 16 years of emissions, you divide by 16, that's your annual average.

Section 203 requires an applicant to, "Use methods under Section 210 to demonstrate compliance with Section 203."

So if we go to Section 210, it prescribes standard methods an applicant can use in sections .05 and .08 or specialized methods in Sections .09 and .12.

So the one that Perpetua and DEQ used is Section 210.12. And we're all good here, this is all working fine. It says that you can use a method called T-RACT, which is Reasonably Available Control Technology, to demonstrate compliance with the TAP increments in Section 586. So if you do that, if you can't meet the TAP increments in 586, you can meet them by applying this reasonably available control technology. And the regulations give you a little bit of a bonus. They -- instead of having to meet the thresholds in 586, they allow you a ten-fold increase in that threshold.

Okay. So let's say you can emit one unit under 586. Well, now if you use reasonably controlled technology, they're going to let you emit 10 units and you'll still be in compliance. Okay. You're still not going to injure human health unreasonably.

So Section 210.12(B) again states this ten-fold bonus as the cancer risk probability of less than 1 to 100,000. So before with the TAPs increments it was one to a million, now, we're at 1 to 100,000. And the regulation states, "Which is equivalent to ten times the applicable AACC listed under 586." That's where we get that ten-fold bonus.

Now, Section 210.12(C) says that you can demonstrate that you meet the T-RACT AACC, the ten-fold increased AACC, if you -- if you can meet that -- excuse me. If you can meet that amount, then you don't have to do any further demonstration of compliance with Section 161 which is, you know, that's not unreasonably injuring human health.

There are other methods. 210 says that you can use -- or excuse me -- 212 -- 210.12 says there are a couple of other methods you can use: 212.09, I think, net emissions or whatever in addition to T-RACT, but that's not what we're talking about here.

What DEQ and Perpetua did is they did a project

specific adjustment factor is what they called it. And what they did was they took the annual arsenic -- they took the arsenic emissions, the total emissions, and instead of dividing by the life of the mine, which would be your annual emissions as required under the regulations, they divided by a 70-year human lifetime.

So what that essentially does is it lessens the emissions significantly. They were able to comply with the ten-fold AACC level if they did that.

But deleting the emissions that way does not comply with the fact that you need to be comparing your annual emissions, and not, you know, including another 54 years of nothing to derive that figure for your annual emissions. So we don't believe what Perpetua did here complies with the state's rules.

We also don't believe, to the extent that they're arguing that, oh, you can do other things to demonstrate compliance, to demonstrate that there's not an unreasonable risk to human health, we don't see that anywhere in the record.

There's a declaration by Kevin Schilling, who is an atmospheric scientist not a cancer risk assessment scientist, who tried to justify their use of this 70-year dilution factor. We just don't see the evidence that -- again, even if you read the rules to allow something like

that, we just don't see the rationale or the justification or the support in the record to demonstrate that this was a reasonable decision based on the record, and not arbitrary and capricious.

I have taken a lot of Bryan's time. I'm going to stop for questions. But I'm sorry, Bryan, and I hope they'll be a little lenient on the time understanding that, of course, the other parties should have the same amount of time as well.

BOARD MEMBER STEELE: So I just have a couple of questions.

BOARD CHAIR BOWEN: Go ahead.

BOARD MEMBER STEELE: So is there any human habitation that's being impacted, you know, like for 16 years of this project? Or are we mainly talking about the access road?

MS. THROWER: Well, the access road is really just regarding the particulate matter.

Outside the ambient air boundary where the arsenic issue comes in, Yellow Pine is the closest community. I mean, we don't know. We can do a dilution factor and everything, we don't know how far out you would have to go to actually comply with the TAPs increments, the ten-fold TAPs increments.

I think Yellow Pine is about 10 miles west of

the mine site. There are -- there's a population there that lives there year-round. It's not huge, but, you know, rural people are afforded the same protections --

BOARD MEMBER STEELE: Yeah.

MS. THROWER: -- under the Clean Air Act as anybody else.

BOARD MEMBER STEELE: For sure.

MS. THROWER: The Nez Perce Tribe that uses the fishing and gathering and hunting -- I can't attest to the amount of time they spend there -- they're not my client. But in terms of, you know, it's not just an area that people pass through on their way to somewhere else.

BOARD CHAIR BOWEN: Any other questions?

BOARD MEMBER MCELROY: Mr. Chairman.

BOARD CHAIR BOWEN: Yes.

BOARD MEMBER MCELROY: I have a quick question. So the 70-year dilution factor that you're calling out, does DEQ have any guidance documents that walks through how to use that type of factor? Or has this approach been used in other air permits that the DEQ has issued in the past?

MS. THROWER: Not that we are aware of. During discovery we asked DEQ if they could provide us with any other permits that used this type of dilution factor, and we did not get any documents from that. They simply do

not have that.

So we are assuming that this is really the first time in a very precedential move to use this kind of project-specific dilution factor for this permit.

BOARD CHAIR BOWEN: Any other questions?

(No response.)

BOARD BOARD BOWEN: Okay. Mr. Hurlbutt, you've got 30 minutes. We were prepared for 30 each, so 30 minutes, you've got 30 minutes.

MR. HURLBUTT: Appreciate it.

MS. THROWER: Thank you. I definitely appreciate that. I'll have a better lunch with my colleague.

MR. HURLBUTT: Yeah. All right. So I'm going to turn to the issue of DEQ allowing Perpetua to submit a number of plans later, after the permit was already approved, after public comment period had already happened. Those plans still haven't been submitted, they're required to be submitted 30 days before operations might start.

So the permit allows for Perpetua to submit these four plans -- the fugitive dust control plan, the haul road capping plan, the access management plan, and the operation and maintenance manual -- later.

But the Air Rules require, as I'll walk through,

that plans and other information about the project be submitted by the applicant, be evaluated by DEQ, and be subjected to public comment before DEQ issues a permit or makes a final decision on a permit.

And I'll also walk through how relevant case law on meaningful public involvement supports this, and shows that important project details like those that will be included in these plans cannot be shielded from public comment, as was done here.

So starting with the Air Rules -- and this is not nearly as in-depth or as confusing as the arsenic standard stuff that Julie just walked through -- but I'm going to talk about Air Rules.

Let's start with Section 202 of the Air Rules. This is what talks about what needs to be in an application, required information for an application. And this is in Air Rule 202.01.A(i). Required -- applicants must provide, quote,

> "Site information, plans, descriptions, specifications, and drawings showing the design of the stationary source facility or modification, the nature and amount of emissions, including secondary emissions, and the manner in which it

will be operated and controlled." End quote.

Air Rule Section 209 also requires public comment. And it states there that required information for public comment is, quote,

"The department's proposed action together with the information submitted by the applicant and the department's analysis of that information will be made available to the public," end quote. That's 209.01(c)(1).

The four plans that haven't been submitted include:

The type of required information from Air Rule Section 202;

Information about how the site's going -- the facility is going to be operated and how emissions are goings to be controlled;

And it includes the kind of information that the Section 209 requires to be made available during the public comment period;

And the analyses that DEQ is going to perform in the future when it reviews these plans that Perpetua is supposed to submit is the kind of analysis that Section 209 requires to be put forth before the public to review

and comment on before a permit is approved.

Two of the plans have to do with dust control, that's the fugitive dust control plan and the haul road capping plan.

The fugitive dust control plan, that's permit condition 2.6. You can see that at REC 0375, 376.

The haul road capping plan, that's permit condition 3.13 at RAC 0385 through 86.

And the fugitive dust control plan requires, among other things, quote,

> "Specific criteria to determine what frequency and type, water and/or chemical, of dust suppressant must be applied, and appropriate suppressant application rates," end quote.

So the fugitive dust control plan is going to include information about how often Perpetua is going to use dust controls, what types of dust controls they're going to use, and the rates at which they're going to apply them. And this is super important information, as Julia already mentioned.

While there are other sources of fugitive dust from blasting and other operations at the site, the main source is from the haul roads. And how dust is going to be controlled on those haul roads goes straight to the

heart of whether this project can comply with the National Ambient Air Quality Standards.

Similarly, the haul road capping plan, it requires a silt content sampling plan; it requires an arsenic rock sampling plan; and it also requires specifications for how Perpetua is going to inspect and maintain the haul roads.

These plans, these do indeed -- well, first of all, they are plans. They have plans in the name of them. And remember, the required information the applicant must submit includes plans. And it also includes information, specifications, descriptions related to how the site will operate, and how pollution will be controlled. And that's exactly what these plans are and what they include. They describe how Perpetua will operate and control the roads, and how they will try and control dust at the site.

So instead of deferring them to the future, they should have been developed now. There's no reason not to develop them now and submit them to the public for comment before making a decision on the final permit.

And this isn't just kind of a technical gotcha thing. Again, this is really important as the record shows in the air modeling that's included with the Statement of Basis -- I have it right here.

Appendix B to the Statement of Basis has the ambient air quality impact analysis. And as we pointed out in our briefing, DEQ and Perpetua model, what would happen if instead of achieving 93.3 percent dust control, which is what Perpetua is targeting to achieve, what would happen if they instead achieved slightly less dust control and only controlled 90 percent of the dust?

In that modeling they also said, and let's suppose that Perpetua cut its emissions by a lot instead of a -- or cut its operations by a lot. Instead of producing 180,000 tons per day of materials, what if those were scaled back to just two-thirds, so 120,000 tons per day?

When this modeling was performed, a huge cut of the amount of operations -- so there's going to be a lot less driving around and a lot less dust potentially being generated -- and then just a tiny reduction in the effectiveness of controlling dust from those roads, again dropping from 93.3 percent dust control to 90 percent dust control.

That modeling that's in the records shows that the project would not comply with the NAAQS for coarse particulate matter. That's not in dispute. That's in the record. That's at REC 0691 through 0692 where DEQ describes this, and then there's 0693, further

information about that for a couple of pages.

So again, just a small reduction in how effectively they control dust in the roads, even coupled with a huge drop in production going on at the mine will result in the NAAQS being violated.

So this is a super important issue. And the idea that the details in these plans could just be developed later, after the project's been approved by DEQ, after the public's already submitted public comments, does not comport with the Air Rules, Sections 202 and 209.

These are the type of required information that the applicant needs to provide before a permit is issued, and the type of information that needs to go before the public, and DEQ's analysis of what's in those plans and whether it's good enough also needs to go before the public, and that was not done here.

The same is true of the access management plan. This is permit condition 2.7. Like the other plans, this is a plan, again it's the accent management plan -- access management plan. And Rule 202 requires plans to be submitted by the applicant during the permitting process.

And that plan includes information, specifications, and descriptions of how Perpetua will

operate and control the Stibnite Road project with respect to access management.

Access management is another important issue; it relates to what Ms. Thrower just discussed about the appropriate ambient air boundary. Instead of whether and how the public access is being managed, does bear on whether DEQ used the appropriate ambient air boundary for this project.

In the permit the access management plan is required to:

1. Identify the boundary and access points, and specify measures to discourage public access.

And 2. It's also supposed to identify access points that will be monitoring -- that will be monitored, the frequency they'll be patrolled, and the methods that will be used to discourage access.

Again, these are descriptions and specifications and plans about the project that have not yet been developed, not submitted for public comment, but DEQ approved the permit anyway without having that information.

And again, that's not in accordance with the Air Rules of Section 202 that clearly require that kind of information to be provided by the applicant, and Air Rules 209 which require the public to be able to comment

about that information and DEQ's analysis of it before the permit is issued.

BOARD MEMBER STEELE: So I've got a comment. So, you know, IDAPA has rules for fugitive dust. And within those rules, you know, you have to comply with that. And there is a permit condition for that in the permit to comply with the fugitive dust rules. It could also be looked at that these plans are in addition to that to help ensure that those fugitive dust rules are complied with. Have you looked at it that way?

Because this is a very common practice for DEQ to issue a permit and require a plan to be developed at a later date to help ensure compliance with other permit conditions.

MR. HURLBUTT: And so that may or may not be appropriate with complying with the IDAPA provisions that are specific to fugitive dust control.

But whether or not that's true, it's not appropriate to do this when you've got an issue, such as compliance with the National Ambient Air Quality Standards.

And again, that part of Statement of Basis that I pointed out with the modeling where just a tiny increase in fugitive dust control could mean that the NAAQS are violated shows that this is the kind of

situation where you need to have that kind of information considered before and evaluated by the Board.

And that's supported by two cases that we've cited in our briefing and discussed. These are two Federal Court of Appeals cases, Clean Water Act cases dealing with what's required to have meaningful public comment when a pollution permit is being issued, what things need to be put before the public, or which things could be saved for later.

This is the Environmental Defense Fund case that had to do with small municipal storm water discharges and permits for those. The EPA set up a program where instead of setting forth criteria for each small municipality to meet that would be subject to public comment, they were going to let the municipalities develop their own plans to meet six criteria EPA had identified later as to how they would reduce discharges.

That got challenged in court. The Ninth Circuit Court of Appeals held that the plans that those communities were going to come up with were the kind of substantive information about how the facilities would be operated to reduce discharges that's required to be subject to public comment and can't be shielded from public comment

BOARD MEMBER PURDY: So your issue is

specifically around your fear that there will be a lack of public comment opportunity during the development of these four plans? Has DEQ established that they're not going to allow public comment on those plans?

MR. HURLBUTT: The permit as currently written does not allow for public comment on those plans. It calls for Perpetua to submit those plans to DEQ, and it says DEQ will review and then approve them. There's no period afforded for public comment.

But I will also note that public comment after the permit has already been issued, while I suppose slightly better than no public comment, would still not comply with the Air Rules requirements under Section 202 and Section 209 that we discussed. Meaningful public comment has to happen before the final decision's been made on the permit.

BOARD MEMBER PURDY: But they're not allowed to begin operation until those plans are in place and fully approved.

MR. HURLBUTT: Correct. And in the 2nd Circuit in the Waterkeeper case that we cite, similar to the Environmental Defense Fund case, this involved large CAFOs. The EPA proposed that nutrient management plans that specified how pollution was going to be managed on these sites could be submitted later without public

review.

The 2nd Circuit disagreed with that and said that without meaningful public comment, those need to be submitted to the public before issuing those permits.

The same situation here: the fugitive dust control plan, the haul road capping plan, and the access management plan, they all contain substantive and important details about how Perpetua will control dust and manage access at the site, so they cannot be shielded from public review prior to DEQ issuing -- and need to be available prior to DEQ issuing any permit.

And the last thing I'll note on this issue about the plans being deferred: The recent EPA letter from March 12th -- which I don't know if you've all had a chance to review -- but it raises some serious concerns about things that have yet to be put forth to the public for comment.

On page 2 of the letter EPA notes that -- yeah, requests that certain plans do be made available to the public, and I'll just quote here. Near the end of the letter EPA says, quote,

> "Moving forward, we expect that all information relied upon to issue permits by the State of Idaho's permitting program be made available for public

review at the time that draft permits are made available for public comment," end quote.

For whatever reason, EPA seems to be willing to give DEQ a pass here and let DEQ to move forward with these late plans without public comment for Perpetua's permit.

But EPA is signaling here, I think, that it's in alignment with what we're saying that the rules actually require this information to be put forth earlier in the process to allow for meaningful public comment, and that it expects Idaho to do so in the future.

So we would ask you to set aside and remand the permit with directions that DEQ require these plans to be submitted; that they be subjected to public comment along with DEQ's analysis of those plans and their adequacy before making any final decision on the permit.

Any other questions about the plans before I move on to dust control?

So the last issue -- I think this is the third of four issues in our brief. But the last issue being argued now is DEQ's assumption that Perpetua will achieve 93.3 percent dust control. And our argument to that is that it's arbitrary and capricious.

Again, I'm going to say this again, and I

already talked about it, but this Appendix B, the modeling report and the analysis that was done shows that just a tiny reduction in dust control, Perpetua doesn't meet that 93.3. Even if they scale back their operations a ton and they are generating way less dust, they would be violating the NAAQS for particulate matter. So only slightly less dust control to cause NAAQS violations.

The target is for Perpetua to meet this 93.3 percent, but the permit lacks any enforceable conditions to ensure Perpetua will actually achieve such a high level of dust control.

The permit does have some conditions related to dust control. And DEQ might be able to reasonably assume that the project will result in a, you know, pretty good dust control based on that, but there's nothing in there that's really tied to achieving 93.3 percent as opposed to say 90 percent or 85 percent.

Again, just getting back to the Air Rules, Air Rules Section 203 provides that DEQ can't issue a PTC unless it first determines that the facility, quote, "...would not cause or significantly contribute to a violation of any Ambient Air Quality Standards."

Here DEQ acknowledged that throughout the record -- and we cite this a lot in our briefing -- that achieving this 93.3 percent is critical to achieving

NAAQS compliance; that it's a very high and aggressive level standard, and it will automatically require quote -- well, yeah, DEQ states in the record that it will be, quote, "Challenging to consistently and continuously achieve the targeted level of fugitive dust control," end quote. That's REC 0431.

DEQ modeling staff said, quote, that they, "Recommend the permit requiring aggressive implementation of measures to achieve above 93 -- to control 93 percent control efficiency," end quote. That's at REC 0691.

Elsewhere in the record they say that, "Vigilant inspection and monitoring will be required to achieve that."

But again, the permit doesn't actually require meeting 93.3 percent or greater dust control. There's no requirement in the permit itself to meet that.

There are two tables in the permit that have the number 93.3 in it, those are not emission limits or enforceable conditions of the permits, those are just listed targets and talking about the different things going on at the facility.

And even if those listing of 93.3 in those tables were to be considered some kind of limit in the permit, there's nothing enforceable about it. There is no monitoring to see what level of dust control is

actually being achieved, or there is no testing to see at startup kind of what dust control levels are being achieved.

If there were those things, then you might be able to have some kind of actual limit on 93.3 percent. It's not in there.

What the permit does have is the facility dust control plan and haul road capping plan that we've already talked about a little bit, and some other provisions related to fugitive dust.

But none of those things are tied specifically to meeting 93.3 percent as opposed to, say again, 90 percent, which is a pretty high level of control and would not satisfy the NAAQS.

BOARD MEMBER STEELE: So you say that it's arbitrary and capricious, yet there's quite a bit of record for where that 93.3 percent came from.

And, you know, the range, you know, from a conservative standpoint, 90 percent was used for dust, for the dust suppressant; it could have been 94, 95, it could be up to like 98 percent just for the dust suppressant alone. And with the water, the control efficiency could be 75 to 95 percent. So, I mean, in theory there could be up to a 99 percent control, 99.1, something like that.

So to say that it's arbitrary and capricious, I mean -- I mean, I guess I'd like you to elaborate about why.

MR. HURLBUTT: Sure.

BOARD MEMBER STEELE: Like what -- where's the better information that DEQ could rely on to make this decision?

MR. HURLBUTT: So we're not saying that it was arbitrary and capricious for DEQ to conclude that it might be possible to achieve 93.3 percent control. And I think a lot of information in the record you're talking about shows that DEQ, in its technical expertise, can decide that that is an achievable level of control that could be accomplished here.

What is arbitrary and capricious is to conclude that that will be controlled here, because the permit lacks specific conditions tied to actually achieving that as opposed to, say again, 90 percent, which is still a really high level of control, but it's not actually adequate to comply with Ambient Air Quality Standards. None of the things in the permit are tied to that.

There's been mention of this 10 percent opacity monitoring; looking around, seeing with your eyes what it looks like; if it looks like it's a little too dusty, then corrective actions need to be taken. That's great

and that's fine, but there's nothing in the record that shows how that relates to achieving 93.3 percent as opposed to 92 or 91 or 80 percent dust control.

It's a good practice -- that's great that they're doing it -- but our key point is that even if Perpetua comes up with some pretty good plans; submits them to DEQ; DEQ thinks they look pretty good; signs off on them; moves forward with the project; achieves a high level of dust control; that high level of dust control might be 93.3 percent, it might be 88 percent, it might be 95 percent.

DEQ can't approve a project though unless it determines that the project, based on its operations and the limits in the permit, will comply with the air quality standards. And so it was arbitrary and capricious to do that here.

DEQ can say this has a shot at achieving 93.3 percent, and might meet it, but that's not what's required. DEQ has to find that it will not cause a violation of air quality standards.

There might be a lot of other situations where a permit is for a facility and it's not teetering on the edge of non-compliance like this one is. In other situations having a ballpark target for dust control might be fine because there's more wiggle room.

But again -- and I know I've already mentioned this four times, I'm going to mention it a fifth time -- the modeling that's in the record shows that just even if they cut their operations by a whole third, this tiny change in dust control efficiency is modeled to cause NAAQS violations.

And the permit doesn't have anything that precisely leads to 93.3 percent dust control. The project could move forward and be operating and causing NAAQS violations every day, and no one would know any better, and they'd be in perfect compliance with their project, potentially achieving 90 percent dust control.

VICE CHAIR MACMILLAN: So, Bryan, I was just wondering if anybody -- do miners have an idea just how much -- without any control, how much dust would actually be generated? I didn't see that in any of the documents. And the reason I ask that, unless you know how much you begin with, how do you know if there's a 10 percent reduction or zero percent reduction?

MR. HURLBUTT: I think they do know or they have estimates. This modeling starts from, assuming they're driving around this much and generating this much dust, then they say okay, if we control different things by different amounts, then what are the results? And I don't -- yeah. So they do start with that.

VICE CHAIR MACMILLAN: Okay.

MR. HURLBUTT: Yeah.

BOARD MEMBER STEELE: So this might be a question I'll need to ask the DEQ. But Schilling in his declaration, he did, there's a quote in here that he said that the permit -- that the modeling group recommended that the permit require aggressive implementation measures to achieve above 93 percent control efficiency for fugitive particulates from the roadways.

You're saying it's your belief the permit does not require that, it does not require that compliance?

MR. HURLBUTT: It does not. I mean, the fugitive dust control plan requires Perpetua to come up with a plan for how they're going to determine how often to apply materials, which types, and what amounts. And again -- and I'm happy to assume that they'll do a pretty good job of that, but again, how they're going to achieve 93.3 instead of some other lesser amount.

BOARD MEMBER STEELE: Okay.

MR. HURLBUTT: I guess the one last thing I'd say on the 93.3 percent control is that, again, the reason I think the recent EPA letter helps support this, on the first page, the bottom paragraph, EPA raises concerns about the fugitive dust control plan and says at one point, quote,

"The EPA understands that not all details of an approvable plan can be known in advance. But without permit conditions requiring the source to demonstrate that the plan will achieve the required level of control, IDEQ may have limited ability to reject or require improvements to a plan that falls short."

And this matches our main point that even if they submit a pretty good plan and DEQ signs off on it and they follow that plan to a T, IDEQ is not going to actually have the ability to enforce a 93.3 percent dust control because they're never going to know whether Perpetua is actually achieving that, and there is nothing in the permit to ensure that it is.

So with that, we would ask that you set aside, remand the permit for DEQ to either add additional permit conditions, modify the amount of operations that are allowed, or otherwise take action to ensure that the PM 10 NAAQS will be complied with before issuing any permit.

BOARD CHAIR BOWEN: Thank you. Any other questions?

(No response.)

BOARD CHAIR BOWEN: Okay. Thank you very much.

MR. HURLBUTT: Thank you.

BOARD CHAIR BOWEN: We appreciate it.

Now, with the hour, what's the will of the Board? Are you willing to move into the respondents' arguments, or do you want to take a break?

All right. Do we need a motion to take a break?

MS. YRIBAR: Yeah.

BOARD CHAIR BOWEN: All right. I'll entertain a motion to break for lunch.

VICE CHAIR MACMILLAN: I move we break for lunch.

BOARD MEMBER SIGLER: I second it.

BOARD CHAIR BOWEN: Everyone in agreement say aye.

BOARD MEMBER PURDY: How long?

BOARD CHAIR BOWEN: Half an hour.

It's been moved and seconded. All in favor?

(AYES.)

BOARD CHAIR BOWEN: Any opposed?

(No response.)

BOARD CHAIR BOWEN: Thank you. We're adjourned for lunch.

(Thereupon the luncheon recess was taken at 11:55 a.m.)

AFTERNOON SESSION

--oOo--

(Thereupon the afternoon session resumed at 12:32 p.m.)

BOARD CHAIR BOWEN: Okay. We'll call the meeting back to order and we're now on record.

Carol, can you hear us?

BOARD SECRETARY MASCARENAS: Yes, I can.

BOARD CHAIR BOWEN: Great. Thank you.

Now, let's hear from the respondents DEQ and then Perpetua. You've each got 30 minutes.

MS. YOUNG: You ready for me?

BOARD CHAIR BOWEN: We're all ready. The floor is yours.

MS. YOUNG: And thank you for taking a lunch. I'm sure nobody wanted to listen to me while hungry, so I appreciate that.

Again, thank you for hearing this appeal today. My name is Hannah Young. I represent the Department of Environmental Quality. I'm their lead DAG and I'm representing DEQ today.

I do again just want to underscore that it really is an exceptional effort by the Board to read all of the materials and spend the time preparing, so we really appreciate your efforts here today.

I want to begin by discussing this permit from a really high level. As you're now aware from reading the voluminous record and the many, many filings, this permit has been highly scrutinized internally and externally. And, as a result, the permitting process has been complex and lengthy. In fact, it took nearly three years. Development of this permit also included three public comment periods, two public informational meetings, four permit iterations and, in general, just a level of examination that has been unmatched.

The efforts by DEQ demonstrate its desire to not only engage with the public but to issue a permit that is protective and legally defensible.

Now, if you were to only hear from the petitioners today or only read their briefing in the matter, you would be left with a disingenuous impression of this permit. They use words in their brief like rushed, partial, incomplete, vague, to describe the permit and the process, and they also make claims that DEQ is precluding the public from participating and from viewing the permit, and nothing could be farther from the truth. In fact, DEQ has engaged with these same petitioners during all three public comment periods and during the informational meetings, responding to the same claims they've made today if you look at the response to

comments documents. And early in the process, DEQ even made changes to the permit based on their comments that were reasonable and made sense. So we're listening.

As I said, the record relating to this permit is large: It contains emails, correspondence, guidance documents, public comments, public response to comments document. In fact, just the last response to comment document was 85 pages alone. There are three draft permits. Of course the -- I forget if it's 400- or 500-page Statement of Basis and the permit itself.

Upon review of the record you will find, I am confident, that there is not a single part of this permit this has not been considered, studied, and examined by DEQ. And the parts that are not in the permit that the petitioners would like to be there have similarly been studied, examined, and debated.

You know, ultimately DEQ is here defending its decision to issue that permit, just like they've done to the public; to the EPA as we've seen through these letters being introduced; to the hearing officer, and now, of course, to you all at the Board.

Issuing permits is DEQ's job, and DEQ continues defending this permit it issued because it's a good permit written by the experts at DEQ.

Many of the permitting decisions are discussed

in the declarations of bureau chief Mike Simon and atmospheric scientist Kevin Schilling which I know those declarations have already been referenced so far. Together those two gentlemen have a combined 60 years of experience in the air permitting and air quality world. There are a lot of other highly skilled, highly qualified DEQ staff persons that were involved in this permit, including Ms. Floyd, the air quality division administrator who's been at DEQ for 24 years.

Now, petitioners don't like some of DEQ's decisions, and that's fine. I would say that not liking some of our decisions is inevitable, quite frankly. But dislike is not the legal standard, and rightfully so.

The important legal standard is that DEQ was reasonable, acted in accordance with the law, used lawful procedure, and acted in a way that was not arbitrary, capricious, or an abuse of discretion. And clearly DEQ has met that standard.

Finally, one last aspect I'd like to discuss from a high level, and then I promise I'll turn to the discrete issues. And that is that if the Board today finds that DEQ erred on any of the issues raised, then the Board would be changing how the DEQ does business and how DEQ writes permits.

Mr. Steele has sort of taken the wind out of my

sails a little bit to this point in that he raised that there are a lot of customary practices here that DEQ used in writing this permit. And I don't bring this up to say that, you know, this is the way it's always been done so this is the way we should do it, no.

What I'm saying is that DEQ made no exceptions for Perpetua; they cut no corners; they used their standard, custom permitting practices that they relied upon their professional judgment in making, and in adhering to those professional judgments in issuing the permit today.

So with that, I will now turn to the four specific issues brought forward in this petition: The Stibnite Access Road, the submission of project plans, the 93.3 dust control, and arsenic emissions from the roads.

As to all four of those issues, the hearing officer who first heard this matter found that DEQ -- found in DEQ and Perpetua's favor, and determined that we acted reasonably and in accordance with law.

And I recognize that today you are reviewing this matter de novo; in other words, you don't have to defer to what the hearing officer decided.

That being said, the hearing officer thoroughly considered this matter for over a year, and he issued a

very thoughtful, very well written decision that covers all of the issues that you're hearing today. And so I would urge you to rely on the hearing officer's decision which, of course, is in the record, and to also uphold his decision that DEQ acted reasonably and in accordance with the law.

I know these arguments have been fully briefed, you've heard about them, I'll do my best not to belabor them. And, of course, please ask, you know, any questions.

So the first issue is the access route. Petitioners obviously do not agree with DEQ's decision to preclude the Stibnite access route from the ambient air boundary.

There are two points I want to emphasize here:

And the first is that DEQ was absolutely reasonable and acted within its authority when it relied upon Perpetua's assertion that it will have the authority to exclude the general public and only allow guests of the mine.

Section 123 of the Air Rules provides,

> "All documents, including applications for permits to construct, must contain a certification by a responsible official, and that

certification must state that based on information and belief, the statements and information in the document are true, accurate, and complete."

In the permit application Perpetua stated it will have full control over the mine site and the ability to not just control, but exclude, the general public.

Here again is an example of DEQ following its typical process in relying on the assertions made by a permittee, and that makes, I think, particular sense in light of the certification requirement that's in the rules.

To decide that DEQ was unreasonable here is to now say that DEQ is required to investigate or fact check every assertion made by a permittee. And I think it's obvious that they simply do not have the time or resources for that sort of undertaking.

I would also add that this scenario, wherein a permittee does not own the entire facility/property, is not uncommon. We often see facilities (sic) that do not own their entire property but lease neighboring property, maybe they need an easement or an access agreement to part of the property. And all DEQ does in those situations, just like it did here, was get a representation that the permittee does or will have

control over that property. We cannot possibly look at those lease agreements or look at those access agreements and make a claim that that's valid. We're not going to insert ourselves in that type of examination, and we're not a third-party arbitrator, like a court ultimately, or a Board. And so we're not going to involve ourselves. So this is, like I said, it's very common practice.

And here, despite what petitioners have said -- and I know Perpetua will speak at this more at length -- but we have not been presented with any actual evidence that Perpetua will not have control of the mine site and the ability to preclude access at the time the mine is operational. Until and unless DEQ is presented with that evidence, DEQ continues to reasonably rely on Perpetua's assertions.

The permit itself also contains numerous conditions actually requiring Perpetua to have control over the route and the ability to preclude access, which I know was brought up earlier. So condition 2.7 requires a host of things like security escort vehicles, guardhouses, locked gates, warning signs, registration of guests, et cetera, which -- in the access management plan, which must include specific measures Perpetua will use to discourage public access.

If Perpetua does not meet those permit

conditions and, in other words, does not exclude the general public, they will be violating their permit, and their permit will need to be modified or they can be subject to an enforcement action.

The second point I want to make is that DEQ properly used its discretion and did act in conformance with both DEQ and EPA guidance. Both guidances state, "It's appropriate to exclude areas from ambient air where there are measures in place to exclude the general public."

Now, petitioners claim, as you just heard, that DEQ did not act in conformance with that guidance, and they seem to, I would say, oversimplify the guidance and say there are only general public and those directly associated with the facility, and that's just not true.

So I'd like to give you an example, if you'll indulge me. If I visit a facility, which I am often to do in this role, say the Idaho National Lab, because I'm on a guided tour, which happens frequently, or perhaps in my role as representing DEQ. When I am not -- when I am on-site, I am not a member of the general public, but I did receive permission -- right? -- to be on-site. I'm there for a limited purpose; I cannot go anywhere I please; I'm expected to meet safety requirements while I'm on-site; I can only be in certain locations; I often

have to wear a dosimeter; I need to sign a release or liability form; I need to wear a hard hat and the right type of shoes in certain areas. But I'm certainly not an INL employee or one of their contractors.

And to unpack this even further. If I'm driving down Highway 20, which I often do, I'm a member of the general public driving on Highway 20. But the moment I turn onto their facility, I become a guest of that facility. And if I wasn't a guest and I was not allowed to be there, I would certainly be asked to leave. And if I didn't, I would be subject to both civil and criminal trespass. And if I didn't follow the required protocols while on-site, I would also be required to leave. This would be true if the Board were to visit INL; this would be true if a group of school children were visiting the INL.

And I only provide this as an example that it's very common for DEQ to permit a facility knowing that there may be guests allowed on-site. And those guests are not considered members of the general public. So when they're on-site, just like when I'm at INL, I'm not being protected as if I'm within the ambient air; I'm not being protected from potential -- I mean, INL has a Title 5, or I don't know if it's a Title 5, they have an air permit of some sort -- I would not be receiving the NAAQS

protections while I'm on-site that I would be if I left. I'm not a member of the public, but I'm not associated with the facility.

So again, this example is just to highlight that this is not uncommon, and it's absolutely in conformance with guidance.

So in summary, DEQ has thoroughly considered this issue, and while petitioners don't agree with this decision, it is supported by the record and it is reasonable.

BOARD SECRETARY MASCARENAS: Mr. Chair, I have a question.

BOARD CHAIR BOWEN: Yes, Carol.

BOARD SECRETARY MASCARENAS: I, not being familiar with the INL myself, I have thought about that scenario and how we control things, how things are controlled there.

But what about the aspect of, at the INL they can restrict access and control. It goes to the plaintiff's argument, there's two parts that need to be met, control and then the exclusion of access, and surely INL can also prevent access to the facility. Could you respond to that aspect of the argument?

MS. YOUNG: Yes, Chairman and Ms. Mascarenas. I hope I'm understanding your question correctly.

But yes, just like INL, Perpetua will be required to not only control access while it's on site, but preclude the general public, which I would say they do.

And if you've been to the national lab you know that it's a highly secure site with, you know, guards, et cetera, at guard towers when you enter. And if you're not allowed to be there for that specific purpose, if you do not do things like sign the liability waiver, et cetera, then you're not allowed on-site.

So it's not just controlling what you're doing while you're there, but it's also precluding you from entering the site period unless you've met whatever requirements.

And I understand it's not a perfect analogy. No site will be perfectly analogous to another because INL has all sorts of national security concerns and other things. But it's, again, just to highlight that this is not an uncommon situation for there to be more than just general public at the facility.

BOARD CHAIR BOWEN: So just a follow-up question to that. So if a member of the public rolls up to the gate and says, "I want to pass through," are they going to be able to pass through if they desire as a guest of the facility, or are they restricted from entering the

site?

MS. YOUNG: I think that question is probably best answered by Perpetua, so I'll defer to them if that's all right, but --

BOARD CHAIR BOWEN: Okay.

MS. YOUNG: -- my understanding is that they will be allowed to enter if they meet the various requirements, and they will no longer be a member of the general public. I hope that answers your question.

BOARD CHAIR BOWEN: So the assumption is that control will be granted to Perpetua?

MS. YOUNG: Oh, absolutely. Perpetua has to have that level of control and that ability, otherwise they're violating their permit.

BOARD CHAIR BOWEN: Okay.

BOARD SECRETARY MASCARENAS: Thank you.

MS. YOUNG: Yes. Thank you.

BOARD MEMBER STEELE: So to follow up on that a little bit. The petitioners refer to the EPA letter that there was mention that EPA still has some concerns, but then they go on to say in the last sentence of that first paragraph on the second page, whatever approved plan that gets developed, there should be something in that plan that maintains, you know, basically control.

MS. FLOYD: Right.

BOARD MEMBER STEELE: Is it DEQ's intention to do that?

MS. YOUNG: Oh, absolutely. Absolutely. And I would also take issue to some extent with some of the language in this letter. For example, they say that, "There must be measures to maintain continuous monitoring of the public's movement"; they're not the public, they're not the general public.

EPA is not as familiar with this site, this facility as DEQ is, so that's fine. But they're not considered the public. The plan will require, as well as I'd say the permit itself requires that their -- that their movements be monitored and tracked. So absolutely that's the requirement.

And now that you've mentioned it, Mr. Steele, their letter also notes that DEQ's decision here was, as quoted, "Generally consistent with EPA's revised policy on exclusions from ambient air."

BOARD CHAIR BOWEN: And just one follow-up. Let's say the permit goes through the NEPA process with U.S. Forest Service, and they determine or their stipulation is that you must provide public access through the site. What happens to the permit if they make a general ruling like that? What's the status of the permit?

MS. YOUNG: Yes, that would be a change in circumstances; right? And not to throw Perpetua under the bus here, but that's a little bit of the risk that they took by applying for the process while the NEPA process was still ongoing.

You know, but the bottom line -- and I don't want to -- Mr. Pooser will talk about this much more eloquently than I -- but the importance of the mine plan and why a lot, not just this piece, is riding on the mine plan. If the mine plan's not approved, then there's no project anyway so then they don't need an air permit anyways, right?

But if it were to be approved with that caveat that they would have to be -- general public on that road, for example, that would change the analysis, and we'd probably have to go back to the drawing board on the permit.

VICE CHAIR MACMILLAN: Mr. Chairman.

BOARD CHAIR BOWEN: Yes.

VICE CHAIR MACMILLAN: What kind of inspections or monitoring does DEQ typically provide or have happen at mines? I can speak to fish farms, I know something about that. But a mine that's as big as this one, how do you measure compliance with the permit?

MS. YOUNG: Sure. I think with any facility

there's sort of the standard ways that you measure compliance.

One of them is that the permit itself contains a number of quite rigorous reporting and recordkeeping requirements for things specific to access. So DEQ needs to see those records and they need to, you know, see that Perpetua is keeping track of that information.

The other standard way is that DEQ learns, for example, that these permit conditions aren't being followed is when DEQ is on site conducting inspections, which they will be. We often get complaints from folks notifying us, which then DEQ has a requirement to follow-up on those complaints and verify the veracity of those.

And then we often see a lot of self-reports where the facility is letting us know, you know, they've had a -- not a good example here -- but an exceedance or whatever the case may be.

Here the Forest Service, for example, being a, you know, land manager, and keeping us well apprised of the NEPA process, I think DEQ feels also comfortable that that party is going to be keeping us informed about what's going on on-site as well.

But I think the two primary ways that DEQ will be checking on compliance here are those robust

recordkeeping requirements and the inspections that occur.

And just like with any facility, DEQ simply does not have the resources to be on-site 100 percent of the time, that's just an impossibility. But when they are on-site, which happens frequently, they find, you know -- if they find violations -- which they do -- then those would need to be dealt with accordingly

VICE CHAIR MACMILLAN: So as follow-up then, I guess the key point is there's a routine inspection process that DEQ has --

MS. YOUNG: Absolutely.

VICE CHAIR MACMILLAN: -- of mines, and so there's some confidence that you would catch misdeeds, for example -- and maybe misdeeds is not the right word.

MS. YOUNG: Sure.

VICE CHAIR MACMILLAN: But errors in judgment or something.

MS. YOUNG: Absolutely, and that happens regularly.

VICE CHAIR MACMILLAN: All right. Thank you.

MS. YOUNG: Yes. Thank you.

The second topic for consideration by the Board is the decision to allow Perpetua to submit permit

required plans after permit issuance.

And again I want to start by noting that this is common practice for DEQ, as I think Mr. Steele actually already mentioned that this was common practice. And again, if the Board were to find that that was not an allowed practice, every single permitting program at DEQ would have to change how it does business. And this practice really does make sense given the complex realities of permitting various industries.

As Mike Simon testified in his declaration, which is in the record,

> "It is common for the permit program to require certain plans, such as an O&M manual or fugitive dust control plan, to be prepared by the permittee post-permit issuance. This allows the permittee to prepare a specific plan or manual based on the actual equipment purchased and installed, the manufacturer's instructions and recommendations, as well as the operational characteristics of the facility after construction is completed."

And I want to note that it's not just common practice, but it is common practice because the permit

itself contains the conditions and details necessary to ensure compliance with the rules. The plans do not do that. The plans are not what -- are not what are telling us that the rules are met; the permit does that. But the plans provide those operational details that flush out -- flesh out how those permit conditions may be met. I like to think of it as the permit is the what, and the plans are a little bit of the how.

So an example: Section 2 of the permit contains eight separate conditions related to the control of fugitive dust. Condition 2.1 describes the reasonable precautions Perpetua must take. And 2.1 alone contains six substantive requirements.

Condition 2.6 then requires Perpetua to develop a fugitive dust control plan. And condition 2.6 itself contains 12 substantive requirements of what must be further addressed in the plan.

So it's -- you know, it was brought up earlier of whether this was, whether things might have been arbitrary or capricious by DEQ. I think an obvious way DEQ might have been arbitrary and capricious is if they said prepare a fugitive dust plan that will control fugitive dust period. That's not what happened here. There's a lot of specificity in the permit that dictates what must be in that plan, and that's, I think, very

critical here.

BOARD MEMBER PURDY: Does that -- sorry to interrupt.

Does that include the 93 plus percent control?

MS. YOUNG: Absolutely. And I can turn to that now or I can address --

BOARD MEMBER PURDY: No, it's okay.

VICE CHAIR MACMILLAN: So Mr. Chairman. I will anyway.

So the petitioner has pointed out that the DEQ rule requires plan submission --

MS. YOUNG: Right.

VICE CHAIR MACMILLAN: -- as part of the permit application.

MS. YOUNG: Right.

VICE CHAIR MACMILLAN: So how -- how do we get around that?

MS. YOUNG: And I know that Perpetua was going to speak to this too, but I'll address it also.

And I would say that the language that they're relying upon, 402.01, I disagree with their reading of the rule, for one. The rule section states:

"Required information. Site information, plans, descriptions, specifications, and drawings showing the

design of the stationary source facility or modification, the nature of the amount of emissions, and the manner in which it will be operated and controlled."

It seems to me that that list of what's required site information, plans, descriptions, specifications, and drawings is regarding to showing the design of the stationary source, which the plans and specifications for the design of the source are absolutely required early on.

I also want to note a little bit of inconsistency in petitioners' argument in that their latest reply that they filed they say that they understand that the operation and maintenance manual that DEQ is requiring -- which is a plan -- is okay; it's okay that that comes later, they just don't like the other plan. That's a very inconsistent approach and application of the rule in my mind. And --

I'm sorry, I thought I saw a hand raised.

But the last point I want to make a point of is the EPA letter, to the extent that they're relying upon that, also signals that it's fine to use plans, and they talk about information being made available to the public after those plans are approved by DEQ.

The hearing officer -- I lied, sorry, this is my last point.

The hearing officer in his decision also stated that there is no prohibition in the rules that would not allow DEQ to require plans to be submitted later, and in fact, the permit -- the rule language gives DEQ wide discretion in what types of information can be in a permit, and what types of permit conditions, such as the condition to submit a plan. So there's wide discretion there too.

BOARD MEMBER PURDY: I made a note during the petitioners' presentation that they referenced Section 202 multiple times.

MS. YOUNG: Yes.

BOARD MEMBER PURDY: And I don't remember if that was an EPA or an Idaho Code section?

MS. YOUNG: Yeah, that's the rule. And I think that that 202 section is about the permit conditions that DEQ has discretion to include, though I could be misremembering.

BOARD MEMBER STEELE: It's the application.

MS. YOUNG: Yeah.

(Unreportable simultaneous cross-talk.)

BOARD MEMBER PURDY: It's that the application had to be all open to public comment and --

MS. YOUNG: Oh, okay. Sorry, the 209 section was public comment. Thank you.

So I'm happy to turn to that too. So actually, thank you for that lovely segueway, because my second point is that petitioners are claiming that this practice of having plans being submitted later deprives the public from meaningful involvement which, again, I take serious issue with. And that section of the rule 209 simply says that, "The public should be allowed an opportunity to comment on the draft permit." An opportunity.

Here they have had three, because there have been three draft permits that have all gone out for public comment, so that obviously has been met. And there's nothing in there saying that those plans need to be required to be set out for public comment, which, again, EPA seems to agree with in that they're saying that information like a plan should be available to the public. Which, since we're subject to the Public Records Act anyways, are absolutely available to the public at any time.

But all that's to say that what Section 209 of the Air Rules requires is that the permit, the draft permit be allowed to be commented on. That's what occurred here.

And I would further argue that there's nothing

in the plans that the petitioners haven't already had the opportunity to comment on because, like I said, the true substantive requirements are in the permit, and they've had an opportunity to engage with DEQ on that.

The permit says that they're going to use a chemical suppressant. We've talked about the control for the chemical suppressant. We've talked about the need for it to be applied. There's a plethora of conditions related to that. The plan might say the exact hours that the chemical suppressant needs to be applied; based on the manufacturer's label will give you an actual application rate, say every four hours, whatever, but the plan -- the facility hasn't been constructed yet, so they haven't purchased that chemical. That's the kind of detail.

And so as far as what the rules are requiring, and the rules wanting the public to be able to engage with the permit, I would say that's absolutely being satisfied here.

BOARD MEMBER PURDY: Thank you.

MS. YOUNG: Thank you.

So I think I've covered this issue well, I'll move on to the -- and I will note that there were a couple of cases that the petitioners referenced, and I'm going to defer to my esteemed counsel to address those

for you.

The third issue is that petitioners contend DEQ lacked a reasonable basis in determining that the project can achieve 93.3 dust control from the haul road.

And again, if you hear only from the petitioners here or read only their brief, you would be left with a disingenuous impression that DEQ is not confident that this level of control will be met based on the permit conditions. And as we heard from petitioners, you may even be left with the impression that dust control is difficult or outdated. Again, not true. And, in fact, as was brought up, DEQ has rules for the reasonable control of dust.

This is nothing new. There are a lot of facilities that DEQ requires a fugitive dust plan, and that require that, you know, this type of issue be dealt with.

So I want to briefly note that in petitioners' reply, and it was sort of brought out during the conversation earlier, that petitioners agree at this point that the 93.3 control is achievable. So I won't get into the calculation of how that was done. But they seem to take issue with the adequacy of the permit conditions for meeting the 93.3 percent control.

So there are several permit conditions that are

relevant here and that speak to this level of control, which, again, the 93.3 is not an emissions limit, it's a control efficiency. So measuring it and saying 93.3 percent is going to be met is asking for an absolute; it's asking for something that DEQ simply could not provide. If you remanded the permit to DEQ and said we need confirmation that 93.3 percent is going to be met based on, you know, something that the petitioners are asking for, that's an absolute. But absent some sort of long-term study on-site, that information is not going to be able to be provided.

But the permit condition, if those are met, then DEQ has a very high level of confidence that the 93.3 will be met because that 93.3 percent was not pulled from a hat, but is based on the method, standards, and data relied upon by EPA. And you'll see it referenced in the record at AP 42, that's the name of the guidance document that determines the control efficiency.

But back to the permit conditions. So conditions 2.1, 2.2, and 2.6, amongst others, require Perpetua to apply water and chemicals to the roads to control dust.

And as noted earlier in the conversation, DEQ chose a very conservative number of 90 percent in the range, the most conservative number that comes from AP 42

in the 90 to 99 percent control efficiency for the chemicals.

Condition 2.2 requires Perpetua to monitor the frequency and methods used to control fugitive dust at least once every 12 hours.

2.4 requires daily, facility-wide inspections and hauling activities to ensure that the control efficiency is achieved. There is corollary recordkeeping requirements related to that, which DEQ will, of course, be reviewing.

And condition 2.5 mandates that fugitive dust control measures be applied to haul roads on a frequency such that visible emissions from vehicle traffic do not exceed 10 percent opacity. And if emissions do exceed that level, Perpetua must take immediate corrective action until fugitive dust is achieved.

And I think it was Mr. Simon who noted in his declaration that these daily inspection and haul road opacity requirements are more stringent than any other permit DEQ has issued.

So petitioners have used the term aggressive when it comes to these conditions, and we can call it aggressive if you will, that's fine, but it's certainly not a novel approach.

DEQ is well versed in controlling fugitive dust.

I talked about the AP 42 that they used and relied upon in determining that if these permit conditions are met, then this control efficiency will be achieved.

And again, you know, those conditions may seem stringent or they may seem aggressive, but DEQ only puts permit conditions in a permit with the expectation that the permittee will comply. So if the permittee does what it's required to do, complies with the permit, then confidence by the experts at DEQ who have analyzed all of this information is very, very high that the 93.3 percent will be met.

BOARD CHAIR BOWEN: Hannah, a follow-up question here. I think one of the claims that petitioners made is that the permit lacks enforceable criteria. One of the things that I read in the record is this issue of opacity.

Can you translate for the lay folks of us what that actually looks like on the ground as far as what enforcement looks like relative to the criteria?

MS. YOUNG: Yeah. Absolutely. And as a former -- or also a layperson to layperson, I'll do my best. Again, the experts at DEQ, their declarations and their Statements of Basis are really critical here.

But my understanding is that DEQ will also be on-site to do these, you know, when they're doing their

inspections and determining opacity, just like Perpetua will be required to do.

And DEQ staff have actually been trained on determining opacity. So they have a level of training that says this is -- this is 10 percent, you know, this is that threshold. And they have to go to training -- I think the training is done by EPA -- and they look at different dusty conditions, and they actually get trained on how to do that. And so they have a level of confidence with the 10 percent number that, you know, they could identify that.

It's actually, in my mind, a pretty low threshold in that if you're seeing dust, you need to do something about it.

And I also want to note that all of this is actually quite conservative when you consider the winter months when there shouldn't be any dust and, you know, the rainy days. And just the consistent application of water and chemicals, you shouldn't really be seeing dust.

BOARD CHAIR BOWEN: So what -- overall what's the general response to the assertion that there's no enforceability to the 93.3? There's nothing in the permit that's enforceable? What's your response to that, in general?

MS. YOUNG: I mean, again --

BOARD SECRETARY MASCARENAS: Mr. Chair, if I can add to that question?

BOARD CHAIR BOWEN: Sure.

BOARD SECRETARY MASCARENAS: In particular, seeing that the fact that the criteria or the 93.3 percent within our table lacks enforceability.

MS. YOUNG: So I'm hoping I heard the question right; it sounds like you're sort of asking the same thing.

Again, it's not an emission limit, it's a control efficiency. And DEQ will determine that that 93.3 percent has been met if the permit conditions have been met.

All of the permit conditions, including the ones which are just an example of what's in the permit, if those are not met, then DEQ does not have confidence and would consider the control efficiency of 93.3 percent to not have been met.

So it's imperative on Perpetua to meet these conditions. And if they meet these conditions, confidence is very high, again based on AP 42, the data, the studies, et cetera, that the 93.3 percent is being met.

BOARD MEMBER PURDY: So mathematically maybe it's a they must do A plus B plus C, and if they do those

things, it will equal 93.3 greater air control efficiency. So they're not measuring the right side of the equation, they are measuring the, Are you doing A? Are you doing B? Are you doing C?

MS. YOUNG: I couldn't have said it better myself.

BOARD MEMBER PURDY: Within the permit conditions --

MS. YOUNG: Absolutely.

BOARD MEMBER PURDY: -- you would do that.

MS. YOUNG: Absolutely.

BOARD MEMBER STEELE: Another analogy would be like if you have a dust scrubber, and you have particulates coming in, you can't pay money to always have that be measured at the outlet, but you can monitor flow and pressure drop. And if those are always being met, you're going to be --

BOARD MEMBER PURDY: You have confidence in the reading.

MS. YOUNG: Exactly. It's a control efficiency, right, and so it's a perfect example. Okay.

So I have no idea where I'm at on time, my apologies, but I will move onto my final issue, if I may.

BOARD CHAIR BOWEN: You have about five minutes.

MS. YOUNG: Perfect. Right on track.

Lastly, petitioners have alleged that DEQ created a project-specific adjustment factor to artificially dilute the ambient arsenic concentrations attributable to the project. And ultimately here petitioners are claiming that DEQ acted outside the scope of the rules.

And I really only have one point to make here and that is that DEQ did act in conformance with the rules.

You know, I think ultimately petitioners misunderstand DEQ's analysis. And to be fair, it is a technical analysis and it relies on a number of rule sections. And again, as I just said, you know, I am not an atmospheric scientist, I'm not a scientist of any sort, so I will do my best to sort of emphasize the points I would like you all to be thinking about. But I would encourage you to read the section of Kevin Schilling's declaration where he talks about this analysis for, you know, really the best authority as to this point.

But again I want to emphasize that DEQ's approach does fit squarely within the Air Rules, and I would absolutely take issue with the claim that there's been an artificial dilution.

So first DEQ started with the AACC, the applicable acceptable ambient concentration, in 586 which provides that lifetime cancer risk of one in one million for arsenic.

DEQ then performed a T-RACT analysis that's specifically allowed in the rules, Section 210.12.C. And that further refined the acceptable health risk to one in 100,000.

Now, what petitioners dislike is that during that modeling and analysis, DEQ used specific information -- which they don't normally have -- which is the 16-year life of the mine to refine its analysis, as the AACC assumes that the project will be going for 70 years. And that's fine.

When most facilities are constructed you think it's permanent, you have no idea how long it's going to operate, so you're just assuming it's going to operate for someone's lifetime. Here we know that it's not going to operate for more than 16 years. And, in fact, if they were to change their mind, they would run into issues with what has been permitted here.

And that 16 years, that 16-year life of mine was the most relevant data, and it was the best information, and it was inputted to come up with the most accurate projections.

Now, petitioners would like that specific process to be set forth in rule; that's an impossibility. The point of modeling and the point of these engineering analyses are to use the methods and data that are relevant to that specific project, and that's what DEQ did. That's all they did. They didn't further divide by 70 the life of the mine. They further refined the AACC to a calculation of 16 over 70, and they applied that. Which essentially all that's doing is saying we know it's not going to operate for 70 years, we know it's going to operate for 16.

And built into that there are a lot of conservative assumptions, which is very common in modeling and those analyses, or so I'm told.

And ultimately DEQ was required to demonstrate that the project's arsenic emissions would not injure or unreasonably affect human health or animal life or vegetation as required by the rules in Section 161 and 203.

And DEQ feels very confident that they met that standard based on the rules and based on their modeling analyses.

And again, I am happy to do my best to answer questions as to that point, but I would again point you to the experts at DEQ who are much more well versed in

this, and also to point out that the hearing officer found that as to this point DEQ provided unrebutted expert testimony, and the petitioners have not done that. They have not brought forward any experts who have taken specific issue with how that modeling was done and with how those various inputs were set forth in the analysis.

So with that, I would simply like to reemphasize that petitioners simply dislike or disagree, as a matter of opinion, the decisions made by DEQ, but they have failed to prove at every turn that DEQ committed any errors in its thorough and diligent preparation of this permit; they failed to demonstrate that DEQ acted unreasonably; that they violated any Constitutional or statutory provision or an excess of authority or used unlawful procedure or were arbitrary or capricious or an abuse of discretion.

And, in fact, the opposite. I hope what I've demonstrated here to you today is that with every single issue DEQ has a thoughtful and reasoned basis for the decision that it made.

So again, I would thank you for your thoughtful consideration of this matter. And if there are any questions, I'm happy to do my best to answer those.

BOARD MEMBER MCELROY: Mr. Chairman.

Thank you for walking us through those four

points. I do have a question on the second point, and I apologize for not asking it when you were talking through it, we just moved so quickly to the third one.

MS. YOUNG: Yeah. Sorry. Yeah. Absolutely.

BOARD MEMBER MCELROY: The point regarding the submittal of plans in the application, and in Section 2.02 it talks about the site information plans, da da da, showing the design of the stationary source -- which makes sense. But then the back half of that sentence ends with, "...and the manner in which it will be operated and controlled."

And so help us understand, in this case the fugitive dust control plan would be the method that you control those, the fugitive emissions. So how do we not meet that back half of the sentence in the application by not submitting the fugitive dust plan?

MS. YOUNG: Yeah. Absolutely. And I don't want to get too technical in statutory analysis here, but I would read that final comma and "and" as a standalone provision, "The manner in which it will be operated and controlled" as a stand-alone requirement, which DEQ absolutely has in the permit, "the manner in which it will be operated and controlled."

And a lot of those permit conditions we haven't talked about today because they're not being challenged.

There's a lot of operational requirements in the permit. But I think that the word "plan" doesn't necessarily relate to that final "and."

BOARD MEMBER MCELROY: I'm asking -- that's the application procedures.

MS. YOUNG: Oh, right, of the application.

BOARD MEMBER MCELROY: Yeah, in that section it's talking about what's required in the application.

MS. YOUNG: Right. I'm sorry.

BOARD MEMBER MCELROY: And in the back half of that statement, "And the manner in which it will be operated and controlled --"

MS. YOUNG: Yes, I'm --

BOARD MEMBER MCELROY: -- in the application. So that's what I'm trying to resolve, if that's in the plan that's not submitted.

MS. YOUNG: Yeah. And I apologize for speaking over you, but I understand your question better now.

And similarly, I think the same thing applies that what they're required to demonstrate in that section that you've just read, that piece in the application that needs to be met, which is "The manner in which it will be operated and controlled," not the plans related to that sort of final phrase, you know.

So it's a little bit of a matter of

interpretation of how DEQ would interpret that rule section, which DEQ is afforded great deference in interpreting its own rules.

But I don't see that as requiring the -- Perpetua to submit the plans at that point in time related to the manner in which it will be operated and controlled. I think they do need to demonstrate, obviously, the manner in which it will be operated and controlled, but requiring them to have a lot of those details that we talked about during the application is just an impossibility.

BOARD CHAIR BOWEN: Thank you. Okay. Any questions?

BOARD MEMBER STEELE: Yeah, one.

So with respect to arsenic, you know, petitioners talked about the unreasonable risks to public health and Yellow Pine was mentioned. In the modeling analysis, was there any demonstration that the arsenic concentrations all the way, 10 miles out to like a Yellow Pine, would impact like a human habitation?

MS. YOUNG: Right. So what the modeling was required to demonstrate is that there would not be an unacceptable risk to human health at the boundary of the mine and beyond. And that was demonstrated.

BOARD MEMBER STEELE: Okay. Thanks.

BOARD CHAIR BOWEN: Okay. Thank you.

MR. POOSER: Would it be possible to take a little break, just a little five-minute break?

BOARD CHAIR BOWEN: Oh, sure.

(Thereupon there was a brief recess.)

BOARD CHAIR BOWEN: Okay. Ready to reconvene.

We'll now hear from Perpetua. You've got 30 minutes. If you'd state your name again for the record, please?

MR. POOSER: Yeah, Christopher Pooser representing Perpetua.

Thank you, Mr. Chairman and members of the Board.

I don't intend to repeat what Ms. Young has so eloquently stated. Obviously we agree with DEQ, we agree with her defense of the permit, but I will be kind of covering some of the same ground, and I wanted to give you the perspective from Perpetua as well as answer any questions that you may have.

So I asked Paula to pull up this map just so you can kind of get an idea of kind of where the project is.

Can you turn that, Paula?

MS. WILSON: Well, yes.

MR. POOSER: One more. Getting there.

MS. WILSON: Is this still the right document?

MR. POOSER: Yeah, it is, it just needs to be turned. And then scroll. There you go.

MS. YOUNG: There you go.

MR. POOSER: So I wanted to give the Board, I think everybody knows generally where the location is. You can see kind of McCall kind of in the upper left; Cascade is kind of in the lower left, and then you can see Yellow Pine which is about 10 miles to the west of the project at the top. And just to kind of give you an idea of kind of where the project sits. And it's in a very remote-like location.

And this project is a combination of a patented mine claims, which Perpetua owns and controls, and it also includes unpatented mine claims which are on public lands, National Forest Service lands.

And this is a good project. I mean, it's going to produce precious metals; it's going to produce antimony -- if I can say that word right -- and it's, antimony is, domestically is very rare, and it's used for the country's national security, it's important for our country's national security.

And this site was mined for decades. People may be familiar with it. It was abandoned. And Perpetua has been pursuing this project for many years, and Perpetua is actually already on-site and is doing pre-permitting

work primarily related to cleaning up the water quality that's on the site.

And Perpetua's ultimate goal is to leave this project and the site better, better than how it found it.

And so the permit that's before you today is one of many permits that Perpetua has to obtain for the site. There's already been, you know, discussion about the mine plan. Perpetua needs approval from the Forest Service for the mine plan for it to actually have the project.

Perpetua is required to get Clean Water Act permits.

It's required to get permits related to kind of financial assurances.

It's required to get dam safety permits.

And that's just to kind of name a few of the regulatory processes that Perpetua is required to go through to make this project a reality.

Ms. Young kind of touched on the timeline as far as the permit development here, and it was nearly three years. And I only kind of point that out because this was a rigorous and thorough process over that three-year period.

Ms. Floyd talked about, in her declaration, how the typical permit to construct of a mine or source like this one that has public comment takes 150 days. This

permit process took 1,032 days.

So the result -- I mean, the result of this rigorous and thorough process was a rigorous and thorough permit.

And so I'll go ahead and take the issues in the order that Ms. Young spoke to: So starting with the access road, moving onto the operational work plan, talking about the 93.3 percent, and then finally the arsenic averaging.

With respect to the access road, this concerns the ambient air boundary for the facility. And the question that's really been posed to the Board is whether or not DEQ abused its discretion in finding that Perpetua had the legal right to control the site and to preclude the general public, and also kind of the practical ability to exclude the general public access.

And with respect to the legal control, petitioners allege that Perpetua does not have the legal right to exclude the general public to the -- over the access road. And that is an assumption that is based on their assumption that the Forest Service is requiring public access through the site under the mine plan, and that Perpetua can't close this road. And that is just simply not the case. It's untrue and it's not supported by the record that's before you today.

And I'd like to give you just a little bit of context behind the mine plan. As I mentioned, this project is a kind of patchwork of patented and unpatented mining claims. And to control the site, Perpetua has to have Forest Service approval of its mine plan.

And once Perpetua obtains approval from the Forest Service for the mine plan, it will be authorized to operate in accordance to the mine plan.

And one of the key aspects of this mine plan is the creation of the operational boundary for the project. And the operational boundary, which is essentially established for safety and operational reasons, but Perpetua will have the authority, once that operational boundary is established, to control access to that operational boundary, and it will give Perpetua the legal right to exclude public access to their operational boundary, and that includes the access road.

So let me back up a little bit kind of on the timeline with respect to the mine plan. So Perpetua initially submitted the mine plan to the Forest Service in 2016. And that -- in the proposal that it submitted, there was no access road. Perpetua has no need for this road. It has no purpose whatsoever to its operations. And some residents, particularly Yellow Pine residents, voiced concerns about that, because traditionally they

had been able to go past the site.

And Perpetua was asked to consider whether there was some accommodation that could be made with respect to the concerns that the Yellow Pine residents had made. And so what Perpetua did is propose this access road. It wants to be a good neighbor; it wanted to be responsive to some of the concerns of the residents.

And as proposed in the mine plan, Perpetua will have legal authority to control and to exclude the public over the access road. We'll have full control and the ability to preclude public access on this road.

And so, in essence, I mean, the access would be provided to only those who kind of wish to take a shortcut kind of through the project, so they're going through for a limited reason. And they have to agree to the conditions of access.

And so Perpetua is, you know, setting those conditions for safety concerns, for operational concerns. And the people that want to move across the site, which is not the general public but this very kind of select, this select few, are going through at Perpetua's discretion. Perpetua can exclude access to the site. In fact, it can actually close the site for years during construction, during operations; it can close the site for, you know, any kind of concerns about inclement

weather, safety concerns; it has that ability to shut off access to the access road.

BOARD CHAIR BOWEN: We have a question. Go ahead.

BOARD MEMBER STEELE: So if that control road is shut off, how do folks access those areas? How do they get to Yellow Pine and things like that?

MR. POOSER: So if you see Yellow Pine, so just to the, you know, just to the west.

BOARD MEMBER STEELE: Yeah.

MR. POOSER: If you drop down and you come down and there's a black road that kind of goes, it's marked in black that kind of goes to the right, that road kind of ties into the existing Burntlog Road, and then people can pass through that way.

BOARD MEMBER STEELE: Okay.

MS. FLOYD: Can you see that?

BOARD MEMBER STEELE: Yes.

MR. POOSER: So again, kind of under the mine plan that Perpetua has proposed to the Forest Service, it is trying to establish this operational boundary. And the importance of that operational boundary is that it is an ambient air boundary for the purposes of a permit. So Perpetua needs to get that -- needs to get that approved, needs to get that approval. And it is obviously vital to

the project itself.

And so the petitioners, their assumption that the Forest Service is requiring this public access is just simply not true.

Perpetua has proposed this access as part of the mine plan, and once it has approval of the mine plan, it will have that ability to control that operational boundary and exclude the public from the operational boundary, and that includes the access road.

And another point I'd like to make is that ultimately this is the petitioner's burden of proof in this proceeding. And the only factual support that they've actually raised that Perpetua will not have legal control, will not be able to preclude access are two memos that are in the record that were prepared for the Forest Service. And they actually state exactly the opposite. And I kind of point those out.

One is called the Stantec memo, and it's at record 2558.

And there's another more lengthy air quality report that also references the access road, and that is at record 2684.

And both of these documents just simply report what is in the mine plan. And they --

Both of these documents acknowledge that

Perpetua will have legal control of its operational boundary under the mine plan.

Both of these documents acknowledge that the access road can be justifiably excluded from the project's ambient air.

And both documents also acknowledge that EPA has agreed that the access road is excluded from the ambient air.

And I'd like to point out that, you know, there's been some discussion about the EPA letter and the EPA reference to still having kind of concern about whether or not Perpetua has a legal right to exclude access. And I would encourage you to look at those pages because they refer -- because -- back up just a second.

Again, this ambient air boundary was extremely important to the project. Perpetua needed to know early on that that access road was not going to be considered ambient air. And so once it was asked to kind of consider the access road in the mine plan, it approached DEQ and it asked DEQ early on if they could reach some kind of understanding of how this access road could be accommodated under the Air Rules. And that, in turn, led DEQ to communicate with EPA.

And so when you look at those documents, they're specifically referencing EPA's statement that it was good

with DEQ's evaluation of the access road, and that it would not be included in ambient air.

So it's a little disingenuous for EPA to kind of come back at this late time and raise this issue based on its prior representation.

VICE CHAIR MACMILLAN: So will the hauling trucks be using the access road?

MR. POOSER: No. The access road's, it's a completely different thing. Again, Perpetua doesn't need the road. It has no operational value whatsoever.

And so they'll be building this road, you know, for this limited, for this limited purpose, but it's complete separate from the mine operations itself.

VICE CHAIR MACMILLAN: Well I can just imagine somebody in a pickup or something meeting one of those big, huge, gigantic --

MR. POOSER: Yeah, that's not the case. Yeah, not the case.

And so I think kind of at the end of the day this is more like a challenge in sequencing. I mean, Perpetua needs to get Forest Service approval for the mine plan; it needs to get approval from DEQ for its air quality permit; it needs to go through all the other regulatory processes that it's required to go through in order to permit the project. And the fact of the matter

is is that Perpetua can't begin construction until it has the mine plan. And it's expecting the mine plan to be issued in the last quarter of this year. And once it has the mine plan, then it will have the authority that it needs to undergo the project, and it will have the authority that it needs to begin construction.

The second aspect of the access road that Ms. Young handled very, very well, Perpetua does have obviously the practical ability to control access and to exclude the general public. And the permit is quite clear about what Perpetua has to do to actually exclude the general public. And it will have, you know, guard shacks, it will have boundaries. Nobody is going to just drive through the project. That simply cannot happen.

What happens is if people do choose to kind of go through the project, they have to come up, they have to stop, they're going to have to go through a safety briefing, they're going to have to agree to kind of the conditions of passing the site. And then Perpetua will monitor this entire process. It's required to have surveillance, and so it -- and then the travelers that are going through, they have to check in and they also have to check out, and they can't stop. There's -- it's just a pass-thru. All it is is just a pass-thru.

So ultimately DEQ's decision here was it's in

compliance with EPA guidance, and Perpetua has the legal right to control, Perpetua has the legal right to exclude the general public, and the access is actually controlled, and unsupervised access is prohibited.

I can take any questions you have on the access road.

BOARD MEMBER STEELE: So real quick on that memo on the REC 2558, the memo from -- to Brenda with the Forest Service, is that correct, from Eric Clark?

MR. POOSER: Correct.

BOARD MEMBER STEELE: So you said that the operational boundary would be the ambient air boundary?

MR. POOSER: Correct.

BOARD MEMBER STEELE: So the understanding is DEQ has an ambient air boundary, but the Forest Service plans, whatever that operational boundary is, is going to be the ambient air boundary?

MR. POOSER: Yes.

BOARD MEMBER STEELE: Could that change from what it is right now?

MR. POOSER: Well, let me understand that question. So everything that DEQ did to evaluate the air impacts from the facility and whether or not they were NAAQS compliance was based on operational boundary, which is the ambient air boundary. And so if there was some

change to that ambient air boundary, there would have to be, most likely, a different analysis done.

BOARD MEMBER STEELE: But the operational boundary itself has been set and is currently what the ambient air boundary is?

MR. POOSER: So the operational boundary will be set, so it will be established by the mine plan once the Forest Service approves the mine plan.

BOARD MEMBER STEELE: Okay.

MR. POOSER: And that will set the operational boundary, which is what Perpetua relied on for its application for the permit.

And, you know, to reiterate, Perpetua was very clear in application materials that it, that it will have approval, and that it was basing its analysis of the air quality impacts in the compliance with the NAAQS based on the mine plan being approved and the operational boundary being set.

BOARD MEMBER STEELE: So if for some reason that operational boundary is different, Perpetua will have to come back to the DEQ?

MR. POOSER: I think theoretically. I mean, theoretically. Because, again, the operational -- the operational boundary is the ambient air boundary.

BOARD MEMBER STEELE: Yeah.

MR. POOSER: So if somehow it expanded, I would say they probably would not have to, you know, undergo any permit changes; I can't speak if it somehow shrinks.

But the mine plan that is in front of the Forest Service right now, which is -- again which Perpetua expects to be approved later this year, that is what the air ambient boundary and operational boundary is.

BOARD MEMBER STEELE: Okay. Thank you.

MR. POOSER: Let me address the work plan. These are operational work plans. And petitioners argue that DEQ has violated the Air Rules with these operational work plans, and they kind of -- there's talk -- they talk about three different rule violations.

One, they're talking about how these plans should have been submitted with Perpetua's application materials -- and I'd like to get to Ms. Elroy's question in a second.

And they've also argued that these plans need to be fully developed at the time the permit is issued.

And then they also have arguments that these permits or these plans have to be subject to public comment.

And I think this begins at Rule 202 as was discussed earlier. And again, this is talking about a new stationary source and what the application materials

are for a new stationary source such as the project. And I think it's important to read the, kind of the introductory language that's in 202. And it talks about:

> "The applications for permit to construct must be made using forms furnished by the department.
>
> "The application shall be certified by the responsible official in accordance with Section 123 -- 123, and shall be accompanied by all information necessary to perform any analysis and to make any determinations required by Sections 200 to 228."

And that language is very important there because DEQ is actually determining what information is necessary as, you know, per the rules.

And I think if you look back at the permit chronology, you will note that DEQ actually deemed the application incomplete a number of times, and Perpetua was required to submit some supplemental information and updated information with respect to the permit. And so DEQ is exercising its authority fully under Rule 202 to ensure that the, that the permit and application was fully complete.

And then when you move on to the required

information. Again, we've -- Ms. Elroy's talked about sort of the three -- the three different categories, if I'm reading this right.

So I think what the petitioners have really kind of sort of focused on is the first provision which talks about the site information, the plans, descriptions, specifications, and drawings showing the design of the stationary source facility, their modification. And, you know, its opposition to these operational work plans are not plans under this rule. They are not plans that are showing the design of the stationary source; they are operational work plans.

And then the other -- the other components of the application is the nature and amount of emissions, and then the manner in which it will be operated and controlled.

And that was the question that you had, Ms. Elroy. And I think there's kind of two responses to that:

One is what I mentioned earlier, that it's DEQ that's using its discretion on determining what is actually necessary in the permit application so it can actually develop the permit.

And kind of aligned with that point is that DEQ is developing a permit. These work plans are permit

conditions. So it's kind of difficult to understand how a permit condition should be part of the original application materials.

And so Perpetua would surely have, you know, identified the roads as fugitive dust sources, and it would have proposed, you know, controls, and how those would be operated and how those would be controlled, but there's no permit -- there's no permit conditions yet. And again, these plans were all permit conditions. And so there's no requirement whatsoever that these plans be submitted as part of the application materials.

BOARD MEMBER STEELE: Is there a requirement for them to even be developed?

MR. POOSER: I think that's up to DEQ's discretion. I mean, they have the ability -- they have obviously the discretion and ability to build out this permit and determine what the conditions are.

And you'll see in our permit that there are four plans that have to be developed based on the actual operation of the facility.

Does that answer your question?

BOARD MEMBER STEELE: Yeah. I mean, I guess where I'm going with it is there's really no regulatory requirement for each one of those specific plans to be developed, it's really been up to DEQ's discretion to

help determine compliance with the permit that these plans will help ensure compliance with?

MR. POOSER: I'm not familiar with an Air Rule that specifically requires the development of a particular plan. I think it's a case-by-case, permit specific. But clearly DEQ has the discretion to develop these permit requirements and to put these plans in the permit.

BOARD MEMBER STEELE: Okay.

BOARD MEMBER MCELROY: Thank you for walking through that. And just to make it clear in my head. As I look at those three buckets, that third bucket and the manner in which it will be operated and controlled, if I understand you correctly, Perpetua, they included in their air application when they identified the fugitive emissions associated with, for example, the road, they concluded that they would control it with the dust suppressant, or they included some reference in their air application what they were going or what they were proposing to do to operate and control it? Is that how you close the whole loop?

MR. POOSER: Yes, I think that's correct. It's been a while since I looked at the application itself to see if that's specifically in there. I would assume it was because, you know, the haul roads are a big emissions

source on the project, and so DEQ would -- I mean, I'm sorry, Perpetua -- and I'm assuming, it's been a while since I read the application -- would propose how these are going to be controlled.

And it's very common, as we already kind of talked about, for chemical dust suppressant and water to be used together to control fugitive dust. And it's actually in the rules itself.

BOARD MEMBER MCELROY: Okay.

MR. POOSER: And so I think Perpetua would have proposed that.

BOARD MEMBER MCELROY: So that's exceptionally helpful considering that there are four issues that we're talking about on these plans, and it's one of the four. And I'm hearing you use words like "I think" and "I assume."

Is there any way, Mr. Chairman, that we can get validation, yes, that was part of the application? Because then to me it's one of the four issues that checks the box.

BOARD CHAIR BOWEN: I'm assuming we'd have to go back to the record ourselves unless we can ask somebody to research that.

MS. YRIBAR: I can provide a reference for you.

BOARD CHAIR BOWEN: You can provide us a

reference for it.

BOARD MEMBER MCELROY: Thank you, Mr. Pooser, that was very helpful.

MR. POOSER: So that kind of leads to the next allegation that petitioners have made with respect to that these have to be -- these plans have to be submitted to public comment.

And when you look at Rule 209 specifically it talks about, it says,

> "The department's proposed action, together with information submitted by the applicant, and the DEQ's analysis of the information."

And as Ms. Young aptly explained, the content of these plans is very detailed within the permit itself, and those were subject to public comment.

And as far as any concern about public comment, Ms. Young addressed that from DEQ's perspective. And I think this -- the way DEQ's policy kind of treats these operational work plans, it makes complete sense. And as --

One of the examples she gave was that the fugitive dust control plan, for example, requires this chemical dust suppressants, and it requires the chemical dust suppressants be used and applied consistent with

manufacturer's instructions and recommendations.

And when Perpetua is developing its permit application, it doesn't know what chemical dust suppressant it's going to use. It's not that far in the process. Even when the permit is actually issued, it doesn't know what chemical dust suppressant it's going to use. And so -- and that is -- and that is important because there's many, many manufacturers of chemical dust suppressant, and they have different instructions and different recommendations.

And what Perpetua is required to do under the permit is to kind of put that detail into the fugitive dust plan, you know, explain how it is to be mixed; how it is to be applied; what are the application rates; when to apply it; how to use it in different weather conditions. All of that will depend on the particular chemical dust suppressant that it uses.

Another example, like in the fugitive dust plan, is the speed limits. Perpetua is supposed to post and limit maximum speeds on the haul roads. And that is dependent upon the actual construction of the haul roads. It depends on the grade, how many turns are there?

So things like this cannot be -- cannot be submitted as part of the application, they're not even known when the permit is issued before they even have

permission to construct, they only come later. And so it is completely reasonable to have some of the detail, have the framework and the permit is subject to public comment, and then have the detail kind of come in later.

And so I think, you know, at the end there's just nothing in the Air Rules themselves that required these pre-construction operating plans to be fully developed at the application stage or at the permit issuance stage.

VICE CHAIR MACMILLAN: Question.

MR. POOSER: Yes.

VICE CHAIR MACMILLAN: And this doesn't pertain to PTC, but when you use those dust suppressants, so it tamps down the dust, where does the dust go then? My question really pertains to water quality. Does DEQ then, when they are considering -- and I have no -- it's not a point source, I don't think.

But from a water quality perspective, do those suppressants go into the water and potentially affect water quality?

MR. POOSER: I don't know the answer to that question.

VICE CHAIR MACMILLAN: But DEQ, I would assume, would?

MS. YOUNG: If I may, Mr. Chairman, answer the

question. I don't know that --

VICE CHAIR MACMILLAN: Sure.

MS. YOUNG: I know that this was something that has been discussed. It's certainly not in front of the Board today, however, but it's -- it is certainly something that DEQ is aware of.

I'm barely an air attorney, I'm definitely not a Clean Water Act attorney, and so I don't know the details of that, but I do know it's on the agency's radar.

VICE CHAIR MACMILLAN: Thank you.

MR. POOSER: Yeah. And I would assume that this is part of the manufacturer's, you know, recommendations and specifications.

VICE CHAIR MACMILLAN: Right. Right.

MR. POOSER: That's going to address that issue as well.

BOARD MEMBER PURDY: Yes. Those products are going to have directions for use and application rates and application timing and what are going to be required to control --

VICE CHAIR MACMILLAN: I would imagine so.

BOARD MEMBER PURDY: -- their run-off.

MR. POOSER: Yeah. Yeah. And how you apply it, if you apply it in certain weather conditions, et cetera.

BOARD MEMBER PURDY: When you can and cannot apply it.

MR. POOSER: Yes. Right. Yes. So let me turn to the fugitive dust emissions on the unpaved haul roads which is the issue with respect to the 93.3 percent.

So as has been discussed, the permit establishes a 93.3 percent control efficiency for fugitive dust. And this is specific to the haul roads. These unpaved haul roads.

And it's important to note -- I think Ms. Young kind of -- and I just want to reiterate what she said -- is this is control efficiency, it's not a permit limit. I mean, haul roads are not emissions sources that can be measured. You can't put a stack on a road. You can't measure the fugitive dust that's coming off a road.

And so the way that DEQ has dealt with this is established a control efficiency which it used for its modeling, and then it needs to ensure that the permit can achieve that 93.3 percent.

And so there's really kind of two questions that the petitioners initially brought up in this contested case petition:

And they were whether or not DEQ had kind of abused its discretion, number 1, in its choice of 93.3 percent.

And then the second question was really kind of the determination of the control analyses that were in the permit were sufficient to actually achieve the 93.3 percent.

The first question about DEQ's sort of choice of the 93.3 percent has already been addressed as Mr. Hurlbutt kind of acknowledged that they're not contesting that any longer.

And again, there's been previous discussion about the EPA documentation that shows below, like on chemical dust suppressant between 90 and 98 percent, and water between 75 and a hundred percent.

And so there really is no question that 93.3 percent is achievable for a project like this, and that DEQ was completely reasonable in making that determination.

And then that leads to the next question, and I think this has been addressed enough already. But it really is kind of like, you know, all of these permit conditions, as they add up in DEQ's determination, its decision that all of these different permit conditions add up to ensure that this 93.3 percent control efficiency can be achieved if all those conditions are met.

And so the petitioners seem to want to look at

each one of these permit conditions in isolation, individually, and you just simply can't do that. I mean, and there was some mention during the argument that there's just -- that none of the conditions in the permit tied to the 93.3 percent, and that's just not -- that's just not true.

When you look at the fugitive dust plan in particular, and the requirements for the control of fugitive dust with chemical dust suppressants, water, et cetera, and then you also have -- and you also have a lot of different dust -- fugitive dust control that Ms. Young kind of highlighted. And then you even have --

The permit even goes further than that in something that hasn't been talked too much thus far is the production limits that are in the permit. There are life of mine production limits that limit how much daily hauling and excavation can be done at the site.

And that is another way that DEQ limited the fugitive dust emissions coming from the haul roads is by limiting how many, you know, essentially trucks can be on these roads at any one time in its production.

In addition, there's been a discussion about the haul road capping plan, and it has silt limits. The DEQ required that the road material has to have a maximum of 4 percent silt. And Perpetua is required to monitor that

sample and to ensure that the roads meet that -- meet that requirement.

And then you have all the many monitoring and daily monitoring and daily recordkeeping requirements of the permit.

How am I doing on time?

BOARD CHAIR BOWEN: Right about 10 minutes to wrap up.

MR. POOSER: Okay. I'm doing good then.

So the last issue is this arsenic averaging. And I don't have a ton to say about this. I think that Ms. Young said it very, very well. I think it's addressed very eloquently in the hearing officer's determination and Mr. Schilling's declaration. But I think there's some important points that I think need to be considered here.

And we're talking about the AACC. And from my own education, the acceptable ambient concentration for carcinogen with respect to arsenic, and that is based on -- that number that is in Section 586 is based on a one in one million determination. It's a determination that one in a million is an acceptable risk based on a lifetime exposure of arsenic. And so what that means is that there's a continuous exposure for 70 years; so every minute of every day for 70 years there is exposure there.

And I was in the back and couldn't see who made the comment, but there was a comment made about exposure time is kind of critical for TAPs -- and it is. And this is a 70-year -- this is a 70-year exposure time is kind of what we're dealing with.

And so when you look at the Air Rules, they allow for that adjustment that Ms. Young talked about. When there's T-RACT and that risk, and that acceptable risk comes in, it's kind of lowered to one in 100,000. And again based on a 70-year continuous exposure, chronic exposure.

And so, you know, DEQ, we think they were completely appropriate in evaluating if this risk was acceptable here. And it refined its analysis based on the 16-year life of the mine.

And, as I mentioned, there's production limits in the permit, and those are based on the life of the map -- they're based on the life of the mine. Perpetua only has so much ore to produce. And so regardless if the mine operates for 16 years or 70 years, the production limit caps the amount of arsenic emissions because there's only so much ore to be had.

And so in that sense this does not dilute emissions at all; the emissions are what -- the emissions are based on the available ore on the site.

And so in looking at the 70-year exposure DEQ model, the highest annual arsenic emissions from the project for the 16 years, and then it took into account the fact that there was going to be 54 years of no arsenic emissions, and we thought that was completely reasonable under the analysis and the rules that DEQ used.

And there was a question about the impact, kind of how far out the arsenic exposure goes. And there's a -- I'd like to give you a site so you can actually see kind of on the map what the impacts of the arsenic is from the modeling that was done.

And Paula, I don't know if you can pull this up, but it's number, document number 36.

MS. WILSON: Okay. Hang on a sec. Okay. There is document 36.

MR. POOSER: And then if you go to page 353 of the PDF.

MS. WILSON: Is this the page you want?

MR. POOSER: Yeah, that's it.

So this kind of, just sort of illustrates where there was one sort of problem area that DEQ is evaluating the risk for. But you can kind of see how far out the arsenic goes based on the maximum -- the maximum risk they were using for this analysis.

BOARD MEMBER STEELE: So where is Yellow Pine compared to this?

MR. POOSER: So it would be --

BOARD MEMBER STEELE: The upper left corner?

MR. POOSER: Yeah, it would be 10 miles to the west.

BOARD MEMBER MCELROY: What was the AACC for arsenic? Just to put the table into perspective.

MR. POOSER: 2.0002. It's one in a million so I think it's .002, or .002 --

UNIDENTIFIED SPEAKER: Yeah.

MR. POOSER: Yeah, for the one in 100,000. So I just wanted to provide that because I know the question had been asked twice.

So with that, I'll conclude my remarks.

BOARD CHAIR BOWEN: Okay. Any other comments, questions?

(No response.)

BOARD CHAIR BOWEN: Okay. Thank you very much. We are prepared for a 10-minute rebuttal if you'd like to take that?

MS. THROWER: All right. Thank you, Mr. Chairman. I think we'll follow the same format as we did the first go-round.

So I'll address the ambient air issues. You

know, DEQ said that it's reasonable to rely on Perpetua's assertions, application certified, they signed it and everything, that they're excluding the public, general public and only allowing guests of the mines. It's because they've labeled everybody as guests of the mine. I mean, it is -- it's, you know, unreasonable. And anybody that goes there for any reason, even if they, to go through that road to access public land, even if they went there not even knowing they were going to pass through an active mine site, they're supposed to be considered guests of the mine?

I mean, this is -- this is Perpetua's way of getting around not being able to exclude that road or to exclude that road from ambient air protections because it is a road that is to remain open for public use to access public land.

You know, these people don't have any intent on visiting the mine; they won't be allowed to visit the mine. As I said, they might not even know that they were going to be passing through an active mine site.

You know, we're not asking DEQ to go out necessarily and do investigations of Perpetua's legal authority to exclude the public from here, but we are asking them to look at the entire record and all the evidence in there.

And there are statements about how this road is going to be open, it is part of the -- inconsistent with the U.S. Forest Service travel management plan as a public road to access public recreation site.

You know, to the extent that DEQ just ignored all of that, that is unreasonable, that's arbitrary and capricious.

If we look at the Administrative Procedures Act, an agency is supposed to make decisions based on all the evidence in the record. Again, we're not saying go out and get titles to this or that or whatever, but there's evidence in the record that this road is to remain open for public use. So, you know, they couldn't close it; they couldn't exclude the public completely, so they labeled everyone as guests of the mine.

I don't think that the INL example is really -- you know, it's not really relevant here. And I understand situations, there's probably not an exact situation like this, every situation is going to be, have to be evaluated on a case-by-case basis. But Ms. Young, you know, talks about visiting INL on-site wearing a hard hat, wearing a dosimeter.

You know, as far as we know, as far as we understand from the access management plan or what was, you know, in the record regarding a potential access

management plan, all we know is people are going to sign a paper saying they're guests of the mine. I don't even know if they're going to really understand and realize that they are going to be breathing in a lot of particulate matter and a lot of arsenic.

You know, I think there's a, you know, sort of a sense, I think, from the DEQ and Perpetua about, well, you know, people are just going to be passing through here, you're not going to breathe this for a long time. But the Clean Air Act, I mean, you know, it -- that's the purpose of the Clean Air Act is to provide these protections to the public even if you're just passing through a road.

I mean, there's facilities where there's -- and I'm not super familiar with INL but, you know, there's facilities, and I assume this is one, that, you know, there's a highway and maybe there's facilities on both sides, and both of those facilities have an ambient air boundary, but the highway is excluded from the ambient air boundary, it has ambient air protections. So I don't think the INL example is quite on point here.

I wanted to go back a little bit. I'm not going to have Ms. Wilson pull up the map, but there's a lot of -- even Google gets it wrong so, you know, it's a complicated area. There's, you know, it's not paved

roads; it's a, you know, it's public land; there's a lot of rivers and mountains and all sorts of things going around there, so it's hard to get the layout of the roads and the access and everything there. So I'm going to refer you to our opening brief that we filed before this Board on page 17 and 18 which is REC 3476 and 3477. And then I'm going to go through some of the statements from the hearing officer's decision about access to that site and sort of the layout of the land.

Currently this is not a shortcut; this is the only way to get from the north entry to the south entry to public lands to recreational sites for people. That is -- well, sorry. I take that back. That is -- that will be the only way for people to get to that area if you exclude them from the rest of the ambient air boundary. There is a road on the north side of the ambient air boundary that is a circuitous route that can get to these recreational sites, but that would go through the ambient air boundary and that will be closed to the public. So, you know, it's not a shortcut. This is the only way that people in Yellow Pine can and will be able to get to these other recreational sites is going straight through the mine site.

Again, it was mentioned that these people are there for a limited reason; yes, they are there for a

limited reason to pass through to use the public land. They're not there as a guest of the mine; they're not there to visit the mine; they're not there to, you know, eat lunch at the mine; they're not there to, you know --

I mean, you know, I think EPA's policies and DEQ's guidance recognizes that there are certain people that would normally maybe be part of the public that aren't the public that are visiting the mine, like invitees, people bringing deliveries, you know, contract workers, things like that. Sure, those people are excluded from the general public. But people passing on this road just to get to public lands are not guests of the mine.

There's been discussion about, you know, there's not a lot of people out here; you know, the general public is very few. Well, I mean, if you consider everyone as guests of the mine, there is no general public, this is true. But, you know -- and Yellow Pine is far away.

But I want to make the point that this is an important recreational area for people. People go there and they spend a lot of time there in the summer. They spend -- our standing declarations, I'll refer you back to those -- some people spend a lot of time hiking, backpacking, fishing, camping with their kids, at just in

areas that are right outside of that ambient air boundary.

So, you know, when we start talking about, oh, well, you know, it doesn't matter that there's not a lot of people there; it does to them and it does to the Clean Air Act. The Clean Air Act doesn't distinguish, like, well, okay, we can apply these rules if we're in the city versus these rules; we'll have a little bit laxer rules if we only think, you know, a hundred people live there or something like that. That's not how the Clean Air Act works. The Clean Air Act is there to provide protection to everybody in the public, whether you're in a rural area, whether you're in the city.

And not to mention all the Nez Perce Tribe members that routinely use that area for hunting, fishing and gathering and spiritual activities.

I wanted to mention the EPA letter. It was mentioned, I believe, by Perpetua that, hey, this discusses that they're okay with the access road.

But if you look at their letter, they're talking about the ambient air boundary. So I discussed this about how, you know, that Perpetua has to have physical or some sort of other barriers to preclude people from the ambient air boundary. And that is what EPA is discussing that they are okay with, and they are --- and

they think that that meets the policy, but that is not including the access route.

BOARD CHAIR BOWEN: Two minutes.

MS. THROWER: Okay. So arsenic. Ms. Young said the permit is customary. This is -- it's customary for them to dilute arsenic emissions. There was page 42 of our brief, footnote 6, there's references there to memos between DEQ staff about their concerns, about looking for legal counsel on this issue of whether they can dilute the arsenic by seven years instead of doing a real average annual emission standard.

There was talk about specific information, that they have specific information that this mine is only going to occur for 16 years for emissions, rather than the AACC assumes that a facility is going to operate for 70 or more years.

There are specific processes set out in the rules for specific information. For example, the rules have a short-term exception. Section 210.15 allows a facility to have a 10-foot bump, just like with T-RACT, but a 10-foot bump in the AACC if your facility is operating for less than five years.

The other option is that you use annual average emissions. There's no other rule for project-specific adjustments.

BOARD CHAIR BOWEN: Would you wrap up?

MS. THROWER: Okay. When DEQ passed these rules, they made that cancer assessment, you know. What DEQ here is saying is that they think that being exposed to a high concentration of emissions for 16 years is the same as low concentrations of emissions for 70 years.

They haven't made that cancer risk assessment. This was an atmospheric scientist declaration by Kevin Schilling that basically just provided the same rationale for the project-specific adjustment that was in the response to comments that we don't agree with. And there's no additional cancer risk assessment that says that that was appropriate for them to do.

And with that, I will turn it over to my colleague.

BOARD CHAIR BOWEN: Okay. Thank you.

MR. HURLBUTT: Thank you. All right. So first on allowing Perpetua to submit plans later after the permit has been approved, I just want to touch on a few things that came up.

The first one is I think I heard both DEQ and Perpetua suggest, how could they possibly come up with these plans now? That would be ridiculous, it's just too much detailed information and it's too burdensome.

The whole permit, the permit application, the

Statement of Basis is full of all kinds of complicated, complex, technical, specific details about tons of aspects about this mine, and the idea that they couldn't come up with how frequently and in what amounts they're going to apply dust controls, or how they're going to actually access -- manage access at the site is just absurd, and the operational boundary is a good example of that.

During Mr. Pooser's talk the operational boundary was up there. Perpetua explained how they decided on this operational boundary a long time ago. I think deciding on that boundary was probably way more complicated than coming up with plans for how they're going to control dust, how they're going to control access management and things like that that are in these required plans that have not yet been submitted.

Related to that, the EPA letter talks about the access management plan. And I heard Ms. Young say that absolutely the access management plan is going to track public access through the site.

EPA in its letter recommended that the plan include some kind of continuous monitoring, "Maintain continuous monitoring of the public's movements through the site," and DEQ is saying absolutely that will be in the plan. I don't know what basis there is for saying

that absolutely that will be in the plan.

If you look at permit condition 2.7 which lays out what needs to be in the access management plan, it says, among other things, "Public access to the facility may be monitored by the use of security escort vehicles or other things."

And this gets to the underlying problem here. We don't yet know what's in the access management plan. Our clients, other members of the public, EPA have not been able to comment on what's actually in the access management plan because it hasn't been developed yet, and it's not going to be submitted for public comment. This permit has already been approved without these kinds of important details being before the public and being subject to their comments.

Again, there could be the kind of monitoring of public through the site, but there's no requirement in the permit that that actually be included.

Next is interpreting Section 202 about what needs to be required in an application. Ms. Elroy had a good point about 202 saying site information, plans, descriptions, specifications, and drawings, and that those relate to the facility; they also relate to the nature and amount of emissions; they also relate to the manner in which things will be controlled; you can't weed

those out of there. And of course not every single detailed specification can reasonably be included in an application; it's what are the important ones that need to be in there.

And that's where, as Mr. Pooser pointed out, at the beginning of Section 202 it says that the application must include, quote, "All information necessary to perform any analysis or make any determination required under Sections 200 through 227."

So those are the determinations that DEQ has to make that this project will comply with National Ambient Air Quality Standard; will comply with arsenic TAPs; will comply with other standards.

So no, unimportant details that don't go towards whether this is going to comply with air quality standards might not need to be part of the plan's information, description, specifications.

But if that information is important and actually goes towards whether this permit will comply with air standards, they absolutely need to be included. And so that would include here dust control.

I'm going to mention this for the sixth time in the record, if they do not meet their dust control by just a tiny bit, the project will violate the NAAQ. And until we see application rates and timing and frequency

of dust control measures, there's no way DEQ could have done the analysis it needed to do to make its determination that this project will comply with the PM 10 NAAQ. That's the kind of information that needs to be put before the public. That's what those two federal appellate court decisions that I referenced support.

I guess with that I'll turn to the 93.3 percent issue unless anyone has questions about the plan? I sense that everyone is pretty ready to get out of here.

Just two points on meeting the 93.3 percent dust control target. As I pointed out, there is nothing that specifically ties any of these permit conditions to actually achieving 93.3 as opposed to some slightly lesser amount like 90 percent or 85 percent. I didn't hear DEQ's attorney or Perpetua's attorney point to anything that does that. There's sort of the sense that, well, there's a lot of things in here, and if you consider them all together, that's enough to hit 93.3 percent. And that's just, that's not true.

Those things are enough to think that this is probably going to do a pretty good job at dust control, it's not going to come in at, you know, 5 percent dust control or something terrible like that. But there's just no basis for saying that, well, yeah, this will hit 93.3.

What provisions in the permit are any different than if they were trying to hit 90 percent dust control, or 85 percent dust control, or 98 percent dust control? Everything that's in the permit is just pretty good practices for pretty good dust control that will probably do a pretty good job. But this idea that they're going to hit 93 and barely meet the NAAQS is not supported by what's in the permit or anything in the record.

And then the final thing on 93.3 percent. DEQ suggested that, gosh, there's just nothing we could do about this, they're asking for something impossible here. But there are things that could be done about it.

Source testing is something that's commonly done to see how a particular pollution control might work.

There could be ways to test at initial operations how the dust control is actually going, to see if it's coming in at 93.3 percent.

And then there's also the available practice in the Air Rules of having ambient air boundary monitoring. This is in Section 211 of the rules. DEQ can require ambient air boundary monitoring. That would be a backstop that could confirm that based on everything DEQ and Perpetua says will happen will achieve 93.3 percent and would not cause a NAAQS violation, that will confirm that that is actually happening if there was ambient air

boundary monitoring around the site.

Additionally, there could just be changes to what's done. There are other sources of fugitive dust that could be limited. The operations could be limited. There's not -- there are things that could be done to ensure that the project will comply with the NAAQS that have not been done now.

And unless there's any further questions, I thank you.

BOARD CHAIR BOWEN: Thank you.

Thank you to everybody that's presented. Appreciate it.

Is it the desire of the Board to enter into executive session? I'll entertain a motion.

VICE CHAIR MACMILLAN: Yes, sir. Mr. Chairman, I move the Board enter into an executive session pursuant to Idaho Code 74-206(1)(f) to communicate with legal counsel for the public agency to discuss the legal ramifications of and legal options for pending litigation or controversies not yet being litigated but imminently likely to be litigated.

I request that a roll call vote be taken and that the vote -- and that vote be recorded in the minutes of this meeting.

BOARD CHAIR BOWEN: Thank you. Do I hear a

second?

BOARD MEMBER MCELROY: Second.

BOARD CHAIR BOWEN: Elaine, would you take a roll call vote, please?

BOARD CLERK GANINO: Yes, Mr. Chairman.

Mark Bowen.

BOARD CHAIR BOWEN: Aye.

BOARD CLERK GANINO: Dr. Randy MacMillan.

VICE CHAIR MACMILLAN: Aye.

BOARD CLERK GANINO: Carol Mascarenas.

BOARD MEMBER MASCARENAS: Aye.

BOARD CLERK GANINO: Beth Elroy.

BOARD MEMBER ELROY: Aye.

BOARD CLERK GANINO: John Sigler.

BOARD MEMBER SIGLER: Aye.

BOARD CLERK GANINO: Clayton Steele.

BOARD MEMBER STEELE: Aye.

BOARD CLERK GANINO: Pat Purdy.

BOARD MEMBER PURDY: Aye.

BOARD CHAIR BOWEN: Motion carries. We adjourn to executive session. Thank you.

Thanks, everybody.

(Thereupon the Board convened into executive session off the record.)

BOARD CHAIR BOWEN: Randy, do we have a motion?

VICE CHAIR MACMILLAN: Mr. Chairman, I move that the Board resolve out of the executive session and that the meeting of the minutes reflect that no action was taken during executive session.

BOARD CHAIR BOWEN: Thank you.

We have a motion, do we have a second?

BOARD MEMBER SIGLER: Second.

BOARD CHAIR BOWEN: We have a motion and a second.

Elaine, would you take a roll call vote, please?

BOARD CLERK GANINO: Yes, Mr. Chairman.

Mark Bowen.

BOARD CHAIR BOWEN: Aye.

BOARD CLERK GANINO: Dr. Randy MacMillan.

VICE CHAIR MACMILLAN: Aye.

BOARD CLERK GANINO: Carol Mascarenas.

BOARD MEMBER MASCARENAS: Aye.

BOARD CLERK GANINO: Beth Elroy.

BOARD MEMBER ELROY: Aye.

BOARD CLERK GANINO: John Sigler.

BOARD MEMBER SIGLER: Aye.

BOARD CLERK GANINO: Clayton Steele.

BOARD MEMBER STEELE: Aye.

BOARD CLERK GANINO: Pat Purdy.

BOARD MEMBER PURDY: Aye.

BOARD CHAIR BOWEN: Motion carries. We're back in session.

The first order of business is a five-minute break. We'll be right back.

(Thereupon there was a brief recess.)

BOARD CHAIR BOWEN: Okay. Call this meeting back to order. I want to certainly thank everybody for the effort that's been put into this. We have -- as a Board we've heard a lot, there's a lot to consider.

Any comments from the Board?

(No response)

BOARD CHAIR BOWEN: Without that, I will entertain a motion.

VICE CHAIR MACMILLAN: Mr. Chairman, I move the Board take the issue as presented, the amended petition for review of preliminary order, under advisement, and issue a written final order within 56 days of today's hearing.

BOARD CHAIR BOWEN: We have a motion. Do we have a second?

BOARD MEMBER MCELROY: Second.

BOARD CHAIR BOWEN: We have a motion and a second.

Elaine, will you take a roll call vote, please?

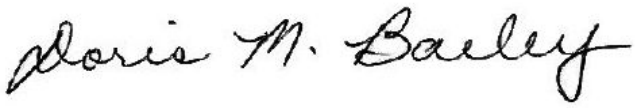
BOARD CLERK GANINO: Yes, Mr. Chairman.

Mark Bowen.
BOARD CHAIR BOWEN: Aye.
BOARD CLERK GANINO: Dr. Randy MacMillan.
VICE CHAIR MACMILLAN: Aye.
BOARD CLERK GANINO: Carol Mascarenas.
BOARD MEMBER MASCARENAS: Aye.
BOARD CLERK GANINO: Beth Elroy.
BOARD MEMBER ELROY: Aye.
BOARD CLERK GANINO: John Sigler.
BOARD MEMBER SIGLER: Aye.
BOARD CLERK GANINO: Clayton Steele.
BOARD MEMBER STEELE: Aye.
BOARD CLERK GANINO: Pat Purdy.
BOARD MEMBER PURDY: Aye.
BOARD CHAIR BOWEN: The motion is carried.
With that, we're ready to adjourn. Do we have a motion to adjourn?
VICE CHAIR MACMILLAN: So moved.
BOARD CHAIR BOWEN: Do we have a second?
BOARD MEMBER SIGLER: Second.
BOARD CHAIR BOWEN: All in favor?
(AYES.)
BOARD CHAIR BOWEN: Thank you. We are adjourned. Thank you very much.
(Proceedings concluded at 3:43 p.m.)

CERTIFICATE OF CERTIFIED SHORTHAND REPORTER

STATE OF IDAHO }
} ss.
COUNTY OF ADA }

I, DORIS M. BAILEY, CSR NO. SRL-1074, a Certified Shorthand Reporter, certify:



That the proceedings were transcribed by me or under my direction, to the best of my ability;

That the foregoing is a true and correct transcription of all proceedings, to the best of my ability;

That I am not a relative or employee of any attorney or party;

I further certify that I am not financially interested in the action.

IN WITNESS WHEREOF, I set my hand and seal this 19th day of March 2024.

DORIS M. BAILEY
CSR #SRL-1074, RPR, CRR
Notary Public
Post Office Box 2636
Boise, Idaho 83701-2636

My Commission Expires: June 12, 2028

--oOo--

BOARD CHAIR BOWEN: It's Monday, May 1st, 2024, 9:00 AM. This is Mark Bowen, Chairman of the Idaho Board of Environmental Quality.

I call to order this special meeting of the Idaho Board of Environmental Quality. In addition to being a public meeting, we are also on the record on the matter of Air Quality Permit to Construct Issued to Perpetua Resources Idaho, Inc., agency case number 0101-22-01, OAH case number 23-245-01.

This special meeting is being held in the state office of the Department of Environmental Quality.

For those present in the meeting room, please sign in on the sheet provided at the entrance.

There won't be an opportunity for public comment today.

Elaine, could you please take roll?

BOARD CLERK GANINO: Yes, Mr. Chairman.

Mark Bowen.

BOARD CHAIR BOWEN: Here.

BOARD CLERK GANINO: Dr. Randy MacMillan.

Randy? He's there, I see him there. Randy? He's not responding. I'll go back and try him again.

Beth Elroy.

BOARD MEMBER ELROY: Here.
BOARD CLERK GANINO: John Sigler.
BOARD MEMBER SIGLER: Here.
BOARD CLERK GANINO: Clayton Steele.
He's online also.
BOARD MEMBER STEELE: Here.
BOARD CHAIR BOWEN: There we go.
BOARD CLERK GANINO: Pat Purdy.
BOARD MEMBER PURDY: Here.
BOARD CLERK GANINO: We'll go back to Randy MacMillan.
VICE CHAIR MACMILLAN: Here.
BOARD MEMBER BOWEN: There we go.
VICE CHAIR MACMILLAN: I'm here.
BOARD CHAIR BOWEN: We got you, Randy. Thanks.
VICE CHAIR MACMILLAN: All right.
BOARD CHAIR BOWEN: And Carol's not joining us; correct?
BOARD CLERK GANINO: Correct.
BOARD CHAIR BOWEN: Okay. All right. So the Board --
BOARD MEMBER STEELE: Clayton Steele here.
BOARD CHAIR BOWEN: Clayton, we've got everybody. Thank you.
BOARD MEMBER STEELE: Okay. Thanks.

BOARD CHAIR BOWEN: The Board intends to take action at this meeting. No additional statements or oral argument will be taken at this meeting. A court reporter is present to record the Board's discussion.

We will now move on to the agenda items. Agenda number 1 is the option for the Board to go into executive session. I will entertain a motion.

BOARD MEMBER ELROY: I move the Board enter into executive session pursuant to IC 74-206(1)(f) to communicate with legal counsel for the public agency to discuss the legal ramifications of and legal options for pending litigation, or controversies not yet being litigated but imminently likely to be litigated.

I request that a roll call vote be taken and that vote be recorded in the minutes of this meeting.

BOARD CHAIR BOWEN: We have a motion. Is there a second?

VICE CHAIR MACMILLAN: Second.

(Reporter clarification.)

BOARD CHAIR BOWEN: Randy, Dr. MacMillan.

We have a motion and a second. We'll now call a roll vote.

Elaine.

BOARD CLERK GANINO: Yes, Mr. Chairman.

Mark Bowen.

BOARD CHAIR BOWEN: Aye.
BOARD CLERK GANINO: Dr. Randy MacMillan.
VICE CHAIR MACMILLAN: Aye.
BOARD CLERK GANINO: Beth Elroy.
BOARD MEMBER ELROY: Aye.
BOARD CLERK GANINO: John Sigler.
BOARD MEMBER SIGLER: Aye.
BOARD CLERK GANINO: Clayton Steele.
He's online also.
BOARD MEMBER STEELE: Aye.
BOARD CHAIR BOWEN: There we go.
BOARD CLERK GANINO: Pat Purdy.
BOARD MEMBER PURDY: Aye.
BOARD CHAIR BOWEN: The motion has carried. We will now move to executive session.
Thank you.
(Thereupon there was a brief recess.)
BOARD CHAIR BOWEN: All right. I'll entertain a motion.
BOARD MEMBER ELROY: I move that the Board resolve out of executive session and that the meeting of the minutes reflect that no action was taken during the executive session.
BOARD CHAIR BOWEN: We have a motion.
MS. YRIBAR: Clayton.

BOARD CHAIR BOWEN: Do we have a second?
BOARD MEMBER STEELE: Second.
BOARD CHAIR BOWEN: We have a motion and a second. All in favor? I guess we'll take a roll call vote.
Elaine, will you take a roll call, please?
BOARD CLERK GANINO: Yes, Mr. Chairman.
Mark Bowen.
BOARD CHAIR BOWEN: Aye.
BOARD CLERK GANINO: Dr. Randy MacMillan.
VICE CHAIR MACMILLAN: Aye.
BOARD CLERK GANINO: Beth Elroy.
BOARD MEMBER ELROY: Aye.
BOARD CLERK GANINO: John Sigler.
BOARD MEMBER SIGLER: Aye.
BOARD CLERK GANINO: Clayton Steele.
BOARD MEMBER STEELE: Aye.
BOARD CLERK GANINO: Pat Purdy.
BOARD MEMBER PURDY: Aye.
BOARD CHAIR BOWEN: Motion carries. So we are back on the record after executive session.
We're now on agenda item number 2, Amended Petition for Review of Preliminary Orders Filed in the Matter of Air Quality Permit to Consent -- Construct Issued to Perpetua Resources Idaho, Inc., Agency Case

number 0101-22-01, OAH case number 23-245.

This is an action item to discuss and adopt a final order prior to service of a written order within 56 days of the March 14th, 2024 oral argument.

I'll entertain a motion.

BOARD MEMBER ELROY: I move based on the foregoing, the DEQ Board finds:

Number one. DEQ acted responsibly in determining that Perpetua will have legal control of the Stibnite Road access route such that it could properly be excluded from consideration as ambient air.

Number 2. DEQ acted responsibly in determining that Perpetua what will have physical and practical control of the Stibnite Road access route such that it could properly be excluded from the consideration as ambient air.

Number 3. DEQ did not violate the air rules by allowing Perpetua to submit some plans after the PTC was issued.

Number 4. The PTC includes enforceable conditions that will achieve 93.3 percent dust control.

Number 5. There was insufficient evidence to support DEQ's evaluation of the ambient air concentration.

The DEQ Board moves to remand this matter to the

hearing officer for further factual development in accordance with the terms of this order.

We further direct our legal counsel to draft a final order in accordance with the terms of our decision, and to serve it on the parties by Thursday, May 9th.

BOARD CHAIR BOWEN: We have a motion. Do we have a second?

BOARD MEMBER PURDY: Second by Pat Purdy.

BOARD CHAIR BOWEN: We have a motion and a second. We will now have a general discussion. I'd open it to Board members to discuss any of the items, 1 through 5.

MS. YRIBAR: You want to just call on people?

BOARD CHAIR BOWEN: Yeah, let's start.

Dr. MacMillan, I'll start with you.

VICE CHAIR MACMILLAN: Mr. Chairman, I do not believe DEQ's creation and application of a project-specific adjustment factor can be supported by Idaho's air quality rules. I believe DEQ has misinterpreted how the acceptable ambient concentration for carcinogens, the AACC, must be applied if it is to comply with our air quality rules.

Further, and most disturbing to me, is that the creation of a project-specific adjustment factor suggests that there is a significant ignorance about cancer,

carcinogens, and carcinogenosis.

While DEQ experts correctly identified the AACC as the gold standard for minimizing cancer risk, they failed to recognize that the ACC -- the AACC fundamentally functions to limit the initiation of cancer, not only after 70 years, but every day of a person's life, starting at birth.

By applying the, what I would call short-sighted project-specific adjustment factor to the Stibnite Gold Project, DEQ created a misleading risk analysis that greatly underestimates the actual cancer risk.

With your permission, Mr. Chairman, I would like to explain further.

BOARD CHAIR BOWEN: Go ahead, Dr. MacMillan.

BOARD MEMBER MCMAHON: Mr. Chairman?

BOARD CHAIR BOWEN: Yes, go ahead.

BOARD MEMBER MCMAHON: By way of background, the Board should know that I have received considerable graduate education, was a senior research fellow conducting post-doctoral research, and spent considerable part of my career as a research comparative pathologist. Prior to entering a private enterprise here in Idaho, I was a professor of veterinary and aquatic animal medicine.

During my training, teaching, and research, I

became well versed in numerous aspects of cancer biology, including how cancer is initiated, how it -- how cancer is promoted, and how it progresses.

The biological processes associated with cancer are the same whether the cancer occurs in humans, other mammals, fish, or mollusks.

The AACCs that we see in Section 586 of our air quality rules are air emission concentration limits exclusively intended to minimize the risk of starting cancer. Cancer starts when a carcinogen such as arsenic is inhaled and causes mutation in cellular DNA. That mutation is inheritable, meaning it is passed from the mutate cell to daughter cells.

Also, depending on various physiological variables, cancer can quickly or slowly lead to uncontrolled, neoplastic cell growth that is cancerous cell growth, and development of a tumor grossly recognized as cancer.

One of the challenges of cancer as a human disease is that it is not readily recognized in its early stages. This should not be surprising when you consider that humans contain 10 to 100 trillion cells.

Often it is only after considerable growth that a grossly or histologically recognizable cancer becomes evident. Sometimes it's not detected until a person

feels ill, seeks medical attention, or dies.

To reiterate, once cancer is initiated, neoplastic, uncontrolled cellular replication may occur relatively quickly, or it may take many years, perhaps more than 70 years for detection of a recognizable cancer.

The take-home message is the cancer starts well before it is recognized. You don't need 70 years for it to appear. There are multiple variables that impact the initiation, promotion, and progression of cancer, such as age, immune status, comorbidities, and co-factors.

The co-factor with the Stibnite Gold Project would be dust, particularly pm 2.5 or smaller particles, all of which contain arsenic.

Inhaled dust can linger for extended periods in our lungs. Such dust is associated with a variety of pathologic processes that can amplify or enhance the development.

But most germane in this contested case are carcinogen dose and duration. The greater the dose of carcinogen exposure, the greater is the chance of cancer initiation; the longer the duration of carcinogen exposure, the greater is the risk of developing cancer.

Low dose exposure, as embodied in the AACC and applied daily for up to 70 years, would be expected to

limit cancer to only a one in one million chance.

The higher dose, such as associated with this short-term project in a T-RACT acceptable concentrations, would be expected to limit cancer to one in 100,000 chances, even after 70 years.

DEQ concluded that the Stibnite gold project cancer risk exceeds the AACC associated risk and exceeds the T-RACT associated risk.

The Idaho rules are not ambiguous. There is an acceptable risk associated with the AACC standard. There is an an acceptable risk associated with DEQ-approved T-RACT projects, and there is an acceptable risk associated with the short-term project that is five years or less. There are no other acceptable risks identified in Idaho's air quality rules.

DEQ's project-specific adjustment factor creates a new, higher level of cancer risk for 16 years. DEQ assumes 70 years is required for cancer to develop. That is an incorrect assumption.

The AACC, the T-RACT, and short-term AACC emission exposure limits are actually daily limits that apply over a person's entire lifetime, regardless of how long they live. The acceptable cancer risk remains one in one million or one in 100,000. Higher carcinogen doses increase the cancer risk every day of a person's

life. A higher daily dose for 16 years elevates the cancer risk even more.

Application of the project-specific adjustment factor allows DEQ to ignore 16 years of higher cancer initiation risk. The PTC proposes to allow 16 years higher daily carcinogen doses, and disguises such doses using a non-rules-based mathematics. Use of the project-specific adjustment factor ignores 16 years of cancer initiation due to higher carcinogenic arsenic dose that is otherwise allowed by rule. The AACC, the T-RACT, and short-term project AACCs dictate an annual average compliance.

DEQ further violates this compliance point by instituting a five-year rolling average compliance. Such a creative compliance point allows even further departure from our air quality goals, and specifically compliance with Section 161 of our air quality rules.

And personally it grieves me to disagree with DEQ. I regard DEQ staff as a team of environmental heroes. They have a daunting task to protect our environment and, in particular, help the people, animals, and plants, while fostering financial success. But even heroes make mistakes.

In my opinion, DEQ has misapplied the Idaho air quality rule, and they do not have authority to create

new cancer risks.

Thank you.

BOARD CHAIR BOWEN: Thank you, Dr. MacMillan.

Ms. Elroy, any comments?

BOARD MEMBER ELROY: Yes. Dr. MacMillan very eloquently expressed my opinion as well.

I will share with all of the parties of this case that the Board has extensive technical knowledge and experience associated with, as Randy explained, as well as decades of air permitting experience on this Board. So we do feel like due to the Board's expertise, it greatly helped us navigate through a very challenging contested case.

I do want to call out the legal support that we received by the Deputy Attorney General Ann Yribar. Her legal expertise absolutely helped us also navigate through this case, and I do want to just say thank you to Ann and recognize her for her expertise and support in navigating us through this case.

Thank you.

BOARD CHAIR BOWEN: Thank you.

Mr. Sigler, any comments?

BOARD MEMBER SIGLER: Yes, this is John Sigler.

I concur with Dr. MacMillan's summary and added comments. I think that very adequately and accurately

puts forward not only the review that's been done by the Board, but technical experts and the legal staff, that going forward we will have a solid foundation for providing the instructions that we're going to do here shortly.

BOARD CHAIR BOWEN: Thank you.

BOARD MEMBER SIGLER: That's all.

BOARD CHAIR BOWEN: Thank you.

Mr. Steele, any comments?

BOARD MEMBER STEELE: No, I do not have any comments.

BOARD CHAIR BOWEN: Thank you.

Mr. Purdy, any comment? discussion?

BOARD MEMBER PURDY: Sorry. Trying to find the unmute button.

No, I do not have any comments. Thank you.

BOARD CHAIR BOWEN: Thank you. I'd just like to add a general discussion to just --

The Board would like to acknowledge the effort of all participants. There's been a tremendous amount of work on everybody's behalf on this. We understand how complicated and how much work has gone into this. We want to express gratitude for everybody's participation. I think everybody here is interested in the safety and health of the citizens of Idaho.

And I also would like to acknowledge and thank the work of our Attorney General, Ms. Yribar, her assistance.

So with that, we have a motion and a second. Elaine, will you take the roll, please?

BOARD CLERK GANINO: Yes, Mr. Chairman.

Mark Bowen.

BOARD CHAIR BOWEN: Aye.

BOARD CLERK GANINO: Dr. Randy MacMillan.

BOARD CHAIR BOWEN: Randy, you need to unmute.

VICE CHAIR MACMILLAN: I was, but aye.

BOARD CHAIR BOWEN: Thank you.

BOARD CLERK GANINO: Beth Elroy.

BOARD MEMBER ELROY: Aye.

BOARD CLERK GANINO: John Sigler.

BOARD MEMBER SIGLER: Aye.

BOARD CLERK GANINO: Clayton Steele.

BOARD MEMBER STEELE: Aye.

BOARD CLERK GANINO: Pat Purdy.

BOARD MEMBER PURDY: Aye.

BOARD CHAIR BOWEN: Motion carried.

We've reached the end of our agenda today. I'd entertain a motion to adjourn.

BOARD MEMBER ELROY: So moved.

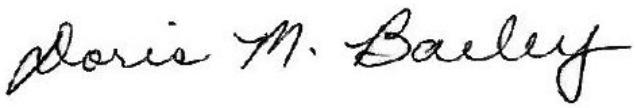
BOARD CHAIR BOWEN: Do I have a second?

BOARD MEMBER SIGLER: This is John. I second.
BOARD CHAIR BOWEN: We have a motion and a second. All in favor say Aye.
(AYES.)
BOARD CHAIR BOWEN: Any opposed?
(NO RESPONSE.)
BOARD CHAIR BOWEN: Hearing none, we stand adjourned.
(Proceedings concluded at 11:35 a.m.)

CERTIFICATE OF CERTIFIED SHORTHAND REPORTER

STATE OF IDAHO }
} ss.
COUNTY OF ADA }

I, DORIS M. BAILEY, CSR NO. SRL-1074, a Certified Shorthand Reporter, certify:



That the proceedings were transcribed by me or under my direction, to the best of my ability;

That the foregoing is a true and correct transcription of all proceedings, to the best of my ability;

That I am not a relative or employee of any attorney or party;

I further certify that I am not financially interested in the action.

IN WITNESS WHEREOF, I set my hand and seal this 9th day of May, 2024.

DORIS M. BAILEY
CSR #SRL-1074, RPR, CRR
Notary Public
Post Office Box 2636
Boise, Idaho 83701-2636

My Commission Expires: June 12, 2028

Idaho Rules of Civil Procedure

Rule 30

(e) Review by the Witness; Changes.

(1) Unless waived by the deponent and the parties, the deponent must be allowed 30 days after being notified by the officer that the transcript or recording is available in which (A) to review the transcript or recording; and (B) if there are changes in form or substance, to sign a statement listing the changes and the reasons for making them. (2) Changes indicated in the Officer's Certificate. The officer must note in the certificate prescribed by Rule 30 (f)(1) whether a review was requested and, if so, must attach any changes the deponent makes during the 30-day period. (3) Witness Failure to Sign. (A) In General, If the deposition is not signed by the witness within the 30-day period, the officer must sign it and state on the record the fact of the waiver of signature, or of the illness or absence

of the witness or the fact of the refusal to sign the deposition together with any reason given for not signing. (B) Use of Unsigned Deposition. The deposition may be used as if it were signed, unless pursuant to Rule 32 (d)(4) the court determines that the reasons given for the refusal to sign require rejection of the deposition in whole or in part.

DISCLAIMER: THE FOREGOING CIVIL PROCEDURE RULES ARE PROVIDED FOR INFORMATIONAL PURPOSES ONLY. THE ABOVE RULES ARE CURRENT AS OF APRIL 1, 2019. PLEASE REFER TO THE APPLICABLE STATE RULES OF CIVIL PROCEDURE FOR UP-TO-DATE INFORMATION.

VERITEXT LEGAL SOLUTIONS

COMPANY CERTIFICATE AND DISCLOSURE STATEMENT

Veritext Legal Solutions represents that the foregoing transcript is a true, correct and complete transcript of the colloquies, questions and answers as submitted by the court reporter. Veritext Legal Solutions further represents that the attached exhibits, if any, are true, correct and complete documents as submitted by the court reporter and/or attorneys in relation to this deposition and that the documents were processed in accordance with our litigation support and production standards.

Veritext Legal Solutions is committed to maintaining the confidentiality of client and witness information, in accordance with the regulations promulgated under the Health Insurance Portability and Accountability Act (HIPAA), as amended with respect to protected health information and the Gramm-Leach-Bliley Act, as amended, with respect to Personally Identifiable Information (PII). Physical transcripts and exhibits are managed under strict facility and personnel access controls. Electronic files of documents are stored in encrypted form and are transmitted in an encrypted

fashion to authenticated parties who are permitted to access the material. Our data is hosted in a Tier 4 SSAE 16 certified facility.

Veritext Legal Solutions complies with all federal and State regulations with respect to the provision of court reporting services, and maintains its neutrality and independence regardless of relationship or the financial outcome of any litigation. Veritext requires adherence to the foregoing professional and ethical standards from all of its subcontractors in their independent contractor agreements.

Inquiries about Veritext Legal Solutions' confidentiality and security policies and practices should be directed to Veritext's Client Services Associates indicated on the cover of this document or at www.veritext.com.

BOARD OF ENVIRONMENTAL QUALITY MEETING

June 12, 2024

IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY
1410 NORTH HILTON STREET
BOISE, IDAHO

Reported by:
Misti L. Alcalde, ID CSR #1137, CA CSR #13338, RPR

BOARD OF ENVIRONMENTAL QUALITY MEETING

BOARD MEMBERS APPEARING IN PERSON:
MARK BOWEN, Chair
DR. JOHN RANDY MACMILLAN, Vice Chair
BOARD MEMBERS APPEARING REMOTELY:
CAROL MASCAREÑAS, Secretary
CLAYTON STEELE
PAT PURDY
ALSO PRESENT: PAULA WILSON, Paralegal, DEQ
ELAINE GANINO, Clerk to the Board

P R O C E E D I N G S

BOARD CHAIR BOWEN: Okay. We'll call this meeting to order. It's Wednesday, June 12th, 2024, 9:00 [sic] a.m.

My name is Mark Bowen, chairman of the Idaho Board of Environmental Quality. I call to order the special meeting of the Idaho Board of Environmental Quality.

In addition to being a public meeting, we're also on record in the matter of Air Quality Permit to Construct issued to Perpetua Resources Idaho, Inc., agency case no. 0101-22-01, OAH case no. 23-245-01.

This special meeting is being held in the state office of The Department of Environmental Quality. For those present in the meeting room, please sign in on the sheet provided by the entrance, but there won't be an opportunity today for public comment.

Elaine, could you please take the roll.

BOARD CLERK GANINO: Yes, Mr. Chairman.

Mark Bowen.

BOARD CHAIR BOWEN: Here.

BOARD CLERK GANINO: Dr. Randy Macmillan.

VICE CHAIR MACMILLAN: Here.

BOARD CLERK GANINO: Carol Mascareñas.
BOARD MEMBER MASCAREÑAS: Here.
BOARD CLERK GANINO: Clayton Steele.
BOARD MEMBER STEELE: Here.
BOARD CLERK GANINO: Pat Purdy.
Pat, I think you're still on mute.
BOARD MEMBER STEELE: Pat, are you here?
Pat, are you here for roll?
BOARD MEMBER PURDY: Yes. I'm sorry, I thought I said "here."
BOARD CHAIR BOWEN: Okay. Thank you.
The board attempts to take action at this meeting. No additional statements or oral arguments will be taken at this meeting. The court reporter is present to record the board's decision.
We'll now move on to agenda items. Agenda item no. 1, executive session pursuant to Idaho Code 74-206(1)(f).
I'll entertain a motion.
VICE CHAIR MACMILLAN: Mr. Chairman, I move the board enter into an executive session pursuant to Idaho Code 74-206(1)(f) to communicate with legal counsel for the public agency to discuss the legal ramifications of and legal options for pending litigation or controversies not yet being

litigated but imminently likely to be litigated. I request that a roll call vote be taken and that vote be recorded in the minutes of this meeting.

BOARD CHAIR BOWEN: We have a motion. Do we have a second?

BOARD MEMBER STEELE: Second.

BOARD CHAIR BOWEN: We have a motion and a second.

Is there any discussion?

Hearing none, we have a motion and a second. We'll now conduct a roll call vote.

Elaine.

BOARD CLERK GANINO: Mark Bowen.

BOARD CHAIR BOWEN: Aye.

BOARD CLERK GANINO: Dr. Randy MacMillan.

VICE CHAIR MACMILLAN: Aye.

BOARD CLERK GANINO: Carol Mascareñas.

CAROL MASCAREÑAS: Aye.

BOARD CLERK GANINO: Clayton Steele.

BOARD MEMBER STEELE: Aye.

BOARD CLERK GANINO: Pat Purdy.

BOARD MEMBER PURDY: Aye.

BOARD CHAIR BOWEN: The motion is carried.

We'll now move into executive session.

(EXECUTIVE SESSION COMMENCED.)

BOARD CHAIR BOWEN: I'll now entertain a motion to get out of executive session.

VICE CHAIR MACMILLAN: Mr. Chairman, I move that the board resolve out of executive session and that the meeting of the minutes reflect that no action was taken during the executive session.

BOARD CHAIR BOWEN: We have a motion.

Do we have a second?

BOARD MEMBER MASCAREÑAS: I second.

BOARD CHAIR BOWEN: We have a motion and a second.

Elaine, will you take the roll, please.

BOARD CLERK GANINO: Yes, Mr. Chairman.

Mark Bowen.

BOARD CHAIR BOWEN: Aye.

BOARD CLERK GANINO: Dr. Randy MacMillan.

VICE CHAIR MACMILLAN: Aye.

BOARD CLERK GANINO: Carol Mascareñas.

BOARD MEMBER MASCAREÑAS: Aye.

BOARD CLERK GANINO: Clayton Steele.

BOARD MEMBER STEELE: Aye.

BOARD CLERK GANINO: Pat Purdy.

BOARD MEMBER PURDY: Aye.

BOARD CHAIR BOWEN: Motion carries. We're now back on record after executive session. We're

moving to agenda item no. 2, discuss and adopt order relative to motions filed on May 23rd, 2024. Petitioners motion for clarification and/or reconsideration and respondent's and intervener respondent's joint motion for reconsideration and/or clarification of final order.

This is an action item to discuss and make a decision prior to service of the written order. I'll entertain a motion.

VICE CHAIR MACMILLAN: Mr. Chairman, I move that the board order the following:

Petitioner's motion for clarification and/or reconsideration is denied. The joint motion for reconsideration and/or clarification of final order is granted in part and denied in part.

The Board of Environmental Quality clarifies its decision as to the effective date of the final order. The Board of Environmental Quality denies the request to reconsider its decision on the ambient arsenic concentration issue.

The Board of Environmental Quality denies the request to reopen the proceedings or hold additional hearing before the board.

The Board of Environmental Quality

denies the request for additional clarification or instructions to the hearing officer.

BOARD CHAIR BOWEN: We have a motion.

Do we have a second?

BOARD MEMBER STEELE: Second.

BOARD CHAIR BOWEN: We have a motion and a second. That was Clayton who seconded.

Is there any discussion? I'm going to go through the roster for any discussion.

Dr. MacMillan, any discussion?

VICE CHAIR MACMILLAN: None.

BOARD CHAIR BOWEN: Carol Mascareñas, any discussion?

BOARD MEMBER MASCAREÑAS: No comments.

BOARD CHAIR BOWEN: Clayton Steele, any discussion?

BOARD MEMBER STEELE: No.

BOARD CHAIR BOWEN: Pat Purdy, any comments?

BOARD MEMBER PURDY: No.

BOARD CHAIR BOWEN: We will call for a vote.

Elaine, would you call for a vote, please.

BOARD CLERK GANINO: Yes, Mr. Chairman.

Mark Bowen.

BOARD CHAIR BOWEN: Aye.

BOARD CLERK GANINO: Dr. Randy MacMillan.
VICE CHAIR MACMILLAN: Aye.
BOARD CLERK GANINO: Carol Mascareñas.
BOARD MEMBER MASCAREÑAS: Aye.
BOARD CLERK GANINO: Clayton Steele.
BOARD MEMBER STEELE: Aye.
BOARD CLERK GANINO: Pat Purdy.
BOARD MEMBER PURDY: Aye.
BOARD CHAIR BOWEN: The motion is carried.

The board will issue our final written final order either today or tomorrow depending on signatures.

We've reached the end of our agenda. I'll entertain a motion to a adjourn.

VICE CHAIR MACMILLAN: So moved.
BOARD MEMBER STEELE: Second.
BOARD CHAIR BOWEN: We have a motion and a second.

Will you call roll call vote, Elaine.

BOARD CLERK GANINO: Yes, Mr. Chairman.

Mark Bowen.

BOARD CHAIR BOWEN: Aye.
BOARD CLERK GANINO: Dr. Randy MacMillan.
VICE CHAIR MACMILLAN: Aye.
BOARD CLERK GANINO: Carol Mascareñas.

BOARD MEMBER MASCAREÑAS: Aye.
BOARD CLERK GANINO: Clayton Steele.
BOARD MEMBER STEELE: Aye.
BOARD CLERK GANINO: Pat Purdy.
BOARD MEMBER PURDY: Aye.
BOARD CHAIR BOWEN: We stand adjourned. Thank you everybody. Thanks for your participation.
(Meeting adjourned.)

BEFORE THE BOARD OF THE ENVIRONMENTAL QUALITY
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047	
NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON, Petitioners,	BEQ Case No. 0101-22-01 OAH Case No. 23-245-01
vs.	
DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent.	
and	
PERPETUA RESOURCES IDAHO, INC., Intervenor.	

REPORTER'S TRANSCRIPT OF PROCEEDINGS:

HEARING DAY 1

9:00 a.m. at 1109 South Main Street, Suite 220,

Boise, Idaho

On October 17, 2024, before

Hearing Officer Dylan Lawrence

Reported by:
Vanessa S. Gosney, CSR #752, RPR

APPEARANCES:

For the Petitioner, Nez Perce Tribe and Idaho Conservation League:

ADVOCATES FOR THE WEST, INC.
By: Bryan Hurlbutt, Esq.
Post Office Box 1612
Boise, Idaho 83701
Telephone: (208) 730-6961

P R O C E E D I N G S

HEARING OFFICER LAWRENCE: We are here in the matter of the air quality permit to construct P-2019-0047. It is OAH case number 23-245-01 and DEQ case number 01-01-22-01.

My name is Dylan Lawrence. I am acting as a hearing officer in this matter. We obviously have lots of people in attendance. Vanessa, the court reporter, has already taken down everybody. So just in terms of introductions, I am thinking if counsel who are actually questioning witnesses in the hearing can introduce themselves and I will start with DEQ.

MS. YOUNG: Hannah Young, representing the Department of Environmental Quality. I am with the attorney general's office.

HEARING OFFICER LAWRENCE: And how about Perpetua?

MS. HANCOCK: Nicole Hancock with Stole Rives.

HEARING OFFICER LAWRENCE: How about for the petitioners? And I realize we have a few different petitioners. We will start with the ones in the room and then move to Zoom.

MS. THROWER: Julia Thrower for Save the South Fork Salmon.

MR. HURLBUTT: Bryan Hurlbutt for Nez Perce Tribe and Idaho Conservation League.

HEARING OFFICER LAWRENCE: Thank you. Again, my name is Dylan Lawrence. I am acting as the hearing officer here.

Any stipulations that the parties have come to that we need to talk about on the record before we get started?

MS. YOUNG: Yes. The parties did stipulate that Kevin Schilling, who is our first witness that we will be asking questions of, has been stipulated to be an expert witness in this matter.

HEARING OFFICER LAWRENCE: And counsel for the other parties, do we agree with that?

MR. HURLBUTT: Yes.

MS. HANCOCK: Yes.

MS. THROWER: Yes.

HEARING OFFICER LAWRENCE: Thank you.

So this hearing is being recorded by the court reporter, Vanessa, at the front. And we are recording it on Zoom as well.

And we also agreed that because the parties are doing prehearing statements and

post-hearing written statements that we don't need to open up with opening statements or anything like that.

So are there any other preliminary administrative matters we need to talk about before we let DEQ go? We did talk about order of presentation. It will be DEQ, then Perpetua, and then the petitioners in order of presentation. Anything else we need to talk about before we begin the questioning?

MS. YOUNG: Hearing officer, I would just confirm that DEQ is going to start with Exhibit No. 100 per the parties' discussions.

HEARING OFFICER LAWRENCE: Okay.

MS. YOUNG: So that's my plan.

HEARING OFFICER LAWRENCE: Okay. All right. Anything else?

Okay. I think DEQ is ready. We can swear the witness now.

KEVIN SCHILLING,

a witness having been first duly sworn to tell the truth, the whole truth and nothing but the truth, was examined and testified as follows:

DIRECT EXAMINATION

BY MS. YOUNG:

Q. Again for the record, my name is Hannah Young, and I represent the Department of Environmental Quality.

MS. YOUNG: I know we don't have any microphones so if folks can't hear me, or Bryan, if you can't hear me please let me know and I am happy to try and speak up.

Q. BY MS. YOUNG: Good morning.

A. Good morning.

Q. Kevin, can you start by just stating your name and, again, spelling your last name for the record?

A. Kevin Schilling, S-C-H-I-L-L-I-N-G.

Q. Thank you. Where are you currently employed?

A. The Idaho Department of Environmental Quality.

Q. And what is your current title?

A. Stationary source air modeling supervisor.

Q. Great. How long have you been in that role?

A. Approximately 20 years.

Q. Okay. Now, I know this may be hard to give me an exact number, but in your time at DEQ, do you think you could give me your best guess as to how many air quality permits you have been involved in developing?

A. There will be some large air bars on that, but I would say hundreds, maybe closer to a thousand. It's really difficult to tell because I'm involved in both supervising over review of those as well as actively involved in other projects.

Q. Right. So hundreds would be at least a fair guess, a good guess?

A. Yes.

Q. Great. So you've touched on this a bit, but in your opinion, what does it mean to develop a permit?

A. What it involves is we receive an application. It is reviewed and emission estimates are reviewed and regulatory review as well to see

what regulations apply to the proposed project. And then we have -- it kind of goes in two different directions to both the permit writer and to a modeling review analyst.

The modeling review analyst, his or her job is to evaluate whether the proposed project will cause or contribute to a violation of a standard or a TAPs increment. They write a modeling review memorandum to the permit writer.

The permit writer is in charge of reviewing emission estimates. And then the modeler will also make recommendations on important permit limits that are needed to ensure compliance ultimately. And then the permit writer drafts the permit. And sometimes it goes through public comment and then final permit issuance.

Q. Perfect. Thank you.

So it sounds like the development of a permit can be quite the task.

A. Sometimes. It highly depends. It is highly variable.

Q. Sure.

A. Some are easy and some are very complex.

Q. Fair enough. Thank you.

And again, just a ballpark, but of the

hundreds of permits you have been involved in developing, how many included a TAPs analysis? And just moving forward, when I say "TAPs" or "TAP," I am referring to a toxic air pollutant.

A. I would say most all of them. So again, TAPs, if absolutely nothing else, there's applicability of whether we need to do modeling for the TAPs. And given the large number of TAPs, most of the projects do involve modeling.

Q. Great. So again, it would be hundreds of permits?

A. Yes.

Q. Thank you.

Do you consider yourself a toxicologist?

A. Not at all.

Q. Okay. And why not?

A. My educational background is not in toxicology, although I have taken some course work that touches on toxicology. Nor does my work role involve toxicology work.

Q. Perfect. Thank you.

Are you familiar with the DEQ's rules for the control of air pollution in Idaho?

A. Yes.

Q. Describe your familiarity.

A. I would say I'm very familiar with them. Starting all the way back in graduate school where we had a project that required putting together a permit application and involved contacting the Idaho air quality bureau at that particular time. So that was kind of my first introduction to Idaho rules.

My first job right out of grad school was with DEQ as a program development specialist. That involved working on a large public comment project that involved going through some PSD regulations, so I became quite familiar there.

I was a short timer the first time at DEQ and left for Morrison Knudsen Corporation in their environmental group, which was basically consulting work. Shortly after I took that position, we were hired by the Department of Energy, at that time called the IMEL, to produce an air permitting handbook, which I was one of the principal authors of that. We also did some permitting work for, of course, the MK rail shop at that time. So we did their permitting work and some other permitting work as well. And that was all before -- well, then in -- I almost forgot about this.

In the early 1990s, while I was at MK, DEQ started down the path of taking their toxics policy and promulgating that into regulation. And I was on the Idaho Association of Commerce and Industry. And being familiar with the rules and policy fairly well, I was put on the chairman of the air toxic subcommittee at that time, and we met with DEQ and others in developing those regulations. Unfortunately, I had to leave that position for other project obligations, so I wasn't able to be an intimate part of that process through -- all the way through promulgation.

Q. Sure. So it sounds like, based on everything you have described, you're very familiar with the air rules?

A. Yeah.

Q. Would that be a fair assessment?

A. I believe so.

Q. Great. And did you prepare an expert declaration in this matter?

A. Yes.

Q. And did you review it before it was filed?

A. Yes.

Q. I would like to hand you a copy of your

declaration, which I have marked as Exhibit 100. And then I have a copy for the other parties.

Is this a true and accurate copy of the declaration you submitted? And feel free to take a look at it.

A. To the best of my knowledge.

Q. Great. Thank you.

MS. YOUNG: Hearing officer, I would move to admit Mr. Schilling's declaration into the record as expert testimony and mark it as Exhibit 100.

HEARING OFFICER LAWRENCE: Approved.

(Hearing Exhibit No. 100 admitted.)

MS. YOUNG: Thank you.

Q. BY MS. YOUNG: In advance of today's hearing, Kevin, did you review the other expert declarations submitted by the parties?

A. Yes, I did.

Q. And have you previously been qualified as an expert in this contested case?

A. Yes.

MS. YOUNG: So again, I know there has been a stipulation, but just formally for the record I would move to formally qualify Mr. Schilling as an expert in this matter.

HEARING OFFICER LAWRENCE: Any objections

from any of the parties?

MS. HANCOCK: No objection.

MS. THROWER: No.

HEARING OFFICER LAWRENCE: Okay. Granted.

Q. BY MS. YOUNG: Okay. Thanks for all of that background information.

Let's talk a little bit about the rulemaking history which you have already alluded to. But in your declaration you stated that you participated in the development of Idaho's TAP permitting regulations in the mid '90s; is that correct?

A. Yes.

Q. And you spoke a little bit about this, but could you just again reiterate what the purpose of that rulemaking effort was?

A. Primarily to transform a policy which the regulated community and probably other stakeholders as well saw as not nailed down well enough; wanted something more concrete that could be consistent, predictable.

Q. Great.

A. And focusing on something that would be both easy for industry to use as well as protective of public health.

Q. Great. As the regulations were being developed at that time in the '90s, can you describe the thought process about relying on EPA's unit risk factors?

A. Yes. Going all the way back to the toxics policy that was used in permitting, the cornerstone of that was focused on project risk. In other words, any particular project, whether it is a new facility or a modification, not causing a risk to exceed one in a million or one in 100,000, some things changed with T-RACT going from policy to regulation. And I am just focusing on the carcinogenic parts of it today.

Q. Great. So you mentioned that sort of the cornerstone would be this project cancer risk.

What was the regulated community's reaction to that threshold?

A. Well, you know, there's always a little bit of pushback. One in a million cancer risk is a very small increment of risk, and on the IACI subcommittee I recall having all sorts of nice little demonstrations of how operation of a wood stove over the whole year would cause a risk to the neighbors of a certain level. So there was some struggles in establishing that one in a million

cancer risk. And then that moved into the one in 100,000 provided you use T-RACT.

Of course the URF establishes that link between the risk factor and developing an easy-to-use representation of that being a concentration that represents a one in a million risk given a 70-year exposure.

HEARING OFFICER LAWRENCE: Counsel, can I jump in with a question real quick?

MS. YOUNG: Absolutely.

HEARING OFFICER LAWRENCE: Since it has come up, can you just explain generally for me what unit risk factors are?

THE WITNESS: It would probably be best explained by our toxicologist, but it is basically, and make sure I get this right, the risk associated with exposure of one microgram per cubic meter over a 70-year lifetime.

HEARING OFFICER LAWRENCE: So the 70-year lifetime is sort of built into the unit risk factor?

THE WITNESS: Yeah. Yeah. That's the lifetime, not necessarily the exposure duration.

HEARING OFFICER LAWRENCE: Okay. Thank you.

MS. YOUNG: That's great. Thank you.

Q. BY MS. YOUNG: So just to recap there, it sounds like, based on your experience, the regulated community saw that threshold as stringent?

A. Yes.

Q. Does reliance on the URFs remain a central piece of the TAPs regulations today?

A. Yes. I believe it is really the cornerstone of the whole TAPs program for regulating carcinogenic compounds. You know, maintaining that project risk under one in a million or one in 100,000 when T-RACT is used.

And even in the 2019 rules, the definition of toxic air pollutant carcinogenic increments, it, in fact, references the hundred in a million cancer risk being the criteria, and that the AACCs are an expression of that for a continuation exposure over the lifetime.

Q. And you alluded to this, but in your example of a wood stove, you know, I guess through that example you are sort of illustrating, if I'm understanding you, that there's a lot of inherent risk out there. And when you compare that inherent risk to one in 1 million, one in 1 million would be really small.

Is that an accurate assessment of what you were explaining?

A. Yes, that's my interpretation.

Q. Perfect. Great.

But in most cases or the majority of applications that you see at DEQ, are you analyzing the URF?

A. We're not analyzing the URF. It is in there as a link between the AACC and -- it essentially documents how we came up with the AACC.

Q. Sure.

A. Now, in the regulated community during the development of these regulations, especially the IACI group, it is primarily larger Idaho industries. We have sugar beet factories, potato processors, pulp mills, phosphate fertilizer facilities. All of these facilities we tend to permit on a permanent basis. And they also have relatively consistent operations and consistent emissions from year to year. They may vary within each year, but year one is going to look -- usually look pretty close to year two and year three and et cetera. So the easiest way to regulate that and handle it is to have an increment that's expressed as an annual value.

That way industry goes back -- and the rest of our permitting actions are focused on -- annual is a very nice nugget of time to look at because we have annual PM10 -- well, at that time we had annual PM10 standards, and we have annual PM2.5 standards and NAAQ standards, so we tend to regulate on an annual basis a lot of things. So it becomes easy to use to regulate carcinogenic TAPs on that annual basis.

Q. Sure. Thank you for that explanation.

You stated earlier, I suppose, that you reviewed Mr. Tiedemann's declaration in this matter; is that correct?

A. Yes.

Q. Exposure duration adjustments were both considered and rejected during this 1990s rulemaking process that we were just discussing.

Do you recall him saying that?

A. Yes, I do.

Q. As someone who participated in the rulemaking process, is that in line with your recollection?

A. Not exactly. I think it demands some further explanation. There was a lot of talk about short term, the less than five years, and debate

about that. And there was certainly some statements made about not imposing a whole 70 years' worth of emissions into a less than five-year period. And of course we now have the short-term allowance within the air toxics rules for that.

However, given the nature of the regulated community and what DEQ typically saw, no one foresaw the idea of a temporary project of, like, 16 years or 50 years or 25 years. It's like short-term projects were remediation projects, pilot plants, those type of things. So the regulators didn't -- we didn't really foresee a need for a 16-year duration project. So it just wasn't evaluated, wasn't discussed.

But the cornerstone of the rule still remained a project-imposed risk of one in a million or one in 100,000 with T-RACT.

Q. Thank you.

So that one in 1 million was just assumed to be for a 70-year lifetime?

A. Yes.

Q. Because the project was permanent?

A. Yes.

Q. Thank you.

So again, just to clarify, it sounds like what you're saying is that it wasn't a rejection, it just wasn't really discussed or anticipated?

A. Yes, to the best of my recollection.

Q. And did you review Dr. von Lindern's declaration?

A. Yes, I did.

Q. And in his declaration he also discusses the development of the TAPs rules. And he discusses that the rules were intended to be easy to apply but prescriptive and strict enough to protect public health.

Do you recall him saying that?

A. Yes.

Q. And what is your reaction to that statement?

A. Some agreement. There was a big focus on easy to use, and of course a big focus on needing to be adequately protective of public health. And of course a fair amount of debate amongst everyone about what that means.

I really believe that the intention and the record shows that, again, we come back to project-imposed risk of one in a million for a

project being the primary criteria rather than an annual value never to be exceeded.

Q. Great. Thank you.

Okay. Let's move on and discuss the analysis that DEQ and Perpetua performed for the arsenic emissions for this project.

But I want to start by having you walk us through your typical permitting process. And I recognize you did a little bit of this earlier, but if you will humor me and do it again a little bit more where TAPs modeling is involved. So just how a typical permit comes in and how you review it.

A. Uh-huh. Well, first of all, when it first comes in, our overriding requirement is, is in the rules, that we must -- the application must demonstrate to the satisfaction of the department that operation of the proposed project won't cause or contribute to a violation of a National Ambient Air Quality Standard or TAPs increment. So that's the overriding thing.

And for permitting purposes, we go to Section 210, which addresses the TAPs pre-construction compliance demonstration requirements. And if an applicant uses Section 210, it's determined that they comply with Section

161, which is the overriding rules for control of toxic substance to a point that you won't unreasonably cause adverse health impacts.

Sorry for the butchering of the exact language.

Q. I'm sorry to interrupt, but if it would be helpful, we are also happy to pull up the rules if that would be helpful for either the hearing officer or the witness to have the rules.

HEARING OFFICER LAWRENCE: It is up to the witness. I have my own copy here.

THE WITNESS: I think I have summarized.

Q. BY MS. YOUNG: I think you have accurately summarized them.

A. Yeah. So within Section 210, the application has estimated emissions for the toxic air pollutant associated with their proposed project. They've also submitted like a modeling analysis of those emissions that then demonstrate that they'll be under those AACCs. And we review those analyses, the inputs, how the model has been run. Often that involves an iterative process going back to the applicant because there's deficiencies or we didn't feel their take on it was conservative enough, so we may go back and request

that they do something different. And they may need to completely rework their application in order to address those deficiencies. And we may call it incomplete, and then when it comes back we will reassess their revised submittal.

Q. Great. So it sounds like, based on what you're describing there, a lot of refinements that can occur.

Is that true?

A. Yes. There can be -- they can be as simple as providing just additional justification for something to where, you know, it just gets us to that extra confidence level where we go, okay, that's good enough.

Or it can be a complete reworking to where they have to go back and add additional controls somewhere or move something to a different location to where it has a different impact or fundamentally change their process in extreme cases.

Q. Do these refinements become permit conditions?

A. Yes. What the facility needs to do to demonstrate compliance, what they model has to be using emissions that are either design capacity,

something that is inherently limited by the nature of the process, or specifically limited by a permit condition.

Q. Okay. So with that in mind, now considering the permit application that came in for this Stibnite Gold Project, can you briefly walk us through how that process occurred?

A. Yeah. I will use a bit of an abbreviated part.

Q. I think everybody would appreciate that.

A. We will start at the initial application that came in that had -- I'll also focus on the carcinogenic TAP since that is why we are here.

When the permit initially came in it had the TAPs modeling demonstration that showed compliance with the AACCs -- using the AACCs as an annual benchmark for compliance. So everything was fine there. We drafted, we did a modeling review memorandum, went to the permit writer, the permit was drafted, went out for public comment. There were some concerns they expressed about applicability of certain sources that were not included in the analysis, so there was a whole lot of regulatory uncertainties. And both DEQ and Perpetua took a deep dive back into that and

decided, well, yeah, we should -- we need to include those other emission sources in the analyses.

Q. So just to pause right there to make sure I'm understanding this. Sorry to interrupt. It sounds like based on that first application and the first sort of refinement was to be more conservative and include additional sources?

A. Well, yeah. There was debate about whether it's just being more conservative or whether we're addressing a deficiency in the rules.

Q. Sure. That's fair.

A. And I'm not the permit writer. And luckily I was able to stay out of the details of that particular issue. But anyway --

Q. Yes. Go ahead.

A. -- it involved a need to rework things. And there were several options Perpetua could take. They could take a refined look at how it's being regulated, how emissions are being controlled and a number of different things.

So through a lot of work, Perpetua landed on bringing up the fact that, well, this is going to be a less-than-permanent source, a 16-year life of project source rather than a full 70-year

or permanent project.

So then in looking at our rules, it definitely was something we have not seen very often before. So in looking at that, because the one in a million cancer risk is the cornerstone, addressing for the exposure duration was appropriate given my understanding of how the URF and risk assessment calculations would be conducted.

Q. Perfect. Thank you.

So again, this would be a typical situation wherein you start with an application and the analysis gets refined over time?

A. In that way it's typical.

Q. Sure. I understand there's a lot that was atypical about this particular project.

A. Yes. But making refinements during the process is unfortunately more typical than atypical.

Q. Sure. Thank you.

So you've talked about how the air rules work related to a TAPs analysis. But in your declaration you specifically discuss how the rules support DEQ's analysis and Perpetua's analysis in this permit.

So can you just walk us through or touch on any of the rules that you think are really relevant to the analysis that was performed for the project?

A. Well, one of the big ones in the 2019 rules, and maybe this is one worth bringing up --

Q. Yeah. So just to take a pause then really quick, Kevin, because I think I know where you are going with this. I'm going to ask Michael to share his screen on the Zoom and pull up the 2019 version of the air rules, which I believe you could just take judicial notice of the rules and they don't need to be entered into the record. And I also think they're just demonstrative at the point.

HEARING OFFICER LAWRENCE: Any other parties have concerns or objections?

MS. THROWER: No objection.

Q. BY MS. YOUNG: So if I was following where you were going?

A. Yeah, 125. Ambient air quality increments based on the probability of developing excess cancers over a 70-year lifetime exposure to one microgram per cubic meter, again a carcinogen, and expressed in terms of a screening emission

level or an acceptable ambient concentration for a carcinogenic toxic air pollutant. They're listed in 586.

Q. Perfect. So what is important about this definition?

A. I think one of the -- well, two things, the identification of one in a million cancer risk. The other thing I believe that's important is the link that says this is expressed in terms of the screening emission limit or the acceptable ambient concentration of a carcinogen.

So in my view, this again makes it clear that it focuses on a total project-imposed cancer risk rather than a specific year by year.

Q. Okay.

HEARING OFFICER LAWRENCE: Counsel, can I ask a quick question?

So the rules we have up on the screen now are rules that are not in effect right now?

MS. YOUNG: Yes. Thank you for that. If you would like me to answer or I can draw it from the witness.

HEARING OFFICER LAWRENCE: Please proceed, I just wanted to clarify.

Q. BY MS. YOUNG: So, yes, the hearing

officer just asked if we are looking at the 2019 rules; is that correct?

A. Yes.

Q. And so were these the rules that were in effect at the time the permit was issued in 2019?

A. Yes, I believe so.

Q. If I am doing my math right?

HEARING OFFICER LAWRENCE: I think the permit was issued in 2022.

Q. BY MS. YOUNG: Thank you. The application came in in 2019, but this was also in effect when the permit was issued in 2022?

A. I believe so, yes.

Q. Thank you for that.

HEARING OFFICER LAWRENCE: Thank you.

THE WITNESS: I am trying to remember when CBR.

Q. BY MS. YOUNG: Yes. 2019 and 2022 are sort of the major dispositive time periods, these were the rules that were in effect?

A. Yeah. They weren't remove -- this section wasn't removed because it was no longer -- because there was a fundamental change. We had a rule cleanup.

Q. Yes. And you don't have to worry about

explaining that.

HEARING OFFICER LAWRENCE: Just for my, was that part of the zero-based regulation effort?

THE WITNESS: Yes, it was.

HEARING OFFICER LAWRENCE: Okay.

Q. BY MS. YOUNG: Thank you.

Let's see here, so I interrupted you to bring this up. But you said in your review of the project you sort of started with this definition.

Are there any other rules you want to walk through in terms of the projects -- you know, the permit for this project?

A. We have all of Section 2010, which basically governs how the permit was evaluated from toxic air pollutant standpoint. And that contains the provisions for T-RACT given the factor of ten adjustment if more rigorous controls are used. It also contains the exclusion for sources that are regulated by specific federal rules, the NESHAP and NSPS. And then has some prescriptions of how the analyses are performed and then links back to Section 586, which contains both the screening emission levels, the unit risk factors, and the acceptable ambient concentrations for carcinogens which are expressed as annual averages.

So in Perpetua's case, in order to develop an appropriate factor to compare or an appropriate concentration to compare to the AACC, we needed to account for the exposure duration. So that's essentially all we're doing there, is it was a 16-year exposure duration rather than a 70-year exposure duration, which is the origin of the 16 over 70 factor.

Q. Thank you.

So based on the definition of 586 that you just read, would it be your opinion that the TAPs rules are increment based?

A. Yes.

HEARING OFFICER LAWRENCE: It might be helpful to explain that concept generally for me, what increments are and the relevance here.

MS. YOUNG: Yeah. Thank you.

THE WITNESS: The standards tend to be a limit that -- a total limit of what's in air quality, like we have the PM2.5 annual standard. And that accounts for what you would get if you took a monitor out there and monitored over the same period. So we have the impacts of everything there. We have the project, the whole rest of the facility, any neighboring facilities, and a

background that would need to be included in that.

So it's a standard. You have to figure out a way to be below that one way or another.

Q. BY MS. YOUNG: So just to pause right there. It is taking into account background, for one?

A. Yes.

Q. And for two, it is an annual limit that gets placed on the facility or the project?

A. Yeah. In the case of the annual standard we would have limits to the facility that would control their annual emissions.

Q. Perfect. Thank you. Versus an increment to the hearing officer's question, how does that differ?

A. An increment is just a base-allowed impact for that project. So it doesn't concern itself with what goes on at the whole rest of the facility or what goes at the neighboring facility or what is already there for background. It says you can do this no matter what.

Q. And for 586 and the TAPs rules, the increment is the lifetime, the one in 1 million over a lifetime?

A. One in 1 million over a lifetime of

exposure.

Q. 70 years?

A. Yeah. It can get confusing of going between what's the duration of the exposure versus the lifetime of the receptor.

Q. Perfect. Thank you.

I feel like I've really spent a lot of time on the rules, so thanks for humoring me on that.

In Section 586 you reference that it uses and references the URFs, correct?

A. Yes.

Q. Now, I know this is not the case, but the rules could have used only the AACCs potentially, correct?

A. Yes, they could have. There would have been, in my opinion, no need to put in the URFs on that or draw out such a focus of project risk being limited to one in a million.

Q. If the rules only contained the AACC and did not reference the URFs, correct?

A. Yeah. It would be less clear that it's project risk we're concerned about. I wouldn't say it would be clear that the intent would be just an annual standard because through the rulemaking

process and that entire thing and background, project risk was always sort of the cornerstone focus.

Q. Perfect. Thank you.

So in your opinion, inclusion of the URF demonstrates what?

A. That it's a project cancer risk that is the focus rather than an annual strict increment.

Q. Perfect. Thank you.

HEARING OFFICER LAWRENCE: Apologies, if you have already said. Can you explain why that is? Why the presence of the URF in Rule 586 makes it a project-based risk analysis?

THE WITNESS: It is the combination of that and the definition of the toxic air pollutant carcinogenic increments that we just read through earlier that really says it is cancer risk that is the important thing. The URF provides the vehicle that identifies the relationship between an exposure and cancer risk. So it's kind of a tool that you can use to generate cancer risks for an alternate exposure duration.

HEARING OFFICER LAWRENCE: Okay. Thank you.

Q. BY MS. YOUNG: So in your expert opinion, why is an adjustment based on project

duration appropriate?

A. If you didn't account for such an adjustment, you would be overstating the total amount of emissions that would come from the project. And if you overaccount for the total emissions coming from the project, you would overaccount for the carcinogenic risks.

Q. So to make sure I am understanding, duration then is directly related to the risk?

A. Yes.

Q. Okay. So regarding the five-year rolling average contained in the permit, can you explain why this was an appropriate measure?

A. It goes back to the same cornerstone of the rules being project-imposed risk. As long as project-imposed risk is the criteria and we have a duration of the project of 16 years, what really matters for demonstrating, whether it complies or not, is where are we at after 16 years.

Now, we use something less than 16 years as a responsible vehicle to identify when things might -- you know, if they might be going wrong at an earlier time.

So often for industries that have consistent year-to-year operations, we, again,

center in on that one-hour period.

For something such as Perpetua that has highly variable operations and highly variable emissions, it is not appropriate and is overly constraining to use that one-hour interval. So it was decided that a five-year interval would be much more appropriate for regulating the facility.

Q. So in a completely different context, if the standard was annual, then five-year rolling average wouldn't make sense, right?

A. No, it wouldn't.

Q. But here it is not annual, it is a 16-year project life standard, for lack of a better word, correct?

A. Correct.

Q. So five years is less than that actual standard?

A. Yes.

Q. And it provides you, you said -- I think you used the word "responsible," it is sort of the responsible way of making sure that compliance is being achieved during the project and not at the end when it is sort of too late to make any adjustments.

A. Yes. Exactly.

Q. Perfect.

And you mentioned the variability that this project has, so I guess I will just ask you. Is it your understanding that the mining project -- this particular mining project has a lot of variability year to year?

A. Yes, much more than we see in the vast majority of our permitting projects.

Q. And you don't have to get into the weeds here, but what is some of that variability that you would see at this project?

A. As they open up, and again, Perpetua's team would be better able to describe that, but as they open up new areas of a mine you have something in one area that is being opened up and then a different year a different area opens up. So in opening up those areas it involves different stages of excavation and hauling and different processing. So it's just there's a lot of moving parts there.

Q. Okay. So what impact does this year-to-year variability have on ultimate compliance?

A. Really, the year-to-year variability doesn't affect ultimate compliance. And perhaps a good way to think of that might be is if we have a

pitcher of water. And let's say that the water contained in the pitcher represents ore to be processed. And because of the direct proportionality of things, it also represents the emissions associated with processing that ore. And again, the direct proportionality also would represent the impacts and ultimately the cancer risk.

Now, to the side of that let's have a pan that contains the amount that's processed and all the way up to allowable cancer risk.

So as I take that picture of water I can pour it into the pan in different ways. I can pour it in fairly fast, or intermittently, a little bit now, a little bit later. Slow and continuously. Jerky. That doesn't matter. What matters is that the pan that limits the risk that all the water that's poured is contained in the pan, if that makes sense.

Q. It does make sense. So the way you're pouring it represents the variability from year to year.

A. Yes.

Q. But the pan represents the ultimate risk.

A. Yeah.
Q. Perfect. Thank you.
So in this context, and especially in light of the analogy you just provided, the five-year rolling average makes sense?
A. Yes, it does. Because a little bit of jerks through that is immaterial in ultimate compliance.
Q. And just to double down on your analogy here. The permit does create some side boards as far as limits of ore to be processed?
A. Yes.
Q. So it is not like you can pour it all on day one, for example?
A. Right. I didn't get into making a perfect analogy there.
Q. It is a good analogy, I just wanted to create those side boards or have you discuss those side boards from the permit.
A. Yeah. There are shorter-term processing limits in there that, in fact, were needed not just for TAPs compliance but were primarily needed to assure compliance with the other standards, such as the 24-hour PM10.
Q. Perfect. Thank you.

And just one last question on this rolling average. It is a rolling average, correct?

A. Yes. Basically each year it shifts and drops off the later year and adds on the newer year.

Q. Perfect. Thank you for that clarification.

HEARING OFFICER LAWRENCE: How does that work in the first five years of the project life?

THE WITNESS: Well, at year five is when you then start evaluating that.

HEARING OFFICER LAWRENCE: Okay.

THE WITNESS: I'm not the permit compliance person, so I may be able to be corrected there some. But that's my understanding.

HEARING OFFICER LAWRENCE: Okay. Thank you.

Q. BY MS. YOUNG: But it's not like it's at year five, at year ten, and at year 15?

A. No. It's at year five, and then year six, seven, eight, nine, and then moving on from there.

Q. And I imagine the first five years could have quite a bit of variability as the mine is just becoming operational?

A. I would suspect.

Q. Thanks.

Let's move on to the west end pit issue. And if you want to reference it, it starts on Page 10 of your declaration when you start discussing the west end pit.

A. Page what?

Q. Ten, which is record number 3926. This is Exhibit 100.

Can you explain how the permit limited, let's start with west end pit production?

A. Yes. There's sort of two main limits. There's a total mine limit in there of 788.4 million tons. And then there is a west end pit-specific limit of 50 percent of that, which is 394.2 million tons.

Q. And then how about a limit to non-west end pit production?

A. A limit to the non-west end pit production sources was not needed because even if 100 percent of the production is from non-west end pit sources, we're still in compliance.

Q. Perfect.

Can you explain further why a 50 percent limit wasn't explicitly included for the non-west end pit?

A. Yeah. Maybe if you will entertain me a little bit to make a little bit of an example. I was trying to think of a way to explain this beyond mining. Given that it is Halloween season and we go trick or treating, little Timmy has a basket of candy he got from trick or treating.

HEARING OFFICER LAWRENCE: I think I will need to sample those.

Q. BY MS. YOUNG: Go ahead, Kevin.

A. Timmy's mom is concerned about how he eats, so she said you can only have eight pieces of candy.

Q. Excuse me, eight pieces of candy over how long of a duration? Or I guess it doesn't matter.

A. Well, in this case we'll bring it closer even though she's a really strict mom, just said that's all he can have is just eight pieces.

Q. Perfect.

A. So that's the whole project.

Timmy's mom is also concerned about Timmy getting a little bit overweight so she is concerned about his calories. These Snickers, let's just say they are 100 calories a piece. And then we have sugar-free Werther's Originals. They

are a lot less, let's say 25.

So of course Timmy wants to have all eight Snickers, but that isn't going to work. That violates his calorie intake. So if we wants mainly just Snickers --

Q. And I don't think you told us what the calorie limit was?

A. 500 calories.

Q. Okay.

A. I am having to use math in my head right now.

Q. So just to make sure I'm understanding. If he had eight Snickers that would blow through his 500-calorie limit?

A. Yeah. He would be at 1,000 calories and he would be in violation and sent to his room.

So he can have four Snickers and a collection of Werther's Originals with it and be fine. Or if he just has nothing but Werther's Originals he is still well below his 500-calorie limit.

So it's kind of the same way with the west end pit and the non-west end pit sources. They are kind of sugar free with regard to the impact. So we really don't need to set a limit,

although we have an overall limit of Timmy still can't have more than eight pieces total. So there is still that limit. And if all eight pieces are Werther's Originals, he can't have any Snickers.

So it is kind of the same thing with the west end pit. If all the of the production is non-west end pit production, that leaves no room for any west end pit production.

Q. So the west end pit has the explicit limit in the permit, correct?

A. Yes.

Q. And there is also, as you mentioned, just to underline this, an overarching limit?

A. Yes. The total.

Q. The total limit, thank you. And it is your opinion that between those two limits, that's sufficient?

A. Yes. This still keys in on the fact that the important criteria is project imposed risk rather than treating the AACC as an annual limit in itself.

Q. Perfect.

HEARING OFFICER LAWRENCE: Can I ask a quick question, Counsel?

Is the reason the west end pit is sort

of the limiting factor, is it -- what are the factors that make that? Is it geography? Wind? Is it like the nature of the deposit in that particular location?

THE WITNESS: I think really the Perpetua crew would be best to address that. But the way it works out through the modeling is that those west end pit sources have a driver to the analysis given the location of where they are to ambient air locations. How the ore plays into that, I don't recall explicitly.

But both, yeah, wind, location of where the pits are at, the concentration of arsenic in it. All of those things play into where you have the maximum locations.

And through the analysis, air isn't as homogenous as a lot of people think about it. When we run our models, we have thousands of receptors and it is highly dynamic the way impacts are. So in other words, these impacts aren't all over the entire ambient air surrounding the plant, they are at specific areas.

MR. SHORT: Do you want to --

THE WITNESS: That would be useful.

So as you see there, where the west end

pit is, and the way the prevailing winds are, you can see how the west end pit is positioned to heavily impact that area just northeast.

HEARING OFFICER LAWRENCE: Do we know why the west end pit is more on the east side of the project?

THE WITNESS: Well, that, I can't speak to that one.

MS. YOUNG: So I can formally admit this. This is obviously a demonstrative of an exhibit in Kevin Lewis's declaration. So I could go ahead and move to admit Kevin Lewis's declaration as Exhibit 200?

MS. HANCOCK: 201.

MS. YOUNG: As 201. And we have copies of that which I can pass around. And I believe this is attached to his declaration.

HEARING OFFICER LAWRENCE: Any objections from any party?

MS. THROWER: I don't have any objection, but for Brian's purposes, do you have an REC number you can let him know?

MS. HANCOCK: I do.

MS. YOUNG: Thank you.

HEARING OFFICER LAWRENCE: It definitely

looks familiar to me, but I don't know if I can put my finger on it right now.

MS. YOUNG: It is 4145. So for the transcript it is record number 4145, Exhibit 201.

HEARING OFFICER LAWRENCE: To the extent you need a ruling from me, it is admitted.

(Hearing Exhibit No. 200 admitted.)

MS. HANCOCK: We already provided the record copy. I think we agreed we wouldn't exchange around the declaration.

MS. YOUNG: I'm sorry, for the record, the counsel previously discussed that anything contained in the electronic record doesn't necessarily need to be provided in hard copy if everybody has it.

Q. BY MS. YOUNG: Thank you for that tasty analogy.

In Dr. von Lindern's declaration, I'm looking specifically at Paragraph 19, he states that "DEQ misinterprets the purpose and function of the maximum one-year annual average ambient carcinogen concentration in implementing the TAPs rule."

MS. YOUNG: And again for counsel, that's on Paragraph 19 of his declaration.

THE WITNESS: Yes, I recall that.

Q. BY MS. YOUNG: In your recollection, do the air rules use the word "maximum" when referring to the AACCs?

A. No. The term used in the AACCs are an annual average.

Q. So is the term "one year" used in the rules?

A. No, I don't believe so.

Q. Does the addition of the word "maximum" make sense to you related to the AACCs?

A. I believe the term "maximum" misrepresents the intent of having the rules be applicable for a project total risk. I believe, again, treating the AACCs in this instance as the maximum allowable in any one year is overly restrictive for the facility.

Q. Perfect. Thank you.

In his declaration, in Dr. von Lindern's declaration, Paragraph 21, he also uses the phrase "margin of safety."

Do you recall reading that in his declaration?

A. Yes.

Q. Are you familiar with that term, "margin

of safety"?

A. Somewhat familiar with it. Not so familiar with it in the terms he was using, I believe. I am more familiar with margin of safety being used in the context of regulatory development. As an agency develops a rule you must impart a margin of safety. So in that regard I'm not real clear on understanding of the use of his margin of safety discussion.

Q. So to clarify, tell me if I have this correct. You're familiar with this terminology when it comes to building a regulation?

A. Yes.

Q. But not familiar when it comes to implementing a regulation?

A. Yes.

Q. Why would it be more appropriately discussed or used in the first context of developing a regulation?

A. Well, because you want to develop something that is -- has that margin of safety built into it, and then you design the rule around it so you don't have to reevaluate margin of safety when implementing the rule.

Q. Thank you. So in that same vein, do the

TAPs rules already contain that maybe margin of safety, for lack of a better word, or the conservative pieces that would be needed to create a margin of safety?

A. I believe they would have. Of course, it's always up for debate whether they did that to the satisfaction of various parties. But for example, some of the conservatisms within the rules are that we consider areas of applicability being any area external to the boundary of the mine. In other words, we are not just looking at where someone lives or where someone might live, it is anything that's not under the direct control of the mine.

And then beyond that, we're not making any adjustments for how long -- how many hours per day someone might be there or how many days per year. We're assuming 24 hours a day, 365 days a week [sic] for the entire duration of the exposure, which in this case is 16 years.

Q. So the 16 years, once you know what the project is going to be, you're not then also adjusting any of the other factors like, for example, if you knew it was only operating for eight hours, it is just 24 hours a day, 365 days a

year.

Is that accurate?

A. Right. It can get a little bit confusing because if Perpetua took a limit to limit their emissions to so many hours per day, that would be captured in their permit if they chose to take a permit limit for it.

Q. Sure.

A. And that would be accounted for in their emissions. But the exposure, that assumes that someone is at that receptor 24 hours a day, 365 days a year.

Q. Perfect. Thank you.

A. The assumption is, and the toxicologist would be better able to talk to this, but a conservatism built into the URF as well.

Q. Right. So let's see here, Dr. von Lindern opines that the five-year rolling average reduces arsenic concentrations making or creating an excess cancer risk by 45 percent.

Do you recall that statement?

A. Yes.

Q. Is that something that you would feel comfortable opining about as not a toxicologist?

A. Only to the extent of what I've been

talking about before that our whole position here, and this is the key of everything, is that it's a project risk rather than an annual risk. And if you buy that's what it is and we're not dealing with a year-by-year allowable impact, then all of these other things fall into place. The five-year averaging period, west end versus non-west end pit discussions one way or another there.

So everything hinges on that one concept of whether we're dealing with a project-imposed risk or an annual limit.

Q. So what you've been sort of referring to as the cornerstone of the rules, that's the piece of this analysis that you're comfortable opining on?

A. Yes.

Q. Perfect. Thank you.

So given the claim by Dr. von Lindern and Mr. Tiedemann that DEQ should take a stringent or a strict interpretation of the rules, what's your reaction to that statement or those assumptions?

A. I believe we take a stance with the rules that implements the rules to our best understanding and reasonable understanding of what

they are. We have a case where a lot of different stakeholders wish the rules were either more stringent or less stringent and would like to see them account for co-contributing sources, additive carcinogenic effects, other things that may have just come out in the last 30 years since the rules have been promulgated that deal with new toxicological concepts and whatever else. But we are dealing with the rules we have and we implement them to what we believe is a reasonable and fair assessment to our regulated community. And sometimes we face challenging things that don't completely fit in the box we anticipated them to fit in. And we look at the rules and interpret them accordingly. We firmly believe that making this assessment based on what's in the rules as defining project risk as the cornerstone. We feel it is appropriate to make that exposure duration adjustment.

Q. Thank you.

So based on what you just described, how would you specifically characterize Dr. von Lindern's assessment of the TAPs rules?

A. I believe it's overly restrictive in that it focuses on treating the allowable

carcinogenic impacts as a one-year limit as opposed to a total-project limit.

Q. Thank you.

So I have just two last questions for you.

In your opinion, based on everything we've just discussed, your experience implementing the rules, your personal knowledge of the rule history, et cetera, was the analysis for arsenic emissions performed by DEQ for the project a reasonable approach?

A. Yes. I believe it was not only reasonable, I believe it was the best interpretation of the rules for that. Again, focusing on the project cancer risk.

Q. Did you use sound science?

A. I believe so.

Q. And lastly, based on your experience and expertise, does the permit create an unreasonable -- excuse me, an unacceptable cancer risk?

A. Not as defined by -- not as acceptability is defined by our regulations. And the reasonableness as interpreted by our rules and regulations.

MS. YOUNG: With that I would just reserve time for any necessary redirect.

HEARING OFFICER LAWRENCE: Okay.

MS. HANCOCK: I have one clarification. I said that Mr. Lewis's exhibit was marked as 201. His was actually marked as 200. So if we can make that correction in the record.

MS. YOUNG: I don't have any further questions for Mr. Schilling at this time.

Thanks, Kevin.

HEARING OFFICER LAWRENCE: Okay. Thank you.

Do we want to take a quick break before we go into Perpetua?

MS. HANCOCK: I think a quick break would be great.

HEARING OFFICER LAWRENCE: Okay.

MS. YOUNG: I think 20 minutes to be conservative.

HEARING OFFICER LAWRENCE: Okay. So at about 10:25 we will start reconvening.

(Break taken from 10:07 a.m. to 10:31 a.m.)

HEARING OFFICER LAWRENCE: I think DEQ finished its direct examination of Schilling and next up we have Perpetua. Any other procedural matters we need to address before we do that?

MS. YOUNG: None from DEQ.

HEARING OFFICER LAWRENCE: All right. Please proceed.

CROSS-EXAMINATION

BY MS. HANCOCK:

Q. Thank you for your testimony already this morning, Mr. Schilling. I just wanted to cover a couple of points. The hearing officer had asked you a question about when that five-year rolling average period, what happens in the first five years.

Do you recall that?

A. Yes, I do.

Q. During that first five years under the permit, there are still conditions that would restrict the production limits that would be imposed on Perpetua; is that right?

A. Yes. Additional restrictions were needed to demonstrate compliance with the shorter term air quality standards such as the 24-hour PM10, the 24-hour PM2.5.

Q. And so just in simple terms, on a daily basis, do you recall what the production limit was under the permit on the operations?

A. Was it something around 188,000 tons per day, something around there. And with using the five-year rolling average I believe came out to be around 130-something-thousand tons per day. So there's a difference, but not -- it's not as though they could dump all five years into the first year.

Q. Okay. So just to be clear, if we just round off at 180,000 as the daily limit and 135,000 as the five-year rolling average daily limit for purposes of our discussion, they could produce up to 180,000 tons per day out of the mine, but they would have to operate in a manner that would allow them to average no more than 135,000 tons per day on that five-year rolling average basis; is that right?

A. Yes. Yes.

MS. HANCOCK: Mr. Foster, can you pull up the Rule 210, please?

Q. BY MS. HANCOCK: I want to just first start with subsection 12 of this rule. You're familiar with Section 210 that we're looking at here?

A. Yes.

HEARING OFFICER LAWRENCE: Quick clarification. Which version of these rules do we

have up?

MS. HANCOCK: This would be the 2022 rules.

Q. BY MS. HANCOCK: Under subsection 12B, as in boy, are you familiar with that section there where it says "Compare the source's or modification's approved T-RACT ambient concentration at the point of compliance for the toxic air pollutant to the amount of the toxic air pollutant that would contribute to an ambient air cancer risk probability of less than one to 100,000 (1:100,000)(which amount is equivalent to ten (10) times the applicable acceptable ambient concentration listed in Section 586)"?

Do you see that?

A. Yes.

Q. So once Perpetua opted for the T-RACT control provisions, the cancer risk probability analysis that you performed was to ensure that it operated below a risk probability of one in 100,000?

A. Yes, for a total project-imposed risk.

Q. And is this section in 210 subsection 12(b) what you applied when you were looking at Perpetua's permit?

A. Yes.

Q. Is there anywhere in here that you can see where it talks about annual emissions?
A. No.
Q. In fact, this section doesn't even say anything about an annual amount at all, does it?
A. No.
MS. HANCOCK: Mr. Foster, if we can go up to Section 210 under the title, "Demonstration of Preconstruction Compliance."
Q. BY MS. HANCOCK: Was it your understanding that under Rule 210 that DEQ could consider the production limits of the project as part of its evaluation and analysis?
A. Yes.
Q. And that's because the rule specifically allows you to look at the project design, equipment, work practice, and the operational requirements or any combination thereof?
A. Yes.
Q. Okay. And if we could look under 210.02 subsection D.
Did you understand that under this section DEQ could take into account the physical and operational limits that were described in the application from Perpetua?

A. Yes.
Q. Okay. And if we look at 210 subsection 04.
And under subsection 04 it allows you to also use and consider the applicable specialized methods that were described in subsections 09 through 12; is that right?
A. Correct.
Q. And then if we look at under 12 subsection D.
Did you understand that as part of DEQ's allowances under Section 210.12(d) that you were allowed to take into account and consider the emission limits from the project?
A. Yes.
Q. Thank you.
MS. HANCOCK: I have no further questions.
HEARING OFFICER LAWRENCE: I actually do have a quick question while we have the rule in front of us there.
So Mr. Schilling, my question is about C under subsection 12 there, where it says basically if you comply -- I think paraphrasing it is like if you comply with 586 then you've satisfied -- or maybe it is B. "If the source's or modification's

approved T-RACT" -- so "no further procedures for demonstrating preconstruction compliance will be required."

So my question, just out of curiosity, is what if you don't meet that condition in C? If you reference 586 and you're not showing that you're within 586's confines, what's the next step for compliance in that scenario.

THE WITNESS: If I am understanding the question correctly, they would basically be unable to meet 586 with the implementation of T-RACT, if they can't do that, the permit would be denied. Or if we discovered there was an error that would result in them not meeting that one in 100,000 risk, it may be kicked back to the applicant to rework the entire analysis. Because we can't issue the permit unless they can demonstrate to our satisfaction that it's met.

HEARING OFFICER LAWRENCE: So it is not like there is an alternative route. It is either you meet C in 586 or you don't.

THE WITNESS: Yeah.

HEARING OFFICER LAWRENCE: Okay. Thank you. That's helpful.

Okay. So time for cross-examination,

correct?

Bryan, are you handling this?

MR. HURLBUTT: Yes, I am.

HEARING OFFICER LAWRENCE: Okay. You may proceed.

CROSS-EXAMINATION

BY MR. HURLBUTT:

Q. Mr. Schilling, can you hear me okay?

A. Yes.

Q. Okay. Mr. Schilling, in your experience, prior to the Stibnite Gold Project, did DEQ ever use a project-specific adjustment factor like the one used here to address TAPs compliance where the duration of the project and the seven-year lifetime are factored in?

A. Are you asking -- I didn't hear part of the question, but I believe you were asking outside of this project, have we ever used that 16 over 70 adjustment factor?

Q. Correct.

A. No, we had not.

Q. Okay. And that's in the estimated hundreds of permits that you have been involved at the DEQ, you have never seen that before?

A. Yes. We have never -- we have not encountered applications that were over five years, but less than 70. So the project is unique in that regard that it was of limited duration. So surprisingly enough, we had not seen that happen before.

We have, however, over the years the emission factors have been honed in on and DEQ has been more thorough in assessment of a lot of the emission sources. Way back when I was first starting the modeling of fugitive emission sources was a whole lot more uncertain. Fugitives were sometimes not included in the analyses because models weren't handling them well.

So it's not as though we just dreamed something up. We hadn't encountered the situation before.

Q. Mr. Schilling, have you been involved in any air permits for any other mines in Idaho?

A. Yes. I don't recall the specifics of them, but there's been some phosphate mines. And we will be in the process of evaluating some more. We have one mining project in the door right now.

Q. Do you know if any of those mines were seeking a permit to operate for more than 70 years

or 70 years or more?

A. All of those projects to my knowledge have involved permitting on a permanent basis. So they are not accounting for a shorter lifetime duration of the mine.

Q. Okay. Are applicants required to indicate how long they plan to operate?

A. Only if they want to take credit for a shorter than permanent duration in their permitting -- in their permit itself. If they can demonstrate compliance on a permanent basis, that's the route they go to get their permit.

Q. Okay. I'd like to introduce a hearing exhibit here. This is already in the record at REC1191 through 94. It's titled, "DEQ Position on Arsenic Modeling Addendum" and it goes on from there.

Mr. Schilling, are you familiar with this?

A. Yes, I am.

Q. What is it?

A. This is basically a summary of our approach for the Stibnite project.

MS. HANCOCK: Did you clarify that that is Exhibit 300 for the record?

MR. HURLBUTT: Yes, thank you. Exhibit 300 for the record.

(Hearing Exhibit No. 300 admitted.)

Q. BY MR. HURLBUTT: Mr. Schilling, can you turn to the last page of that, Section 3.4, that's titled, "Substantial Change in Regulatory Approach"?

A. Yes.

Q. And did you write this, Mr. Schilling?

A. Yes, I did.

Q. Do you mind reading that Section 3.4?

A. Sure. "The arsenic modeling addendum is a complete change in the regulatory approaches to demonstrate compliance with toxics. It abandons the Section 210 approach used in the application for an arsenic Section 161-210 hybrid analysis. The methods used in this unique analysis should be thoroughly vetted by DEQ well before permit application is submitted. Month before permit issuance is not time for developing a creative permitting approach with new emission inventory approaches, new modeling analyses and challenges for crafting enforceable permit provisions/limits."

Q. Thank you.

Is it the 16/70 exposure duration

adjustment, is that the substantial change in regulatory approach that you're referencing here?

A. Yes, it is.

Q. Okay. You may have already covered this in your direct testimony, but could you explain what the normal approach is that DEQ would use and how the 16/70 is different?

A. The typical approach that DEQ uses with most of the permit applications is that we -- the annual average is a nice nugget to regulate on. And it's easiest to calculate emissions for an annual -- a maximum annual impact. And when those demonstrate compliance, that's the easiest path to permitting.

Q. Sorry to interrupt, but when you say "when those demonstrate compliance," do you mean comparing them --

A. Yes. Thank you for the question. When they can demonstrate compliance, assuming a repeatable annual impact in treating the AACC as an annual limit. And most of the projects we get, even some of the older mine projects, they permitted it in a way that allowed for consistent operations -- there wasn't the variability component in there. Or what they often did was

overestimated their emissions to where they could get a permit and it just involved year-to-year compliance and not a need to do a five-year averaging period.

So when this first came in to us, you know, we were -- our certainty level -- my certainty level was not so high. And I was concerned about the regulatory applicability of this method. I had put this together expressing my concerns about that.

Follow up to this involved extensive interaction with my permitting team as well as our deputy attorney general at the time and discussions with Perpetua's as well.

So this is kind of the beginning point of a process used to kind of say, hey, we may encounter some rocky points with this approach. Maybe we need to round up the team and we need to talk about it a little bit more.

Obviously I was not wrong in assuming we have some things to discuss.

Q. Thank you.

Mr. Schilling, you testified earlier about the TAPs rulemaking and testified that your recollection is that the TAPs rules were intended

to be consistent, predictable, and easy to use; is that right?

A. Yes.

Q. You also testified about Section 586, that has the carcinogens, URFs, ELs, AACCs. Can you explain again how one, instead of just comparing to the AACC listed in Section 586, can somehow use the URF to come up with a different comparison point?

A. Yes. What we're mainly doing is not so much -- the AACC is an annual representation of one in a million cancer risk. So we're then going to one in 100,000. You use -- the total exposure concentration allows for adjustment for the exposure duration. So the URF defines your basically risk for a unit amount of contaminated exposure. And then using the exposure duration you come up with an exposure concentration, which then can be compared to the AACC, which is that one in a million cancer risk representative of a 70-year lifetime.

Q. Would it be simpler to just compare the annual average AACC listed there to the annual average concentration that was modeled?

A. It would certainly be simpler. I don't

believe it would be more appropriate. Again, what's most appropriate is --

Q. I was just asking if it was simpler.

A. Oh.

Q. Thank you.

MS. YOUNG: Mr. Hearing Officer, I'm sorry to interrupt. But since he was asked a question, can the witness be allowed to finish his answer?

HEARING OFFICER LAWRENCE: I'll allow it.

Go ahead. If you felt like you needed to clarify something, please proceed.

THE WITNESS: It's simpler. I don't believe it is appropriate though. Because we still center on the fact that what matters is project-imposed cancer risk and not a year-by-year evaluation.

Q. BY MR. HURLBUTT: Is it appropriate to use this kind of exposure duration adjustment for any and all of the carcinogens that are listed as TAPs? Here it was used for arsenic, right? But would it be applicable to any TAPs?

A. My understanding would be that it could, but that would be best answered by the toxicologists.

Q. Okay. Do you still have a copy of your declaration in front of you, Mr. Schilling?

A. Yes.
Q. Would you please turn to Paragraph 19 of your declaration?
There you discuss air rule Section 210.15. That applies to short-term --
HEARING OFFICER LAWRENCE: Hold on one second. Bryan, can you let me catch up? Where were you going?
MR. HURLBUTT: Paragraph 19 of Mr. Schilling's declaration.
HEARING OFFICER LAWRENCE: Okay. Thank you.
Q. BY MR. HURLBUTT: Which discusses air rule Section 210.15.
A. Yes. I didn't get the full part of your question.
Q. Yeah. The question was just, the short-term source rule there, does that apply to sources that operate for five years or less?
A. Yes. As defined.
Q. Okay. And does that section grant a ten time increase in the applicable qualifying short-term sources?
A. It allows for a factor of ten adjustment to the allowed carcinogenic risk.
Q. Okay. In your opinion, Mr. Schilling,

could a five-year source get a project-specific adjustment factor like was granted to Perpetua? So five over 70?

A. I think that would demand some more careful evaluation. Since we have a prescriptive rule that addresses a short-term project of five years or less, I am not -- I would need to consult with people. My initial thought would be well, we have a rule that says what you do when you're a project of five years or less duration. I would need to evaluate. My initial thought is that we would have to work within the constraints of that provision if they wanted to use the five-year adjustment.

Now, if you're saying they don't want to use the five-year adjustment rule but just want to use the existing framework of the exposure duration adjustment and use five years under that rather than the specific five-year adjustment allowance in the rule, is that kind of what you're asking?

Q. Sure. Yeah, what do you think about that? I guess I was asking about either. Could you use both approaches?

A. I think there again it would need to be evaluated since the rules did identify a project of

duration less than five years falling in a certain defined bucket of the rules. So my initial thought is that the five-year period kind of caps how much you can really account for things, especially given some of the discussions within rulemaking about addressing these short-term projects defined of as five years or less.

Q. Mr. Schilling --

HEARING OFFICER LAWRENCE: Mr. Hurlbutt, can I jump in? I have a question that would be ridiculous for me not to ask now rather than wait later because it is so related.

Mr. Schilling, I am going to preface this question with a disclaimer that my dad was a hardcore scientist. The STEM gene skipped not only one generation but two, my kids don't have it either. But for all of the expert witnesses, please keep that in mind.

But with respect to this five-year rule that's hard-coded into the rules. My question on that is, like, if that five-year sort of flexibility rule that is in the rules now, if it didn't exist at all and we just had the rest of the rules the same way they are now and someone walked in and applied for a project for just a five-year

duration, how do those two different paths differ? Application of the hard-coded five-year rule versus going through the process that you did to get to 16 over 70, which in this case my hypothetical would be five over 70. I know that is a long question, but I don't know how else to approach it.

THE WITNESS: Yeah. Kind of the hypothetical of -- if I understand this correctly, you're asking what if we did not have the five-year provision within the TAPs rule but an applicant came in with a project of five years limited lifetime.

HEARING OFFICER LAWRENCE: Right, exactly.

Maybe part of it is describing what goes into the math of the hard-coded five-year rule versus the math that you used to get to the 16 over 70 adjustment factor?

THE WITNESS: The 16 over 70 adjustment factor kind of focuses on the URF and the calculation of an exposure concentration that allows consideration of exposure duration. At some point -- and I'm kind of starting to wade into an area of toxicology that is not the most comfortable waters for me.

My initial feeling would be as we get

into five years we start getting into a concern about well, are we dealing with carcinogenic risk versus -- well, chronic risk versus acute. That's one consideration.

I think we also start getting into the case of, well, do we have some concerns over dosing, which I believe is why the five-year thing was put in there to begin with, is that -- long-term exposure is the criteria here and there's not a magical point at which all the sudden it's too much in a short period of time. And there's debate about where that should be and where you should no longer be able to throw a bunch of contaminant on someone.

My interpretation is that the rules have said that is five years, when it is a five-year project this is the path you need to take.

And beyond five years my interpretation is that well, we're now into a carcinogenic long-term exposure and it would be more appropriate to account for that actual duration of dose. And not doing that would be assuming you're actually subjecting a receptor to more pollutant than what they are actually going to be exposed to over their lifetime.

HEARING OFFICER LAWRENCE: Okay. And if I understood the background correctly, am I remembering correctly that there's not really any particular magic to the five years itself, but DEQ receives sort of a regular stream of applications for these remediation projects and other types of projects that are shorter in duration so that is what the rule is there for.

THE WITNESS: Yeah. Regulatory bodies don't always work with perfect science because there's a lot of discrepancy in the scientific community. What ends up in regulation is sometimes something that no one completely agrees upon, but it's sort of the best way to move forward. The factor of ten, well, did it just happen that that's the magical factor that really works? I'm sure you can talk to a bunch of toxicologists and it should be five or 12 or some other number. Maybe it should be ten years instead of five years.

So I think we have some -- explaining it away is like trying to get in the heads of a whole bunch of lawmakers and people involved in negotiated rulemaking. Sometimes it just comes down to this is what we have to deal with it. And we do our absolute best job trying to interpret

what's the intent of the rule, what was the intent of the rulemakers, and is this a reasonable interpretation? Does it make some kind of sense and do we feel it is reasonably protective of public health as prescribed by the intent of the rule.

HEARING OFFICER LAWRENCE: Okay. Thank you.

Mr. Hurlbutt, sorry to interrupt. While you were on that topic I figured I would ask my question on that.

MR. HURLBUTT: That's okay.

Q. BY MR. HURLBUTT: So Mr. Schilling again, you testified earlier that the intent of the rule is to be simple and consistently applied.

Wouldn't it be simplest to have this short-term five-year exception that gets multiplied by ten and no other exceptions based on the duration of a project?

A. Again, it would be definitely simplest. But there's another component of the rules that's important and that is the rules also need to afford reasonable flexibility to the regulated community to conduct business accordingly. I know there's a lot of debate that can be made, you know, where do you cross a line of operational flexibility?

In this case I really think there's a lot of evidence in the record in past rulemaking and the way the rules are written that really corners in on the project-imposed risk is the criteria and not an arbitrary, annual, hardcore cast-in-stone limit that you can't ever exceed.

Q. Mr. Schilling, in this same Paragraph 19 of your declaration, if you still have that there?

A. Yes.

Q. You state, "in general, DEQ determined it would not be appropriate to subject individuals to a lifetime allowable cancer risk within a duration of less than five years."

Why did DEQ think that's not appropriate?

A. Well, there's -- let's see, this is Paragraph 19?

Q. Yes.

A. Excuse me just a minute while I make sure what I was referring to.

Q. Sure.

A. What I am trying to recall is, I am talking about the historical perspective of DEQ to the best of my recollection in that at the time of rule promulgation, DEQ determined it would not be

appropriate to subject a lifetime of cancer risk in a five-year period, therefore the development of that five-year provision for the factor of ten rather than a factor of I think it would be 14 or something like that.

So in other words, my interpretation is that DEQ felt that subjecting that entire slug of carcinogenic exposure or carcinogenic dose into a five-year or less period would not be reasonable.

So I'm interpreting that as an establishment of five years being that -- kind of that cutoff point, the cap to you can no longer put more into things for something less than five years.

Q. Okay. Do you agree that it would not be appropriate to subject an individual to a full lifetime allowable cancer risk for a five-year or less project?

A. I would not be the person to answer that question, again, because I'm not a toxicologist.

Q. Okay. Under your view of the air rules, Mr. Schilling, could a six-year source get a project-specific adjustment factor of six over 70?

A. It would seem so. I would want to confer with the rest of staff and see if there

would be some overriding reason not to.

Q. Okay. And I know you said you're not a toxicologist, but you have worked with the rules a lot and clearly think about human health and said that you have some training in things relating to toxicology.

Do you think it would be appropriate to subject an individual to a full lifetime allowable cancer risk in six years?

A. Well, my thoughts on what I personally feel might be appropriate -- we're kind of getting into a case of going what do I feel about something versus what's allowed under the rules. So I'm struggling a little bit with that.

Right now I am looking at within the regulatory framework we used here, what I'm seeing is the five years is being the bright line, very well known that in the science of things there's usually not very bright lines. We deal a lot with shades of gray. Certainly six years is looking a lot more gray to me than 16 years. I know you're asking a yes-or-no question and I'm maybe answering it more like a -- sounding like a politician.

Before I personally, if I received an application that used an adjustment for six years,

I would want to consult with both my legal team, my management team, and our toxicologist before saying yeah, you're good to go.

Q. Okay. Mr. Schilling, when DEQ assesses TAPs compliance for a new source, does DEQ consider toxic air pollutants from other sources that individuals may be exposed to, earlier sources, later sources, at the same time?

A. No. Going back to your question on simplicity of the rules. There was some discussion of those kind of things during rulemaking. It was decided that the TAPs would be regulated on an increment basis only, that being for the project. So in other words, not just on a facility basis.

You know, in this particular case the project is the entire facility. In a lot of cases we have facilities that have been around for multiple decades and where their emissions have occurred prior to development of the TAPs rules, we don't look at those. They came in with a project, they are given the increment that's allowed by the TAPs rules.

Q. So for TAPs compliance purposes, it's put on a bit of a blinder as to whether there's exposures people might be experiencing before or

after that project; is that correct?

A. That is correct.

Q. Okay. If DEQ received an air permit application for a second mine or an expanded mine or something at this Stibnite project site after this first 16-year project occurs, would DEQ have to consider the amount of cancer risk already eaten up by this 16-year Stibnite Gold Project that's at issue here?

A. You had kind of two options there and it is important to distinguish between them, I believe.

The first option, let's take a hypothetical example that a Perpetua 2 came in and was a completely new plant right next door to Perpetua 1. To the best of my knowledge, we would be looking at that Perpetua 2 plant and they would have the same incremental risk allowance in the --

Q. Sorry to interrupt, when you say "incremental risk allowance," you mean they would have their own new fresh?

A. Exactly. They would have a new one in a million. Their project would be able to impose an additional one in a million or one in 100,000 with T-RACT allowance for that.

Q. Okay.

A. If Perpetua was to modify in some way, and it was determined that it is an actual modification, they would also get another increment just like any other facility that modifies their operations argument given another increment.

Q. And I guess we have been talking about filling up pans or eating up cancer risk, but do you remember, Mr. Schilling, what the amount of the allowable lifetime cancer risk the Stibnite Gold Mine Project was modeled to eat up, if you will?

A. Well, at the maximum receptor, which is a very limited place, I would have to look, but it was less than 50 percent of the T-RACT allowable AACC.

You know, one of the things to consider is that if another mining company went in right next door, it's highly unlikely that they would impact the same receptors. That's not to say it's not a concern, but that was used as one example of why an increment approach was reasonably protective. And I'm not saying whether that's right or wrong, and I have my own opinions, personal opinions about it, but that's the way the rule was developed.

Q. Okay. So if someone lived somewhere else near a highly industrialized area, if multiple sources came in there that were short term, is there -- do you have concerns that one short-term source could eat up a bunch of somebody's cancer risk and then a second source that operates after that first one fills up that full bucket and it overflows eventually?

A. I kind of have --

MS. YOUNG: I just would object to the question as being beyond the scope of what we're talking about for purposes of this project at this hearing.

HEARING OFFICER LAWRENCE: I am going to sustain that. I tend to agree.

MR. HURLBUTT: Okay.

Julia, do you have the copies to share with everyone? I guess this is Exhibit 301. This in the TAPs modeling addendum the statement of basis at record 0710. If you could share that with them, Julie, I would like to introduce that as a hearing exhibit.

MS. THROWER: Yeah. So "Arsenic Modeling Addendum Review, Identify Questions and Concerns"?

MR. HURLBUTT: Yes, please.

MS. THROWER: 301. And for the record it also starts at REC1183.

Q. BY MR. HURLBUTT: Mr. Schilling, are you familiar with this?

A. Yes, I am familiar with it.

Q. I am bringing this up to draw your attention to Table 6, which is in the last page.

A. Table 6? Mine doesn't have tables in it.

Q. So I am looking at REC0714.

MS. THROWER: Okay. I apologize. I gave the wrong exhibit. So I will take those back. I apologize. This will be Exhibit 301 starting at REC0710.

MR. HURLBUTT: Yes.

(Hearing Exhibit No. 301 admitted.)

Q. BY MR. HURLBUTT: I just wanted to draw attention to, again, Table 6, which is the last page of this.

MS. HANCOCK: If we can wait one second, we don't have our copies yet.

THE WITNESS: Just to clarify, this is from the modeling review memorandum that -- or the modeling review of the TAPs addendum; is that correct?

Q. BY MR. HURLBUTT: Yeah. Thank you.

In the arsenic column in that table, the far-right column, that 41.30 percent, is that the number that's the sort of modeled amount of lifetime cancer risk that this project would eat up if somebody was exposed to that?

A. Yeah, the 41.3 percent? Yeah, the maximum modeled adjusted the exposure concentration is the .00095 micrograms per cubic meter. And that ends up being 41.3 percent of the T-RACT adjusted AACC.

Q. And to make sure I understand what you said earlier, if, say, at year 17 some new source came up, whether it was at the Stibnite site or right next door or whatever, they don't have to factor that 41.3 percent of cancer risk that's been eaten up?

A. That is correct.

MS. YOUNG: Same objection as far as outside the scope and calls for speculation.

HEARING OFFICER LAWRENCE: I actually do kind of want to hear the answer real quick.

So please go ahead and answer.

THE WITNESS: Yes, they could. It would be a new source and, again, it's project-specific

increment so it's a different source and we look just at the project.

Q. BY MR. HURLBUTT: Okay. I would like to ask now about this issue with increments versus standards or limits.

Because something is an increment, does that necessarily mean it cannot be an enforceable limit, Mr. Schilling?

A. Well, I'm not sure I'm completely following all of the confusion between the differences between increments and standards. We have here an increment, which is a one in a million cancer risk or one in 100,000 cancer risk, and that is certainly going to be regulated on and made enforceable.

The difference between a standard and an increment is that, you know, a standard accounts for all others -- like an air quality standard. That would be where we need to include all other sources and background and need to stay below a certain threshold.

An increment either allows for just that, an incremental amount of pollution. In some cases like PSD increments, it allows for all other sources beyond a certain point can chew up so much

air quality provided they still stay -- everything still stays below the national air quality standards.

In the case of our TAPs rules, it is a project-specific increment. So the project is -- that's the most the project can chew up is that is their pocket of pollution they're allowed to contribute.

HEARING OFFICER LAWRENCE: Can I jump in real quick? Bryan, I have a quick follow-up question.

Mr. Schilling, that framework that we're talking about right now in terms of like the difference between the ambient standards for the NAAQS, N-A-A-Q-S, versus toxics, does that general framework, does that derive from the Clean Air Act itself or as opposed to is it the State of Idaho that made the determination that toxics are going to be on this project-specific basis versus treated like the National Ambient Quality Air Standards?

THE WITNESS: The toxics are not addressed by the Clean Air Act. That is an Idaho-specific program. So it was negotiated with the regulated community back in the early '90s to develop the rules. So it's Idaho-specific. EPA does not

oversee our toxics program directly.

HEARING OFFICER LAWRENCE: Thank you. Sorry to interrupt.

THE WITNESS: Can you repeat your question again?

Q. BY MR. HURLBUTT: I don't remember exactly where we were.

A. I don't either.

Q. The TAPs rules use increments, but isn't it true that those still are enforceable limits in a permit? You can't go above, as you argue, the acceptable cancer risk. That is a limit, an enforceable limit?

A. Yes.

Q. Okay. Thank you.

Moving on to the five-year rolling average issue.

In your experience at DEQ have you used multiyear averages for assessing emissions for TAPs compliance?

A. I don't believe we have because permit applicants have not submitted something requesting that. They chose to demonstrate compliance using their worst case annual emissions. So that's what we -- we don't go out of our way to do something

that the applicant doesn't request.

Q. Okay. Mr. Schilling, do you know if DEQ or Perpetua ever calculated the maximum annual average arsenic emission for the Stibnite Gold Project?

A. I don't know. I'm not sure whether they did or not nor would we have requested them to if they're proposing to use a five-year rolling average. That is what we're going to analyze and that's what we're going to regulate on.

Q. Okay. So you don't know how much higher the maximum annual average the Stibnite Gold Project is compared to the maximum five-year rolling average that was used?

A. I don't off the top of my head. It could probably be calculated out. Bear in mind, they are also constrained with various production limits to assure compliance with the 24-hour PM10 and PM2.5 as well as annual PM2.5.

Q. Okay. I'm going to pull up Section 210 of the air rules, which you did just discuss with Ms. Hancock.

You are familiar with Section 210 of the air rules, Mr. Schilling?

A. Yes.

Q. I have done some highlighting here, but these are the 2022 rules. In green is Section 2, "Quantification of Emission Rates."

Do you mind reading the highlighted part B underneath there, Mr. Schilling, if you can read it?

A. "The uncontrolled emissions rate of a toxic air pollutant from a source or modification is calculated using the maximum capacity of the source or modification under its physical and operational design without the effect of any physical or operational limitations."

Q. Okay. Thank you. I am going to scroll down still within Part 2 within Section 210.

Do you see that part C and D here also talk about the maximum capacity of the source?

A. Okay. Section C, yes, I see that. Were you wanting me to read that?

Q. Well, yeah, why don't you read part D for T-RACT source, please.

A. "The T-RACT emissions rate of a toxic air pollutant from a source or modification is calculated using the maximum capacity of the source or modification under its physical and operational design with the effect of:"

MS. HANCOCK: Just remember there is a court reporter writing down what you say.

THE WITNESS: I'm sorry.

Q. BY MR. HURLBUTT: So this Section 210.02 is referring to maximum emission rates during this step of the TAPs process; is that right?

A. It's also important to have -- to consider part I and double I in there as well. But yeah, that's the maximum capacity of the source.

Q. Okay. So if this step of the process for emissions looks at the maximum or the maximum subject to be controlled, why don't you need to look at the maximum annual average for comparing TAPs compliance later on? Can you disregard the maximum and use a five-year rolling average later in the TAPs process?

A. We are kind of dealing with two different things here. Let me take just a second here.

Q. Do you guys want me to keep sharing this or stop sharing? I don't know if this is helpful or distracting.

MS. HANCOCK: Maybe until you're done.

THE WITNESS: We have done that. We calculated the maximum emission rate under its

physical and operational design. That doesn't mean that we make assumptions that it operates in a way that it doesn't. But this just says how we need to calculate those emissions, not how we need to assess them in the impact analysis. And using the five-year average allows you to account for how the facility will actually be operated.

I think this seems to be playing sort of a little bit of -- the only term that comes to mind, and pardon me for using it, but it is kind of verbal gymnastics in my mind to be using that. It's like, well, we calculate the maximum emissions that are going to occur under the physical and operational design of the equipment considering how it's being used. And then we assess impacts accordingly.

The fact that it may operate at this maximum hourly rate doesn't mean that we have to assume that it operates that way for five years continuously. That's not the purpose of what we're dealing with in Section D.

Q. So is there some use for these maximum rates in the TAPs compliance process?

A. Yes, most definitely. We want to make sure that what's calculated for the piece of

equipment or the operation is representative of the maximum emissions that occur within the unit of time defined for that source. Like, if we're looking at an hour, it's like, well, yeah, we want to make sure that the generator's running at its maximum load so that we're not underestimating those particular emissions.

Q. But then you don't need to use those later to look at actual compliance --

A. We do use them, we just also account for the duration of their use, which is put in as an enforceable permit limit.

Q. Okay.

A. And this we do for every permit we write regardless of whether we're dealing with this T-RACT or we're dealing with any other industry coming in. We never assume that the thing is going to operate at their maximum for 8,760.

With a caveat to that, an applicant can take that approach to make their permitting simpler and they can avoid getting burdensome permit limits if they make the overly conservative assumption that they can operate at 8,760 at full bore and that meets the rules, we're happy. It reduces the amount of time we have to review the permit. It

makes their permit simpler. You know, even though it is a gross overestimation of the emissions and impacts of the source.

Q. Okay. Thank you.

MR. HURLBUTT: I don't have any further questions. I don't know if Ms. Thrower does.

MS. THROWER: Yeah, I do.

HEARING OFFICER LAWRENCE: Counsel, does anyone have any preferences on whether we take a quick break now or plow through.

MS. YOUNG: I don't have a preference if we plow through or not, but if they go until 12:30, that's an hour. And given that Bryan was the primary on cross, that seems like a lot of time.

MS. THROWER: We represent different clients.

MR. HURLBUTT: You guys were afforded one hour.

MS. THROWER: But we had discussed these weren't hard and fast time limits. We are here at a hearing at the board's request to get information about these issues. If you guys want to cut me off, I will make an objection on the record that I did not have the opportunity to cross-examine this witness.

MS. YOUNG: I just wanted to note is all that I would like -- I tried my best to reserve a little time for redirect, and I just want to make sure I still get that.

HEARING OFFICER LAWRENCE: Right.

And Mr. Schilling, how are you doing? Do you need a break before --

THE WITNESS: I am still good.

HEARING OFFICER LAWRENCE: Okay. You may proceed, Ms. Thrower, but please be cognizant of time.

MS. THROWER: I will try to be as brief as I can.

CROSS-EXAMINATION

BY MS. THROWER:

Q. I think I can still say good morning?

A. Yes, good morning.

Q. All right. Thank you for being here.

I did want to ask a few follow-up questions. You had testified that when you were talking about the 16/70 adjustment factor that you said that duration is directly related to risk.

Do you remember saying that?

A. Yes.

Q. Okay. So in your opinion, is a lower

concentration of a carcinogenic pollutant over a longer period of time always equivalent to a higher carcinogenic pollutant for a lower time in terms of cancer risk?

A. By the methods we use to calculate risk, by the equations we use that involve the exposure duration. Yeah. I think the question you're getting at is if you take the same -- I am wading into toxicology again and I'm not the best person for that. But the way the equation we used works is what matters is the exposure concentration is linked to the actual quantity of material breathed in. And that that's what governs it. So if it is a little more in 16 years versus less than that over 70 provided it's the same quantity, that is an equivalent risk by the equation.

Q. And you would say that's the case for all carcinogenic pollutants?

A. That's the --

MS. HANCOCK: I would object to the scope of this. We're limited to just the arsenic issue here.

HEARING OFFICER LAWRENCE: Can you repeat your question, Ms. Thrower?

MS. THROWER: Yeah. I said, do you think

that that applies to all carcinogenic pollutants?

MS. YOUNG: I would also note an additional objection that Mr. Schilling hasn't been qualified as a toxicologist. It seems like we're wading really deeply into that.

MS. THROWER: But he testified as far as duration is directly related to risk so I am trying to figure out what his basis for that testimony is.

MS. YOUNG: Sure, again, but related to the arsenic, the piece he did the modeling for.

MS. THROWER: So I will rephrase my question.

Q. BY MS. THROWER: So you believe that this exposure duration, which we've been calling, applies to arsenic as a carcinogenic pollutant in all cases?

A. I always get nervous hearing the words "all" or "never." But to the best of my knowledge the equations to calculate the exposure concentration are linear, which would mean yes.

Q. Okay. So when Mr. Hurlbutt was asking you about six over 70, you testified you were a little nervous about doing it in that case; is that correct?

A. Yes.

Q. Okay. Did you consult with a toxicologist for the Stibnite Gold Project prior to this contested case?

A. Not to the extent we have now. I don't believe so.

Q. Okay. I will move on from the toxicology area.

So Mr. Hurlbutt had talked about the five-year short-term source rule. And that is in 210.15 is what we cited to.

So just to have it on the transcript that this rule basically says that if your source is going to operate for five years or less, you can use this rule which gives you a ten-fold adjustment factor to the AACC?

A. Yes.

Q. So you testified that if a five-year source, five-year or less source didn't want to use that rule, but go under the regular rule, what would happen -- or Mr. Hurlbutt asked you if a five-year source or less went under -- wanted to go under the regular rule, what would happen? And I am paraphrasing your testimony, but you said that you have a rule and they would go under the five-year rule.

A. I believe so.

Q. Is that a fair assessment?

MS. HANCOCK: I would object to the extent that we are just restating what has previously been testified to. So it is cumulative in nature, but it also is misrepresenting the full extent of his answer previously. This goes back to the last question as well.

MS. THROWER: Do you want me to go back and ask the court reporter to read his testimony?

MS. HANCOCK: The record stands for what it stands for. You can ask your questions however you want. I am just lodging an objection because I don't know having him reconfirm what he's already testified to in a way that paraphrases it differently than his testimony is the proper way to do it.

MS. THROWER: If you're worried about the differences --

HEARING OFFICER LAWRENCE: I'm going to jump in here. I will sustain the objection. It feels like we are revisiting a lot of testimony that we have already talked about.

Q. BY MS. THROWER: Mr. Schilling, you testified if a source coming in five years or less

would go under a five-year rule?

A. Yes.

Q. And that's the rule that they would use because that rule is there?

A. Uh-huh.

Q. Now, do you have a rule that says what you do if you are more than five years, expected to operate for more than five years?

A. Yeah, it is the standard one in a million cancer risk or one in 100,000 for T-RACT being the increment. So we would use our equation to make an adjustment for the exposure duration in the calculation of the exposure concentration.

Q. Is that what the rule says?

MS. HANCOCK: I am not trying to be obnoxious with this, but the rules say what the rules say, and asking a witness what the rules say, it doesn't --

HEARING OFFICER LAWRENCE: Let me ask a question that I was going to ask anyway that I think may get at this.

Mr. Schilling, I know we have been in the rules a lot. But just taking a step back and just high level, what is the primary textual basis in the air rules themselves for the 16/70

adjustment factor?

THE WITNESS: The rules say, again, what matters is the project-imposed cancer risk. What matters there is total risk. And so we have to properly account for the exposure for that duration rather than 70 years.

The rules don't tell me in my analysis when I'm analyzing NAAQS emissions, how I'm supposed to account for the NO to NO2 conversion that happens in the stack and may happen in the atmosphere prior to monitoring, but that's what we do in the analyses.

The rules don't -- you know, if the rules had everything in them prescribed -- you know, the rules don't preclude what we do, but we believe we took a reasonable assessment of the intent of the rules.

And if the rules had everything, every scenario in there, we wouldn't need scientists and engineers at the agency to implement these. We would have a software program that could just crank through it and issue the permit out and check through does it meet this.

So the fact that the rules don't specifically allow that adjustment doesn't mean we

shouldn't do it or that -- I believe it would be inappropriate not to do it.

HEARING OFFICER LAWRENCE: It was helpful for me.

Ms. Thrower, you may resume, but please try to minimize sort of revisiting prior testimony.

MS. THROWER: Just to this because, Mr. Hearing Officer, you had asked for the textual basis for his testimony.

Mr. Hurlbutt, I hate to put you on the spot, but can you pull up the IDAPA rules 210.12.B.

MR. HURLBUTT: Yes.

MS. THROWER: Thank you. .12.B.

Q. BY MS. THROWER: Okay. So 210.12.B says, "Compare the source's or modification's approved T-RACT ambient concentration at the point of compliance for the toxic air pollutant to the amount of the toxic air pollutant that would contribute an ambient air cancer risk probability of less than one to 100,000."

Is there anything in that rule that you read that allows for an exposure adjustment or that provides textual basis for using an exposure adjustment?

A. I don't see anything that precludes its

use, and it's -- in order to calculate the ambient concentration at the point of compliance for assessment of a one to 100,000 cancer risk. The models we use only generate at most an annual impact, so if we want to assess a 16-year impact, which is the life of the mine or the project duration, we need to use an adjustment factor outside of the model to account for that proper exposure concentration. I can't put in my model for it to generate a project -- a concentration that's representative of the concentration requested here, the T-RACT ambient concentration at the point of compliance, which is the concentration resulting from the entirety of the project, which would be the 16 years.

Q. Well, this is just asking the agency, or whoever is administering the application for the permit, to compare the T-RACT ambient concentration at the point of compliance to the amount of the toxic air pollutant contributing to the cancer probability of less than one to 100,000 which is equivalent to ten times the applicable acceptable ambient air concentration listed in Section 586.

So reading that, isn't this just the simple comparison? You have the ambient air

arsenic concentration that presumably the applicant gave you, and you compare that to the amount of toxic air pollutant listed in Section 586?

A. Yes, but in order to get to the proper averaged concentration, we have to multiply the model out by a factor of 16 over 70 to calculate the correct concentration.

Q. Okay. So I'll warn you, as I said, we are going to get into a little math. But just to go back, you testified that you were the air modeling supervisor.

Did you supervise or were you actively involved in the Stibnite Gold Project permit to construct?

A. A little bit of both. I was more involved in the framework of how we're demonstrating compliance with arsenic and how that is working in the five-year averages and those, and not so much in the direct checking of the model inputs and verifying those. So it was more supervisory and less nuts and bolts.

Q. Okay. So I may go out of the scope of what you know, so just tell me. But you reviewed Dr. von Lindern's declaration, correct?

A. Yes.

Q. And you reviewed the section where it talks about an averaging of the WEP and non-WEP models, being the west end pit and the non-west end pit models?

A. Yes.

Q. So this is the area I want to explore with you. And I also want to talk about this as you've obviously reviewed your toxicologist, Dr. Paden's declaration, right?

A. Yes.

Q. And she calculates her risk assessment based on a certain number of arsenic concentration, correct?

A. I believe so.

HEARING OFFICER LAWRENCE: Is this something we should be asking her when she's a witness?

MS. THROWER: Well, this is sort of more on the basis of where that number came from. I don't believe her declaration went -- from her declaration it looks like she was given this number and she would not know where it was calculated. I can certainly ask her that. But if she says, no, I don't know, and I have lost this witness for the remainder of the hearing.

HEARING OFFICER LAWRENCE: Okay. Go ahead.

Q. BY MS. THROWER: So Mr. Schilling, I am going to hand you Exhibit 303. This is also in the record documents at REC6888.

Can you read what the title of this table is?

A. "TAP Maximum Model Concentrations in AACs."

(Hearing Exhibit No. 303 admitted.)

Q. BY MS. THROWER: Do you have any familiarity or recollection of this table?

A. It is looking familiar of being -- this would actually be best described by --

MS. YOUNG: Sorry, I don't have a copy of this exhibit.

THE WITNESS: Yes, I am familiar with it. Details on it would probably be best answered by Perpetua's consultant, Kevin Lewis.

Q. BY MS. THROWER: To your knowledge, he is the most likely one that would understand where the numbers came from?

A. He would have the best understanding, but I may also.

Q. Okay. Do you have knowledge of the basis of how that number -- I'm sorry. Let me go back.

So if we look at the row for arsenic --
A. Uh-huh.
Q. -- and we look at W2, there's a value there. What is that value?
A. .00095.
Q. Okay. And that's in micrograms per cubic meter?
A. Uh-huh.
Q. So that number, what does that number represent?
A. That is the adjusted impact for the W2 scenario assuming that 100 percent of the production at the mine occurs from that source only.
Q. Okay. Just to get some clarifying questions. What did you mean by "adjusted impact"?
A. I believe the impact of -- again, I would have to go back and assess this more to be absolutely sure, but this could be verified certainly by any questions to Kevin Lewis, but I believe that has been adjusted for the 16 over 70 duration.
HEARING OFFICER LAWRENCE: And just so I know, since this is an appendix, what document did this come from? What does it live in?

MS. THROWER: Yeah. This came from Stibnite Gold Project Permit to Construct TAP Addendum Appendix C.

HEARING OFFICER LAWRENCE: Okay. Thank you.

MS. THROWER: That was REC6088.

Q. BY MS. THROWER: Mr. Schilling, I think maybe more of my questions are going to be directed towards Mr. Lewis, but I just wanted to have one more clarification.

A. Certainly.

Q. One more question here. You said it is the adjusted impact for W2 scenario assuming 100 percent production of that source only.

Do you know what source the W2 model scenario is talking about?

A. I believe -- I would have to go back to the key and see. It's been a while since I have reviewed this, and outside of the context of the entire document it's a little bit difficult for me.

HEARING OFFICER LAWRENCE: Ms. Thrower, if I can jump in.

So ultimately the test here is what I am going to find helpful for resolving and this feels like a line of questioning that is not going to help me out.

MS. THROWER: This does go to Dr. von Lindern's last part of his declaration in terms of WEP and non-WEP averaging. However, as I said, it appears that Mr. Lewis might be the more appropriate person to ask. So I'm fine, if Mr. Schilling doesn't have a recollection right now without reviewing other documents, I'm happy to leave it at that.

HEARING OFFICER LAWRENCE: I think we should.

MS. THROWER: Okay. I have no further questions then.

HEARING OFFICER LAWRENCE: Okay. Thank you.

I do have some questions, and I know you want redirect.

Do you have any idea how much time you need for redirect?

MS. YOUNG: Maybe ten minutes. But I prefer you go first so you can ask them in the way they make sense to you in case there is overlap.

HEARING OFFICER LAWRENCE: Is everyone okay? I am probably in the same ballpark, ten minutes likely. Something like that.

Are we okay to proceed?

Okay. These won't be in any particular

logical order. I apologize in advance. I'm trying to accomplish a few things here.

EXAMINATION

BY HEARING OFFICER LAWRENCE:

Q. So when I read back through the DEQ order and some of the transcripts when this was before the board, I got the sense that there was some discomfort with the fact that there was this 135,000-ton per day figure, right?

Can you remind me what the significance of that figure is? Do you remember that number?

A. The 135,000 tons per day, that number?

Q. Right.

A. I believe that was the five-year rolling average daily production limit.

Q. Right. So what I was sensing, there was discomfort on the board between the fact that -- as I recall, and maybe I am articulating this not correctly, but the 135,000-tons per day, is that what the modeling was assuming was the emissions rate?

A. That's what would go into the long-term modeling for the carcinogenic impacts. It's kind of the same discussion again about the pitcher full

of water and on a daily basis for other reasons we have that higher limit. But for a five-year period, that daily limit is ratcheted down to better reflect a five-year period, which we believe is more representative of long-term chronic impact rather than a short-term limit.

Q. So just kind of paraphrasing. And I don't know if they ever went this far, but it seemed like where somebody was going, with that 135,000-tons per day, why isn't that also like an annual limit in the permit? What I think I'm hearing is that's not necessary because we have fluctuations over time.

A. Yeah. I think again where the whole crux of all of this comes down to is we contend we are dealing with a total project risk evaluation rather than needing to hold to an annual -- each year needing to assume each year is the same year after year after year.

So I think that -- that is basically the question for all of the different points of contention is whether we can use what matters in that whole life-of-mine period, which we have kind of broken out into this five-year rolling average.

Or, as I understand the petitioner

saying, no, you need to look at each year and you need to identify the absolute maximum that each year could emit and evaluate the impacts for that worst case year. And that must be less than this increment that's based on a 70-year exposure.

Q. All right. Thank you.

So another question I have. I think your declaration and the DEQ's hearing statement when it is talking about the 16/70 adjustment factor, it uses the term that essentially this all works, this is all okay when there's an enforceable limit on the duration of operation.

So what is the enforceable limit in the permit for the 16 years?

A. That would be there's the total life-of-mine production limit, going back to my candy example, that sort of governs the whole project over the life of the mine. So by limiting that total production and specifically limiting the west end pit production, that assures that the total amount emitted and the average concentration that that causes, won't cause an excess cancer rate in excess of one in 100,000 as allowed by T-RACT.

Q. Is there any ability under the way the permit is currently worded that they could operate

for more than 16 years or is that baked into the conditions of approval is there is no way they could exceed 16 years?

A. That gets into a bit of an evaluation and there's been hypothetical questions of what would happen if after 16 years they simply requested to go another 16 years.

And we would need to evaluate whether such a request is actually a modification of the permit, which would enable the facility to get another increment, or if essentially they're asking for a permit violation.

We have things that are referred to as sham permits, and that means someone asks for a little bit less right now to be below something and then they later come in and go oh, well, we're going to do something -- we're changing something, we want to do this other thing.

And if it's shown that well, it really wasn't a modification, but you all along wanted to do something else, but you asked for something lesser just in order to get it approved, that's referred to as a sham permit.

Q. Is there any particular reason? Am I correct that there is not an actual permit term

currently that says this is limited to 16 years of operation?

A. It is limited by the total production. So by our risk calculations, you know, you would have the same risk whether that took 16 years or if they took 70 years to produce that same amount.

Q. And even if there's, like, not a practical implication in terms of cancer risk, is there any particular reason that the permit couldn't say, because we are basing all of this on this 16-year assumption and what they are telling us that we will only operate for 16 years, is there some reason that couldn't be baked into the permit as a condition? Does that mess something up?

A. Oh, if the 16 years were actually put in there?

Q. Yeah. Correct.

A. I don't know specifically. There again, I am going to kind of punt a little bit on that. I am the modeling review supervisor and analyst. That kind of goes into more of a permitting question --

Q. And I do mean the question more in terms of is there a permitting reason why that wouldn't work? That would mess up some other aspect of the

permit or something like that?

A. I don't know would be my answer. I don't see where it would mess up something.

Q. Okay.

A. It isn't in the permit and certainly Perpetua would want to weigh in on that.

HEARING OFFICER LAWRENCE: Thank you. Those are all my questions.

Ms. Young.

MS. YOUNG: Okay.

REDIRECT EXAMINATION

BY MS. YOUNG:

Q. I will start, Kevin, with what we were just talking about. And if you, again, don't feel comfortable because this is a little bit outside juror scope, just let me know.

Isn't it true that condition 3.6 of the permit to construct says that the permitee shall haul no more than 788.4 million tons of ore and creates an additional limit from the west end deposit. So I realize that was a confusing question, so let me rephrase.

Isn't it true that Section 3.6 -- or condition 3.6 of the permit contains both an

overarching limit as well as a limit from west end pit production?

A. That's correct.

Q. And isn't it true that the permit also creates an ongoing daily limit?

A. Yes.

Q. So through those two limits, isn't it true that the life of mine is limited to 16 years as the permit is currently written? And if Kevin Lewis needs to answer this as has been alluded to, that's fine too.

A. The production limit, you're talking in terms of limits of production. They are not forced to produce that much. That caps their production. So in the absence of a time limit in there, they could actually extend operations longer. And actually, if they went at a slower pace they would need to extend it longer.

But by extending it longer, since our emissions are proportional on production and concentrations are proportional on emissions and risk is dependent upon the total exposure, you're going to arrive at the same risk whether it would be 16 years or 70 years.

And in fact, I think if they say well,

instead of 16 years we're going to process this ore over 70 years, then we would just be -- we wouldn't have the adjustment factor.

Q. Sure. I was going to ask a follow-up to that and I lost my question. Apologies. I think maybe I'll reserve some additional clarification here for the other Kevin. I appreciate that additional explanation.

I just have a few more questions for you.

It was asked, I believe by the hearing officer, you know, if you have 586 to demonstrate compliance and you have the T-RACT one in 100,000 to demonstrate compliance, what would occur if the -- you couldn't meet either? And you had indicated that the permit would be denied, correct?

A. Yeah. Or they would have to go back and rework it. We couldn't issue a permit without demonstrating compliance.

Q. Perfect. Thank you. So that was going to be my question.

Wouldn't it also be an option for the permit applicant to go back and consider their analysis and make additional refinements, which we talked about earlier is a normal part of the

iterative process?

A. Yes.

Q. Perfect. Thank you.

You were asked by the petitioners if you had ever been involved with a permit where there was this type of adjustment.

Do you recall that question?

A. Yes.

Q. Isn't it true you have never been approached by an applicant to have this type of adjustment before?

A. Yes, that's correct. We wouldn't normally say, hey, use this. We deal with what is requested for their project.

Q. So in the other permits that you've been involved in developing, they simply didn't know at the time of the application what their duration was going to be. They were assuming they would be operating permanently?

A. Yes.

Q. And that's true for the phosphate mines that were referenced earlier; isn't that true?

A. Yes. They were permitted on a permanent basis.

Q. Because they don't know how long they

are going to be operating and they could be operating for many, many years, correct?

A. Yes.

Q. And isn't it true that some of those mines have been operating for many, many years?

A. Yes.

Q. Perfect. Thank you very much.

A. And they have had numerous modifications because they found new areas.

Q. Perfect. Thank you.

Let's see. As to this Exhibit 300 that you were shown, which is your position paper. I noted it doesn't have a date on it, and you might not recall, but do you know approximately when this paper was written? And if you don't know, that's okay.

A. I don't. I know it was prior to permit issuance.

Q. Okay. Thank you.

In the Section 3.4 that Mr. Hurlbutt asked you to read from, which is on the final page, Page 4, you said that the analysis should be thoroughly vetted; is that correct?

A. Yes.

Q. Was it thoroughly vetted?

A. Yes, it was.
Q. Perfect. It also was asked if this was a normal approach.
Do you recall?
A. Yeah, I believe so.
Q. And again, is that because you've never had a permit applicant come to you with a known duration of project from the get-go?
A. That's correct.
Q. So it wasn't creative in that you were trying to necessarily get around the rules, it's just you have never been presented with this problem before.
Would that be a fair assessment? I don't want to use the word "problem," but this type of project?
A. Yeah. It kind of gets into a little bit of semantics as far as how do you interpret the word "creative." And I may have actually even used the term. And it's looking at it, analyzing it, digging into it and figuring out, well, what is the intent of the rule? Okay. Oh, we believe this is what we're trying to control. This is a way to get at it. Oh, this is what really matters. Gee, we never thought about it that way before. Okay.

Let's move forward. Let's check on it, make sure it's a reasonable approach to our interpretation, which we did, and then moved forward with it.

Q. Perfect. Thank you.

Let's see, I think that's the only questions I have as to that exhibit.

Moving on. You were presented with a number of potential hypotheticals, including the possibility that a source would operate for six years.

Is that the situation we're in today?

A. No, it's not.

Q. You were also given some hypotheticals where you responded that you would be entering into more of a gray area.

Do you recall?

A. Uh-huh.

Q. Do you feel like you're in that gray area here with the 16-year duration?

A. I don't believe so. We had thought about that and it seemed like a reasonable estimate of a chronic exposure.

Q. So you don't feel like your judgment and the sound science you used crossed any line here. I believe crossing the line was referenced earlier.

A. No, I don't believe so.
Q. Thank you.
There were also some questions from the petitioners as well as the hearing officer about the rules that were relied on. And you indicated that the rules don't preclude this analysis, correct?
A. Yes.
Q. Isn't it also true that Section 586 supports the analysis that you performed?
A. Yes, in that the relationship between the URFs and the AACCs which are an expression of the one in a million cancer risk for 70-year exposure.
Q. Perfect.
And isn't it true that the definition that we read of the toxic air pollutant carcinogen supports the analysis that you performed?
A. Yes.
Q. And isn't it true that Section 203.03, which requires this analysis be demonstrated to the satisfaction of the department, supports the analysis that you performed?
A. Yes.
Q. And isn't it true that Section 210

supports the analysis that you performed?

A. Yeah. We performed the analyses according to the prescriptive nature of 210.

Q. Perfect.

And the specific section that allows you to perform the T-RACT adjustment is specifically and explicitly stated in the rules, correct?

A. Yes.

Q. There were some questions that I think confused the issue a little bit between the emissions being calculated versus the adjustment after the modeling of the emissions had occurred.

Do you recall that conversation?

A. Yes.

Q. Is there anything that you want the opportunity to explain there as far as the difference between calculating the emissions on the front end versus looking at the actual risk being created on the back end?

A. Only just a concluding statement that what went into the model was maximum emissions as the facility is allowed to operate under its design or the constraints of the permit issued. So that's what went into the model.

MS. YOUNG: Perfect. Let's see here. I

think those are all the questions I have. Thank you, Kevin.

HEARING OFFICER LAWRENCE: Thank you, Mr. Schilling.

MS. HANCOCK: Can I reserve the right to maybe do a brief redirect after lunch?

HEARING OFFICER LAWRENCE: You can reserve the right.

MS. HANCOCK: Would you permit me to do a brief redirect after lunch?

HEARING OFFICER LAWRENCE: On what topic?

MS. HANCOCK: On the topics that was covered by the petitioners.

HEARING OFFICER LAWRENCE: Can you be more specific?

MS. HANCOCK: I just need to make sure -- I want to look at my notes and just make sure, but I want to do a double check to make sure we didn't have something on the record that was incorrect. It wouldn't be longer than ten minutes.

HEARING OFFICER LAWRENCE: Okay. Mr. Schilling, would you prefer to do that now or do you want to wait until after lunch?

THE WITNESS: I don't have a preference. I would defer to anyone who has a pressing issue or a

desire.

MS. HANCOCK: My understanding is he is going to be here throughout the course of the hearing.

HEARING OFFICER LAWRENCE: Unless someone wants to take a break I would be inclined to just go ahead and do it now.

MR. SHORT: I could use a break.

HEARING OFFICER LAWRENCE: Why don't we take a lunch break and do that after lunch.

MS. HANCOCK: Thank you.

(Break taken from 12:21 p.m. to 1:28 p.m.)

HEARING OFFICER LAWRENCE: Okay. We are reconvening in the Perpetua air permit matter. As we left it before lunch, Perpetua had asked to reserve some time for a few follow-up questions for Mr. Schilling, but just informed everybody they don't need to do that any longer. So we're just going to proceed to DEQ's next witness.

MS. YOUNG: Yes. Thank you, Hearing Officer.

HEARING OFFICER LAWRENCE: So we need to swear the witness.

NORKA PADEN,

a witness having been first duly sworn to tell the truth, the whole truth and nothing but the truth, was examined and testified as follows:

DIRECT EXAMINATION

BY MS. YOUNG:

Q. Can you please state your name and spell your last name for the record.

A. Norka Eliana Paden, P-A-D-E-N.

Q. Thank you, Dr. Paden.

Where are you currently employed?

A. I work for the Idaho Department of Environmental Quality.

Q. Perfect.

How long have you been with DEQ?

A. I have been with DEQ for eight years.

Q. For eight years. Thank you.

What is your current title?

A. My title is toxicologist risk assessor.

Q. All right. How long have you been in that role?

A. I have been in that role for eight years.

Q. And where did you work prior to DEQ?

A. In Idaho I worked for the Idaho Department of Environmental Quality for five years.
Q. I'm sorry, before DEQ.
A. I worked for the Idaho Department of Health and Welfare for five years.
Q. What degrees do you have?
A. Perfect.
I have a master's in human ecology. I went to the Free University of Brussels in Belgium. And I graduated with a degree of environmental toxicology, a Ph.D., from Texas Tech University.
Q. So you consider yourself a toxicologist, correct?
A. Yes, I am a toxicologist.
Q. What about your education and background qualifies you as such?
A. I have vast experience doing risk assessments. I have been a toxicologist and practicing for 16 years. Prior to that, overseas also I did over nine years. So I have been doing risk assessments for close to 25 years. That is not in my declaration, but I am just adding that.
Q. Okay. So in your declaration you mention the 16 years, but you're saying that you didn't include those previous nine years when you

were overseas?
A. Yes.
Q. So you are adding that to the record now?
A. Exactly.
Q. Perfect. Thank you.
Let's see, and does your education also go into consideration as far as considering yourself a toxicologist?
A. Yes. That's correct.
Q. Thank you. This might be difficult to give me an exact number, but could you come up with a best guess of how many risk assessments you've performed in your career as a toxicologist?
A. My best guess would be over 50.
Q. Over 50, 5-0?
A. 5-0.
Q. Perfect. Thank you.
And did you prepare an expert declaration in this matter?
A. Yes, I did.
Q. I am going to hand you a copy of your declaration. You can take a minute to review it. After you do, can you tell me if this is a true and accurate copy of what you submitted?

A. Yes, it is.

MS. YOUNG: We've marked that as Exhibit 101.

(Hearing Exhibit No. 101 admitted.)

Q. BY MS. YOUNG: In advance of today's hearing did you review the other expert declarations that were submitted?

A. Yes, I did.

MS. YOUNG: Hearing officer, I would move to first qualify Dr. Paden as an expert witness, and specifically as a toxicologist.

HEARING OFFICER LAWRENCE: Any parties opposed?

MS. HANCOCK: No.

MS. THROWER: No.

HEARING OFFICER LAWRENCE: Approved.

MS. YOUNG: Thank you. I would also move to admit Exhibit 101, Dr. Paden's declaration, into the record as expert testimony.

HEARING OFFICER LAWRENCE: Granted.

Q. BY MS. YOUNG: Thank you.

Okay. Dr. Paden, in your declaration on Paragraph 5 you stated that you reviewed the transcript from the May 1st, 2024, special board of environmental quality meeting in this matter; is

that correct?

A. That is correct.

Q. So you are familiar with the oral comments that board member Dr. McMillan made individually at that meeting?

A. Yes.

Q. Thank you.

In his comments he stated that "DEQ's project-specific adjustment factor creates a new higher level of cancer risk for 16 years."

Do you recall that statement?

A. Yes, I do.

Q. Based on your expertise as a toxicologist, do you agree?

A. I disagree with that. As you can see in my declaration, Table 2, you can see that actually the excess cancer risk for 16 years is lower than at 70 years.

Q. Thank you.

So in your opinion the adjustment factor that DEQ used does not create a higher level of cancer risk?

A. No, it doesn't.

HEARING OFFICER LAWRENCE: Can you speak up a little bit?

THE WITNESS: No, it doesn't.

Q. BY MS. YOUNG: He also stated that "DEQ is making the assumption that 70 years is required for cancer to develop."

Do you recall that statement?

A. Yes, I do.

Q. And do you agree with that statement, and that statement being that "DEQ is making an assumption that 70 years is required"?

A. I don't think DEQ is making that assumption. That 70 year comes from EPA life risk assessment and that's taking into account how long somebody is going to live, for 70 years.

Q. Perfect. Thank you.

So in your declaration, and I'm looking specifically at Paragraph 22, you concluded that DEQ's analysis followed EPA guidelines; is that correct?

A. Yes, that's correct.

Q. And you also conclude that it resulted in an acceptable cancer risk; is that correct?

A. That is correct.

Q. Can you expand on why you came to that conclusion?

A. My declaration, you can see some of the

results that I have on Table 2. But most importantly, the 16 years that we are discussing in this hearing, and that is four in 1 million cancer risk. So that is the below the T-RACT which is below our rule standard for cancer risk.

Q. Great. So you state in your declaration that DEQ followed EPA guidelines. And can you explain why DEQ's reliance on EPA's guidelines is appropriate?

A. If we go to section -- Paragraph 11 in my declaration, I don't know if you have that equation.

Q. Yes.

A. So what I did, I tried to interpret -- so the formula is not stated in the rule, however parts of the formula are in that table. So I tried to --

Q. I'm sorry, I'm going to stop you right there for clarity. When you are talking about that table, per your Paragraph 11, you are talking about Section 586 in the rules?

A. Yes, that's correct.

Q. Thank you.

A. And so I tried to derive or calculate the ACC specifically for arsenic using the values

that you have in that table.

And so when I did that, I compared that and it's the same formula that EPA uses to calculate excess cancer risk. So I conclude that DEQ has in the rules that ACC uses the inhalation unit risk which comes from EPA. And then there is a footnote there that indicates that value is taken from EPA. And so usually when we perform risk assessments we use that approach that I outline in Paragraph 11.

And then Paragraph 12, what I did there, is basically it's an expanded formula of what I have in Paragraph 10.

Q. That's perfect. I actually am going to ask my co-counsel here to share his screen and bring up these formulas that are in the declaration and we'll walk through them a little bit.

MS. YOUNG: Of course, as always, I would certainly welcome you to interrupt me at any time and ask the questions that you need.

HEARING OFFICER LAWRENCE: Are you sure you want to open that door?

MS. YOUNG: I think I am. Famous last words maybe.

HEARING OFFICER LAWRENCE: Real quick.

Could we, just for the record, sort of define what you guys mean by the phrase "risk assessment"? I think it would be helpful to have an elevator risk definition out there.

MS. YOUNG: Sure. I appreciate that.

Q. BY MS. YOUNG: Norka, could you define what it means to conduct a risk assessment?

A. Yeah. A risk assessment, when there is any contaminate in the environment you want to ensure that the concentrations that are going to be in the environment are not going to cause any human health effects, and you usually use the most conservative scenario for a sensitive population. So that is how risk assessments are carried out.

Q. Okay. So you raised a good point, that there is the consideration of sensitive populations.

And does the URF already take into account sensitive populations?

A. Yes, that's correct. So EPA derives those unit risk factors for a wide variety of contaminates, carcinogens, in this case for arsenic. And that value comes from -- usually from experiments they do with animals and that they extrapolate that to humans. And so they use

updated scientific information to come up with a value that is the upper level, the most conservative value that somebody can get exposed through a lifetime and it is not going to cause any cancer risk.

Q. Any excess cancer risk?

A. Any excess cancer risk is at the levels that are permissible, but EPA which is ten amount of four to ten amount of six.

Q. Which is 10,000 to a million? One in 10,000 or to one in 1 million; is that correct?

A. One in 10,000 to one in 1 million, so that's the range.

Q. Thank you.

So here is on Paragraph 10, under Paragraph 10 of your declaration, the formula that you said you had used, which is a formula for the maximum modeled concentrations for carcinogenic TAPs accounting for life of mine production limits.

Is that correct?

A. Yes, that's correct.

Q. And if you go to Paragraph 12. This is, you had stated, an expanded version of that formula on 10; is that correct?

A. That's correct.

Q. Okay. And I'm going to walk us through the formula a little bit. I'm sorry if this is really at the most basic level, but as someone who also does not have any math or science real experience I think it is helpful.

So looking at Paragraph 12, which we can see right now, the ED, the exposure duration.

Do you see that in there?

A. Yes.

Q. Okay. And if you compare that exposure duration, that ED number, to the formula under Paragraph 10, is that where you inputted the 16?

A. Yeah. That's what DEQ used to calculate the permit, and then they used the value of 16 as an exposure duration.

Q. So that 16 represents the exposure duration from EPA?

A. Exactly.

Q. So for Paragraph 12, you have the ET, the exposure time, and that's assumed to be 24 hours a day, correct?

A. Yes. Based on the information, that's on Table 1 of my declaration, that's 24 hours per day.

Q. Thank you.

And then the exposure frequency is 365 days a year, correct?

A. Yes, that's correct. 365.

Q. So we just covered the ET and the EF which is 24 hours per day and 365 days a year, right?

A. Correct.

Q. Now if you look back at the formula on 10, the ET and the EF, again, the 24 hours and the 365 days a year, is it true that it is being represented in this formula under Paragraph 10 as highest annual concentration, which is the 24 times 365?

A. That highest annual concentration is the CA, which is the highest annual concentration. Is that what you were asking?

Q. Let's see here. So maybe I'll just ask you to explain it. Maybe we'll keep 12 up, if you could keep 12 up and then explain how those different pieces of the formula relate to what we're looking at on Paragraph 10.

A. Yeah. If you have both, if you have it side by side so it will be easier to understand. So you have on the left-hand side of the formula the lifetime exposure concentration, which is in

micrograms per cubic meter. And that represents the exposure concentration on the EC on that formula from EPA.

And then that equals to -- on 10 we have the highest amount of a concentration, and that will be equivalent to the CA in Paragraph 12, which is the contaminate concentration in air.

Now, the exposure time and exposure frequency, as you see in Table 1, it's exposure time is 24 and exposure frequency is 365. And then you're going to have exposure duration. But in the denominator, you have AT, AT defined as the lifetime in years, which is 70, times 365, times 24.

So as you can see, if you have a numerator, that 365, that comes from exposure frequency and the 24 that comes from the exposure time, they are going to be canceling out. Meaning that you are dividing the same number -- you have the same number numerator and denominator, so that is going to be one.

So that's the reason I conclude that that's the same formula that comes from EPA and what we use -- what our permit writers use to calculate the 16 years of duration. And the 70, it

is coming from the lifetime exposure of 70 years.

Q. Okay. Thank you for that. And thank you for walking us through that a little more artfully than I was able to.

You reference Table 1 under Paragraph 13. And that's where you see the averaging time, which is the denominator is 70 times 365 times 24. And the reason you don't see -- I'm sorry, let me pause there.

Is that correct?

A. Yes, that is correct.

Q. And the reason you don't see the 365 and the 24 on Paragraph 10 is because they would be on both the numerator and the denominator essentially canceling each other out, correct?

A. Yes, that's correct.

Q. Looking at the simpler formula under Paragraph 10, we see that the 16 has been entered in for exposure duration, correct?

A. Correct.

Q. And in your experience of conducting risk assessments, have you ever put a different site-specific number there?

A. Yes, I did. In fact, usually when we are talking about residential exposures you can use

different values from EPA, 26. Or when you are evaluating a receptor that could be -- a receptor who is going to be exposed, a recreational person who is going to go to the site only for a short amount of time, you can use that exposure duration, that way you don't overestimate the risk.

So if you have information that is provided to me as a risk assessor and they tell me I am going to look at the risk here, to be more accurate I can use that information and put the 26, the 16, 15, whatever number the person is going to get exposed to get an accurate calculation of the cancer risk.

Q. So can you put numbers that are lower 16?

A. Lower than 16? Yes.

Q. So again, just to reiterate, when DEQ provided you with that 16 number, that wasn't atypical in your experience in doing risk assessments to put in a specific number for that exposure duration?

A. Yeah. For the record, I did not calculate this permit, I am just evaluating the permit. So I did not calculate. But I am just evaluating what I was provided. So they did use

the 16 and that's an accurate value and it's conforming with what EPA has in the guidelines.

Q. Perfect. Thank you.

So this would be an adjustment based on the actual exposure duration.

Can you explain why duration is so important?

A. When somebody is exposed to any contaminate, you have to evaluate what are the different -- the time, because that is very important. So if you are getting exposed to a chronic exposure, you know more than one year, that's going to be different than if you are going to get exposed for 24 to 48 hours, which would be an acute exposure. So that is very important.

Q. And it's important in the cancer risk analysis, correct?

A. Definitely. You usually see that a chronic exposure will cause cancer where as acute exposures, at least in toxicology, we don't consider that. We just evaluate if it is emergency, acute exposure. We do not evaluate cancer risk for an acute exposure, but for chronic exposure.

Q. So obviously the 16 years at issue here

would be considered a chronic exposure?

A. Exactly.

Q. And you sort of explained this, but if you could just discuss this again, sort of understanding the difference between the exposure being chronic versus an amount of exposure?

A. Yeah. Exposure being chronic, that's the definition. You expose somebody for more than a year, several months. And sub chronic could be 30 to 90 days. And then acute, 24 to 48 hours. The amount the person is exposed, that also influences what are going to be the outcomes from risk.

Q. Perfect.

So we covered this a little bit about the URF considering sensitive populations, but is it your experience that these risk assessments bake into them a lot of conservatism?

A. They do. In fact, if you go to my exhibit that I put there for my declaration, Exhibit B, it has the original screening levels. So if somebody at DEQ will ask me to do a risk assessment, and that's the screening values that we are going to use.

And you can see I changed the values,

but on the right-hand side I wanted to concentrate on those numbers that they have for first, second, third phase. So there is different age adjustments that EPA uses to be very conservative in the analysis.

HEARING OFFICER LAWRENCE: I'm sorry, I don't think I have the right document in front of me.

MS. YOUNG: Exhibit C, I believe.

And to also let you know, Dr. Paden, Michael has put it up on the screen to confirm we are looking at the same thing.

THE WITNESS: Yeah. We already consider all those. The age adjustments, they mention that in the analysis.

Q. BY MS. YOUNG: And you said earlier that the risk assessment also considers sort of the worst case scenarios for a number of the factors; is that correct?

A. Exactly. When we are looking at any risk assessment we want to look at values that are the worst case scenarios. So we are trying to be conservative so that way we are using a population that is going to be at most risk. So when you are talking about children, like in this case, or

pregnant women, which are the most sensitive, or the elderly, they are sensitive populations. They are already considered in the analysis on that URF and also, as you can see, in the original screening levels.

MS. YOUNG: Great. Thank you, Dr. Paden. I don't have any further questions at this time. Though I would reserve some time for any necessary redirect.

HEARING OFFICER LAWRENCE: Okay.

Perpetua, are you ready to ask Dr. Paden some questions?

MS. HANCOCK: I am.

CROSS-EXAMINATION

BY MS. HANCOCK:

Q. I just have one question. On your Exhibit C that we were just looking at, if we can go to the next page.

Can you tell me what this page reflects?

A. Yeah. These are some calculations for resident risk screening levels for arsenic in air using the highest concentration that I was provided by our permit writer. So that's what we have the screening level. What is highlighted in red,

that's the screening level that we used to say whether or not there is any cancer risk.

Q. Does arsenic have a mutagenic mode of action?

A. No. And that is what we have there. There is a lot of studies, but there is not strong evidence. So to my understanding, EPA has told me, and you can see in their most updated original screening levels value that it is not mutagenic.

MS. HANCOCK: That is all I have. Thank you.

HEARING OFFICER LAWRENCE: Okay. Mr. Hurlbutt, Ms. Thrower, how are you guys breaking up your cross-examination of the witness?

MS. THROWER: I think I will go first.

HEARING OFFICER LAWRENCE: It would be helpful for me to know how you are splitting it up. Are you guys covering particular subject matters?

MS. THROWER: I think I am doing most of it. I will cover everything in her declaration, I believe.

HEARING OFFICER LAWRENCE: And are there any issues here where there's a different analysis or outcome based on your representation of Save the South Fork Salmon versus Nez Perce Tribe and ICL?

Are those different parties relevant to any of this?

MS. THROWER: I don't want to speak for Mr. Hurlbutt, but his clients have different levels of use of the area so I don't know if in terms of talking about risk assessment if there's anything he may follow up in that respect or something like that. So I don't want to -- I think I intend to cover everything for all the petitioners, but I'm not going to say he's not going to want to ask a few questions afterward.

HEARING OFFICER LAWRENCE: That is helpful for me.

MR. HURLBUTT: That's fair. If I have any additional questions, it won't be very many.

HEARING OFFICER LAWRENCE: Thank you, guys.

CROSS-EXAMINATION

BY MS. THROWER:

Q. Good afternoon, Dr. Paden.

A. Good afternoon.

Q. So I want to start with just going through some of your experience as a toxicologist. From your qualifications statement it looks like you have been -- you said you have been an

environmental toxicologist with DEQ for 16 years?

A. For DEQ eight years.

Q. And then another eight years would be the predecessor agency; is that right?

A. For Health and Welfare I worked for five years.

Q. Okay.

A. So 13 years.

Q. Okay. So 13 years with IDWH and DEQ together?

A. Yeah. In total, yes. For the state, 13 years.

Q. And both those agencies, the focus of your work was to provide risk assessments analyses for contaminated sites or superfund sites; is that correct?

A. That's correct.

Q. It sounds like you also provided comments to policymakers and negotiated rulemaking?

A. That's correct.

Q. Were you at DEQ when the TAPs rules were negotiated?

A. No, I haven't. That's before my time.

Q. Okay. And you've done many risk assessments, as you have testified, at least 50 or

so, for contaminated sites.

Do you do any risk assessments for individual permit applications, like the Stibnite Gold Mine Project?

A. Well, that is not considered a risk assessment because that doesn't fall under a superfund site, so CERCLA requires risk assessments for sites that are contaminated. So even if I wanted to, that doesn't fall within the scope of my work.

Q. Okay. Have any of your risk assessments involved analysis of air quality --

A. Yes.

Q. Exposure to air quality?

A. Yes, several. Several.

Q. I wanted to talk about the public health consultations that you mentioned in your declaration. It says you authored six of those public health consultations for the agency for toxic substances and disease registry.

Again, were all those public health consultations on contaminated sites? Or existing contamination versus potential future releases of contaminants?

A. Some of them were petitioned by

nonprofit organizations that was not necessarily a contaminated site, they just wanted to know whether or not exposures to particular contaminates will harm public health and not necessarily superfund sites.

Q. When you say not contaminated sites, you are saying not an officially recognized --

A. Superfund site.

Q. But these nonprofits thought the site might be contaminated, so they wanted you to look into that?

A. Yeah. Correct.

Q. So I want to go back to those risk assessments again. How did you go about calculating a receptor's exposure to a contaminate? And by "receptor," I think that is a new term we have thrown out here. But that would be a human that may be in contact with the contaminate.

So again, how would you go about calculating a receptor's exposure to a contaminate?

A. Usually risk assessments, like I explained before, we evaluate and we take into consideration the most sensitive populations which are children, pregnant women.

Q. Okay. And those risk assessments, do

you typically calculate a different risk, cancer risk, for an adult versus a child?

A. Like I mentioned here for the original screening levels, both are considered together, adults and children. So that's already incorporated in the approach that EPA uses.

Q. Okay. Have you ever separated out cancer risk based on life stages in your public health assessments?

A. In public health assessments, yes. Because I follow ATSDR approach, which is quite different from what EPA requires.

Q. Okay. So I am going to move on to the actual permit application.

The first time you were asked to evaluate the cancer risk from the Stibnite Gold Project was for this contested case, right?

A. Yes.

Q. Okay. And just to make clear, and when I mean the contested case, I mean after the permit was issued.

A. That is correct.

Q. So I want to turn to Page 8 of your declaration. I'm sorry, not Page 8, but Paragraph 8.

Okay. You state here that the cancer risk estimates were accurately calculated.

Do you see that?

A. Yes.

Q. And do you still agree with that statement?

A. Yes, I do.

Q. In Paragraph 10 you show the equation that purports to calculate the lifetime exposure risk. That's what you have testified to what that equation is with Ms. Young?

A. Correct.

Q. So just to back up a little bit. In order to calculate the excess cancer risk by your method you need to calculate the lifetime exposure, correct?

A. Yes.

Q. Okay. And as you said, that's done with the equation in Paragraph 10.

A. Uh-huh.

Q. So I want to focus on this term "highest annual concentration." In this case we're talking about arsenic.

In Paragraph 9, you state that you used the number for the highest annual concentration,

which you called the maximum model annual concentration, as 0.00416 micrograms per cubic meter; is that correct?

A. That is correct.

Q. And the number and the value of the first column in Table 1 is that same number, right, .00416 micrograms per cubic meter?

A. Yes, that's correct.

Q. And you said that you were given a number by DEQ.

Were you referring to the 16 years or were you referring to the highest -- this .00416 number?

A. I consulted with our permit writer and I asked what was the worst case scenario in this case and I used that number to calculate the risk.

Q. Okay.

A. And now in this contested case I was asked whether or not the use of the 16 years is accurate or not. And that's what I used the 16 years to indicate that that was something that is allowed by EPA.

Q. Okay. So the 0.00416 number, you were also just given by DEQ?

A. Yeah. I reviewed documents that went

into the calculation. Usually when you do risk assessments we use a wide variety of data and then you calculate your 95th percentile which is the highest value we can have or an average or a GME. In this case it was this value, which I understand from reading the summary of the permit that that was the worst case scenario from the modeling.

Q. Right. Okay.

Does the accuracy of your cancer risk calculation depend on the accuracy of that number given to you for the highest annual concentration?

A. Yes.

Q. Okay. Would you be concerned about your conclusion that this permit meets that T-RACT cancer risk if you knew that number that DEQ gave you was lower than the higher annual concentration?

A. I am not concerned because I consulted with the permit writers and I trusted that they did the calculations to the best of their ability, therefore my calculation is also accurate.

Q. But if they gave you a number that was lower than the highest annual concentration, would you feel like you would need to redo your analysis?

A. I would sit with them and I would ask them to explain to me why this concentration is

lower. And if I feel that there's some miscalculation, then we will have to have a conversation.

Q. Okay. So Mr. Schilling said that this number was a five-year rolling average and not the highest annual concentration.

Does that give you any concern?

A. I'm not familiar because I am not a permit writer, so I cannot answer that question.

Q. Well, if someone gave you -- as a hypothetical, if someone gave you an average of five numbers and didn't give you the individual numbers, but said, hey, I calculated the contaminate concentration over an average of five years, would you consider that a good analysis in terms of that is the highest annual concentration?

MS. YOUNG: I am just going to object and say asked and answered. I feel like Dr. Paden's already testified that that's more in the realm of a permit writer and that she's already answered the question, essentially.

HEARING OFFICER LAWRENCE: I will give you one more shot Ms. Thrower, and then move on.

Q. BY MS. THROWER: Okay. If someone came to you and said do a risk assessment like you did

here, and I'm giving you for your highest maximum -- or for the maximum annual concentration, I'm giving you a five-year rolling average that I've calculated. Would you be concerned that your cancer risk calculation may not be accurate?

A. In my position as a toxicologist I cannot just be given a number. I need to make sure that the numbers that I'm going to use are reliable. So I consult with the people that I have at DEQ, the manager, the permit writers, and say how did you come up with this concentration so I cannot just, okay, this is a number and you are going to calculate.

And my role as a toxicologist and the model for DEQ is to take care of the environment and human health, so I am not going to put at risk the population that are going to be exposed. So that is my role and I take that to heart.

So I probably won't just take any number that anybody will give me to do a calculation. I will have to double check and make sure that the numbers I am using are accurate.

Q. Okay. Thank you. And I don't mean to suggest you don't take your job seriously.

So let's turn to Paragraph 12 of your

declaration. Again, this is EPA's methodology that Ms. Young had questioned you about.

So this methodology, this equation comes from the risk assessment guidance from EPA for superfund sites; is that correct?

A. That is correct.

Q. And this is the same guidelines or guidance that DEQ is claiming that it is relying on for this 16/70 adjustment factor; is that correct?

A. That is correct.

Q. Does the superfund risk assessment guidance consider incremental sources?

A. Incremental cancer risk?

Q. Yes. Incremental, yeah, so from multiple sources.

A. From multiple sources, I don't think I am understanding the question.

Q. Let me try and rephrase that.

Does the superfund risk assessment guidance ignore other sources of exposure?

A. When you are doing a full-blown risk assessment you have to consider all the exposures from all the media for arsenic: water, soil, air. In this case we are talking about permit and you are talking about something specific which is air

emissions. So I was told that this is what we are using.

And what I am trying to say is that DEQ used a formula that comes from EPA and that the permit writer used to change the exposure duration just as I would do for any other risk assessment.

Q. Right. So I understand you would be looking at different routes of exposure like from air and water for the same contaminant for a risk assessment, but would you be looking at other sources? So for instance, if you were doing a risk assessment on a superfund site, you are looking at contaminant A and whether people can be exposed to that.

Are you looking at other sources of contaminate A that might be around that superfund site?

A. Yeah. This is outside the scope of this discussion, but if you are just curious of the work that I do, yeah, if there are any other sources around a particular superfund site that had to do with arsenic, yes, I would say, yeah, is there any background? Is there any mine over here? But usually we are concerned with a superfund site, we are just evaluating this particular mining area, we

are just going to look at that.

And you can add lines of evidence, whether or not there is background natural occurring arsenic to compare to your project. But I am just going to do my analysis based on that particular superfund site.

Q. Okay. And that analysis involves a lot of different factors, not just exposure duration; is that right?

A. Yes. It is a wide variety of factors.

Q. And you didn't consider any of those factors in your cancer risk calculations for this permit; is that correct?

A. I did not do the calculation myself. I am just trying to demonstrate what the permit writer did and that it aligned with what EPA allows.

Q. Okay. Thank you.

So I want to go to Table 2 of your declaration. In Paragraph 14, Table 2, you use the equation that you had in your earlier part of your declaration to calculate the excess cancer risk probability using the inhalation unit risk for arsenic derived by the EPA. This is getting to be a long question. Let me start that over.

So let's just say Table 2 shows the results of your calculations using those equations you have above in your declaration, correct?

A. Yes, that's correct.

Q. Okay. And it shows in the first row, it shows that if you use the exposure concentration using the 16/70 adjustment factor, your cancer risk is four in 1 million; is that correct?

A. That's correct.

Q. And that is equivalent to one in 250,000? Four in 1 million is equivalent to one in 250,000?

A. No, it is not equivalent. I don't understand what you're trying to say.

Q. I was just trying to see if we can compare it -- well, it's okay.

So again, in Table 2, the second row, it shows if you don't use the 16/70 adjustment factor you calculate the excess to be two in 100,000; is that correct?

A. That is correct.

Q. So in Paragraph 17, in the last sentence of that paragraph you state that "this analysis shows at maximum arsenic levels modeled 0.00416 micrograms per cubic meter for exposure of

16 or 70 years are within the public health guidelines."

Do you see that in your declaration?

A. Yes.

Q. And by "public health guidelines," you mean EPA's guidelines, correct?

A. EPA and also ATSDR's.

Q. Okay. And you conclude that the two in 100,000 cancer risk is within the EPA's recommended range of one in 1 million to one in 10,000, correct?

A. Correct.

Q. But is this two in 100,000 the cancer risk that we're talking about for the T-RACT cancer risk in this case?

A. This is above the T-RACT, but what I was trying to demonstrate, even if it is above the T-RACT it is still within what EPA recommends.

Q. But not what the Idaho rules require?

A. Not the 70, but the 16.

Q. Let's move down to Paragraph 21.

So in Paragraph 21 you mention other sources of recommendations for arsenic concentration ranges, for example, from the Texas Commission on Environmental Quality and the World

Health Organization. And you state, "the maximum modeled air concentration in this case is below those established thresholds," correct?

A. Correct.

Q. Do you agree those thresholds don't really bear on whether this permit application meets the Idaho air rules?

A. These are additional lines of evidence that any toxicologist would use to substantiate that really there is no risk.

MS. THROWER: Okay. I have no further questions.

THE WITNESS: Thank you.

HEARING OFFICER LAWRENCE: Mr. Hurlbutt, do you have anything else?

MR. HURLBUTT: I just have one line of questioning, I don't think it will take long.

HEARING OFFICER LAWRENCE: Okay.

CROSS-EXAMINATION

BY MR. HURLBUTT:

Q. Can you hear me okay?

A. Yes.

Q. You said at the beginning of your testimony that you disagree with Board Member McMillan's statement that this 16/70 approach creates a new cancer risk; is that right?

A. That is correct.

Q. The 16/70 approach allows the project to emit more arsenic over 16 years than if it had to meet the annual AACC every year, right?

A. I am not aware that they are going to emit more. I don't think that is the discussion. It is my understanding that there is a concentration, and that's the value I used. That is the maximum concentration and that's what I used for my calculations.

Q. Okay. You're not aware that the reason the 16/70 approach was used was because if the project's arsenic concentrations were compared to the T-RACT adjusted annual values it would have exceeded those?

A. Yeah. What I was trying to demonstrate here is that if you use -- number one is that you

are allowed to change the exposure duration. So that's the primary role with my declaration. So you are allowed to not use the 70, but 16, and that's what I am trying to demonstrate.

And even if you go farther with the 70, still the risk is not -- is within what EPA recommends. So that is what I am trying to demonstrate in my declaration.

Q. Okay. Even if you think that the project's arsenic emissions create an acceptable risk, they're still higher than what would be allowed if Perpetua had to meet the applicable AACC every year; isn't that right?

A. I don't agree with that statement.

Q. Okay. So you don't think there is a higher risk from arsenic exposure under this project compared to if they had to meet the annual AACC each year?

A. I would have to defer that to Kevin or the permit writer with the AACC or the rolling average, which I am not competent to answer that question.

Q. Okay. So how you can say Board Member McMillan was wrong in saying that this creates a higher cancer risk than what was traditionally done

by DEQ?

A. Because you are talking about 70 years. Dr. McMillan was saying it is creating a new higher cancer risk and I don't see that in my evaluation. I still find that even if you do 70, you're still within what EPA allows.

Q. Okay. But you don't think that this approach is allowing higher levels of arsenic exposure than the normal approach that DEQ has employed that Mr. Schilling testified about?

A. No, I don't think so.

Q. Okay.

MR. HURLBUTT: Thank you.

THE WITNESS: You're welcome.

HEARING OFFICER LAWRENCE: I have a couple of questions.

EXAMINATION

BY HEARING OFFICER LAWRENCE:

Q. So at the conclusion of Mr. Schilling's testimony I asked him a question about the 16-year -- all the modeling is based on 16 years life of mine, so why isn't that actually like a permit condition?

And if I understood his answer

correctly, part of it was essentially that even if they don't produce a lot every year and they stay under their production limits, if they go past 16 years, as long as they're still within their overall production limits, it doesn't change the cancer risk.

Does it sound like I am accurately describing what he testified to?

A. Could you rephrase your question?

Q. Yeah. What I was asking Mr. Schilling was this whole issue of 16 years. So if all of the modeling is based on the assumption that the mine is only going to operate for 16 years, my question is why not have a permit condition that actually says that, that says the mine is limited to 16 years? Do you follow me so far?

A. Yes. Yes.

Q. Okay. And so as I understood his response, it was -- part of it was, well, the first thing is there are production limits in the permit, so that's one thing that kind of takes care of this issue of the length of the mine. And even if Perpetua ramped down its production so that it was going beyond 16 years, but still staying within its overall production limits, the fact that it is

going beyond 16 years doesn't change the overall cancer risk. That's at least what I understood. And I was just curious as to whether you had an opinion about that one way or the other.

A. Yeah. That's accurate. We are doing this average in time and that is what you call lifetime exposure. You are considering -- already when you are doing 16 you are considering somebody being exposed for 16 -- that is the exposure duration, but you are doing it throughout the 70 years somebody will live.

So there is still some -- you are taking into consideration the concentrations that will last and will have that cancer risk over a lifetime.

So just because you are not going beyond 70, the cancer risk concentrations are still being taken into consideration. So just because I didn't say it is going to beyond that, it is not going to stop there. So you've been for 16 years there, so your cancer risk has been evaluated if you would be living for 70 or having your lifetime exposure. So I don't know if you are following me.

Q. I don't mean to be annoying, but to me it seemed like one of the big concerns by the board

is just the whole difference between higher exposures for shorter amounts of time and lower exposures for longer amounts of time. And what I am just trying to figure out is, let's just hypothetically say that Perpetua operates beyond 16 years but they're still staying under all of the other production limits in the permit. How does that change the excess cancer risk?

A. Yeah. This is a very controversial topic, because as I state in my declaration, cancer just has a wide variety of factors. You are not just going to treat the arsenic. Somebody can already have cancer and I go and live by the mine, I cannot blame the mine to be causing my cancer because I already had previous exposure. So it is a very difficult topic to discuss. I'm sure Theresa will have a little better understanding to explain specifically knowing the project and how is it going to operate and when is it going to stop.

Q. Okay. And another question I have, obviously the petitioners haven't gone yet and they will get into their case more specifically, but in my review of the materials they filed. As I understand it, one argument they are making is that DEQ's approach in the application of the 16/70

factor doesn't take into account different cancer risks at different life stages. And I am just wondering what your overall reaction is to that argument from a high level.

A. Yeah. As I explained to Hannah when she asked that question regarding the URF, when you are evaluating cancer risk for any carcinogen, there is that unit risk factor that EPA provides. And when we use that factor, that already takes into account a very conservative approach in which all the most sensitive populations are being evaluated when you are using that factor. And to do that EPA goes through years and years of review. That number is vetted. So we as toxicologists we rely on that to do our risk assessments.

Q. Okay. So specifically, that issue of different risks at different stages, like pregnant women, children, that's baked in, for lack of a better phrase, into the unit risk factor specifically? That's where that occurs?

A. Yes, that's correct.

Q. Thank you. I apologize if you said all that and I just needed to hear it again. Sometimes it helps to hear things multiple times.

Those are all my questions.

Do we have any redirect from DEQ?

MS. YOUNG: Just a few questions. It shouldn't take too long.

REDIRECT EXAMINATION

BY MS. YOUNG:

Q. I don't want to belabor this, maybe this is just something you haven't had the time to think through, but part of what the hearing officer was asking, so let's say that the mine was operated, hypothetically, which is dangerous, but for 17 years. So it took an extra year, but that reduced the year-by-year exposure because they were producing less. That I think is one possible scenario that has been floated.

Would that create a major change to your analysis or do you think it would create a major excess risk at that point if it was one year over but because of the production limit there was less being -- you know, exposure?

A. If you are having an emission or exposure, a concentration that is less, you know, theoretically when you do the calculations, it is going to give you less risk because you are plugging in the lower number.

Q. Right. So the one question I wanted to ask was looking at Paragraph 12, this formula. Under Paragraph 12, the formula, petitioners were asking you about using the annual average versus the five-year rolling average.

Do you recall that?

A. Yes.

Q. Isn't it true that this CA, contaminate concentration and air value, is supposed to be a representative period of emissions; is that correct?

A. Yes. It is a continuous exposure, it is a chronic exposure.

Q. So it is representative of the exposure, not necessarily the maximum exposure at any given point in time?

A. No. It is the continuous exposure, not the maximum.

Q. It is the continuous and not the max?

A. Yes.

Q. Okay. Thank you.

So if a five-year rolling average was actually more representative because of the variability of the project, would that actually be the best number to use as the representative

number?

A. Yeah. That's correct.

Q. Okay.

MS. YOUNG: I don't have any other questions.

HEARING OFFICER LAWRENCE: Okay. Thank you.

Perpetua, anything?

MS. HANCOCK: Nothing further. Thank you.

HEARING OFFICER LAWRENCE: Okay. So this concludes DEQ's case in chief, correct?

MS. YOUNG: Correct.

HEARING OFFICER LAWRENCE: Okay. Well, thank you.

Do we want to proceed to Perpetua or take a break?

MS. HANCOCK: Maybe just a five-minute switch-it-up break and then start again.

(Break taken from 2:31 p.m. to 2:39 p.m.)

HEARING OFFICER LAWRENCE: We are ready to proceed with Perpetua's case in chief.

MS. HANCOCK: Thank you.

THERESA LOPEZ,

a witness having been first duly sworn to tell the truth, the whole truth and nothing but the truth, was examined and testified as follows:

DIRECT EXAMINATION

BY MS. HANCOCK:

Q. Good afternoon, Ms. Lopez. Would you mind starting by giving us an overview of your education background?

A. Yes. I earned a Bachelor's of Science in nutritional science with a minor in zoology from the University of Florida. And I received a Master's in Public Health degree from the University of Colorado Health Sciences Center.

Q. And just because the TV is the microphone, if you make sure you keep your voice up.

What is your role today?

A. Today I am a principal toxicologist with Tetra Tech.

Q. Can you help me understand with your Master's in Public Health and your BS in nutritional science how that translates into a toxicology expert?

A. When I was in college, toxicology was not a major at my university, but nutritional science is the prevla of toxicology. You use the same types of studies to do an analysis of the effects of nutrients on the body as opposed to other chemicals. And in nutrition you have ill effects on both ends, too little or too much. So the science translates directly.

Q. And how long have you worked as a toxicologist?

A. 32 years.

Q. Where are you employed?

A. At Tetra Tech.

Q. And what is Tetra Tech?

A. Tetra Tech is multifaceted environmental engineering company.

Q. In your time there for 32 years, have you always served as a toxicologist?

A. Yes.

Q. Can you describe your role at Tetra Tech, what kinds of things you do as a toxicologist?

A. I have a wide range of projects that I work on. I have government clients, I have private clients. I provide consultation in risk assessment

in toxicology and in public health.

Q. Specifically have you been engaged in cancer risk assessment?

A. Yes. Cancer risk assessments are generally part of any risk assessment that we do depending on the chemicals we are working with.

Q. And throughout the course of your career, do you see chemical engineers performing this type of analysis that you do?

A. No.

Q. Do you have any memberships that you belong to in your role as a toxicologist?

A. I am a member of the Society For Environmental Toxicology and Chemistry as well as for the Society For Risk Analysis which are two professional organizations.

Q. And are they as what it sounds, both specializing one in toxicology, one in risk assessments?

A. Yes.

Q. How long have you been a member of the Society For Risk Analysis?

A. More than 30 years. I started out with the Rocky Mountain chapter about 30 years ago. And I am still a member today.

Q. Okay. And then do you serve in any leadership roles at the Society of Toxicology?

A. At SETC, yes. Well, at the moment I am going to be a session chair for them at their next annual meeting.

Q. And then do you present on toxicology at that annual meeting as well?

A. There are several presentations that are going on that are my work. I am not presenting them, I am having other people present them, but I am there as a session chair and as an attendee. The last presentation I did was for SETC in 2019 at the world conference.

Q. Okay. And then do you hold any certifications?

A. I am considered a qualified person for risk assessments by the government of Saskatchewan.

Q. In Canada?

A. Canada.

MS. HANCOCK: At this time we would ask to have her recognized as an expert toxicologist specializing in exposure and risk assessment.

HEARING OFFICER LAWRENCE: Any parties object or oppose that?

MS. THROWER: No objection.

MS. YOUNG: No.

HEARING OFFICER LAWRENCE: Okay. Granted.

Q. BY MS. HANCOCK: And we previously circulated Exhibit 201, which is her expert declaration, and provided the hearing officer with a record copy of that. At this time we would move to admit that as an exhibit.

HEARING OFFICER LAWRENCE: Any objections to that?

MS. THROWER: No objection.

HEARING OFFICER LAWRENCE: Granted.

(Hearing Exhibit No. 201 admitted.)

Q. BY MS. YOUNG: You are free to reference that at any time. Just at a high-level summary, your expert declaration here covers three main areas, as I've summarized it, and tell me if I'm correct.

The first area you verify that DEQ conducted a proper risk assessment using a methodology that is scientifically proven by adjusting the lifetime arsenic emissions for the operational life of the mine to be the 16 years; is that correct?

A. Yes. They did a proper analysis by EPA methodologies.

Q. And the second area is that you verified that DEQ properly calculated the cancer risk emissions from this permit using that 16 out of 70 calculation and comparing it to the T-RACT AACC of one in 100,000; is that right?

A. Yes.

Q. And the third area you verified that DEQ's use of the five-year rolling average production limits did not exceed that T-RACT cancer limitation of one in 100,000?

A. Yes.

Q. I want to go a little bit through the background of what we heard today but just to make sure we are tacking on the same way.

Can you tell us what an IUR is?

A. An IUR is an inhalation unit risk and it is developed by EPA and published by them.

Q. And what does it measure?

A. It is a risk probability of exposure to a chemical for a lifetime at one microgram per cubic meter that carries an excess lifetime cancer risk of one in 1 million.

Q. So it is measuring a cancer risk in excess of the cancer risk that we see in our everyday lives?

A. Yes.
Q. And were the IURs adopted by DEQ?
A. Yes.
Q. And what do they call it?
A. They call them URFs.
Q. And do you know what URF stands for?
A. Unit risk factor.
Q. The unit risk factor.
How do you know that the unit risk factor is the same as the IUR and adopted by DEQ?
A. You can look at the IURs published by the US EPA and they right down the line compare exactly with the URFs. And I believe that there is one table that, actually in the statute, that noted that that's where they came from.
Q. Okay. Is it commonly accepted within the industry that the IURs and the URFs are the same?
A. Yes.
Q. Do you know what the formula is for a URF that you use in your calculations?
A. To use a URF in a calculation?
Q. Right.
A. It is the toxicity value that you compare an exposure concentration to to estimate

risk from that exposure.

Q. Okay.

MS. HANCOCK: If we could just, Mr. Foster, if you wouldn't mind pulling up Exhibit 203.

Q. BY MS. HANCOCK: I'm sorry for the bulk of this. Normally we look at it electronically. But you recognize Exhibit 203?

A. Yes. It is EPA's health assessment document for inorganic arsenic.

Q. And what's the year of this publication?

A. 1984. March 1984.

Q. And is this a document upon which you rely in the regular course of your role as a toxicologist?

A. I could go back to these documents, but what they do is summarize the approach taken by US EPA and the experts they hired to develop IURs, in this case for inorganic arsenic. They have matching documents for every chemical that they have evaluated. And it documents what they looked at, what they did, and the conclusions that they came to.

Q. Okay. Is this a guidance document that is used as Mr. Tiedemann describes in his declaration?

A. It is not a guidance document. It is a technical background document to show how they came to the conclusion of the IUR.

Q. Okay.

MS. HANCOCK: Your Honor, I would move for the admission of Exhibit 203.

HEARING OFFICER LAWRENCE: Any objections?

MS. THROWER: No objection.

MS. YOUNG: No.

HEARING OFFICER LAWRENCE: Okay. Granted.

(Hearing Exhibit No. 203 admitted.)

MS. HANCOCK: And if we could, Mr. Foster, go to Page 123 of 354 on the PDF.

Q. BY MS. HANCOCK: I am jumping ahead because we are already in this document so I am going to take one fact point out of context here.

You're familiar with Table 6.1?

A. Yes.

Q. Okay. And is this a document that you've looked at before, especially Table 6.1?

A. Yes, I have looked at these before.

Q. Is arsenic a mutagenic mode of action? Or does arsenic have a mutagenic mode of action?

A. EPA does not consider it to have a mutagenic mode of action. Just like Dr. Paden said

earlier today, if you look at how EPA assesses arsenic, even on their printout it says it is not a mutagenic. It is not considered to have a mutagenic mode of action. And that was considered in this document.

Q. And do you know -- we had heard some questions earlier. Do you know if in setting the IUR, or what has now been adopted as the URF, that was taken into account to protect sensitive subpopulations as well?

A. Yes. That is how EPA develops their toxicity values.

Q. Since this background, this is dated in 1984, since this background, has the IUR risk probabilities for arsenic ever been changed?

A. The IUR for arsenic has not been changed since 1984.

Q. Have there been other chemicals that have been updated or changed with new information?

A. Yes.

Q. Okay. So what does that tell you as a professional toxicologist?

A. It tells me that EPA periodically updates their toxicity values based on any new information that they feel changes the conclusions

they made at an earlier time.

Q. And it tells you that no changes were necessary with respect to arsenic, at least as through today?

A. Yes.

Q. Okay.

MS. HANCOCK: If we could just pull up Exhibit 205.

Q. BY MS. HANCOCK: You're familiar with Exhibit 205?

A. Yes.

Q. And what is this document?

A. It appears to be a memorandum to Orvil Green from Robert Wilkosz and Tim Teater.

Q. And do you know who those individuals are, Robert Wilkosz and Tim Teater?

A. I do not know them personally, no.

Q. And this is from the Department of Health and Welfare?

A. Yes.

Q. And the subject line there says, "Request for layman's explanation of what the URF and the TLV are."

Do you see that?

A. Yes.

Q. Are you familiar with what a TLV is?
A. Yes. It's a threshold limit value.
Q. If we go down to the second paragraph. This explanation you can see there that it talks about -- in the first paragraph it talks about that the URF is used to describe the possibility of developing excess cancers over an average of a 70-year lifetime.
Is that accurate and consistent with your understanding of the URF?
A. Yes.
Q. And if we go down to the second paragraph where it says, "each URF represents months of research and often years of policy process. Teams of toxicologists gathered all the toxicological information for each known or suspected carcinogen that could be found around the world. The available data were then rated or point factored per the quality of the research. A URF then is a probability statement derived from this process."
Do you see that?
A. Yes.
Q. And is that consistent with how you understand the URF is utilized?

A. Yes.

Q. It then goes on to say, "Each URF was proposed by EPA and extensively reviewed and debated in public by scientists, health officials, and industry representatives. Every URF represents a consensus of the best science and health opinion of the potency of a given carcinogen."

Do you see that?

A. Yes.

Q. And is that consistent with what you understand is the science and the kind of beef behind the URF number or value that is adopted by the DEQ?

A. Yes. That is the basis for how EPA develops their IURs. And the IUR was adopted by the DEQ and called a URF.

Q. And they also talk about that it was protective of that sensitive subpopulation, we talked about that. But again, that's consistent with what you understood is captured in that value system; is that right?

A. Yes.

Q. Okay. And again, even since this memo was published and authored, are you aware of any changes that have been made to the arsenic numbers

in the IUR or the URF?

A. I am not aware of any changes that have been made to arsenic.

Q. And then let's do one last one here. This one will be 208.

Okay. Are you familiar with exhibit -- I could back up.

MS. HANCOCK: Can I move to admit Exhibit 205?

HEARING OFFICER LAWRENCE: Any objections?

MS. THROWER: No.

MS. YOUNG: No.

HEARING OFFICER LAWRENCE: Granted.

(Hearing Exhibit No. 205 admitted.)

Q. BY MS. HANCOCK: Exhibit 208 that is in front of you now, are you familiar with this document?

A. Yes.

Q. What is this document?

A. This is part of a series on risk assessment that EPA has published. This one deals specifically with inhalation risk assessment.

Q. Okay. Is this the one where it has the derivation of the IUR?

A. This does not have a derivation of the

IUR, but it has the calculation for exposure concentration that indicates that you do need to take into account exposure duration as well as frequency in time if that is a consideration for your project.

MS. HANCOCK: Mr. Foster, I am going to go to Page 18 of 68.

Q. BY MS. HANCOCK: While he's going there, Ms. Lopez, did the IUR consider the risks and effects to those subpopulation sensitivities even as bolstered by Exhibit 208?

A. Yes. As it states right there, that the default linear extrapolation approach, which is what was used to develop the IUR and the URF for arsenic is generally considered to be conservatively protective of public health including sensitive subpopulations.

Q. Did you read Dr. von Lindern's declaration, and he had raised some concerns about whether those children and pregnant women were factored in to consideration with the risk -- with the cancer risk probabilities?

A. Yes, I read his statements.

Q. Is that accurate given your experience with what the IURs capture and the data sets that

we've just looked at in these documents?

A. It is not accurate.

Q. And do you have any concerns that the IUR or the URF lacks in consideration of any of the subpopulation groups with specific sensitivities?

A. No. As stated by EPA it does not.

Q. Okay.

HEARING OFFICER LAWRENCE: Could you repeat that question and answer.

(The requested record was read.)

HEARING OFFICER LAWRENCE: Thank you.

Q. BY MS. HANCOCK: Okay. Let's look at Page 22 of 68.

Do you see equation six --

A. Yes.

Q. -- in Exhibit 208? Are you familiar with what this equation measures?

A. Yes. This equation directs how to calculate an exposure concentration from a contaminate concentration in air.

Q. And we just heard from the DEQ's expert toxicologist and she performed a calculation. Is that where these value systems come from?

A. Yes. I believe that's exactly the same equation she had in her statements.

Q. Okay. And so this is a valid methodology to use as a toxicologist for evaluating and including consideration of that exposure duration?

A. Yes.

Q. In your experience does the exposure time matter for any kind of carcinogen?

A. Yes, exposure duration always matters. That is why it is in the equation, that you do have to take that into account. And you have to take into account as well the lifetime in years. That is in the denominator of equation six.

Q. And when you say "the denominator," what is the code that is reflected up there that would capture that?

A. AT, average in time.

Q. And the average in time would mean that as a denominator you saying how much actual exposure is in the numerator and then total possible exposure is in the denominator?

A. The averaging time takes into account the lifetime exposure of exposure because that is how the IUR is developed, it is developed to be protective of a lifetime of exposure. So when your exposure duration does not equal 70 years, you have

to adjust for that in the numerator of the equation.

Q. Thank you. So the lifetime exposure goes in the denominator and then the actual exposure time goes in the numerator?

A. That's correct. And as you can see in here, the other adjustments that they direct you to do are 365 days a year, 24 hours a day. That is the standard in the denominator. If you have any variations of those, you could take those into account as well in the numerator.

Q. So we might come back to this in a few minutes when we do our calculations. But it's critical for what you just said that when you're looking at a lifetime exposure, it is lifetime exposure based on 24 hours a day, seven days a week, 365 days a year?

A. Yes.

Q. And so when you're looking at the numerator, the actual exposure, you want to measure the same 24 hours a day, seven days a week, 365 days a year?

A. You do if that is the maximum exposure that you believe will occur in your project. It can be less, obviously.

Q. And maybe we will do the spoiler now.
A. Sure.
Q. If someone was going to have less days of the year, for example, they celebrate holidays, there's weather events that might not let you operate. How would you account for that in both the numerator and the denominator to make sure you are measuring the same?
A. The denominator doesn't change, but the numerator does change. You would have fewer days per year or perhaps fewer hours per day depending on what that difference is. And then the exposure duration is again the length of the exposure, how many years can you be exposed at this project, at this site.
Q. Okay. So we will come back to that when you do your calculations in just a minute.
I want to turn to the AACC. Can you tell me what the AACC is?
A. It stands for ambient annual cancer concentration I believe, or contaminant concentration. It is a term in the statutes of IDEQ.
Q. Under Section 586 in particular to this?
A. Yes.

Q. How does that relate to the IURs or the URFs for purposes of your calculations as a toxicologist?

A. It is a one in a million risk divided by the IUR to come up with an ambient air concentration to which one could be exposed every day for 70 years without exceeding an excess cancer risk of one in 1 million.

Q. And in this case we have -- you understand that we had -- Perpetua had opted for the T-RACT controls that lowered the cancer risk probabilities to one in 100,000.

A. Yes.

Q. So how do you convert -- make that same calculation using the IURs with respect to the T-RACT numbers?

A. You would use the risk of one in 100,000, which is one E to minus five, divided by that same URF. And then you could come up with an AACC concentration that is ten times higher than the AACC concentration at one in 1 million.

Q. Okay. And we just heard the DEQ's toxicologist perform her calculation utilizing the actual exposure as compared to the lifetime risk exposure under the AACC.

Did you perform a similar calculation?

A. I did.

Q. Okay. And is that the right calculation to perform?

A. Well, the right calculation to perform is this one to come up with an exposure concentration to which you can compare a risk-based screening concentration. Or you can use the IUR to multiply by the exposure concentration as it is shown up there, and that will give you the risk, the lifetime risk.

Q. And did you perform that same calculation with respect to Perpetua's mining permit?

A. Yes.

Q. Actually, how many calculations did you perform?

A. I performed at least three. There are several different ways you can rearrange both the published AACC or the exposure concentration calculation and you will arrive at the same conclusion, which is that the risk should be the same.

Q. And so when you say you performed three different calculations, it is not to get three

different results, is it?

A. No. No, it is to confirm that no matter how you look at it you are coming up with the same answer.

Q. And do you perform those three different calculations so you can verify that the other calculations were performed correctly?

A. Yes.

Q. Okay. So tell me about the first calculation that you performed. And if we want to cross reference it, it is on Page 8 of your declaration, which is Exhibit 201, Paragraph 24.

A. Yes. So this calculation took the exposure, the CA, contaminate concentration in air, which was the emissions from the mine, multiplied it by 24 hours a day, 365 days a year, for 16 years, and then divided by the averaging time in years to develop an exposure concentration that is equal to .00095.

Q. Okay. How did you know to use 16 years as the actual exposure duration in this calculation?

A. Well, using the maximum emissions rate that was developed based on the maximum production of the mine, that would deplete the source in

16 years and that's as long as it could happen. It can't happen beyond the source being removed. So at the maximum emissions for 16 years, that's why I used the 16 years. At that point the source is depleted and there could be no more emissions.

Q. Okay. I want to back up and make sure that we have clear on the record each one of those elements.

You understand that this permit contains a condition that limits the total production that could come out of this mine to approximately 788.4 million tons?

A. Yes.

Q. And so no matter what Perpetua wants to do, they can't pull any more ore out of the ground under this permit other than that amount.

A. That is my understanding.

Q. Okay. And then you also understand that there are permit conditions under this permit that limit how much production they can take on a daily basis; is that right?

A. Yes.

Q. And it's approximately 180,000 tons a day; is that right?

A. That's what I understand.

Q. And so no matter how much they want to take out on a daily basis and how many crew members they have or how many tools they have, they can't take out more than what the permit condition allows at approximately 180,000 tons a day?

A. Yes. That is my understanding that the permit has limits in it.

Q. And then you also understand that on a five-year rolling average, that they cannot average more than 135,000 tons per day on that 5-year rolling average basis?

A. Yes.

Q. And so no matter how much they want to take 180,000 tons a day every day, at some point in a five-year period they have to start tapering down in order to make sure they hit those averages; is that right?

A. Yes.

Q. And you calculated if the mine operated 24 hours a day, seven days a week, taking out the maximum capacity that they could take using that five-year rolling average, that they would take 16 years to deplete the production limits that were allowed under that permit; is that right?

A. Yes. Those are the numbers that I

confirmed before doing my calculation.

Q. And you came up with -- if you do that full calculation, if we look ahead to your Paragraph 28, what was the cancer risk that's presented by that total production limit and that total mine operation under the permit?

A. At limit the concentration is .0095, that is the exposure concentration. You can compare that to the T-RACT AACC by dividing it, and that represents a risk that -- well, you multiply it by one in 100,000 to estimate the risk associated with the .00095.

Q. Okay. So if the mine operates around the clock every day of the year for 16 years straight, what is the cancer risk that is being emitted by those mining operations? What's the actual value that you calculated?

A. The actual risk is four in a million or approximately one in 240,000.

Q. Okay. And that is what you have in Paragraph 28 of your declaration?

A. Yes.

Q. And that one in 240,000, we compare that against the T-RACT cancer risk probability of one in 100,000, and the mining operation is less than

that?

A. Yes.

Q. Approximately two and a half times less than that?

A. Yes.

Q. And if we did that on a percentage basis, do we know what that works out to be?

A. I believe we saw earlier that it works out to be about 40 percent.

Q. Okay. And when you say "earlier," that's because the petitioners had put in Exhibit 303 and it showed that there was -- 301, excuse me, it showed it was 41.3 percent; is that right?

A. Yes.

Q. Okay. And so 41.3 percent you understand means of the cancer risk probability that you have to stay under, in the worst case scenario operating every single day for 365 days a year for 16 years straight, you have taken every ounce of ore out of the ground that you are entitled to take under this permit, you have only used up 41 percent of what that cancer risk probability would be; is that right?

A. Yes.

Q. And we did have some questions earlier today, well, what happens if we build in a 16-year limitation into the permit? And obviously under this example that we've looked at, we have looked at kind of worst case scenario where you are operating in the most concentrated, shortest duration of time to evaluate that cancer risk.

Does that mean it is realistic to think you can get all the ore out of the ground in that 16 years?

A. If the exposure -- the concentration in air was calculated using maximum production and maximum everything and that was going to take 16 years, if you're changing the 16 years and you're not taking out as much every year, then the concentration in air goes down, the emissions go down, which would maybe increase how long it would take to pull it out. But that final calculation would still be the same because you would have a certain concentration that accumulates over a certain amount of time and that is tied to the extent of the ore body.

Q. So for example, of that 24/7, 365 days, if they operated at 50 percent of that, you take into account that there is shift work or holidays

or weather events or whatever life happens that allows you to not work every day all day long, if they were working at 50 percent of that, does that mean that the emissions would be proportionately less because your production is proportionately less?

A. Yes.

Q. Okay. So in other words, it doesn't matter if you spent a longer period of time in order to take the same amount of the production limits that are currently in the permit, it doesn't matter if you took longer to get them out, it doesn't change your risk factor or your risk calculation?

A. It does not change the risk because it does not change the cumulative exposure concentration.

Q. At the risk of being a little bit cumulative here, I am wondering if you can use our white board and do a calculation for us to show that. And I know you have worked one up for us, so either you can do it live or you can use the one we've already worked up and walk us through it. Whichever you prefer.

A. I am happy to do either one. If people

want to watch me do math on the fly, I will do it from scratch.

MS. THROWER: Ms. Hancock, I am just wondering how we can have Bryan see this.

MS. HANCOCK: We can take a picture of it and send it to Bryan.

Bryan, can we take a picture of it and e-mail it to you?

MR. HURLBUTT: Yeah, that's fine.

MS. HANCOCK: So Bryan, we will mark that as Exhibit 220.

MR. HURLBUTT: Okay.

Q. BY MS. HANCOCK: Ms. Lopez, do you want to walk us through this calculation?

A. Sure. The one at the top is the T-RACT AACC, .0023 micrograms per cubic meter per year. And it is assumed that there would be a 70-year exposure because this is based on the URF, which is the 70-year lifetime exposure. The total exposure concentration, the cumulative exposure concentration over 70 years would be 0.161 micrograms per cubic meter. And that is represented by the URF and AACC for T-RACT. And this is at one in 100,000 risk level.

So if you took the maximum production of

the mine, which here I put is .00414 micrograms per cubic meter. This is the maximum emission based on the maximum daily production limit which is what is presented in the permit. 16 years is the number of years until the production limit of the mine is reached. That is the 74 -- I'm sorry, I don't have the number off the top of my head. But the limit of production of the mine based on the ore reserves.

This calculation gives you a cumulative dose over that time of .066 micrograms per cubic meter. So you can see this is below this already. If you --

Q. When you say "this," you mean? Just for the record.

A. I'm sorry. The T-RACT AACC cumulative dose is higher than the dose for exposure to the life of the mine based on production limits.

If you were to take .066 divided by .161, which is the T-RACT AACC cumulative dose, you would come up with a risk that is equivalent to four in a million or one in 240,000. That is one other way to check that the calculation was done correctly.

There were earlier questions that were

brought up about well, what happens if the life of the mine goes longer. And this is the interaction between exposure concentration, emissions rate, and the amount of time that it takes.

If you drop down production 50 percent, let's say for whatever reason, that would have a concurrent drop in the concentration, the exposure concentration. And then that would happen for 32 years, at which point you would still end up with a cumulative dose that is the same, .066.

Q. And in that example that you just walked through, that is at 50 percent production rate; is that right?

A. That is. Because if you're 50 percent production for the emissions, it's going to take you twice as long. But the end result is that you still have the same cumulative dose for your lifetime.

Q. So even if you took 32 years, because you have the lower dose, you're still at a risk level of one in 240,000?

A. That's correct. You can't decrease this without increasing this and vice versa.

Q. And this is really kind of the inverse of what you were doing with the 16 over 70

calculation to begin with. You're just looking at the worst case scenario, the most concentrated amount of mining operations that's going to pull out the most emissions in the shortest amount of time; is that right?

A. Yes. It's my understanding that this had to be calculated on the worst case maximum scenario for mine production.

Q. Okay.

MS. HANCOCK: We would move to admit Exhibit 220 into the record.

HEARING OFFICER LAWRENCE: Any objections?

MS. YOUNG: No.

MS. THROWER: No.

HEARING OFFICER LAWRENCE: Admitted.

(Hearing Exhibit No. 220 admitted.)

MS. HANCOCK: I was just going to also move to admit Exhibit 208 as well into the record, which I think is the last exhibit I need to have admitted. This is the risk assessment, the 2009.

HEARING OFFICER LAWRENCE: Any objections to admitting that one?

MS. YOUNG: No objection.

MS. THROWER: No.

HEARING OFFICER LAWRENCE: Okay. It is

admitted too.

(Hearing Exhibit No. 208 admitted.)

HEARING OFFICER LAWRENCE: Can I ask the question while we have this stuff in front of us?

So I totally get the sort of inverse relationship between duration and exposure concentration and how one goes up and the other goes down and you get the same number.

My question is about, can you summarize for me the science behind that mathematical assumption that the cancer risk doesn't change because the lifetime exposure is the same no matter what you are doing with time and concentration?

THE WITNESS: Sure. Exposure to a higher concentration for a shorter amount of time is the risk equivalent of a higher -- lower concentration for a longer period of time. That is stated in one of EPA's documents. I can point that out to you. But that is the relationship. It is the cumulative dose over a lifetime.

HEARING OFFICER LAWRENCE: Right.

THE WITNESS: In this case the cumulative dose is related to how long the source is there. And that would be 16 years at this production rate. It could be longer if it was a lower production

rate, but the end result is that the cumulative dose does not change.

HEARING OFFICER LAWRENCE: That would be helpful, I think, if I can lay eyes on that EPA document that you referenced.

Is that in one of the ones you have already admitted?

THE WITNESS: I don't think you have admitted it. I don't know. EPA 2005.

MS. HANCOCK: We do have the 2005 EPA document. Perhaps what we can do is grab it on a break, and then can we come back to that one?

HEARING OFFICER LAWRENCE: Yes.

MS. YOUNG: I apologize for interrupting. I would request a break here soon. Maybe this is a good time to take a quick break? I apologize it's in the middle of testimony.

MS. HANCOCK: That's okay with me.

HEARING OFFICER LAWRENCE: How long makes sense?

MS. YOUNG: 15 to 20 minutes.

HEARING OFFICER LAWRENCE: Let's do 20.

(Break taken from 3:24 p.m. to 3:49 p.m.)

HEARING OFFICER LAWRENCE: So as we left off, as I recall, we were doing direct of Ms.

Lopez, and then there was this issue that I asked about a particular document that isn't currently attached to any expert declarations.

Is that right?

MS. HANCOCK: That is correct. It is the 2005 EPA document. We are having hard copies brought over so everybody will have a hard copy. But we will mark it as Exhibit 221 and we will just look at it electronically for right now, if that is okay with everyone, and then you will have a hard copy by the end of the day.

Q. BY MS. HANCOCK: Ms. Lopez, you have to tell us which page to go to.

A. It is Page 10 of Appendix A.

Q. What are we looking at here in this document?

A. This is one of several guidance documents from US EPA and this is the guidelines for carcinogen risk assessment, so it lays out the foundation of how you evaluate carcinogens in a risk assessment.

Q. Okay. And earlier when we were looking at Exhibit 203, that was the 1984 document, you specifically said that is not a guidance document;

is that right?

A. That's right.

Q. Is this one an actual guidance document?

A. This is a guidance document, yes.

MS. HANCOCK: I don't remember if I said this on the record, but we will have this as Exhibit 221.

Q. BY MS. HANCOCK: If we can go to Page 10, did you say?

A. I think it is A-10. It is Page 10 of Appendix A.

Q. And the hearing officer had asked for -- you had described the science when we were talking about Exhibit 220 and if there is a lesser dose or exposure over a longer period of time that is the same as having a higher dose on a shorter period of time.

A. Correct, that was the question. And I think this speaks directly to it from US EPA, that absent data to the contrary, the default assumption is that the cumulative dose received over the lifetime, which is what that .066 would be, it is an appropriate measure of dose or exposure. This assumes that a high dose of such an agent reached over a shorter period of time is equivalent to a

low dose spread out over a lifetime.

And this is speaking as to how the IUR can be used in either way but you do need to take into account exposure duration as well as the concentration to which one is exposed.

Q. And so in this situation, once Perpetua had done its modeling work and determined the maximum emission of arsenic from the mining operations, we know what the dosage amount would be; is that right?

A. The maximum emissions concentration based on maximum production limits for 24 hours a day, 365 days a year, would take 16 years to reach production limits and that is how you come to the cumulative dose of .066.

Q. And having a production limit of 788.4 tons in the permit as a condition of the permit, is that what provides the cancer risk protection in this permit to make sure that the emissions from this mine are in conjunction with the daily limitations of productivity, is that what provides the protection to ensure that there 's never a greater cancer risk posed by this mining operation than the one in 100,000?

A. Yes. Because it limits the amount of

emissions cumulatively until you reach the production limit.

Q. So you can produce less on a daily basis and go a longer period of time and still stay within those exact same calculations that you performed, which would mean one in 240,000 risk probabilities for developing excess cancers as compared to the T-RACT controls?

A. Yes, because the cumulative dose would not change.

Q. Based on your math and your analysis of the calculations that the DEQ toxicologist performed, is the adjustment factor creating a misleading risk analysis that would underestimate the actual cancer risk from this project?

A. No. The method used is completely in line with EPA guidance documents that are not specific to this project, they are not specific to Idaho. They are the standard of practice that EPA sets and they were developed completely outside of this particular process.

Q. And just said more basically, is anyone slicing and dicing these numbers or looking at this permit in a fancy way or creative way that is trying to disguise or hide the actual cancer risk

that is being presented here?

A. No. This is how the science is done. This is the methodology that is required under the guidance documents in conjunction with the use of an IUR or URF.

Q. And is this calculation that you performed, is this settled science in the toxicology field?

A. Yes.

Q. Is this unique to Idaho or is it done beyond Idaho?

A. It is done beyond Idaho. It is not unique to Idaho and it is used throughout the United States.

Q. Okay. Would it accurately reflect the cancer risk presented by this mining permit with the conditions that are in the mining permit if this project were evaluated on a 70-year lifetime exposure?

A. The 70-year lifetime exposure is the basis for the IUR, so you do have to adjust the concentration in air by the exposure duration in order to make an appropriate comparison between an exposure concentration and a dose based on what your exposure concentration is.

Q. And if you didn't make that actual exposure duration calculation, would it be an accurate reflection of the cancer risk that is presented by this mining permit?

A. No, it would not.

Q. Do you believe that DEQ accurately and properly considered the risk from the emissions from the SGP mine?

A. Yes.

Q. And you had the opportunity to read Dr. von Lindern's declaration; is that right?

A. Yes.

Q. And is the effect of -- do you have an opinion as to what the effect is that he's advocating in his declaration as to how this should be calculated?

A. There is quite a bit of discussion in there that regards different life stages as to when someone might be exposed to it and that it might have longer reaching effects than if an adult is exposed. All of those goes to something called a mutagenic mode of action.

Arsenic, I think actually as Dr. Paden showed in her calculations, is not considered to have a mutagenic mode of action, so that adjustment

for that early life stage exposure is not necessary.

But even if it were necessary, as it is considered for other chemicals, that is done actually in the exposure duration.

Q. And have you calculated what his methodology would represent in a value form as compared to the one in 100,000 T-RACT controls?

A. I did not reperform whatever he was trying to do.

Q. Okay. In your professional opinion, would his methodology overestimate the cancer risk value system that would be required by the AACC?

A. Yes. His approach overestimates the risk associated with arsenic in air.

Q. And so it would make it more stringent than what's required under the AACC or under the T-RACT as well?

A. It seems to me that his interpretation disregards the fact that there is a lifetime exposure, but -- I'm sorry, there is a lifetime averaging time but there is not a lifetime of exposure duration.

Q. And if we look at Paragraph 39 of your declaration in Exhibit 201. It is on Page 11 of

your declaration. We had talked earlier about the multiple ways in which you performed a calculation. You have one here in Paragraph 39.

Can you describe what you're calculating in Paragraph 39?

A. Yes. If you took the T-RACT AACC of .0023 that is equivalent of lifetime cancer risk of one in 100,000, and you assume that that has to be met every year, you're actually looking at a risk that is equivalent to one in 7 million. And that's because that AACC assumes that you will be exposed at that concentration for 70 years. So if that is not going to be met, then you have to adjust for the exposure duration, which is a shorter amount of time. So that's what I was discussing there.

Q. Okay. So rather than one in 100,000 as required by the T-RACT, it would apply a new incremental benchmark of one in 7 million?

A. Yes.

Q. You say in Paragraph 41 of your report that the T-RACT AACC represents the chemical-specific airborne concentration at which the risk to an individual, if exposed all day every day for a lifetime, would be one in 100,000.

Would any other interpretation define

fundamental toxicological science used by the EPA in the development of the IURs?

A. Yes, it would.

Q. Okay. I want to talk about the five-year rolling average for a moment.

HEARING OFFICER LAWRENCE: Ms. Hancock, can I jump in with a quick question?

MS. HANCOCK: Sure.

HEARING OFFICER LAWRENCE: Ms. Lopez, on the one in 7 million risk in Paragraph 39. Can you for me just sort of articulate in general terms how protective that's considered in the toxicological world? Are there other times when that one in 7 million would be considered too risky or is that considered pretty safe in just about all contexts?

THE WITNESS: That would be considered safe in about all contexts because again it is an incremental risk. And I think as Dr. Paden spoke to earlier, the risk range that you regulate to is between one in 10,000 and one in 1 million. So this is seven times below 1 in 1 million and that is because it is looking at a risk per year. Cumulative risk, cumulative dose, so that is why it is one in 7 million.

HEARING OFFICER LAWRENCE: All right. Thank

you.

Q. BY MS. HANCOCK: So in other words, seven times higher than what even any of the experts would put in the range of risk analysis?

A. Seven times lower. It is one in 7 million as opposed to one in 1 million which is considered the lower end of that range.

Q. Okay. Let me fix that. In other words, it would be seven times more stringent than the most current stringent standard?

A. Yes.

Q. Okay. And in this situation we're actually -- it is even more extreme because we are comparing it to the T-RACT which would be one in 100,000 is the upper limit within which we have to make sure we don't operate to create a cancer risk; is that right?

A. Yes.

Q. If we turn now to the five-year rolling average. Just at a high level, what is your conclusion as to whether a five-year rolling average production limit ensures that the production from the mine will not exceed the cancer risk at any point of time in that five years?

A. The five-year rolling average allows for

production changes that can happen on a daily basis because of I'm sure many numerous work site conditions that would prevent a maximum production from happening.

But whether it is five years or six years or the full 16 years, in the calculation that IDEQ did, they assumed a maximum emission that could happen for 16 years until the production limit is reached, which is a worst case scenario. And the cumulative dose is then .066. And that will carry an incremental lifetime cancer risk of one in 240,000, which is below the T-RACT standard.

Q. If we could pull up Dr. von Lindern's declaration. I don't know if he is -- if we have a number assigned to it?

MS. THROWER: No, not yet.

MS. HANCOCK: Do you want a number assigned to it?

MS. THROWER: Sure.

(Hearing Exhibit No. 302 marked.)

Q. BY MS. HANCOCK: If we look at Dr. von Lindern's declaration, I would like to turn to Figure 1.

HEARING OFFICER LAWRENCE: How many pages in is that?

MS. HANCOCK: It is on Page 12.

Q. BY MS. HANCOCK: You've had an opportunity to look at Dr. von Lindern's Figure 1; is that right?

A. Yes.

Q. And have you been able to make sense of what you understood Figure 1 to be?

A. I don't necessarily agree with his labelings there, but I think what he was trying to do is graph continuous exposure to the AACC for 70 years. That's what that diagonal line would represent. He has it marked as cumulative risk, but it could also be seen as cumulative exposure, cumulative dose.

Q. Okay. And maybe at the most basic level, does duration of exposure matter in your world, duration of exposure to a carcinogen?

A. Yes, it does matter. And I think this figure shows that it does. Because as you can see, although he has it labeled age and years, I would call that exposure duration. That at 16 years of exposure the risk is two in a million. It doesn't continue on if the exposure stops. That's where the risks would stop.

Q. Okay. So if we look at 16 years of

exposure, we can see there's actually arrows that point to where on that line where the risk would be; is that right?

A. Yes.

Q. And the orange line up top, that is what you understood would be representative of that one in 100,000 T-RACT number?

A. Yes.

Q. So we can see that if it is at 41 percent, which we have looked at other numbers in your calculation of one in 240,000 gets us about the same number, we are well under what would actually be the actual cancer risk in the T-RACT; is that right?

A. That is right. Because that one in 100,000 orange line across the top is the limit of risk. And the risk is four in a million, so that would be at that four in a million stage, what he has here is the AACC. But if you were to put the project-specific exposure concentration in, it would be, at 16 years, it would come up to about the 4 E to the minus six line. It then would continue straight across to the end. It would not continue on diagonally, it would end and go straight across.

Q. Because as we just talked about with a limit on the production limits, there is no more emissions and so no more greater risk being presented by this project; is that right?

A. That's right.

Q. So even after the 16-year life of mine, you wouldn't continue up the exposure line?

A. No, you would not.

Q. If we turn to your declaration, at Figure 1. And this is in your attachment, so for electronically it is Page 18 of 42. Or Page 4 of her Attachment A.

Do you have a similar slope that you have reflected here?

A. Yes. This figure came from the EPA 1984 document. It is one of several that they have in there. And this showed how they did the linear extrapolation to develop the IUR. This one is specific to this study that they looked at. But it is that same slope of the line that you can see on the X axis on the bottom, that the cumulative dose increases the risk, which is on the Y axis, over the course of years.

Q. Okay. And what does this figure tell us about the risk that's presented here? How would we

read this in relation to this permit?

A. That the risk increases with dose, but that dose is cumulative. And once you've hit that total cumulative dose that is related to the production limit, that the risk stops and that would be it, so it wouldn't appear on this line.

But this is -- it's the same concept that was in Dr. von Lindern's Figure 1, that it is linear, it is related to exposure duration, and it is related to cumulative dose.

Q. Just in summary of all the things that we've been talking about, does the permit issued by DEQ present an unacceptable risk as governed by the regulations?

A. No. Because the cumulative risk is about four in 1 million, which is below the standard risk that they were using.

Q. And from your professional judgment as recognized toxicologist expert in this matter, does DEQ's permit analysis ensure that the mining operations will operate in a manner that will not present any excess cancer risk as compared to the T-RACT probabilities?

A. Yes. Their analysis shows that the cumulative incremental cancer risk will be below

that specified in the T-RACT.

Q. Okay.

MS. HANCOCK: That's all the questions I have.

HEARING OFFICER LAWRENCE: Okay. Ms. Young, do you have questions?

MS. YOUNG: I don't have any questions, no. Thank you.

HEARING OFFICER LAWRENCE: I'm sorry, I forgot about the issue we were talking about before, about witness tomorrow. Do we need to do anything on that?

MS. YOUNG: We do, but I haven't had a definitive answer.

MS. THROWER: I wanted to confer with Bryan before I decide for both of us.

HEARING OFFICER LAWRENCE: I just wanted to make sure I wasn't forgetting something.

MS. THROWER: I will do that when we are done here.

MS. HANCOCK: I think now that we have the hard copy exhibits, if we can pass those out, and then I would like to formally move to admit Exhibit 221.

HEARING OFFICER LAWRENCE: Okay. Anybody

object to that?

Okay. It is admitted.

(Hearing Exhibit No. 221 admitted.)

MS. THROWER: We are going to deal with cross-exam the same way we did with Dr. Paden. Bryan may have a question or two in follow up.

HEARING OFFICER LAWRENCE: Okay.

CROSS-EXAMINATION

BY MS. THROWER:

Q. I just wanted to go through and start with your background. So are most of your risk assessments for contaminated sites?

A. The risk assessments I have done range from contaminated sites to I have done some permitting. They are all forward-looking in the sense that you have a particular situation and then you project the risk forward.

Q. Okay. And did you say you did some risk assessments for permitting?

A. I have done some, yes.

Q. Was that in Idaho?

A. It was not in Idaho.

Q. And when you say you did risk assessments that are forward-looking, exactly what

do you mean in terms of are there different factors to consider or I guess can you explain that a little better?

A. Sure. You take the chemical concentration in whatever media you are looking at and you estimate what would happen, what would be the risk, what would be the hazard if someone is exposed to that concentration for a certain exposure duration for a certain exposure time, if it is for cancer over a lifetime, and come up with your risk. So it is all looking forward, it is not looking backwards into the population.

Q. Okay. And is it forward-looking in terms of potential other sources for that same carcinogen that that same receptor might experience?

A. Well, no. Most of them don't need to take that into consideration because you are looking at a site and you are looking at full exposure to that site. Some of the risk assessments I have done on consumer products do take that into consideration, but that is a different regulatory framework, if you will.

HEARING OFFICER LAWRENCE: Ms. Lopez, if you could speak up a little. Since you are facing that

way I am having trouble hearing you.

THE WITNESS: Sure, I'm sorry.

Q. BY MS. THROWER: So what other factors aside from exposure duration do you consider in your risk assessments?

A. It depends on the risk assessment. It can be exposure time. It can be exposure frequency. Exposure time is the hours per day. Exposure frequency would be days per year. Exposure duration is the number of years. There can be other considerations in there such as an intake rate for inhalation, it would be the inhalation rate. If you are going to figure out the actual dose you are going to need the body weight as well. So those are some of the factors that could be taken in.

Q. Did you consider any other factors other than this exposure duration for this permit?

A. Well, the calculation assumed a 365-day-per-year exposure frequency and a 24-hour-per-day exposure time, so those were taken into account as directed by EPA to do a risk calculation.

Q. But no body weight. For instance, I assume body weight is taken into account for

exposure to children versus an adult?

A. It would be if we were looking at a different kind of assessment. But IURs are based on exposure concentration and not a dose.

Q. If you could turn to your declaration. I want to go ahead and look at Page 2. Maybe I meant to look at your memorandum.

Let's go to your memorandum that is attached to your declaration, Page 2. That is ERC4292.

So can you read the third bullet point there under -- you have a paragraph that starts, "This memorandum supports my expert opinion on the first two issues." Can you read that third bullet point?

A. Yes. "This memorandum addresses the use of a short-term adjustment factor provided for in IDAPA210.15 of the air rules allowing a ten times adjustment to the AACC for short-term projects. This is an example of the use of exposure duration and risk assessment. And the adjustment for exposure duration in other risk assessments is also appropriate."

Q. Okay. So you state in that bullet point that the use of short-term adjustment factors

provided for in 210.15.

Can you explain where that is in 210.15?

A. Sure. They are discussing an adjustment to the AACC based on a short-term exposure, short term there meaning five years versus 70 years, which is consistent with what the EPA would do to incorporate an exposure duration into an exposure concentration.

Q. So when you say five years, this is what we've been referring to as the short-term source adjustment provision?

A. Yes.

Q. And so your understanding is that that short-term source provision allows a ten times adjustment to the AACC in Section 586; is that correct?

A. No. What I'm saying there is that these regulations do recognize that there is a difference in exposure duration that has to be taken into account when you are evaluating risk.

Q. Okay. And do you see anything in the regulations that take into account doing exposure adjustments to look at risk for anything that is planning to operate for more than five years?

A. It does address, and I'm sorry I don't

know the exact number, but it does address taking into account project-specific considerations. So yes, I do believe it is in there.

Q. But you can't point to anything right now?

A. Section 210.12 maybe. I don't have the regulation in front of me, I'm sorry.

Q. Do you want me to pull that up or do you know if that is the exact provision or you're not sure? I don't want to scroll through the entire rule. I don't think anyone wants it at this point.

Okay. That's fine.

So let's look at the last paragraph on Page 2 of your memorandum. Can you just read that first sentence of that last paragraph, please?

A. The one that starts "Based on my review"?

Q. Yes, thank you.

A. "Based on my review of the relevant documents, in my opinion the foundation of the TAPs rule is consistent with the scientific principles underlying dose response assessments that are established by EPA. IDAPA586 reflects EPA risk assessment methodology that prompts adjustment of the exposure duration to assess the dose response

risk assessment properly."

Q. So what specific documents did you review that established the foundation of the TAP rules for you?

A. Well, the foundation of the TAP rules are the IURs that came from the US EPA. If you were going to use the US EPA, the toxicological values, you have to adopt the EPA guidance documents that regulate how they are to be used.

Q. Okay. Is there any documents that lay the foundation for using exposure duration adjustments that were ultimately incorporated in the rules?

A. Well, by adoption of the IURs you have adopted how they are going to be used. And EPA directs, in EPA 2009, I think, is the one we showed, also in EPA 1989 that was introduced earlier, and several other guidance documents, how they are to be used.

Q. So we've talked about the TAPs being an incremental standard.

What is your understanding of an incremental standard?

A. I don't believe we've agreed that they are an incremental standard. They are an

incremental unit and it is based on risk.

Q. Okay. So what does it mean for you when it's an incremental -- like the term "incremental," what does that mean to you?

A. An incremental risk over that that would be experienced otherwise in life.

HEARING OFFICER LAWRENCE: Ms. Thrower, now I am having trouble hearing you.

Q. BY MS. THROWER: So on Page 5 of your memorandum, you talk about the IRU as an incremental risk considering unrelated risk present over a lifetime.

Do I have the right page?

A. I'm not sure.

HEARING OFFICER LAWRENCE: While she is looking for that, can someone remind me what particular document we are in right now?

MS. HANCOCK: Exhibit 201.

MS. THROWER: It is her declaration. And I am trying to figure out if this is from the declaration itself or if it is in the memorandum that was attached.

Q. BY MS. THROWER: So in Paragraph 22 of your declaration, you start to discuss the same formula from the EPA superfund guidance that

Dr. Paden discussed, correct?

A. Yes.

Q. And again that formula is from the EPA superfund risk guidance?

A. Yes. This is from EPA2009 that is the guidance for the superfund.

Q. And you use the same number, very close to the same number. I think you and Dr. Paden differ by the last digit there, but it's neither here nor there at this point. But you use the same number that Dr. Paden did to calculate your excess risk, cancer risk; is that correct?

A. I used, yes, the same concentration.

Q. And you also call that the highest model annual arsenic concentration; is that correct?

A. Yes.

Q. And did you just obtain that number from Perpetua or DEQ?

A. I was provided it by Perpetua.

Q. So you didn't do any calculations on your own to derive that maximum concentration?

A. No, I am not an air modeler.

Q. And you're not familiar with how the number was derived?

A. I did ask how the number was derived,

and it was derived on maximum production to come up with the maximum emission rate.

Q. Okay. Do you understand it is a five-year rolling average?

A. Yes.

Q. Okay. Obviously from your declaration you talk about that.

Is a five-year rolling average necessarily going to be a maximum emission rate?

A. Under what timeframe?

Q. Annual.

A. No. It is a five-year rolling average.

Q. I want to go to Paragraph 39 of your declaration. And I just want to go through the second sentence where you state, "if the T-RACT AACC of .0023 micrograms per cubic meter for arsenic were based on a one-year exposure then the risk presented by that value was about one in 7 million."

Can you explain how you got that calculation?

A. Yes. You take the .0023, multiply it by one year, and divide it by 70. And the resulting number has to be multiplied by 1 E minus five, sorry, it is one in 100,000, since the T-RACT AACC

of .0023 is based on a one in 100,000 incremental lifetime risk.

Q. So this would be an analysis you would do to get this lifetime risk if your source was only planning to operate at one year?

A. Well, you would take the concentration that the project gives you that they're going to produce. I wouldn't take the AACC. This is the risk associated with that AACC for one year.

Q. I apologize. Let's say they are maximum emissions equalled to that AACC?

A. Yes.

Q. Then your cancer risk assessment or calculation here of one in 7 million this is basically based on if this was a one-year project?

A. Yes.

Q. So under the air rules, again we talked about the short-term sources that operate for five years or less having this exception. For a source operating for six years or more -- and Mr. Hurlbutt asked Dr. Schilling about six-year sources. For a source operating six years or more, would they be able to go through this T-RACT AACC provision under this exposure duration theory using an adjustment of six years over 70?

A. I think that would be up to IDEQ. I think if you do that you have to accept a limit on your project.

Q. So presumably if a source was only operating over six years, all the emissions would occur in that six years. I understand under the exposure duration adjustment you spread those out over 70 years.

But in the case of someone in the area for six years, let's say a child, is loading a lifetime risk of arsenic exposure within six years the same risk for a child as it is for an adolescent or adult?

A. According to EPA's methodology and their toxicity values, yes.

Q. Okay. And Section 586 specifically says that the AACCs are annual averages.

What's your basis in Paragraph 37, why don't you turn to that, where you state "the AACCs are not annual average air concentrations limits or standards."

What is your basis for making that statement?

A. The AACCs are an inverse based on the risk of the IUR, and they are a risk-based

concentration that represents a concentration that a person could be exposed to 24 hours a day 365 days a year for a lifetime without exceeding a risk of one in 1 million if we are talking about the AACCs or one in 100,000 if we are talking about the T-RACT AACCs.

Q. And just above that in Paragraph 35 you said that, in the second sentence in Paragraph 35 you say that "omitting this adjustment," the exposure duration adjustment, "is contrary to common scientific practice and the intent of the air rules as reflected in DEQ documents."

And I added a couple of words there because I think there was just a little bit of typographical error there.

You attach to your memorandum, you attach A, an Idaho DEQ 1992 and 1993 documents. So if we could turn to that document.

MS. THROWER: Bryan, can you pull that one up on the screen? So that's RE4405. And this is not one of the attachments that was directly attached to her declaration, but it was like that big group of attachments that I think you guys sent over separately or something. I don't know.

So Bryan, if you can scroll so we're at

comment 108.

MS. HANCOCK: Do you have hard copies of it?

MS. THROWER: No. This was attached to Ms. Lopez's declaration.

HEARING OFFICER LAWRENCE: 4405, was that the REC number?

MS. THROWER: 4405, yeah.

MR. HURLBUTT: Sorry, the one displayed is the one without the REC number.

MS. HANCOCK: Maybe if we could go up to the title page just so we can orient her?

THE WITNESS: Okay.

HEARING OFFICER LAWRENCE: Title page of 4377.

MS. HANCOCK: What I am trying to figure out is if this is part of what we admitted as an exhibit.

HEARING OFFICER LAWRENCE: It is in the big binder that you guys provided to me.

MS. HANCOCK: Okay.

Q. BY MS. THROWER: So just to go back. So you said that omitting this -- in Paragraph 35 in your declaration, you state that "omitting this adjustment is contrary to the common scientific practice and the intent of the air rules as

reflected in DEQ documents."

In this document that's up on the screen, it appears that this is a response to comments during the rulemaking. And comment 108 is from a commenter from the public about that it is not appropriate for an industrial park situation, there will never be residential application. It talks about a refined analysis that should be liberalized to include different model, actual meteorological data, more appropriate risk factors, actual hours of operation, more accurate emission factors obtained.

Now, if we go down to, Ms. Lopez, if you can see the last paragraph on that page, the last paragraph that is the response to comments, first sentence? Can you read that for me, please?

A. Can you be more specific about what you want me to read?

Q. It starts with "It is not possible."

A. "It is not possible for IDHW to carve out special exemptions or emission factors for potential or hypothetical new or modified industrial sources or exposure scenarios. Our rules must take a balanced approach that is generally applicable and consistently applied."

Q. Okay. That's fine. Thank you.

Is this one of the documents that you reviewed that is the basis for your statement saying that omitting an adjustment factor is contrary to the intent of the air rules?

A. Yes, this is one of the documents.

Q. And this says that IDHW doesn't want to carve out special exemptions; is that correct?

A. That's what it says.

Q. Could those special exemptions be exposure duration scenarios?

A. No. That wouldn't be a special exemption. That would be part of the exposure concentration equation that existed even in 1993.

MS. THROWER: Thank you. I have no further questions.

HEARING OFFICER LAWRENCE: Mr. Hurlbutt, are you going to ask a few?

MR. HURLBUTT: Yes, please. I have just one line of questioning I would like to follow up with.

CROSS-EXAMINATION

BY MR. HURLBUTT:

Q. Ms. Lopez, suppose a person has already been exposed to a source of arsenic air emissions for part of their life and then they are exposed to the Stibnite Gold Project for 16 years.

Would that person's cumulative arsenic exposure be greater than if they had been exposed to just the Stibnite Gold Project?

MS. HANCOCK: I'd object. That is outside the scope of what we are talking about here. We are purely talking about excess cancer rates within the permit limitations here.

HEARING OFFICER LAWRENCE: I appreciate -- I will give a little latitude.

Go ahead, Bryan.

Q. BY MR. HURLBUTT: Do you want me to ask the question again?

HEARING OFFICER LAWRENCE: Yes, please.

Q. BY MR. HURLBUTT: Sorry, do you want me to ask the question again, Ms. Lopez?

A. Yes.

Q. So if somebody was already exposed to arsenic for part of their life and then they were

exposed for the full 16 years of the Stibnite Gold Project, would that person's cumulative arsenic exposure be greater than if they had only been exposed to the Stibnite Gold Project?

A. Their cumulative risk of exposure from the Stibnite Gold Mine Project would be exactly what is estimated. It doesn't change what somebody may or may not have come into it with. That's not what the permits do. That's not what risk assessment science does from the EPA.

Q. But would that person's cumulative arsenic exposure be greater than if they had only been exposed to the Stibnite Gold Project?

A. Are you asking me to hypothesize what their exposure may have been, what they absorbed and what they took in? May or may not be. That is not taken into consideration when EPA put out their risk assessment guidance.

Q. If someone had been exposed to, say, the same amount of airborne arsenic as the Stibnite Gold Project will cause over 16 years and then they were also exposed to the Stibnite Gold Project, their exposure would be higher, right, than if they had not been exposed to anything prior to the Stibnite Gold Project?

A. I think if you are looking at someone's cumulative exposures from every source over a lifetime then yes.

Q. Okay. And that person's risk of cancer would be greater, right?

A. I'm not sure I understand your question. These are population-based risks, so anybody's individual cancer risk depends on their individual factors.

Q. So if somebody's lifetime cumulative exposure is greater than the exposure that would occur from the Stibnite Gold Project, would their cancer risk be higher?

A. Again, that is an individual cancer risk and this is a population-based cancer risk. So their total exposure would be greater, would their individual cancer risk be greater? I can't answer that question.

Q. Okay. What if someone was exposed to the Stibnite Gold Project for 16 years. And then after that for the next 54 years of their 70-year life they were exposed to a source continuously at that AACC annual applicable level.

Would their 70-year exposure exceed the acceptable cancer risk?

MS. HANCOCK: I would continue the same line of objections. We are talking about the hypotheticals that are well outside the bounds of this permit.

HEARING OFFICER LAWRENCE: I am starting to agree, Mr. Hurlbutt. I think we have covered this topic enough, and I kind of agree that it is -- we're looking at project-based risks here.

MR. HURLBUTT: Just one final question.

Q. BY MR. HURLBUTT: The risk analysis you performed did not factor in the possibility of somebody being exposed to another source prior to or after being exposed to the Stibnite Gold Project; is that right?

A. That's right. It is a risk assessment based on the exposures at the mine.

MR. HURLBUTT: Okay. Thank you. No further questions.

HEARING OFFICER LAWRENCE: Any redirect from Perpetua?

MS. HANCOCK: I don't have any further redirect.

HEARING OFFICER LAWRENCE: Anything else with respect to Ms. Lopez we need to talk about?

Okay. Thank you, Ms. Lopez.

So we are at 4:45. Thoughts about what to do for the rest of the day?

MS. HANCOCK: Kevin Lewis is our next witness and I don't know that we are going to get through him. I propose we start him tomorrow. Or I could do his expert qualifications if you want to maximize the minutes, whatever you prefer. But I am not going to get very far with him.

HEARING OFFICER LAWRENCE: Counsel for the other parties, any strong opinions?

I personally would be inclined to go ahead and shut down for the day. My brain is not going to be able to absorb a lot more. That would be my thought.

MS. YOUNG: I still have the same pending question.

HEARING OFFICER LAWRENCE: Let's take a short recess while they discuss.

(Break taken from 4:45 p.m. to 4:47 p.m.)

HEARING OFFICER LAWRENCE: Do you have an update for us?

MS. YOUNG: Yes, thank you. So both counsel, all parties, have graciously agreed to allow Dr. Paden to not return tomorrow. But it is DEQ's intention for Mr. Schilling to be available

and attend the hearing all day tomorrow if there were any questions. But I appreciate everybody's willingness to let her not come back.

HEARING OFFICER LAWRENCE: Okay. Thank you.

Anything else we need to do today before we --

MS. HANCOCK: Nope, I don't think so.

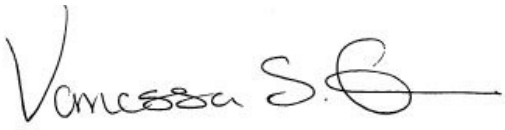
HEARING OFFICER LAWRENCE: All right. We will adjourn for the day.

We will start at 9:00 tomorrow.

(Hearing adjourned to the following day at 4:48 p.m.)

REPORTER'S CERTIFICATE

STATE OF IDAHO)
) ss.
COUNTY OF ADA)



I, VANESSA S. GOSNEY, Certified Shorthand Reporter and Notary Public in and for the State of Idaho, do hereby certify:

That prior to being examined, the witness named in the foregoing deposition was by me duly sworn to testify to the truth, the whole truth and nothing but the truth;

That said deposition was taken down by me in shorthand at the time and place therein named and thereafter reduced to typewriting under my direction, and that the foregoing transcript contains a full, true and verbatim record of said deposition.

I further certify that I have no interest in the event of the action.

WITNESS my hand and seal this 31st day of October, 2024.

VANESSA S. GOSNEY
RPR and Notary
Public in and for the
State of Idaho.

Idaho Rules of Civil Procedure

Rule 30

(e) Review by the Witness; Changes.

(1) Unless waived by the deponent and the parties, the deponent must be allowed 30 days after being notified by the officer that the transcript or recording is available in which (A) to review the transcript or recording; and (B) if there are changes in form or substance, to sign a statement listing the changes and the reasons for making them. (2) Changes indicated in the Officer's Certificate. The officer must note in the certificate prescribed by Rule 30 (f)(1) whether a review was requested and, if so, must attach any changes the deponent makes during the 30-day period. (3) Witness Failure to Sign. (A) In General, If the deposition is not signed by the witness within the 30-day period, the officer must sign it and state on the record the fact of the waiver of signature, or of the illness or absence

of the witness or the fact of the refusal to sign the deposition together with any reason given for not signing. (B) Use of Unsigned Deposition. The deposition may be used as if it were signed, unless pursuant to Rule 32 (d)(4) the court determines that the reasons given for the refusal to sign require rejection of the deposition in whole or in part.

DISCLAIMER: THE FOREGOING CIVIL PROCEDURE RULES ARE PROVIDED FOR INFORMATIONAL PURPOSES ONLY. THE ABOVE RULES ARE CURRENT AS OF APRIL 1, 2019. PLEASE REFER TO THE APPLICABLE STATE RULES OF CIVIL PROCEDURE FOR UP-TO-DATE INFORMATION.

VERITEXT LEGAL SOLUTIONS

COMPANY CERTIFICATE AND DISCLOSURE STATEMENT

Veritext Legal Solutions represents that the foregoing transcript is a true, correct and complete transcript of the colloquies, questions and answers as submitted by the court reporter. Veritext Legal Solutions further represents that the attached exhibits, if any, are true, correct and complete documents as submitted by the court reporter and/or attorneys in relation to this deposition and that the documents were processed in accordance with our litigation support and production standards.

Veritext Legal Solutions is committed to maintaining the confidentiality of client and witness information, in accordance with the regulations promulgated under the Health Insurance Portability and Accountability Act (HIPAA), as amended with respect to protected health information and the Gramm-Leach-Bliley Act, as amended, with respect to Personally Identifiable Information (PII). Physical transcripts and exhibits are managed under strict facility and personnel access controls. Electronic files of documents are stored in encrypted form and are transmitted in an encrypted

fashion to authenticated parties who are permitted to access the material. Our data is hosted in a Tier 4 SSAE 16 certified facility.

Veritext Legal Solutions complies with all federal and State regulations with respect to the provision of court reporting services, and maintains its neutrality and independence regardless of relationship or the financial outcome of any litigation. Veritext requires adherence to the foregoing professional and ethical standards from all of its subcontractors in their independent contractor agreements.

Inquiries about Veritext Legal Solutions' confidentiality and security policies and practices should be directed to Veritext's Client Services Associates indicated on the cover of this document or at www.veritext.com.

Case Docket No. 0101-22-01
OAH Case No. 23-245-01

EXPERT DECLARATION OF KEVIN SCHILLING

I, KEVIN SCHILLING, hereby declare under penalty of perjury and pursuant to the law of the State of Idaho that the foregoing is true and correct:

I. Introduction

1. My name is Kevin Schilling. I am the Stationary Source Air Modeling Supervisor for the Stationary Source Bureau at the State Air Quality Division of the Idaho Department of Environmental Quality (DEQ) in Boise. I have held this position since September of 2004; however, the title of the position and location within the organizational structure of the Air Quality Division has changed over time.

2. Presently, two staff positions, both Air Quality Dispersion Modeling Analysts, report directly to me. Darrin Mehr fills one of those positions and the other is filled by Christina Boulay. Ms. Boulay filled the position vacated by Dr. Pao Baylon, who left DEQ in 2023 for employment with a private environmental consulting company. Dr. Baylon was the lead Air Quality Dispersion Modeling Analyst for review of the Perpetua Resources Idaho, Inc. (PRI) Stibnite Gold Project (SGP) air impact analyses that were submitted with the Permit to Construct (PTC) application.

3. My role in the permitting of the SGP has been both supervisory and technical/policy review and evaluation. As mentioned above, Dr. Baylon was the lead in review and verification of impact analyses submitted with the application, and he also performed supplemental analyses to support DEQ's conclusion that the SGP would not cause or contribute to violation of air quality standards or increments. Where air impact modeling methods used by PRI and presented in the PTC application were atypical or of questionable appropriateness, Dr. Baylon discussed the approach, data, and analyses with me. Prior to permit issuance, Dr. Baylon, DEQ Permit Writer Kelli Wetzel, Permitting Supervisor Darrin Pampaian, Stationary Source Bureau Chief Mike Simon, and I discussed various aspects of the SGP, including proposed operations, emission calculations, permit provisions needed to assure compliance, and monitoring and recordkeeping requirements. This was done to provide a comprehensive assessment of DEQ's confidence of NAAQS and TAP compliance in a weight-of-evidence type approach. At the conclusion, DEQ was highly confident that operation of the SGP, as described in the application and as required by the DEQ PTC, will not cause or contribute to a violation of a National Ambient Air Quality Standard (NAAQS) or exceed an applicable Toxic Air Pollutant (TAP) increment.

A. Assignment

4. The *Final Order in the Matter of Air Quality Permit to Construct P-2019.0045*[1] ("Final Order") indicated there was "insufficient evidence to support DEQ's analysis of the ambient arsenic air concentrations." Three remaining issues were identified by the Board of Environmental Quality (DEQ Board) for resolution. These are:

[1] REC 3706, *Final Order in the Matter of Air Quality Permit to Construct P-2019.0047*, *Nez Perce Tribe, Idaho Conservation League, and Save the South Fork Salmon v. Idaho Department of Environmental Quality*, Case Docket No. 0101-22-01, OAH Case No. 23-245-01 (Final Order at 12).

a. DEQ did not act reasonably in using a five-year rolling average for T-RACT that was not properly supported by permit conditions.

b. There was insufficient evidence to support the T-RACT analysis limiting the non-West End pit production limit.

c. DEQ did not act reasonably and in accordance with law when it applied the 16/70 calculation to the ambient arsenic air concentration analysis.

5. The identified issues pertain to specific requirements for how analyses and developed permit conditions and restrictions must provide for satisfactory assurance that the facility will operate as described in the application and as needed to comply with applicable air quality standards and/or increments. The accuracy, representativeness, and/or conservatism of methods and data used to estimate impacts were described in detail in the PTC application materials submitted by PRI and in DEQ's *Modeling Review Memorandum* and the *TAPs Addendum Modeling Review Attachment* attached thereto.[2] The aspects of methods and data used in the analyses are not in question by any of the three remaining issues, and this report will not revisit or expand on DEQ's confidence in the results of impact analyses. This report will address the above-listed issues by showing how DEQ's regulatory interpretation is appropriate and that the permit conditions adequately assure compliance with the arsenic T-RACT TAP increment.

B. Summary of Opinions

6. This Expert Declaration will show that:

a. Use of a 5-year rolling average production limit for assessing compliance with the T-RACT AACC is appropriate because long-term exposure to a given concentration over the life of the project is the critical parameter for the risk-based AACCs. Short-term fluctuations in impacts do not affect compliance and do not impact long-term exposure concentrations.

b. A specific limit on non-West End Pit production is not necessary to assure compliance with T-RACT AACCs. Since West End Pit production is the risk driver in analyses, the combination of a limit on total production and a limit on the fraction of total production that may occur from West End Pit sources is adequate to assure compliance with the T-RACT AACC.

[2] *See* REC 699, 701-711, 719-720, Idaho Department of Environmental Quality, *TAPs Addendum Modeling Review Attachment* to the PRI SGP *Modeling Review Memorandum* (January 6, 2022) (REC 697-713, Demonstrating Compliance with IDAPA 58.01.01.203.02 (NAAQS) and 203.03 (TAPs) as it relates to air quality impact analyses) ("DEQ's TAPS Modeling Attachment"). For convenience, a true and correct copy of DEQ's TAPS Modeling Attachment is attached hereto as Exhibit A.

c. DEQ acted reasonably and in accordance with law when it applied a 16/70 factor to adjust concentrations for comparison to the T-RACT AACC. The Expert Declaration of DEQ Environmental Toxicologist Dr. Norka Paden [3] shows that the factor is appropriate because cancer risk estimates, as evaluated by the EPA risk model, are conservative and are a function of a combination of concentration, exposure time, exposure frequency, and exposure duration. Dr. Paden's Declaration provides the primary justification for using the 16/70 factor to account for the limited duration SGP, and this Declaration provides a brief description of how that meets the requirements of carcinogenic TAP permitting rules.

C. Qualifications and Experience

7. I received a Bachelor of Science (BS) degree in Environmental Science, with a minor in chemistry, from Washington State University in 1986. After graduation I was employed by Washington State University as a Research Assistant at the Laboratory for Atmospheric Research while attending graduate school. I received a Masters of Science (MS) degree in Environmental Engineering (specializing in atmospheric chemistry, air pollution meteorology, air pollution monitoring, and atmospheric pollutant dispersion) from Washington State University in 1988.

8. I initially began employment with DEQ (at that time the Division of Environmental Quality) in 1989 and then left the agency in 1990 for employment with Morrison Knudsen Company, a large Idaho-based construction company. I worked in Morrison Knudsen's Environmental Group, performing a wide range of air quality related projects where a key focus was air pollutant impact assessment. These projects included permitting, pollutant emissions estimation, atmospheric dispersion modeling, air pollution monitoring, and industrial hygiene functions.

9. In the mid-1990s, I actively participated in the initial development of Idaho's TAP permitting regulations while working at Morrison Knudsen. I provided technical and regulatory assistance to the Idaho Association of Commerce and Industry (IACI). IACI negotiated with DEQ on the development and promulgation of the TAP rules. I held the position of Chair of the Air Toxics Subcommittee during part of the multi-year negotiations. I stepped down from Chair of the subcommittee before final promulgation of the TAP rules because of other project obligations at Morrison Knudsen that required extensive work outside of Idaho. The work on the IACI Air Toxic Subcommittee involved:

a. Evaluation of the basis from which carcinogenic and non-carcinogenic air impact limits would be established.

b. Ensuring that the interests and concerns of the regulated community were considered in the development of regulations.

[3] *Expert Declaration of Dr. Norka Paden* (August 13, 2024) ("Paden Decl."), ¶¶ 11-18.

c. Structuring regulations in a format that is easily used in the context of air permitting for industrial facilities and DEQ.

10. I returned to DEQ in December of 2001, working in the Technical Services Division where I primarily reviewed air impact modeling analyses submitted as part of air permit applications. I transferred to the Air Quality Program Office as the Stationary Source Air Modeling Coordinator in 2004. Later my title was changed from *coordinator* to *supervisor*.

11. My primary responsibilities as Stationary Source Air Modeling Supervisor are both management/administrative and senior level technical and regulatory oversight. A critical component of my position in the Stationary Source Modeling Group is performing, reviewing, and overseeing technical and regulatory aspects of air impact analyses that satisfy regulatory requirements for permit issuance. Where project-specific conditions present unique circumstances, and there is uncertainty in the acceptability of proposed technical and regulatory approaches to address those unique circumstances, DEQ collectively employs its expertise and experience to develop and evaluate the approach.

II. Background Discussion

A. Permitting Requirements for TAPs

12. TAPs were regulated only by *Idaho Air Rules* Section 161[4] prior to the mid-1990s. DEQ developed a permitting TAPs Policy to provide consistency in how TAPs would be addressed in air permitting. The foundation of that policy was to ensure that a proposed project would not cause impacts to ambient air exceeding: 1) non-carcinogenic pollutant concentration levels that are based on occupational exposure limits; and 2) carcinogenic pollutant concentration levels that are based on EPA inhalation Unit Risk Factors (URFs) (as described in more detail in the Expert Declaration of Dr. Norka Paden[5]) and a selected acceptable lifetime cancer risk. The unit risk is lifetime[6] excess cancer risk estimated to result from continuous exposure to a toxic air contaminant at a concentration of 1 microgram/cubic meter of air ($\mu g/m^3$).

13. The regulated community (those applying for and regulated by an air quality permit from DEQ) expressed concerns in the early 1990s regarding DEQ regulation of TAPs by policy. The regulated community, under the representation of IACI, then engaged in regulatory negotiation with DEQ to establish TAP rules for air permitting. The goals of the negotiations were to develop rules that: 1) are reasonably protective of public health, but still afford flexibility to regulated

[4] *Idaho Administrative Procedures Act 58.01.01, Rules for the Control of Air Pollution in Idaho* ("Idaho Air Rules"), Section 161, Toxic Air Pollutants. This Section states: "Any contaminant that is by its nature toxic to human or animal life or vegetation must not be emitted in such quantities or concentrations as to alone, or in combination with other contaminants, injure or unreasonably affect human or animal life or vegetation."

[5] Paden Decl., ¶¶ 12-16.

[6] 70 years was selected as a lifetime.

facilities and projects; 2) are relatively easy to understand and implement; and 3) do not require excessive expenditure of time and resources by DEQ and the permittee during the permitting process.

14. During development of the TAP rules, DEQ's reliance on EPA URFs remained the regulatory approach cornerstone for developing consistent acceptable methods to evaluate impacts to ambient air for carcinogenic TAPs. A DEQ internal memorandum[7] responding to a request for layman's explanation of URF & TLV/100 stated, "Within IAQB (Idaho Air Quality Bureau) New Source Review (NSR) policy, URFs are used to calculate acceptable ambient levels for a given carcinogen. IAQB generally establishes that an ambient concentration which causes no more excess cancers than one in a million (1×10^{-6}) is acceptable." In the early stages of TAP regulation development, DEQ sent IACI a letter that provided a "straw-man" of possible TAP regulatory language.[8] That regulatory straw-man proposal stated the following for procedures to demonstrate compliance for emissions of carcinogenic pollutants:

> "For sources that can demonstrate, using Department-approved methods, that emissions of carcinogens contribute an ambient air cancer risk probability of less than 1:1,000,000 and that emissions of non-carcinogens contribute to an ambient air concentration less than one percent of the Threshold Limit Value, no additional procedures are needed."

15. During development of the TAP rules, DEQ continually asserted that carcinogenic TAPs resulting from a permitting project should be regulated to prevent an unacceptable excess cancer risk based on a 70-year lifetime. Excess inhalation cancer risk probability over a 70-year lifetime is calculated from the EPA Inhalation Unit Risk and the Exposure Concentration, as described in the Expert Declaration of Dr. Norka Paden.[9] The formula is as follows:

Excess Cancer Risk Probability = (IUR)(EC)

Where: IUR = Inhalation Unit Risk per $\mu g/m^3$ of exposure
EC = Exposure Concentration in $\mu g/m^3$

An acceptable arsenic concentration can be calculated by rearranging the formula and solving for EC using an allowable risk of 10^{-6} (1-in-1,000,000) and a IUR of $0.0043/(\mu g/m^3)$ for arsenic. The resulting EC is 2.3 E-4 $\mu g/m^3$, which is the AACC listed in *Idaho Air Rules* Section 586. This clearly shows how the EPA cancer risk model was used to generate AACCs to protect against lifetime cancer risk from long-term exposures.

---

[7] State of Idaho Department of Health and Welfare, Division of Environmental Quality. *Request for layman's explanation of URF& TLV/100*. From Robert Wilkosz and Tim Teater. To Orvil [sic] Green. March 7, 1991. A true and correct copy of this memorandum is attached hereto as Exhibit B.

[8] State of Idaho Department of Health and Welfare, Division of Environmental Quality. Letter from Robert Wilkosz, Bureau Chief, Technical Services Bureau, to Dick Rush, Vice President, IACI. July 29, 1992. A true and correct copy of this letter is attached hereto as Exhibit C.

[9] Paden Decl., ¶ 15.

16. Dr. Paden further explains that the Exposure Concentration can be calculated using the contaminant concentration, exposure time, exposure frequency, exposure duration, and applicable averaging time by the following:

$$EC = (CA \times ET \times EF \times ED)/AT$$

Where: EC = Exposure Concentration ($\mu g/m^3$)
CA = Contaminant Concentration ($\mu g/m^3$)
ET = Exposure Time (hours/day)
EF = Exposure Frequency (day/year)
ED = Exposure Duration (years)
AT = Averaging Time (70 years x 365 days/year x 24 hours/day)

17. The above formula is used to calculate an Exposure Concentration for a specified project duration over a 70-year average lifetime. This Exposure Concentration can then be compared to a concentration limit that is protective for lifetime cancer risk, such as the AACC or the T-RACT AACC. Although the AACC is expressed as an annual average, it represents the concentration averaged over a 70-year lifetime, as defined by how it was generated from URFs and how it is intended to limit long-term exposure concentration and limit the associated excess cancer risk to 1-in-1,000,000. When the Exposure Duration is equal to the 70-year Averaging Time, and the Exposure Frequency and Time are conservatively set to 365 day/year and 24 hours/day, then the Exposure Concentration is simply equal to the Contaminant Concentration, which is the annual impact obtained from the model. Since the vast majority of DEQ permitting projects are of permanent operations (70 years), no adjustment of the Contaminant Concentration is required to obtain the Exposure Concentration.

18. The SGP will have an Exposure Duration of 16 years, the applicable Contaminant Concentration (an annual value obtained from modeling results) is 0.00416 $\mu g/m^3$, the Exposure Frequency is 365 days/year, and the Exposure Time is 24 hours/day. The calculated Exposure Concentration is then:

$$EC = \frac{(0.00416\ \mu g/m^3)(24\ \text{hours/day})(365\ \text{days/year})(16\ \text{years})}{(24\ \text{hours/day})(365\ \text{days/year})(70\ \text{years})} = 0.00095\ \mu g/m^3$$

As observed in the equation, with conservative assumptions for exposure time and frequency, the equation reduces to the 16/70 factor that was used in DEQ's analysis to account for the limited life of the mine. This demonstrates how a 16/70 adjustment factor to annual estimated impacts is appropriate.

19. DEQ air permits are issued to facilities primarily for permanent and consistent operations where resulting emissions vary little through time. Rather than develop a carcinogenic TAP rule that provided for a project-specific lifetime in the calculation of allowable carcinogenic TAP concentrations in ambient air, DEQ provided simpler regulatory language that provides a concentration limit based on a 70-year continual exposure and expressed that exposure as an annual

average exposure concentration. TAP permitting regulations in *Idaho Air Rules* Section 210.15 provide a short-term project adjustment factor of 10 to apply to the allowable AAC when a project will have a duration of less than 5 years. This shows: 1) an adjustment in the exposure concentration is appropriate (in this case, the rules adjust the AACC rather than the exposure concentration); 2) an adjustment greater than 10 cannot be used for projects of duration less than 5 years. In general, DEQ determined it would not be appropriate to subject individuals to a life-time allowable cancer risk within a duration of less than 5 years. Therefore, the adjustment was capped at 10, rather than using a higher value or values calculated from exposure durations of 5 years of less (e.g., 70 years/5 years = 14 or 70 years/2 years = 35). These short-term projects were most commonly remediation and pilot-scale projects having a duration of up to several years.

B. Form of the Arsenic AACC

20. *Idaho Air Rules* Section 586 state that the AACCs "in this section are annual averages." The rules also state that the Toxic Air Pollutant Carcinogenic Increments "are based on . . . a seventy (70) year lifetime exposure." The former is the averaging period of the modeling results (CA), and the latter is the average period of the lifetime exposure concentration (EC) used for determining excess cancer risk. Air impact analyses only demonstrate compliance with standards when the analyses use the same averaging period as the applicable standard. An annual average impact concentration does not demonstrate compliance with a 24-hour standard. In the case of carcinogenic TAPs, the applicable standard is a pollutant-specific inhalation cancer risk posed in ambient air that results from allowable emissions from the proposed project for the life of the project. That acceptable cancer risk is either 10^{-6} (1-in-1,000,000) as expressed in the AACC or 10^{-5} (1-in-100,000) when controls meeting T-RACT are used. The listed annual AACCs are an expression of that standard when applied to a permanent project/facility that has no permit restrictions on operating duration. These AACCs were developed using the EPA inhalation Unit Risk Factors (URFs) that existed at the time *Idaho Air Rules* Section 586 was promulgated. The *Idaho Air Rules* do not preclude use of an exposure concentration adjustment for impacts, and the EPA risk model that was used in the development of the AACCs provides for this adjustment to calculate the exposure concentration.

C. Arsenic Compliance Approach for SGP

21. The arsenic TAP compliance demonstration approach used by PRI for the SGP permitting analyses was thoroughly described in DEQ's *TAPs Addendum Modeling Review Attachment* of the DEQ *Modeling Review Memorandum*[10] for the SGP. This Expert Declaration will summarize the regulatory approach used to demonstrate compliance and provide additional justification for that approach. It will not reiterate the conservatism of the data and methods of the modeling approach used to estimate arsenic impacts to ambient air, as that is not an identified issue.

22. During development of final SGP permitting analyses, PRI expressed concern that compliance with AACCs could not be demonstrated with the conservative assumptions used in

[10] REC 698, 710-711; DEQ's TAPS Modeling Attachment at 2, 14-15.

previous analyses, including the assumption that the SGP was a permanent source rather than one of 16-year duration. Rather than revise the analytical approach to provide a less conservative assessment of impacts, I proposed that compliance with carcinogenic TAP increments could be based on cumulative cancer risk of the limited-duration project rather than the worst-case annual impact for a project of limited duration. Since the AACC annual average is an expression of a 1-in-1,000,000 cancer risk limit for permitting projects, modeled impacts (annual contaminant concentration) must be adjusted to an exposure concentration that is appropriately comparable to the annual average AACC. Therefore, annual impacts for a project with a 16-year duration could be multiplied by a 16/70 factor to more appropriately compare to the AACC, which is based on a 70-year exposure duration. Similarly, year-to-year variability in emissions could be distributed over an alternative averaging period, provided there is still an adequate periodic evaluation that long-term risk limits are not exceeded.

23. My justification for the acceptability of using a 16/70 factor to adjust modeled impacts was based on technical/scientific considerations, my personal working-level knowledge of DEQ's TAP rules, and my limited knowledge of carcinogenic risk assessment and its relation to the TAP rules. Because of the unique 16-year project duration of the SGP and because *Idaho Air Rules* only identify AACC values for 70 years and less than 5 years, I discussed the approach with the DEQ permitting team prior to proposing use of the method. The DEQ permitting team concluded that the exposure duration consideration was an appropriate adjustment to the calculation of an exposure concentration (EC) for comparison to the T-RACT AACC, and it was concluded by the team that this approach was consistent with implementation of the URFs and identified acceptable excess cancer risks (1-in-1,000,000 or 1-in-100,000 when T-RACT is used) adopted by DEQ as AACCs into *Idaho Air Rules* Section 586.

III. Response to Remaining Issues Identified by the Board of Environmental Quality

A. DEQ Acted Reasonably in Using a 5-Year Rolling Average for T-RACT and it was Supported by Permit Conditions

24. *Idaho Air Rules* Section 586 state that AACCs are annual averages. The implication of the stated issue is that when a standard or increment is specified for a certain averaging-period, then any limits imposed on operations should be for the same averaging period or a shorter averaging period. For example, an operational limit designed to limit emissions that is based on a 5-year averaging period would not be adequate for assuring compliance with an annual average standard. This is because variability in operational rates within the 5-year period could result in a violation of the annual standard while still complying with the 5-year operational limit in the permit. For short-term 1-hour standards, DEQ uses 1-hour averaged operational limits and 1-hour averaged monitoring requirements. Permit requirements to assure compliance with a 1-hour limit would not be based on longer averaging periods such as daily rates because the 1-hour limit could be exceeded while still complying with the daily rate.

25. As I have established earlier in this declaration, carcinogenic TAP AACCs were established to ensure that impacts of any carcinogenic TAPs from a project or facility would not cause a lifetime cancer risk over 1-in-1,000,000 or 1-in-100,000 when using T-RACT. Cancer risks used to establish AACCs were based on EPA's cancer risk model (using established EPA URFs), where risk is dependent on an exposure for a certain project duration, and the risk varies linearly with exposure duration. Because limiting total project-caused cancer risk is the underlying criteria for carcinogenic TAP regulation, any permit limits must only assure that concentrations in ambient air over the total duration of the project do not cause a potential exposure concentration associated with a 1-in-1,000,000 or 1-in-100,000 cancer risk. Therefore, compliance with the carcinogenic AACCs would still be demonstrated if processing rates were only limited to the 788.4 million tons over the life of the mine (combined with the restriction on West End Pit production as described in the next section). Use of a 5-year averaging period for limiting processing rates easily accomplishes this requirement for a project with a 16-year duration, and it provides for reasonable periodic assurance of compliance with the long-term limit.

26. The *Final Order* from the DEQ Board[11] asserted that, "A five-year rolling average allows considerable daily and annual increases in exposures which are contrary to limits set forth in the Air Rules." Because pollutant-specific total project cancer risk is the blanketing objective of regulating carcinogenic TAPs, and since risks as assessed by the EPA risk model are a function of exposure concentration (accounting for exposure duration over a lifetime), any daily and annual variability is inconsequential to the exposure concentration and resulting risk. For example, assume a processing rate of 200,000 tons/year results in an annual arsenic impact of 3.0 E-4 $\mu g/m^3$, 153,000 tons/year results in 2.3 E-4 $\mu g/m^3$ (equal to the standard), and processing 100,000 tons/year results in an annual impact of 1.5 E-4 $\mu g/m^3$. Then assume a facility processes 200,000 tons during years one and two, 100,000 tons during years three and five, and 153,000 tons during year four. The total material processed over five years is 753,000 tons, and the mean annual processing rate is 150,600 tons/year. The same mean processing rate would result from processing 150,600 tons for each of the five years, and this would result in the same average annual air impact and the same carcinogenic exposure concentration. Since the exposure concentration (a resulting project caused concentration averaged over a lifetime) is a measure of compliance with AACC, the five-year rolling average is consistent with limits in *Idaho Air Rules* for carcinogenic TAPs.

B. DEQ had sufficient Evidence Supporting Limits on non-West End Pit Production

27. Final maximum potential arsenic exposures resulting from the SGP, as limited by permit conditions, were calculated from maximum modeled annual impacts and post-processing of those impacts by the following equation[12,13]:

---

[11] REC 3713 (Final Order at 19).

[12] REC 710-711, DEQ's TAPS Modeling Attachment at 14-15.

[13] *See* REC 1947-48, *Stibnite Gold Project Permit to Construct Application TAP Addendum.* Prepared for Perpetua Resources Idaho, Inc., Prepared by Air Sciences Inc., October 5, 2021 (full document at REC 1921-2146).

$$LifeExposure_{Wi,j,n} = \left[\left(WEPExposure_{Wi,n}\right)(50\%) + \left(nonWEPExposure_{Sj,n}\right)(50\%)\right]\left[\frac{16\ year\ LOM}{70\ year\ exposure}\right]$$

Where:

W_i	=	West End Pit scenario, where i = 1 to 4
S_j	=	Non-West End Pit scenario, where j = B1, B2, H1, H2, H3, H4, Y1, Y2, and Y3.
n	=	specific receptor.
$LifeExposure_{Wi,j,n}$	=	lifetime exposure in µg/m^3 for West End Pit scenario i, non-West End Pit scenario j, at receptor n.
$WEPExposure_{Wi,n}$	=	annual maximum modeled impact in µg/m^3 for West End Pit scenario i at receptor n
$nonWEPExposure_{Sj,n}$	=	annual maximum modeled impact in µg/m^3 for non-West End Pit scenario j at receptor n
16 *year LOM*	=	maximum life-of-mine
70 *year exposure*	=	lifetime exposure used for development of AACCs in *Idaho Air Rules*

The issued permit provided a total mine production limit and a production limit for West End Pit operations. The *Final Order* from the DEQ Board[14] stated, "However, the equation listed above shows that the non-West End Pit production was also limited by 50%. The Board of Environmental Quality was unable to determine from the record where this 50% reduction came from or whether it was actually applied when doing the calculation."

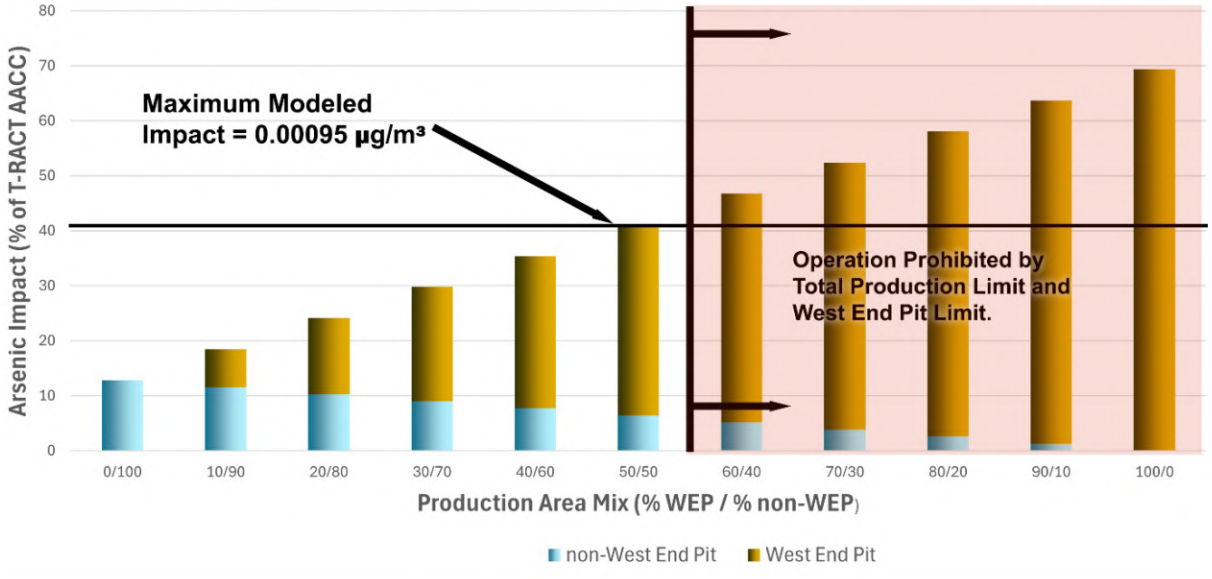
28. The DEQ Board, in the *Final Order*, fails to understand how the issued PTC appropriately and effectively limits both West End Pit and non-West End Pit production. The listed equation provides worst-case impacts for the various scenarios, but by itself it does not fully explain how certain sources must be limited by the permit to assure that the SGP operates as described in the application and in compliance with applicable standards and increments. The PTC limits total hauling and excavation from the mine to 788.4 million tons (West End Pit production combined with non-West End Pit production) and limits hauling and excavation from the West End Pit to 394.2 million tons, which is equal to 50% of total allowable production. Impacts to critical receptors (those having impacts that may approach the T-RACT AACC) are far greater for West End Pit sources than for non-West End Pit Sources. Analyses performed by DEQ during review of the application[15] showed that maximum arsenic impacts when 100% of the allowable production is from non-West End Pit sources (0.0023 µg/m^3 before adjusting for the life of the mine and 0.00053 µg/m^3 after adjusting for the life of the mine) are well below the maximum impact when 100% of allowable production is from West End Pit; therefore, with both a limit on total production and West End Pit production, an additional limit on non-West End Pit production is not necessary to assure that the SGP operates as represented in the application and as needed to

[14] REC 3714 (Final Order at 20).

[15] *PERPETUA RESOURCES IDAHO, INC. – P-2019.0047 PROJ 62288 - Lifetime Arsenic Exposure for Scenarios W1-W4 (DEQ's Post Processing Analysis).xlxs*. Excel Workbook. DEQ, 2021. A true and correct copy of this Excel workbook is provided concomitantly with this declaration and identified as Exhibit D.

assure that applicable emissions do not exceed the arsenic T-RACT AACC. Non-West End Pit production is limited to the facility-wide 788.4-million-ton limit for total hauling and excavation at the mine if there were no West End Pit production.

29. Production is effectively limited from non-West End Pit sources because of the following relationship:



$$Production_{Non\text{-}WEP} = Production_{total} - Production_{WEP}$$

Where:

$Production_{Non\text{-}WEP}$ = production from non-West End Pit Sources
$Production_{total}$ = Total allowable production.
$Production_{WEP}$ = production from West End Pit Sources (not to exceed 50% of $Production_{total}$)

30. The effect of a limit on total production and West End Pit production can be observed by showing how maximum arsenic impacts change with changes in the fraction of total allowable production that occurs from the West End Pit. This was done for the single receptor that had the highest overall exposure concentration. Figure 1 shows how the total adjusted impact is affected by changes in the West End Pit production. The Figure shows how total impacts increase as West End Pit production increases and non-West End Pit production decreases. Figure 1 also shows how impacts would increase above the adjusted combined impact of 0.00095 µg/m^3 for West End Pit allowable production above 50% of the total allowable production from combined West End Pit and non-West End Pit sources.

Figure 1: Maximum Arsenic Impacts as a Function of the Percentage of Total Allowable Production that may Occur from West End Pit Sources

C. DEQ Acted Reasonably and in Accordance with Law when it Applied the 16/70 Calculation to the Ambient Arsenic Air Concentration Analysis

31. The DEQ Board, in the Final Order, misses the point that project-caused pollutant specific cancer risk is the overriding criteria of acceptability and that AACCs, expressed as an annual average, are provided to simplistically apply to permanent sources with emissions of low variability. The Final Order states that "nowhere in the Air Rules does it provide that a project that will operate more than 5 years but less than 70 years may be adjusted in proportion to the amount of time it will operate." Idaho Air Rules do not preclude the use of such a factor within the context of the regulatory intent. *Idaho Air Rules* do not alter EPA's science nor preclude its use, which includes use of a 70-year lifetime exposure duration in calculating AACCs. For projects with an enforceable operational life of less than 70 years, an adjustment for reduced exposure duration is appropriate. Total project-caused carcinogenic risk has been identified as the criteria from which the AACCs were established, as has been described earlier in this Declaration. When specific parameters associated with a project subject to the AACCs are not consistent with the assumptions/conditions that went into development of the AACCs, DEQ staff are compelled to adjust for those in an appropriate and/or conservative manner. DEQ then used its authority to write reasonable permit conditions per IDAPA 58.01.01.211 to limit total production including specific limitations on the West End pit.

32. Additionally, DEQ did not adjust the AACC. DEQ adjusted the applicable modeled impact concentration, which has a duration of 16 years, to an exposure concentration representative of a 70-year lifetime. With this adjustment, the exposure concentration can be compared to the AACC or the T-RACT AACC. The adjustment involved assuming maximum modeled impacts persist for the 16 years of mine life, and then those impacts are evenly distributed over a 70-year period to be consistent with the assumptions of carcinogenic TAP regulations.

33. Apart from the DEQ Board's identified issue with lack of specific allowance in the *Idaho Air Rules* to use an adjustment factor to account for project duration, the *Final Order* also stated that "DEQ did not provide sufficient evidence in the form of an expert opinion from a toxicologist or other qualified expert regarding the cancer risk associated with the 16/70 adjustment." As previously mentioned, outside of DEQ's adjustment factor of 10 specified for short-term sources of less than five years, cancer risk associated with exposures between 5 and 70 years are based on the EPA risk assessment model, using established URFs and exposure concentrations. DEQ's toxicologist, Dr. Norka Paden, demonstrated in her declaration[16] that use of the 16/70 adjustment factor is appropriate to calculate exposure concentration impacts of a 16-year project to be compared to the T-RACT AACC, which is based on a 70-year lifetime.

IV. Conclusions

34. Regarding the three remaining issues identified by the DEQ Board on the arsenic analysis supporting issuance of the DEQ PTC, DEQ concludes:

[16] Paden Decl., ¶ 18.

A. A 5-year rolling average production limit and associated monitoring of production was appropriate and reasonable because the criterion of acceptance is project-caused excess inhalation cancer risk. Short-term variability is inconsequential to the total risk.

B. Limits on total production along with a limit on West End Pit production effectively limits non-West End Pit production. A separate limit on non-West End Pit production is not necessary because compliance with the T-RACT AACC is still demonstrated when 100% of total allowable production is from non-West End Pit sources.

C. DEQ acted reasonably and in accordance with law when applying the 16/70 factor to generate an Exposure Concentration to compare against the T-RACT AACC. As demonstrated, AACCs are an annual representation of the acceptable Exposure Concentration for a permanent project and a 1-in-1,000,000 excess cancer risk. Standard EPA risk assessment methods (the same methods used to develop the AACCs) were used with the modeled annual concentration to calculate an Exposure Concentration representative of the 16-year project duration while conservatively assuming a 24 hour/day Exposure Time and a 365 day/year Exposure Frequency. This reduces to the 16/70 factor applied to the modeled concentration.

EXHIBIT A

TAPs Addendum Modeling Review Attachment

1.0 Introduction and Summary

Perpetua Resources Idaho, Inc. (PRI) submitted the *Stibnite Gold Project (SGP) Permit to Construct Application TAP Addendum* (*TAP Addendum*), prepared by Air Sciences Inc. (Air Sciences) and submitted to DEQ on October 5, 2021. The TAP Addendum reassessed source applicability to Toxic Air Pollutant (TAP) permitting requirements, refined TAPs regulatory methods to demonstrate compliance with applicable TAP increments, revised and/or refined operations and operational parameters affecting TAP emissions, and refined TAP air impact analyses. The revisions and refinements made for the TAP Addendum also reduced PM_{10} and $PM_{2.5}$ emissions, and this effect is presented in this *TAPs Addendum Modeling Review Attachment* (*Modeling Review Attachment*).

2.0 Scope of TAPs Addendum

DEQ reevaluated TAPs compliance regulatory interpretations and impact assessment methods following the second public comment period of February 18, 2021, through March 19, 2021. Areas of revision in response to issues identified after the public comment period included:

- Revising source-specific TAP impact assessment applicability, primarily identifying what sources can be excluded because they are "covered" or "addressed" by a National Emissions Standard for Hazardous Air Pollutants (NESHAP) or New Source Performance Standard (NSPS).
- Refining regulatory methods used to demonstrate compliance with TAP increments.
- Refining TAP emission calculation methods and dispersion-affecting parameters.
- Reassessing TAP impacts resulting from revised and/or refined methods and data.
- Providing a best-estimate of actual TAP emissions that will occur from operation of the mine, and then comparing this to maximum permit-allowable emissions.

PRI and Air Sciences, PRI's permitting consultant, submitted the *TAP Addendum* on October 5, 2021.

3.0 Revised NESHAP/NSPS TAP Exclusion

DEQ and PRI reevaluated TAP source applicability after the second public comment period in response to expressed concerns regarding sources excluded as per *Idaho Air Rules* Section 210.20 (excluding sources that are "covered" or "addressed" by a NESHAP). TAP applicability is explained in greater detail in the main body of the DEQ Statement of Basis. As a result of the reevaluation, some additional sources were included in the TAP impact modeling analyses that were not previously. TAP sources from gold mining that were modeled in the final TAP analyses included: drilling, blasting, excavating, hauling, prill silos, rock dumps and storage piles, and tailings.

Air Sciences consulted with DEQ to refine TAP compliance demonstration methods from what was originally submitted in the application. The refinement was primarily needed to show compliance with the

arsenic Acceptable Ambient Concentration of a Carcinogen (AACC). The revised methods are described in the submitted *TAP Addendum* and this DEQ *Modeling Review Attachment*.

4.0 TAPs Refined Compliance Demonstration Approach

PRI, in consultation with DEQ, used a highly refined TAPs analysis approach to demonstrate compliance with applicable TAP increments. This approach involved the following:

- AACC Adjustment for Toxic Air Pollutant Reasonably Available Control Technology (T-RACT) Utilization.
- TAP Emission Averaging Period.
- AACC Adjustment for the Operational Life of the Mine.

4.1 AACC Adjustment for T-RACT Utilization

Idaho Air Rules Section 210.12 allows TAP impacts of 10 times the AACC if the application demonstrates that T-RACT is used for the TAP emission sources. This represents a life-time cancer risk of 1-in-100,000. An adjustment cannot be made for non-carcinogenic TAPs listed in *Idaho Air Rules* Section 585.

Review of the T-RACT demonstration is performed by the DEQ permit writer and is described in the main body of the DEQ Statement of Basis.

4.2 TAP Emission Averaging Period

Annual average emissions of carcinogenic TAPs are typically used in the dispersion model to estimate maximum annual impacts. PRI refined the analyses by using source-specific emission rates that are representative of a 5-year averaging period. This approach is appropriate because carcinogenic impacts are of concern from a long-term exposure basis.

4.3 AACC Adjustment for the Operational Life of the Mine

AACCs were established based on a 1-in-1,000,000 cancer risk over a 70-year lifetime, as stated in *Idaho Air Rules* Section 006.125:

> ***Toxic Air Pollutant Carcinogenic Increments**. Those ambient air quality increments based on the probability of developing excess cancers over a seventy (70) year lifetime exposure to one (1) microgram per cubic meter (1 ug/m3) of a given carcinogen and expressed in terms of a screening emission level or an acceptable ambient concentration for a carcinogenic toxic air pollutant. They are listed in Section 586.*

PRI indicated the maximum life-of-mine will be 16 years. Life-time exposures to carcinogenic TAPs were refined by multiplying the maximum modeled annual impact by a ratio of 16/70. Section 5.7 of this *Modeling Review Attachment* provides more details on this adjustment for the project.

5.0 Refined TAP Emission Estimates and Modeling Methods/Parameters

This section describes changes made to TAP emission estimates and to methods/parameters used in the impact modeling analyses.

5.1 Operational Adjustments

PRI and Air Sciences proposed and committed to several operational adjustments to reduce actual and estimated TAP emissions:

- Installing and operating dust collection systems on drilling rigs (determined to be T-RACT).
- Capping the haul roads that are outside of the pits and development rock storage facilities (DRSFs) with clean (lower levels of arsenic) development rock (determined to be T-RACT).
- Eliminating the West End Development Rock Storage Facility, which eliminated the highest-emitting operational scenario W5.
- Limiting long-term mining production to an average of 135,000 tons/day for a 5-year rolling average.
- Constructing the Burntlog access road with offsite materials containing "background" levels of arsenic.
- Updating the bulldozing emission factor using the SGP site-specific silt content.

5.2 General Modeling Methods and Parameters

Modeling methods and parameters used in TAP impact analyses presented in the *TAP Addendum* are largely identical to those used in the previously submitted application. These include the air dispersion model used, meteorological data, terrain, building downwash, ambient air boundary, and receptors. TAP modeling was conducted for the 14 operational modeling scenarios, consistent with the NAAQS analyses. Modeling Scenario W5 was eliminated from the arsenic modeling, as discussed in Section 5.8 of this *Modeling Review Attachment*.

The meteorological dataset processed using McCall, Idaho, cloud cover data was used for analyses in the *TAP Addendum*. Impacts were not assessed using the dataset processed using the Bulk Richardson (BULKRN) method for boundary layer parameter calculations. EPA considers both methods to be acceptable. Although modeled impacts tend to be somewhat larger when using meteorological data processed by the BULKRN method, DEQ contends that the impact analyses are still largely conservative compared to actual impacts anticipated. Conservative aspects include: continual operation of the worst-case operational scenario; operation at maximum allowable rates for the averaging period; no reduction in winter-time emissions from fugitive sources, accounting for emission suppression effects of increased moisture.

5.3 TAP Modeling Applicability

Table 1 provides a comparison between applicable facility-wide maximum potential TAP emissions for the highest-emitting scenario (W3) and TAP screening emission levels (ELs) from *Idaho Air Rules* Sections 585 (for non-carcinogens) and 586 (for carcinogens). Note that TAPs also classified as HAPs

emitted from sources "addressed" or "covered" by NSPS or NESHAP were not required to be evaluated for compliance with TAP increments in accordance with *Idaho Air Rules* Section 210.20. Furthermore, PRI has determined that the West End Development Rock Storage Facility will not be constructed. This change eliminated Modeling Scenario W5 (the highest-emitting scenario described in the main body of the DEQ *Modeling Review Memorandum*) as a potential operating scenario. After eliminating Modeling Scenario W5, it was determined that Modeling Scenario W3 is the highest-emitting scenario for all TAPs.

Table 1. TAP MODELING APPLICABILITY DETERMINATION (HIGHEST-EMITTING MODELING SCENARIO: W3).

HAP/TAP	Emissions (lb/hr)			EL (lb/hr)		Determination

Table 1. TAP MODELING APPLICABILITY DETERMINATION (HIGHEST-EMITTING MODELING SCENARIO: W3).						
HAP/TAP	Emissions (lb/hr)			EL (lb/hr)		Determination
	(a)	(b)	Total	(c)	(d)	
Thallium	8.1E-3	5.2E-4	8.7E-3	7.0E-3	--	Non-carcinogenic EL exceeded
Uranium	8.1E-3	5.2E-4	8.7E-3	1.3E-2	--	EL not exceeded
Vanadium	2.3E-2	8.4E-4	2.4E-2	3.0E-3	--	Non-carcinogenic EL exceeded
Trimethyl Benzene	--	1.1E-2	1.1E-2	8.2E+0	--	EL not exceeded
Tungsten	8.1E-3	5.2E-4	8.7E-3	3.3E-1	--	EL not exceeded
Zinc	2.9E-2	2.2E-3	3.1E-2	6.7E-1	--	EL not exceeded

a. Total HAP/TAP emissions for EL evaluation from mining (i.e., pits, blasting, haul roads, stockpiles and DRSF, tailings storage facility, access road, and underground exploration) and leaching. Emissions from sources covered/addressed by NSPS/NESHAP are not included in the evaluation for modeling applicability.

b. Total HAP/TAP emissions for EL evaluation from processing and production (i.e., ore processing [crushers and transfer, prill silos], ore concentration and refining [autoclave, electrowinning cells and pregnant solution tank, retort, furnace, carbon kiln], process heating [POX boiler, carbon regeneration kiln, propane vaporizer, solution heater], lime production [limestone crushers, screens, mill, transfers, lime kiln, kiln feed, lime mill, pebble lime silo, lime silos, lime mill crushing], aggregate production [portable crushers, screens, transfers], concrete production [central mixer, cement silos, aggregate bin], HVAC [heaters], emergency power [emergency generators, fire pump], fuel storage [gasoline fuel and tanks]). Emissions from sources covered/addressed by NSPS/NESHAP are not included in the evaluation for modeling applicability.

c. Non-carcinogenic EL from *Idaho Air Rules* Section 585.

d. Carcinogenic EL from *Idaho Air Rules* Section 586.

Table 1 shows that the SGP facility-wide potential TAP emissions exceed the respective EL for arsenic, beryllium, cadmium, cyanide, formaldehyde, manganese, nickel, phosphorus, aluminum, barium, calcium carbonate, calcium oxide, iron, sulfuric acid, thallium, and vanadium. Therefore, modeling was required for these 16 TAPs (11 non-carcinogenic and five carcinogenic TAPs) to demonstrate compliance with Acceptable Ambient Concentrations of Non-Carcinogens (AACs) and AACCs.

5.4 TAP Modeled Emission Rates

Table 2 lists the source-specific modeled emission rates for all 11 non-carcinogenic TAPs that required modeling (worst-case modeling scenario for all non-carcinogenic TAPs: W5). Table 3 lists the source-specific modeled emission rates for all five carcinogenic TAPs that required modeling (worst-case impacts for arsenic are associated with modeling scenario W2; worst-case impacts for all other carcinogenic TAPs are associated with modeling scenario W1). Note that all source-specific emission rates listed in Tables 2 and 3 were extracted by DEQ's modeling staff from the submitted modeling input files.

The total modeled emission rates for all non-carcinogenic TAPs are equal to the total facility-wide HAP/TAP emissions as stated in the permitting emissions inventory (excluding sources addressed by NSPS/NESHAP), evaluated at 180,000 T/day (see last two rows of Table 2). However, for carcinogenic TAPs, modeling was performed using an emission inventory that included T-RACT controls, long-term mining production limits, and other emission inventory refinements, as described in Section 4.0 of this *Modeling Review Attachment* (see last three rows of Table 3).

Table 2. MODELED EMISSION RATES FOR NON-CARCINOGENIC TAPS (WORST-CASE MODELING SCENARIOS).

a. Aluminum (worst-case modeling scenario: W5).
b. Pounds per hour.
c. Barium (worst-case modeling scenario: W5).
d. Calcium carbonate (worst-case modeling scenario: W5).
e. Calcium oxide (worst-case modeling scenario: W5).
f. Cyanide (worst-case modeling scenario: W5).
g. Iron (worst-case modeling scenario: W5).
h. Manganese (worst-case modeling scenario: W5).
i. Phosphorus (worst-case modeling scenario: W5).
j. Sulfuric acid (worst-case modeling scenario: W5).
k. Thallium (worst-case modeling scenario: W5).
l. Vanadium (worst-case modeling scenario: W5).
m. The Haul Road was represented in the model as a series of volume sources. The emission rates listed in this table represent each individual volume source.
n. Total emission rates at 180,000 tons per day were derived from Worksheet "TblA" in the emission inventory dated October 5, 2021. The total emission rates in this row represent all facility-wide HAP/TAP emission sources from mining, leaching, and processing and production (excluding emissions from sources "addressed" or "covered" by NSPS/NESHAP).

Table 3. MODELED EMISSION RATES FOR CARCINOGENIC TAPS (WORST-CASE MODELING SCENARIOS).

a. Arsenic (worst-case modeling scenario: W2).
b. Pounds per hour.
c. Beryllium (worst-case modeling scenario: W1).
d. Cadmium (worst-case modeling scenario: W1).
e. Formaldehyde (worst-case modeling scenario: W1).
f. Nickel (worst-case modeling scenario: W1).
g. The Haul Road was represented in the model as a series of volume sources. The emission rates listed in this table represent each individual volume source.
h. Total T-RACT emission rates – calculated based on T-RACT controls, long-term mining production limits, and other emission inventory refinements, as described in Section 4.0 of this *Modeling Review Attachment* – are derived from Tables B-W2 (for Arsenic) and B-W1 (for Beryllium, Cadmium, Formaldehyde, and Nickel) in Appendix B of the *TAP Addendum*.
i. Total emission rates at 180,000 tons per day were derived from Worksheet "TblA" in the emission inventory dated October 5, 2021. The total emission rates in this row represent all facility-wide HAP/TAP emission sources from mining, leaching, and processing and production (excluding emissions from sources "addressed" or "covered" by NSPS/NESHAP).

5.5 Cyanide Modeling Emission Source Parameters

Modeling analyses for cyanide introduced two new emission sources that were not previously evaluated by DEQ: tailings storage facility (model ID: TSF) and mill tanks (model ID: MILLTANKS).

1. The tailings storage facility was modeled by Air Sciences as a surface-based (zero release height above ground-level and zero initial vertical dimension) AREA source. The easterly and northerly lengths were calculated as square-root of the TSF area (easterly length = northerly length = $\sqrt{1{,}338{,}158\ square\ meters}$ = 1,157 meters).

2. The mill tanks were grouped and modeled by Air Sciences as a single VOLUME source. The tanks sit on the ground, so the release height was set to the average tank height of 12.2 meters (40 feet). The initial lateral dispersion (σ_y) was calculated as the equivalent diameter of the combined (18) tank area divided by the single VOLUME source coefficient of 4.3:

$$\sigma_{y(MILLTANKS)} = \frac{Equivalent\ diameter}{4.3} = \frac{\sqrt{\Sigma(d)^2}}{4.3} = 42.8\ feet$$

The individual tank diameters (d) are: two tanks at 40 feet, four tanks at 52 feet, six tanks at 54 feet, and six tanks at 20 feet.

DEQ typically requires that tailings storage facilities be modeled as an AREAPOLY source with an outline that follows the contour of the emission source, and that mill tanks be represented in the model as individual volume sources; but, given that the maximum modeled concentration for cyanide is safely below the AAC (0.08%), DEQ's modeling team accepted the modeling analysis submitted by Air Sciences and concluded that it confidently demonstrates that the cyanide AAC will not be exceeded.

5.6 Deposition Modeling

Air Sciences applied particle deposition algorithms in the impact modeling for particulate TAPs. The particulate deposition parameters used in the NAAQS compliance analysis were derived for PM_{10} and $PM_{2.5}$ (see Tables 22 and 23 in the main body of the DEQ *Modeling Review Memorandum*). Dust-related metal TAP emissions include total particulates (all size fractions of particulate matter [PM] up to PM_{30}). Therefore, the deposition parameters for PM were calculated using the same methodology and EPA references used for PM_{10} and $PM_{2.5}$ in the NAAQS compliance demonstration analyses. The PM deposition parameters are provided below in Table 4. The same density values were used as in the previous TAPs modeling analysis. However, an additional deposition characterization bin was added to better handle deposition of 10 µm to 30 µm particulates; mass fractions were adjusted accordingly.

Table 4. PARTICULATE MATTER DEPOSITION PARAMETERS BY SOURCE CATEGORY.

[a.] See Table 23 in the main body of the DEQ *Modeling Review Memorandum*.

5.7 Carcinogenic TAP Modeling Lifetime Exposure Adjustment

Maximum modeled concentrations for carcinogenic TAPs were adjusted to account for the life-of-mine production limits, which affects the lifetime exposure.

PRI evaluated the highest modeled annual carcinogenic TAP concentration from each of the 14 modeling scenarios for lifetime exposure as follows:

$$Lifetime\ exposure\ \left(\frac{\mu g}{m^3}\right) = \frac{Highest\ annual\ concentration\ \left(\frac{\mu g}{m^3}\right) \times 16\ (mine\ operation\ years)}{70\ (years, lifetime\ exposure)}$$

This equation assumes that the highest annual concentration from the 14 modeling scenarios is repeated for 16 years of mining operation. This was then averaged over 70 years to calculate the 70-year lifetime exposure.

PRI and Air Sciences contend that calculating lifetime exposure based on 16 years of mining operation is conservative. The annual emissions for carcinogenic TAP modeling are based on 135,000 tons/day (see Section 5.1 of this *Modeling Review Attachment*) and 365 days per year. Over 16 years, this equates to a potential mining production of 788.4 million tons:

$$\frac{135{,}000\ \left(\frac{tons}{day}\right) \times 365\ \left(\frac{days}{year}\right) \times 16\ years}{1{,}000{,}000\ \left(\frac{tons}{million\ ton}\right)} = 788.4\ million\ tons$$

The actual life-of-mine total production as described in the SGP *Refined Proposed Action* (*ModPRO2*) mine plan is only 402.86 million tons (Perpetua 2021), which is 51.1% of the potential life-of-mine production represented in the above equation and related emission evaluations.

5.8 Arsenic Compliance Demonstration for Modeling Scenarios W1-W4

To demonstrate compliance with the AACC for arsenic, PRI applied two additional operating limitations:

- The removal of Modeling Scenario W5 as a potential operating scenario
- Limiting the West End Pit's life-of-mine potential mining production to 50% of the total life-of-mine potential mining production of 788.4 million tons: 50% * 788.4 million tons = 394.2 million tons

PRI has determined that the West End Development Rock Storage Facility (DRSF) will not be constructed. This change eliminated Modeling Scenario W5 from the arsenic modeling evaluation. The remaining four West End Pit modeling scenarios (W1–W4) are evaluated using the 70-year lifetime exposure equation from Section 5.7 and adjusting for the proposed West End Pit life-of-mine production limit of 50% of the total production as follows:

$$LifeExpose_{Wi,j,n} = \left[\left(WEPExpose_{Wi,n}\right)(50\%) + \left(nonWEPExpose_{Sj,n}\right)(50\%)\right]\left[\frac{16\ year\ LOM}{70\ year\ exposure}\right]$$

where:

W*i*	=	West End Pit scenario, where *i* = 1 to 4.
S*j*	=	non West End Pit scenario, where *j* = B1, B2, H1, H2, H3, H4, Y1, Y2, and Y3.
n	=	specific receptor.
$LifeExpose_{Wi,j,n}$	=	lifetime exposure in µg/m³ for West End Pit scenario *i*, non West End Pit scenario *j*, at receptor *n*.
$WEPExpose_{Wi,n}$	=	annual maximum impact in µg/m³ for West End Pit scenario *i* at receptor *n*.
$nonWEPExpose_{Sj,n}$	=	annual maximum impact in µg/m³ for non West End Pit scenario *j* at receptor *n*.
16 year LOM	=	maximum life-of-mine.
70 year exposure	=	Lifetime exposure used for development of AACCs in *Idaho Air Rules*.

The above equation was used to calculate the lifetime arsenic exposure from the West End Pit scenarios (W1–W4) on a receptor-by-receptor basis. Combining the concentrations from Modeling Scenarios W1–W4 with the highest concentration from the remaining non-West End Pit scenarios (B1, B2, H1, H2, H3, H4, Y1, Y2, or Y3) conservatively ensures that the maximum potential impacts from applicable sources are evaluated and remain below AACCs.

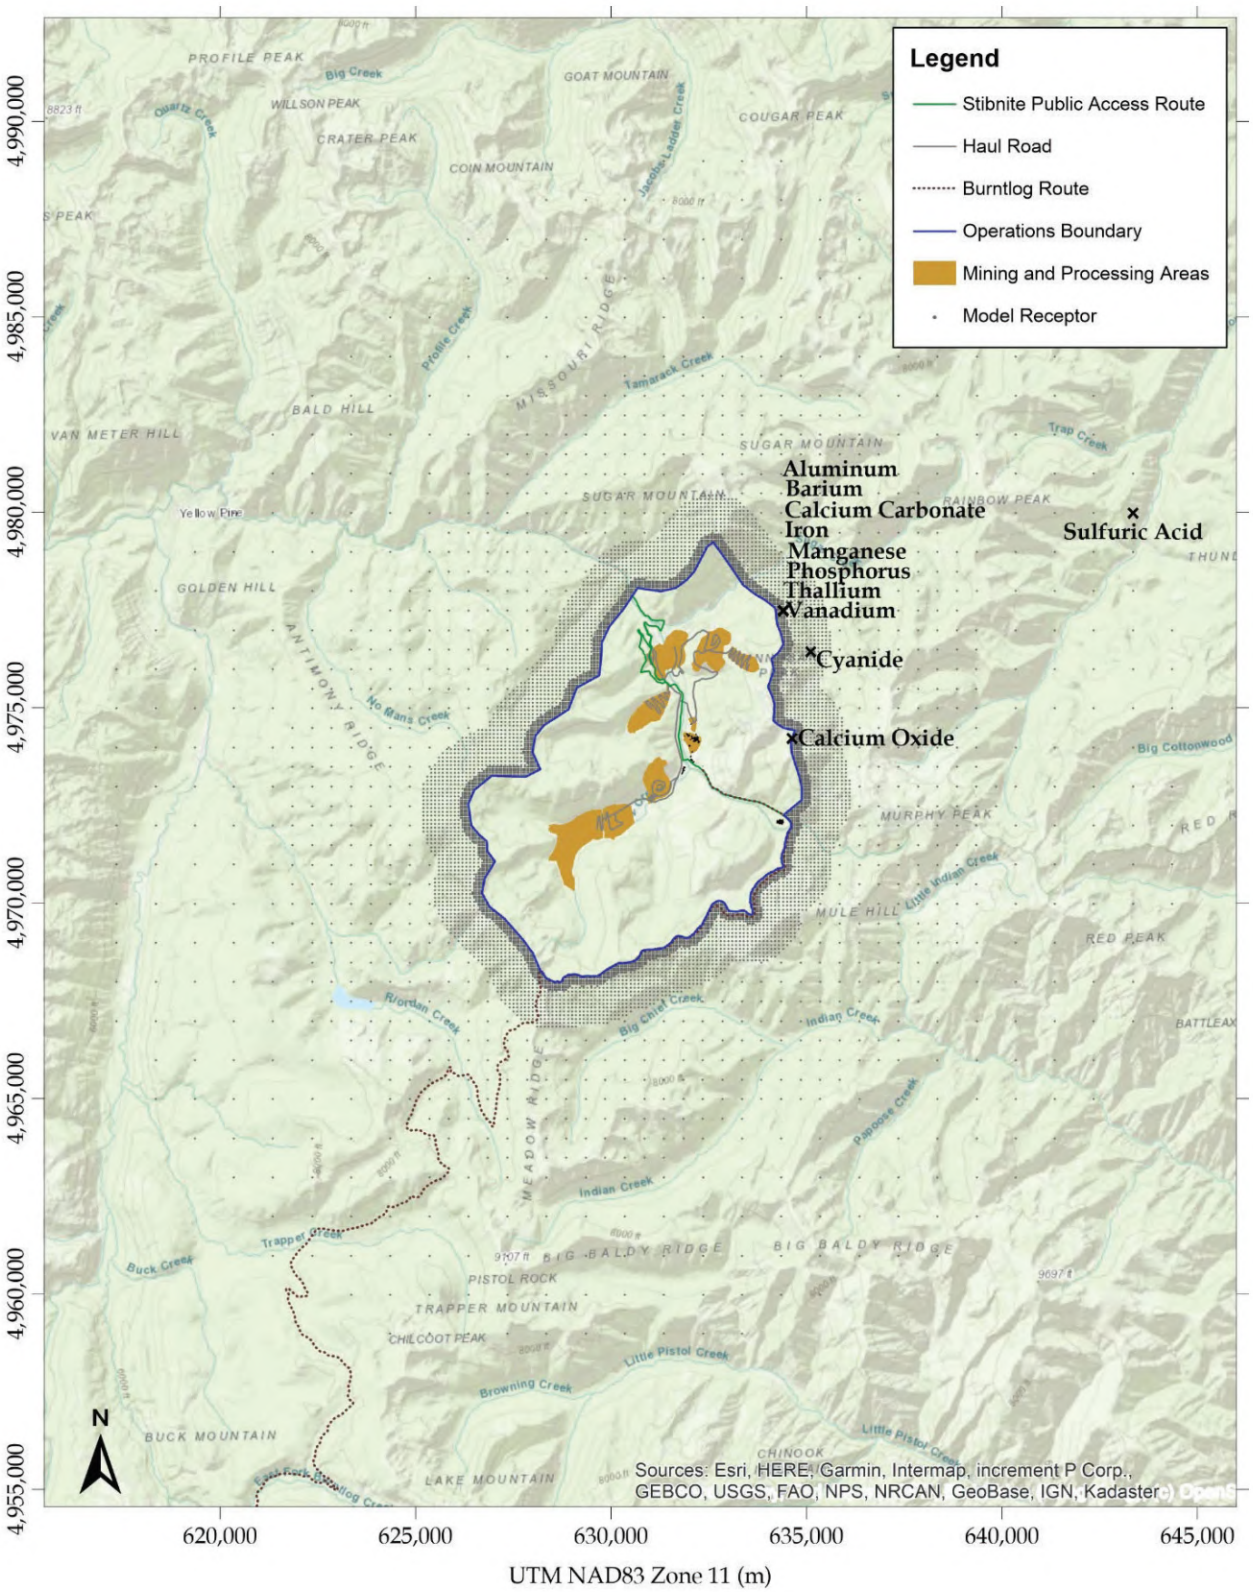
PRI contends that calculating lifetime arsenic exposure based on the proposed West End Pit life-of-mine production limit of 50% of the total production is conservative. The actual life-of-mine total production from the West End Pit as described in the ModPRO2 mine plan is only 198.26 million tons (Perpetua 2021), which is 50.3% of the proposed West End Pit life-of-mine production limit of 394.2 million tons.

6.0 Impact Results

TAP impact analysis results, as submitted in the *TAP Addendum* and as further assessed by DEQ, are discussed in this section. The effect of various operational refinements also reduced PM_{10} and $PM_{2.5}$ impacts, and this is discussed in Section 6.2.

6.1 TAP Impact Analyses Results

This section describes the revised TAP impact analyses and demonstrates that applicable TAP emissions resulting from operation of the SGP will not result in increased impacts that exceed AACs or AACCs.



6.1.1 Modeling Non-Carcinogenic TAPs

The non-carcinogenic TAPs subject to impact modeling requirements to demonstrate compliance with AACs of *Idaho Air Rules* Section 585 were modeled at the emission levels shown in Table 1 above. The maximum 24-hour modeled concentration for each of the 14 modeling scenarios demonstrates compliance with the applicable AAC, as summarized below in Table 5. PRI elected to include Scenario W5 in the modeling analysis for non-carcinogenic TAPs. Figure 1 illustrates the locations of the maximum impacts for each non-carcinogenic TAP.

Table 5. RESULTS FOR TAPS IMPACT ANALYSES FOR NON-CARCINOGENIC TAPS.					
Toxic Air Pollutant	**Averaging Time**	**Maximum Modeled Concentration ($\mu g/m^3$)[a]**	**Model Scenario**	**AAC[b] ($\mu g/m^3$)**	**Percent of AAC**

Figure 1. SGP NON-CARCINOGENIC MAXIMUM TAP IMPACT LOCATIONS.

6.1.2 Modeling Carcinogenic TAPs

The carcinogenic TAPs subject to impact modeling requirements to demonstrate compliance with AACCs of *Idaho Air Rules* Section 586 were modeled using an emission inventory that includes the T-RACT controls, long-term mining production limits, and other emission inventory refinements, as described in Section 4.0 and 5.0 of this *Modeling Review Attachment*.

The maximum modeled impact for each of the 14 modeling scenarios demonstrated compliance with the T-RACT AACC, as summarized below in Table 6. The SGP maximum concentrations were adjusted to account for the life-of-mine production limits, which affect the lifetime exposure, and to account for the elimination of Modeling Scenario W5. See Sections 5.7 and 5.8 of this *Modeling Review Attachment* for more detail. The locations of the maximum impacts for each carcinogenic TAP are presented in Figure 2. Arsenic concentrations are considerably lower in areas away from the location of maximum impact as shown in Figure 3.

Table 6. RESULTS FOR TAPS IMPACT ANALYSES FOR CARCINOGENIC TAPS.

Toxic Air Pollutant	Averaging Time	Maximum Modeled Lifetime Exposure Concentration ($\mu g/m^3$)[a,b]	Model Scenario	AACC[c] ($\mu g/m^3$)	T-RACT[d] AACC	Percent of T-RACT AACC
Arsenic	Annual	0.00095	W2	0.00023	0.0023	41.30%
Beryllium	Annual	0.00001	W1	0.0042	0.042	0.02%
Cadmium	Annual	0.000002	W1	0.00056	0.0056	0.04%
Formaldehyde	Annual	0.00007	W1	0.077	0.77	0.01%
Nickel	Annual	0.00001	W1	0.042	0.42	<0.01%

a. Micrograms per cubic meter.
b. The lifetime exposure concentrations are based on the proposed restrictions discussed in Sections 5.7 and 5.8 of this *Modeling Review Attachment*.
c. Acceptable Ambient Concentration of a Carcinogenic TAP.
d. Toxic Air Pollutant Reasonably Available Control Technology allows the AACCs to be increased by a factor of ten per *Idaho Air Rules* Section 210.12(b).

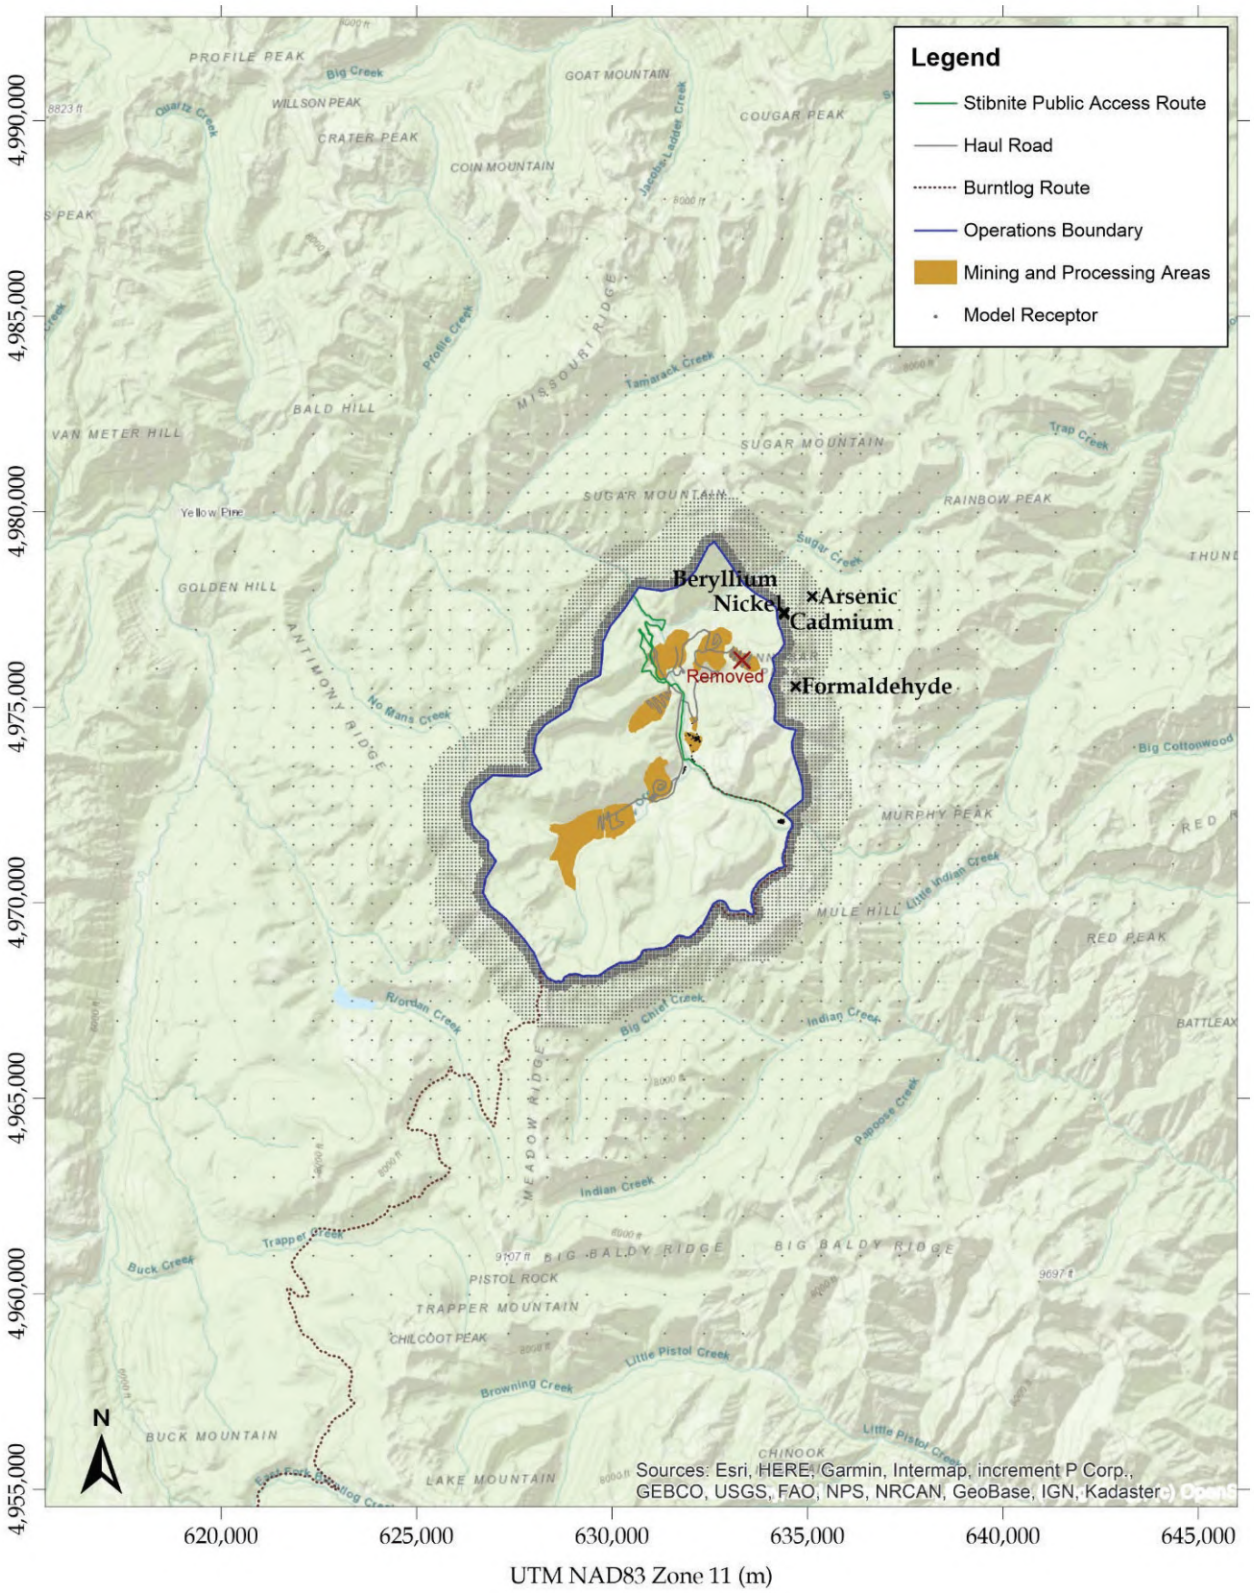

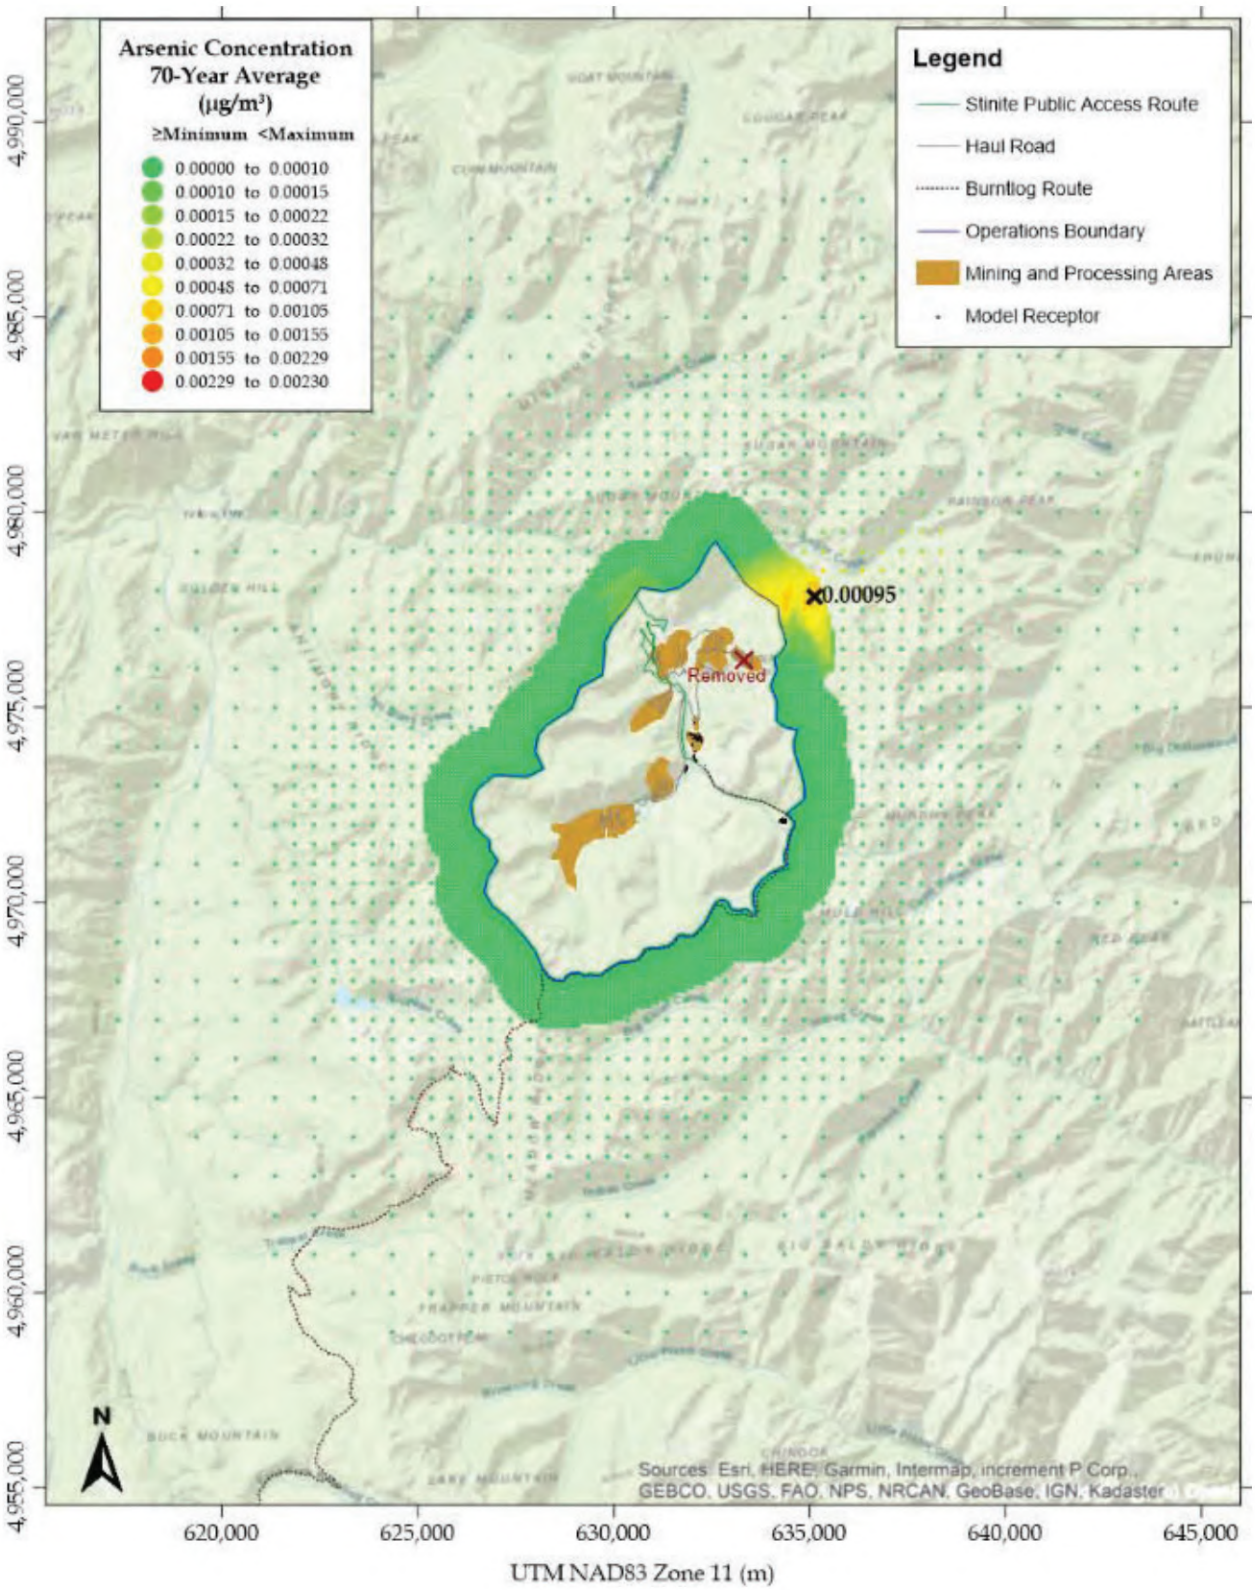

Figure 3. SGP CONTOURS OF LIFETIME ARSENIC IMPACTS.

6.2 *Effect of Changes to Modeled PM_{10} Results*

PRI has determined that the West End Development Rock Storage Facility will not be constructed. This change eliminated Modeling Scenario W5 as a potential operating scenario. In Section 4.1.4 in the main body of the DEQ *Modeling Review Memorandum*, DEQ identified PM_{10} NAAQS exceedances at four hotspot receptors when using the BULKRN meteorological dataset for Modeling Scenario W5 (the highest PM_{10} impact modeling scenario). When Modeling Scenario W5 is removed, the highest modeled impacts are predicted to occur for Modeling Scenario W3, which represents the transport of development rock from the West End Pit to the Hangar Flats Development Rock Storage Facility.

Table 7 presents results for the cumulative NAAQS impact analyses for Scenario W3. Results still exceed the 24-hour PM_{10} NAAQS even when Modeling Scenario W5 is eliminated. However, there is only one hotspot receptor exceeding NAAQS. The modeled violation is also predicted to occur during winter. This is a critical consideration because during winter, not only are fugitive emissions minimized because of the higher moisture content of material handled or driven over, but background concentrations in such remote areas are also generally much lower because of the absence of wildfires and dust-generating sources.

Table 7 also lists the results when using temporally varying backgrounds, instead of a single-value background, in the cumulative NAAQS impact analysis (using the "SEASON" and "MONTH" options in AERMOD). The highest daily average PM_{10} concentrations measured at Stibnite for every season and month in 2014 were used as inputs in the model. Table 7 shows that the SGP facility *safely* demonstrates compliance with the 24-hour PM_{10} NAAQS when temporally varying backgrounds (both seasonal and monthly) are used instead of the single-value background. Summing modeled design values with a single-value background that is on the upper end of the distribution results in a very conservative estimate of total impacts. DEQ strongly believes that using temporally varying backgrounds that respect seasonality is appropriate for the SGP facility, and that using the highest value in the period interval is very conservative.

TABLE 7. RESULTS FOR 24-HOUR PM_{10} CUMULATIVE NAAQS IMPACT ANALYSES FOR MODELING SCENARIO W3.

Backgrounds Scenario	Max. Conc.[a] ($\mu g/m^3$)[b]	Model Scenario	Back. Conc.[c] ($\mu g/m^3$)	Total Conc.[d] ($\mu g/m^3$)	NAAQS ($\mu g/m^3$)	Percent of NAAQS
Single-Value Background	116.9	W3	34.0	150.9[e]	150	100.6%
Seasonally Varying Backgrounds	123.5[f]	W3	*Seasonal*	123.5[f]		82.3%
Monthly Varying Backgrounds	123.5[f]	W3	*Monthly*	123.5[f]		82.3%

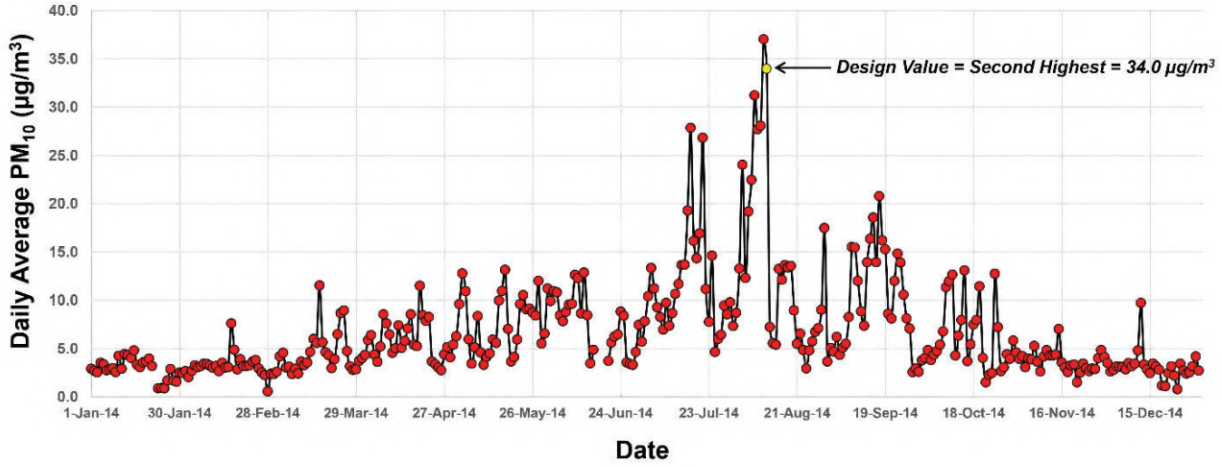
a. Max. Conc. = maximum modeled design concentration.
b. Micrograms per cubic meter.
c. Back. Conc. = background concentration.
d. Total Conc. = total (modeled + background) concentration.
e. One hotspot receptor exceeds NAAQS.
f. The maximum modeled design concentration already incorporates the seasonal and monthly background values.

The time series plot in Figure 4 and the box-and-whiskers plot in Figure 5 illustrate the variability in daily average PM_{10} concentrations collected at the Stibnite Site in 2014. Figures 4 and 5 confirm that the highest concentrations from the modeled and monitored datasets do *not* occur simultaneously. Highest modeled impacts are predicted to occur during winter while the highest background concentrations were measured at Stibnite during summer. Therefore, the summation method, where total impacts are

calculated by summing modeled design values with a background concentration that is also consistent in form with the regulatory design value, results in a very conservative estimate of the total impact for comparison to NAAQS. DEQ concludes that use of temporally varying (i.e., seasonal and monthly) backgrounds for SGP is justified. DEQ is highly confident that operation of the SGP will not cause or contribute to a violation of NAAQS.

PM_{10} and $PM_{2.5}$ NAAQS compliance was previously demonstrated prior to refinements and adjustments proposed in the submitted *TAP Addendum*. The main body of the DEQ *Modeling Review Memorandum* discussed and considered results from both modeling with meteorological data processed using the BULKRN method and modeling with data processed using cloud cover data, and DEQ concluded that NAAQS compliance was demonstrated with a high degree of confidence. The adjustments and refinements described in the *TAP Addendum* further increase DEQ's confidence in NAAQS compliance.

Figure 4. TIME SERIES OF DAILY AVERAGE PM_{10} CONCENTRATIONS MEASURED AT STIBNITE IN 2014.



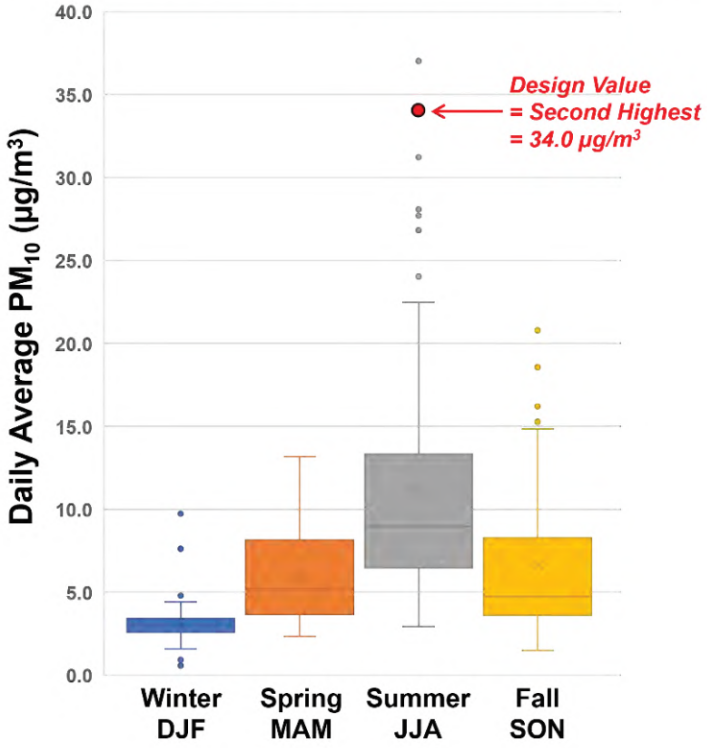


Figure 5. BOX-AND-WHISKERS PLOT FOR SEASONAL PM_{10} BACKGROUND CONCENTRATIONS MEASURED AT STIBNITE IN 2014.

In Figure 5 the middle line of each box represents the median. The "x" in the box represents the mean. The bottom and the top lines of the box represent the 1st quartile (25th percentile) and the 3rd quartile (75th percentile), respectively. The whiskers extend to the minimum and maximum values not considered outliers. Outliers are plotted individually.

7.0 Conclusions

This section provides conclusions of the *TAP Addendum* and DEQ's review of the *TAP Addendum*.

7.1 Conclusions of Revised TAP Analyses

The revised and refined TAP analyses:

- Revised TAP-applicable sources at the SGP facility.
- Proposed additional emission control measure and adjusted operations to reduce TAP emissions.
- Refined the approach used to demonstrate compliance with TAP regulations.

The submitted application, with the adjustments and refinements to analyses as described in the *TAP Addendum*, demonstrated to DEQ's satisfaction that the emissions of applicable TAPs will not result in impacts to ambient air that exceed TAP increments of *Idaho Air Rules* Section 585 and 586.

7.2 Effects of Adjustments/Revisions on NAAQS Compliance Demonstrations

The submitted application, prior to the *TAP Addendum*, demonstrated compliance with NAAQS to DEQ's satisfaction; and the operational measures proposed in the *TAP Addendum* will only further reduce estimated emissions. Eliminating Modeling Scenario W5 impacts, with the elimination of the West End Development Rock Storage Facility, affects the 24-hour PM_{10} impact modeling analysis for SGP. Modeling Scenario W3 is now the scenario producing the highest modeled impacts, and NAAQS compliance is easily demonstrated when using temporally varying background PM_{10} values, which were obtained from onsite monitoring data.

7.3 Conservatism of Permitting Analyses

Emissions and locations from which emissions occur are highly dynamic at mining facilities. This presents unique challenges for permit development because permits must include limits and operational requirements that ensure air quality standards are not violated. Permitting rules require that air impacts be assessed using maximum potential emissions as limited by either the capacity of the unit/operation or as limited by enforceable permit provisions. A permit where actual emissions are nearly representative of maximum allowable emissions, through imposing permit limits, would be exceedingly complex and require overly burdensome monitoring and record-keeping requirements. To avoid this, applicants typically calculate allowable emissions and perform impact analyses based on simplistic operational scenarios that largely overstate emissions estimated to occur from the facility.

PRI and Air Sciences have asserted that the submitted emission estimates, operational scenarios, and air impact analyses associated with the permit application greatly overstate best-estimated values. This point is evident when comparing the permit application materials and analyses with those presented in ModPRO2, PRI's revised mine plan and associated impacts. ModPRO2 is used in support of the Environmental Impact Statement (EIS).

Subject: Request for layman's explanation of URF & TLV

Attached, per your request is a draft explanation of URF and TLV/100 concepts as utilized in TAP NSR. This, of course, represents our tox. based views of what will do the job. We defer this draft to you for final decision as to what a layman might understand.

In developing emissions limits for new permitted facilities, the Idaho Air Quality Bureau (IAQB) uses the terms Unit Risk Factors and Threshold Limit Values. The following is an explanation of these terms and how they are used.

UNIT RISK FACTOR

A unit risk factor (URF) is used to describe the possibility of developing excess cancers over a average 70 year lifetime. This is based on being exposed to concentration of one microgram of a carcinogenic (cancer causing) substance in one cubic meter (1 $ug/m^{3)}$ of air over the 70 years. The term excess cancers means cases of cancers in excess of what would be normal for a given population. For example, if there was normally 5 cases of a given type of cancer in Anytown USA before a given exposure to some substance and 7 after the exposure, there would be 2 excess cancers.

Inhalation URFs are developed by the U.S. Environmental Protection Agency for carcinogenic substances. Each URF represents months of research and often years of policy process. Teams of toxicologists gathered all the toxicological information for each known or suspected carcinogen that could be found around the world. The available data were then rated or point factored per the quality of the research involved. A URF then is a probability statement derived from this process. Each URF was proposed by EPA

Celebrate IDAHO 1890·CENTENNIAL·1990™

Printed on Recycled Paper

and extensively reviewed and debated in public by scientists, health officials and industry representatives. Every URF represents a consensus of the best science and health opinion of the potency of a given carcinogen.

URFs are usually expressed as a number times 10 to some negative power. For example, benzine, an organic hydrocarbon found in various petroleum products and cigarette smoke has a unit risk factor of 8.3×10^{-6}. This means that there are 8.3 chances in one million of getting cancer if a person is exposed to 1 ug/m^3 24 hours a day for 70 years.

Another example would be asbestos. Asbestos has a URF of 2.3×10^{-1}. That means that if exposed to 1 ug/m^3 concentration for 70 years, the chances of getting cancer would be 2.3 in 10.

Within IAQB New Source Review (NSR) policy, URFs are used to calculate acceptable ambient levels for a given carcinogen. IAQB generally establishes that an ambient concentration which causes no more excess cancers than one in a million (1×10^{-6}) is acceptable. Once an acceptable ambient level is established, IAQB can then back calculate via engineering equations to an acceptable emission rate (in pounds per hour) for a given stack.

THRESHOLD LIMIT VALUE

Threshold Limit Value (TLV) is a time weighted exposure limit developed by the Occupational and Safety Administration and or the American Council of Government Industrial Hygienists. This value is used to limit the exposure of informed workers to a given toxic substance in the work place. The value is based on exposure of adult males working an eight hour shift. The IAQB uses TLV information to screen proposed new source emissions levels. The IAQB divides the TLV first by a value of 10 due to the fact that an ambient air exposure of a carcinogen means people are usually living under that exposure longer than eight hours out of 24. This value is then again divided by 10 to compensate for the fact that not everyone who is potentially exposed is an adult male. Other people may be more sensitive. The TLV thus is divided by a total of 100 for use in setting an acceptable ambient level.

For example, the TLV for cyanide is 5 milligrams per cubic meter (mg/m^3). An acceptable ambient level under IAQB policy would be 5 divided by 100 or 0.05 mg/m^3. For another example, the TLV for Lindane (an insecticide) would be 0.5 mg/m^3 concentration. The acceptable ambient level would be 0.5 divided by 100 or 0.005 mg/m^3.

As with carcinogens, the TLV derived acceptable ambient levels are used by the IAQB engineers to back calculate an acceptable stack emission rate for any proposed new source. A more pointed treatment these concepts can be found in The Toxic Air Pollutant NSR Policy Summary or the more thorough Draft Guidance Manual for Obtaining a Permit to Construct, Modify or Operate an Air Pollution Source.

Dick Rush, Vice President
IACI
P. O. Box 389
Boise, ID 83701

Dear Mr. Rush:

Attached is the DEQ list of ideas for rules to control new sources of toxic air pollutants in Idaho. This submittal should be considered a "straw-man" in that our deputy attorney general has not had adequate time to review this material. Nor has anyone from the State Bureau of Health had opportunity to comment. I will continue to try to get that input prior to our next meeting. But for now, we must consider this specific submittal for discussion purposes only.

The package is formatted so that comparisons can be made to the existing Air Quality Rules. If you have any questions, please call me.

Sincerely,

Robert Wilkosz
Bureau Chief
Technical Services Bureau

TOXIC AIR POLLUTION
-- RULES CHANGE IDEAS FROM DEQ

IDAPA 16.01.01003 -- DEFINITIONS.

Approved Fuels. Natural gas, propane gas, liquified petroleum gas, distillate fuel oils, residual fuel oils, and diesel fuel; except that waste oil, gasoline, or refined gasoline are not approved fuels.

Environmental Remediation Source. An emission source that functions to remediate or recover any release, spill, leak, discharge or disposal of any petroleum product or substance or any hazardous waste as defined by IDAPA 16.01.01003,44, from any soil or ground or surface waters. Any Environmental Remediation Source shall have an operational life of no greater than five (5) years from the inception of actual operations to the cessation of actual operations.

Pilot or Experimental Plant. An emission source that functions to test processing, mechanical, or pollution control equipment to determine full-scale feasibility.

Occupational Exposure Limit. Refers to airborne concentrations of substances and represents conditions under which it is believed that nearly all workers may be repeatedly exposed day after day without adverse effects. Occupational exposure Limits can be found in Threshold Limit Values for Chemical Substances and Physical Agents and Biological Exposure Indices with Intended Changes for 1991-92 or the current edition, adopted by the American Conference of Governmental Industrial Hygienists, or the National Institute for Occupational Safety and Health (NIOSH) current Relative Exposure Limit (REL), or the Occupational Health and Safety Administration (OSHA) Air Contaminate Standards, current Permissible Exposure Limit (PEL) or current Worker Protection Standards for Agricultural Pesticides promulgated by the Environmental Protection Agency under the Federal Insecticide, Fungicide and Rodenticide Act (FIFRA). In the case of conflicting values, the most stringent value shall take precedence.

Unit Risk Factor. *These factors describe the probability of developing excess cancers over a 70 year lifetime exposure to 1 ug/m^3 of a given carcinogen. Unit Risk Factors Can Be Found in the Federal Register Vol. 56 No. 35 / Thursday February 21, 1991 / Rules and Regulations Appendix V. or listed on the Integrated Risk Information System (IRIS) of the U.S. Environmental Protection Agency or listed in the Health Effects Summary Tables promulgated*

by the U.S. Environmental Protection Agency Office of Health Effects Assessment and the Office of Air Quality Planning and Standards. In the absence of U.S. EPA accepted risk factors, risk factors under review by the EPA Carcinogen Risk Assessment Verification Endeavor (CRAVE) shall be used on an interim basis.

IDAPA 16.01.01012, PROCEDURES AND REQUIREMENTS FOR PERMITS TO CONSTRUCT AND OPERATING PERMITS.

IDAPA 16.01.01012,02. *Permit to Construct. No owner or operator may commence construction ..., except that no permit to construct is required for ~~the following classes of equipment which have actual and allowable emissions of less than one hundred (100) tons per year of any air contaminant or and would not significantly increase the emissions of a major facility~~ sources which:*

a. have actual and allowable emissions of less than one hundred (100) tons per year of any air contaminant

and

b. would not significantly increase the emissions of a major facility

and

c. will not have an ambient air concentration of any air contaminant that would, as demonstrated using Department-approved methods:

i. cause or significantly contribute to a violation of an ambient air quality standard,

or

ii. cause an ambient concentration in excess of one percent of the Threshold Limit Value,

or

iii. cause a cancer-risk probability in excess of one in one million:

and

list: including but not limited to.

d. *which belong to one of the following classes of equipment:*

i. *Air conditioning or ventilating equipment not designed to remove air contaminants generated by or released from equipment;*

ii. *Air contaminant detectors or recorders, combustion controllers, or combustion shutoffs;*

iii. *Fuel burning equipment for indirect heating and for heating and reheating furnaces using gas exclusively with a capacity of less than fifty (50) million BTU's per hour input;*

iv. *Other fuel burning equipment for indirect heating with a capacity of less than one million (1,000,000) BTU's per hour input;*

v. *Mobile internal combustion engines, marine installations and locomotives;*

vi. *Stationary internal combustion engines in accordance with the following:*

100 horsepower or less -- unlimited hours of operation
101 to 200 horsepower -- 450 hours per month
201 to 400 horsepower -- 225 hours per month
401 to 600 horsepower -- 150 hours per month

vii. *Stationary internal combustion engines used exclusively for emergency power generation which burn an approved fuel and which operate less than 200 hours per year;*

viii. *Laboratory equipment used exclusively for chemical and physical analyses, including ventilating and exhaust systems for laboratory hoods;*

ix. *Environmental characterization activities including emplacement and operation of field instruments, drilling of sampling and monitoring wells, and any other activities specifically exempted by the Director;*

x. *Pilot or experimental plants located at least 1/4 mile from any recreational area or residence or other structure not occupied or used solely by the owner of the facility or the owner of the property upon which the facility is located; which operate less than one year; and that also meet one of the following conditions:*

1. *use a slip stream from an existing process stream not to exceed ten percent of that existing process stream, or*

2. *have actual uncontrolled emissions which are not significant;*

xi. *Any emission source or sources provided that the actual uncontrolled facility-wide emissions are not significant, and the uncontrolled emissions would not significantly contribute to ambient air quality concentrations;*

xii. *Any other class or size of equipment specifically exempted by the Director. A list of those sources unconditionally exempted by the Director will be maintained by the Department, and made available upon request.*

IDAPA 16.01.01012,13. *Procedure for Issuing Permits*

a. General procedures ...

b. Additional procedures ... attainment or unclassifiable area ...

c. Additional procedures ... federal Class I area ...

d. Procedures for operating permits ...

e. The Department ... fluid model ...

f. Modification of permits ...

g. Additional procedures for demonstrating compliance with the toxic substances provision 01.01011,01.

i. For sources that can demonstrate, using Department-approved methods, that emissions of carcinogens contribute an ambient air cancer risk probability of less than 1:1,000,000 and that emissions of non-carcinogens contribute to an ambient air concentration less than one percent of the Threshold Limit Value, no additional procedures are needed.

ii. For sources not recognized by the Department as environmental remediation sources that cannot demonstrate, using Department-approved methods, that emissions of carcinogens contribute an ambient air cancer risk probability of less than 1:100,000 and that emissions of non-carcinogens contribute to an ambient air concentration of less than one percent of the Threshold Limit Value, a permit cannot be issued unless the source has achieved the greatest degree of emission reduction that has been adequately

demonstrated and declared acceptable by the Department's Division of Health.

iii. *For remediation sources that cannot demonstrate, using Department-approved methods, that emissions of carcinogens contribute an ambient air cancer risk probability of less than 1:10,000 and that emissions of non-carcinogens contribute to an ambient air concentration of less than ten percent of the Threshold Limit Value, a permit cannot be issued unless the source has achieved the greatest degree of emission reduction that has been adequately demonstrated and declared acceptable by the Department's Division of Health.*

iv. *Department-approved methods will consist of the following:*

(a) *Comparison of maximum potential emissions to the screening emission limits for carcinogens and non-carcinogens as documented in Appendix A1 or A2 of the Toxic Air Pollutant list as promulgated but the Division of Environmental Quality. Maximum potential emissions can be determined by actual emissions testing using U.S. Environmental Protection Agency approved methods subject to review and approval by the Division of Environmental Quality or estimates of the maximum potential emissions using standard scientific and engineering principals and practices subject to review and approval by the Division of Environmental Quality*

The State is reviewing and approving EPA policy... this is redundant

We need to open up in that we want to be able to approve more than EPA approved...

(b) *Atmospheric dispersion modeling, using only U.S. Environmental Protection Agency (EPA) currently approved models, applied according to EPA's Guidelines on Air Quality Models, and as approved for the application by the Division of Environmental Quality.*

average in what respect
- emission levels
- met conditions

1. *For carcinogens, multiply the average hourly concentration by a persistence factor of 0.15 to convert the hourly average to an annual average The resulting product is then multiplied by the unit risk factor to obtain a an ambient air cancer risk probability.*

or other long term model procedures allow better factor than 0.15

test

2. *For non-carcinogens, multiply the average hourly concentration by persistence factor of 0.15 to convert the hourly average to an annual average The resulting product is then compared to one one hundredth (1/100 of the appropriate occupational exposure limit.*

(c) *Any other method approved by the Director.*

Case Docket No. 0101-22-01
OAH Case No. 23-245-01

EXPERT DECLARATION OF NORKA E. PADEN, Ph.D.

I, NORKA E. PADEN, Ph.D., hereby declare under penalty of perjury and pursuant to the law of the State of Idaho that the foregoing is true and correct:

Qualifications

1. My name is Norka E. Paden. I am an Environmental Toxicologist with 16 years of experience and have been with the Idaho Department of Environmental Quality's (DEQ's) Toxicologist/Risk Assessor since 2016. I am responsible for toxicological and risk assessment analyses for contaminated sites and toxic exposures statewide. I provide toxicological expertise for contamination issues related to air, water, and soil. I deliver written comments to policy makers and stakeholders during negotiated rulemaking that involves selenium, copper, and arsenic human health water quality criteria. I mentored a professor from Lewis-Clark State College on the risk assessment of air pollutants in the Lewiston Valley and was acknowledged in the paper, "Observations of volatile organic and sulfur compounds in ambient air and health risk assessment near a paper mill in rural Idaho, U.S.A," published in the 2020 *Atmospheric Pollution Journal*. In 2023, I delivered technical comments for the Idaho Department of Health and Welfare's "Letter Health Consultation for the Lewiston Clark Air Quality Study," and DEQ received commendation from the Nez Perce Tribe for the technical support.

2. I received my Master of Science in Human Ecology at the Free University of Brussels, Belgium, and Ph.D. in Environmental Toxicology from Texas Tech University. Prior to joining DEQ, I worked for the Idaho Department of Health and Welfare from 2011 through 2016 and authored six public health consultations and 12 letter health consultations, which are written responses to a specific request for information about health risks related to a hazardous material, chemical release, or specific site, under the Agency for Toxic Substances and Disease Registry (ATSDR) cooperative agreement. While working at GEI Inc., a Colorado environmental consulting firm from 2008 to 2011, I provided technical expertise in preparing risk investigations for Superfund sites, drafted technical reports on toxicity evaluations, and supported clients by writing technical reports and rebuttals during rulemaking meetings. I served as an adjunct faculty member for the Department of Community and Environmental Health at Boise State University from 2012 to 2015. I currently serve on various advisory committees in Idaho including the Cancer/Cluster Analysis Work Group, Fish Consumption Advisory Project, One Health Consortium, Groundwater Monitoring Technical Group, and Federal-State Toxicology Risk Analysis Committee. I am also a member of the Society of Environmental Toxicology and Chemistry (SETAC) and Editorial Board of the Journal of Integrated Environmental Assessment and Management.

Assignment

3. I have been asked by DEQ's Air Quality Division to review and evaluate the issue: "DEQ did not act reasonably and in accordance with law when it applied the 16/70 calculation to the ambient arsenic air concentration analysis" and provide this declaration to assist the Hearing Officer as the trier of fact. This declaration provides evidence in the form of an expert opinion

as a toxicologist, as the Board of Environmental Quality (DEQ Board) suggested in its *Final Order in the Matter of Air Quality Permit to Construct P-2019.0047* (Final Order).[1]

Summary of Opinions

4. Based on the information provided, cancer risk estimates using 16-years, and 70-years of exposure duration are both within the range of public health guidelines of 1 in 1,000,000 to 1 in 10,000 (i.e., one in a million to one in ten thousand) for protection of human health as suggested by the United States Environmental Protection Agency's (EPA's) target cancer risk range. Based on this assessment, the estimated lifetime cancer risk from exposure to arsenic through inhalation using the exposure duration of 16 years (lifetime of the mine) followed EPA's guidelines that are the framework for DEQ's Rules for the Control of Air Pollution in Idaho and falls within EPA's target cancer risk range of 1 in 1,000,000 to 1 in 10,000 (i.e., one in a million to one in ten thousand) and is not expected to increase cancer risk under current permit operating conditions.

Documents reviewed

5. I reviewed the May 1, 2024, DEQ Board meeting minutes transcript and background of the Perpetua-Stibnite Gold Mine Permit to Construct issued in June 2022 and subsequent documents on the case docket No. 0101-55-01 OAH No 23-245-01: May 23 Memorandum in Support of Joint Motion for Reconsideration and/or Clarification of Final Order, June 12 Order on Petitions for Reconsideration and/or Clarification of Final order, and July 8 Scheduling Order.

Background and Discussion

6. Based on my interpretation, the DEQ Board supported DEQ on four of the five matters. The fifth matter related to Section 586 of the "Rules for Control of Air Pollution in Idaho" (IDAPA 58.01.01) and DEQ's approach to arsenic and cancer risk. The DEQ Board found insufficient evidence to support DEQ's ambient arsenic air concentration analysis and determined that further factual development was needed on this issue. The DEQ Board remanded this issue to the Hearing Officer.

7. Dr. McMillan indicates that DEQ misinterpreted the acceptable ambient concentration (AACC) for carcinogens to comply with the air quality rules. He disagrees with the project-specific adjustment factor (16 years of mining operation), contends that DEQ failed to recognize the AACC functions to limit cancer initiation not only after 70 years but every day

[1] *See* REC 3716, *Final Order in the Matter of Air Quality Permit to Construct P-2019.0047*, *Nez Perce Tribe, Idaho Conservation League, and Save the South Fork Salmon v. Idaho Department of Environmental Quality*, Case Docket No. 0101-22-01, OAH Case No. 23-245-01 (Final Order at 22).

of a person's life starting at birth, and posits that DEQ's analysis underestimates the actual cancer risk (MacMillan 2024).[2]

8. Based on the analyses presented below, the cancer risk estimates were accurately calculated; the methodology for the calculations adheres to toxicological guidance and analytical practices to modify exposure duration and did not underestimate risk.

9. After reviewing the permit's cancer risk calculations and the toxic air pollutant rules, I researched cancer risk from arsenic exposures through inhalation. I calculated exposure concentrations and excess cancer risks for a residential inhalation exposure scenario (for a person living at a residence) using the maximum modeled annual concentration (potential worse-case scenario) of 0.00416 µg/m^3, calculated by analyses of the permit application, for the following exposure duration scenarios of 16 years (lifetime of the mine), and 70 years (EPA's lifetime exposure). The following paragraphs summarize my findings.

10. The permit application and DEQ review documentation states that cancer risk calculations used modeling scenarios, applied to develop AACCs outlined in the rules, and evaluated via the 70-year lifetime exposure. The maximum modeled concentrations for carcinogenic toxic air pollutants were modified to account for the life-of-mine production limits that affect the lifetime exposure using the following formula (DEQ 2022)[3]:

$$Lifetime\ exposure\ \left(\frac{\mu g}{m^3}\right) = \frac{Highest\ annual\ concentration\ \left(\frac{\mu g}{m^3}\right) \times 16\ (mine\ operation\ years)}{70\ (years, lifetime\ exposure)}$$

Cancer Risk Calculation in the Idaho Air Rules mirrors EPA's Guidelines

11. Section 586 in IDAPA 58.01.01, "Rules for the Control of Air Pollution in Idaho" (Idaho Air Rules), provides the following values for carcinogen toxic air pollutants: unit risk factors (URF) from EPA, screening emission levels (EL), and acceptable ambient levels for carcinogens (AACCs) (i.e., determined to cause cancer over lifetime exposure). The acceptable ambient levels for carcinogens are based on the cancer unit risk values from EPA and correspond to a one in one million cancer risk (DEQ 2019)[4]. In other words, the AACC for arsenic compounds presented in Idaho Air Rule Section 586 is calculated using EPA's Excess Cancer Risk Probability formula shown below:

---

[2] *See* Board of Environmental Quality Special Meeting (May 1, 2024) Transcript ("SM Tr.") 10:19-21 ("I believe DEQ has misinterpreted how the acceptable ambient concentration for carcinogens, the AACC, must be applied if it is to comply with our air quality rules"); *see also* SM Tr. 11:2-11.

For convenience, a true and correct copy of DEQ's TAPS Modeling Attachment is attached hereto as Exhibit A.

[4] Idaho Department of Environmental Quality. *Idaho Administrative Bulletin*. Boise, ID, September 4, 2019–Vol 19-9, page 388 ("The acceptable ambient levels for carcinogens are based on the cancer unit risk values from the Environmental Protection Agency and correspond to a one in a million cancer risk") (citing EPA 2019). A true and correct copy of page 388 is attached hereto as Exhibit B.

Excess Cancer Risk Probability = IUR x EC

Where Excess Cancer risk = 10^{-6} (1 in 1,000,000 one in a million)

IUR for arsenic is = 4 x 10^{-3} (0.0043)

EC = exposure concentration or acceptable ambient concentration (AACC)

AACC= (10^{-6})/ 4.3 x 10^{-3}

AACC= 2.3 x 10^{-4} = 0.00023 µg/m^3

The arsenic lifetime concentration associated with an excess cancer risk of one in one million is 0.00023 µg/m^3.

12. Under EPA's methodology for human health risk assessments, cancer risk calculations are done using a lifetime exposure set at 70 years. The exposure duration is the amount of time an individual is exposed to the contaminant being evaluated and is typically given in years. The exposure duration can be modified based on the site-specific information using the following formula to calculate screening values (EPA 2009)[5].

EC = (CA x ET x EF x ED)/AT

Where: EC (µg/m^3) = exposure concentration;
CA (µg/m^3) = contaminant concentration in air;
ET (hours/day) = exposure time;
EF (days/year) = exposure frequency;
ED (years) = exposure duration; and
AT (lifetime in years 70 x 365 days/year x 24 hours/day) = averaging time

13. **Step 1: Exposure Concentration Calculations**: I calculated exposure concentrations using the maximum modeled arsenic concentration in air (0.00416 µg/m^3), exposure time (24 hours per day), exposure frequency (365 days per year), and averaging time for 70 years of lifetime (EPA's default value) exposed for 365 days and 24 hours per day for a resident scenario with exposure durations of 16-years (life time of the mine), 70- years (EPA's default lifetime exposure) using EPA's approach and the formulas presented above. Table 1 shows the results for the calculations:

Table 1. Values used for the exposure concentration calculation.

Contaminant Concentration in Air (µg/m^3)	Exposure Time (hours/day)	Exposure Frequency (days/year)	Exposure Duration (years)	Averaging Time	Exposure Concentration µg/m^3
0.00416	24	365	16 (lifetime of the mine)	70x365x24	0.00095
0.00416	24	365	70 (EPA's default lifetime exposure)	70x365x24	0.00416

[5] Environmental Protection Agency (EPA). 2009. Risk Assessment Guidance for Superfund Volume I: Human Health Evaluation Manual (Part F, Supplemental Guidance for Inhalation Risk Assessment). EPA-540-R-070-002. OSWER 9285.7-82. Available at: https://semspub.epa.gov/work/HQ/140530.pdf. Accessed on July 18, 2024.

14. **Step 2: Cancer Risk Calculations:** To calculate cancer risk, I used the Inhalation Unit Risk (IUR) for arsenic from EPA's Integrated Risk Information System (IRIS) and the exposure concentrations calculated in Table 1 using the following formula (EPA 2009).[6] As previously mentioned, this is the same formula used for the AACC calculation in the Idaho Air Rules. Results of these calculations are presented in Table 2. *See* IDAPA 58.01.01.586.

Excess Cancer Risk Probability = IUR x EC

Where: IUR $(\mu g/m^3)^{-1}$ = Inhalation Unit Risk (for arsenic is 0.0043); and
EC $(\mu g/m^3)$ = exposure concentration

EPA defines excess cancer risk as an additional risk of cancer from exposure to a contaminant beyond an individual's risk of cancer from everyday life. Excess cancer risk is the probability that an exposed individual will develop cancer from exposure over a lifetime (70 years)[7]. The methodology EPA uses for the calculation of the excess cancer risk includes the inhalation unit risk (IUR) value, based on toxicological studies, the value selected for the inhalation unit risk represents a continuous exposure (24 hours/day and 7 days/week) and is supported by years of research from scientists at EPA's Integrated Risk Information System (IRIS) and the Superfund Health Risk Technical Support Center[8].

Table 2. Excess cancer risk calculations and interpretation.

Exposure duration (in years)	Inhalation Unit Risk $(\mu g/m^3)^{-1}$	Exposure Concentration $(\mu g/m^3)$	Excess Cancer Risk Probability	Interpretation	Within EPA's Recommended range > 1 in 1 million to < 1 in 10,000
16 (lifetime of the mine)	0.0043	0.00095	4.09E-06	4 in 1 million	Yes
70 (EPA's default lifetime exposure)	0.0043	0.00416	1.79E-05	2 in 100,000	Yes

15. DEQ used EPA's methodology for adjusting exposure duration given the known exposure duration (lifetime of the mine). The modification of the exposure duration is also consistent with DEQ's screening level risk assessment methodology for any contaminated site in Idaho (i.e., EPA's Regional Screening Levels)[9]. Inputs and outputs of the EPA's Regional Screening Levels online calculator using the parameters outlined in Table 1 (i.e., exposure duration, exposure time, lifetime in years) yield the same cancer risk estimates shown in Table 2 and are

presented in Exhibit C.[10] Two parameters that were modified in the EPA's Regional Screening Level Calculator were: exposure frequency from 350 days (EPA assumption is that the receptor takes 2 weeks of vacation every year away from the contamination) to 365 days/year, which is more conservative. The other parameter that was modified was the target hazard quotient (THQ) from 0.1 usually used when screening multiple contaminants to THQ=1.0, commonly used when screening only one contaminant, in this case arsenic.

Cancer Risk Estimates and T-RACT within EPA's acceptable range

16. Toxic Air Pollutant Reasonably Available Control Technology (T-RACT) for carcinogens outlined in the Idaho Air Rules: cancer risk probability of less than one in one hundred thousand (1 in 100,000) (IDAPA 58.01.01.210.12.b) falls within the EPA's recommended range of > 1 in 1 million to < 1 in 10,000 presented in Table 2.

17. The cancer risk estimates from exposure to 0.00416 µg/m^3 arsenic (maximum arsenic concentration calculated from modeling using potential worse-case scenario) through inhalation 24 hours a day, 365 days, and for 16 years (lifetime of the mine) is four additional cancers in a population of one million people exposed. The probability for a resident to develop cancer after exposure to 0.00416 µg/m^3 arsenic through inhalation 24 hours a day, 365 days, and for 70 years (EPA's default lifetime exposure) is two additional cancers in 100,000. These excess cancer risk estimates are within the range EPA considers acceptable (<1 in 10,000 to > 1 in 1,000,000) [7]. EPA considers excess cancer risk < 10^{-6} (1 in 1,000,000) to be negligible, 10^{-4} (>1 in 10,000) and 10^{-6} to 10^{-4} (1 in 1,000,000 to 1 in 10,000) to be acceptable (EPA 1989)[11]. This analysis shows at the maximum arsenic levels modeled (0.00416 µg/m^3) for exposures of 16, or 70 years are within the public health guidelines, and DEQ followed EPA's guidelines when using the 16-year exposure scenario (lifetime of the mine).

Cancer Risk Considerations

18. Other factors may play a role in analyzing cancer risk, such as existing cancers in the population, arsenic background concentrations at the site, sensitive populations living near the site, and uncertainty of maximum arsenic concentration derivation. According to the American Cancer Society, cancer affects 1 in 3 people in the United States, meaning that over a lifetime, an American's probability of getting any cancer is 0.333333 (ACS 2024)[12]. Adding the probability of 2 in 100,000 (excess cancer risk calculated for someone exposed for a lifetime of 70) to 0.333333, the probability of an individual getting cancer increases to 0.333353; this difference is very small.

19. From the toxicological point of view, enough evidence exists on the carcinogenic effects (urinary bladder, lung, and skin) of inorganic arsenic (IARC 2012)[13]. People who accidentally eat arsenic for a long time can develop some diseases. Sources of arsenic for ingestion include food (seafood, fish, algae, cereals), air (coal-fired power and smelting), and water (EFSA 2009)[14]. Evidence indicates that long-term exposure to arsenic mainly through drinking water is of great concern to human health due to daily consumption and occurrence in several regions of the world over the past decades (Martinez et al. 2011)[15]. Some occupational studies have documented lung cancer due to inhalation exposures to arsenic, and EPA has used these studies to derive the Inhalation Unit Risk (IUR) (EPA 2024)[16].

20. Cancer risk depends on a wide variety of factors such as alcohol and tobacco use, sun light and radiation exposures, age, diet, hormones, obesity, infectious agents, cancer-causing agents, family history, immunosuppression, and chronic inflammation (NIH 2015)[17]. The literature indicates that inorganic arsenic causes harmful effects mainly through the initiation of oxidative stress (when there are many molecules called free radicals in the body and not enough antioxidants to eliminate them), alterations to DNA (DNA and RNA are both macromolecules essential for life), protein modification, and RNA expression as Dr. McMillan alluded; however, these effects are mainly documented from exposures to elevated levels of arsenic in drinking water (EPA 2024)[18]. The literature also reveals that further cancer studies are needed to understand the mechanisms of arsenic carcinogenesis (Zhou & Xi 2018; Speer et al. 2022)[19,20].

Cancer Risk Calculations were not underestimated

21. Additional information to support DEQ's calculation did not underestimate cancer risk, including the no significant concentration level of 0.067 µg/m^3 (i.e., air concentration at 1 in 100,000 excess lung cancer mortality) from the Texas Commission on Environmental Quality (Erraguntla et al.2012)[21]. The value is used to evaluate ambient air monitoring data to protect the public against adverse health effects from chronic exposure to arsenic. The maximum modeled air concentration 0.00416 µg/m^3 is below this threshold. The maximum modeled air concentration of 0.00416 µg/m^3 is within World Health Organization's recommendations for concentrations of arsenic range from 1–10 ng/m^3 (0.001–0.01 µg/m^3) in rural areas, 3–30 ng/m^3 (0.003–0.03 µg/m^3) in noncontaminated urban areas (WHO 2000)[22].

Conclusion

22. I conclude that DEQ's analysis followed EPA's guidelines and that results from a shorter duration exposure (i.e., 16 years) is within EPA's target risk range of 1 in 1,000,000 to 1 in 10,000 (i.e., one in one million to one in ten thousand) and is not likely to increase cancer risk by the arsenic air emissions calculated by the analyses of the air permit application (maximum arsenic-modeled concentrations).

EXHIBIT A

TAPs Addendum Modeling Review Attachment

1.0 Introduction and Summary

Perpetua Resources Idaho, Inc. (PRI) submitted the *Stibnite Gold Project (SGP) Permit to Construct Application TAP Addendum* (*TAP Addendum*), prepared by Air Sciences Inc. (Air Sciences) and submitted to DEQ on October 5, 2021. The TAP Addendum reassessed source applicability to Toxic Air Pollutant (TAP) permitting requirements, refined TAPs regulatory methods to demonstrate compliance with applicable TAP increments, revised and/or refined operations and operational parameters affecting TAP emissions, and refined TAP air impact analyses. The revisions and refinements made for the TAP Addendum also reduced PM_{10} and $PM_{2.5}$ emissions, and this effect is presented in this *TAPs Addendum Modeling Review Attachment* (*Modeling Review Attachment*).

2.0 Scope of TAPs Addendum

DEQ reevaluated TAPs compliance regulatory interpretations and impact assessment methods following the second public comment period of February 18, 2021, through March 19, 2021. Areas of revision in response to issues identified after the public comment period included:

- Revising source-specific TAP impact assessment applicability, primarily identifying what sources can be excluded because they are "covered" or "addressed" by a National Emissions Standard for Hazardous Air Pollutants (NESHAP) or New Source Performance Standard (NSPS).
- Refining regulatory methods used to demonstrate compliance with TAP increments.
- Refining TAP emission calculation methods and dispersion-affecting parameters.
- Reassessing TAP impacts resulting from revised and/or refined methods and data.
- Providing a best-estimate of actual TAP emissions that will occur from operation of the mine, and then comparing this to maximum permit-allowable emissions.

PRI and Air Sciences, PRI's permitting consultant, submitted the *TAP Addendum* on October 5, 2021.

3.0 Revised NESHAP/NSPS TAP Exclusion

DEQ and PRI reevaluated TAP source applicability after the second public comment period in response to expressed concerns regarding sources excluded as per *Idaho Air Rules* Section 210.20 (excluding sources that are "covered" or "addressed" by a NESHAP). TAP applicability is explained in greater detail in the main body of the DEQ Statement of Basis. As a result of the reevaluation, some additional sources were included in the TAP impact modeling analyses that were not previously. TAP sources from gold mining that were modeled in the final TAP analyses included: drilling, blasting, excavating, hauling, prill silos, rock dumps and storage piles, and tailings.

Air Sciences consulted with DEQ to refine TAP compliance demonstration methods from what was originally submitted in the application. The refinement was primarily needed to show compliance with the

arsenic Acceptable Ambient Concentration of a Carcinogen (AACC). The revised methods are described in the submitted *TAP Addendum* and this DEQ *Modeling Review Attachment*.

4.0 TAPs Refined Compliance Demonstration Approach

PRI, in consultation with DEQ, used a highly refined TAPs analysis approach to demonstrate compliance with applicable TAP increments. This approach involved the following:

- AACC Adjustment for Toxic Air Pollutant Reasonably Available Control Technology (T-RACT) Utilization.
- TAP Emission Averaging Period.
- AACC Adjustment for the Operational Life of the Mine.

4.1 AACC Adjustment for T-RACT Utilization

Idaho Air Rules Section 210.12 allows TAP impacts of 10 times the AACC if the application demonstrates that T-RACT is used for the TAP emission sources. This represents a life-time cancer risk of 1-in-100,000. An adjustment cannot be made for non-carcinogenic TAPs listed in *Idaho Air Rules* Section 585.

Review of the T-RACT demonstration is performed by the DEQ permit writer and is described in the main body of the DEQ Statement of Basis.

4.2 TAP Emission Averaging Period

Annual average emissions of carcinogenic TAPs are typically used in the dispersion model to estimate maximum annual impacts. PRI refined the analyses by using source-specific emission rates that are representative of a 5-year averaging period. This approach is appropriate because carcinogenic impacts are of concern from a long-term exposure basis.

4.3 AACC Adjustment for the Operational Life of the Mine

AACCs were established based on a 1-in-1,000,000 cancer risk over a 70-year lifetime, as stated in *Idaho Air Rules* Section 006.125:

> ***Toxic Air Pollutant Carcinogenic Increments**. Those ambient air quality increments based on the probability of developing excess cancers over a seventy (70) year lifetime exposure to one (1) microgram per cubic meter (1 ug/m3) of a given carcinogen and expressed in terms of a screening emission level or an acceptable ambient concentration for a carcinogenic toxic air pollutant. They are listed in Section 586.*

PRI indicated the maximum life-of-mine will be 16 years. Life-time exposures to carcinogenic TAPs were refined by multiplying the maximum modeled annual impact by a ratio of 16/70. Section 5.7 of this *Modeling Review Attachment* provides more details on this adjustment for the project.

5.0 Refined TAP Emission Estimates and Modeling Methods/Parameters

This section describes changes made to TAP emission estimates and to methods/parameters used in the impact modeling analyses.

5.1 Operational Adjustments

PRI and Air Sciences proposed and committed to several operational adjustments to reduce actual and estimated TAP emissions:

- Installing and operating dust collection systems on drilling rigs (determined to be T-RACT).
- Capping the haul roads that are outside of the pits and development rock storage facilities (DRSFs) with clean (lower levels of arsenic) development rock (determined to be T-RACT).
- Eliminating the West End Development Rock Storage Facility, which eliminated the highest-emitting operational scenario W5.
- Limiting long-term mining production to an average of 135,000 tons/day for a 5-year rolling average.
- Constructing the Burntlog access road with offsite materials containing "background" levels of arsenic.
- Updating the bulldozing emission factor using the SGP site-specific silt content.

5.2 General Modeling Methods and Parameters

Modeling methods and parameters used in TAP impact analyses presented in the *TAP Addendum* are largely identical to those used in the previously submitted application. These include the air dispersion model used, meteorological data, terrain, building downwash, ambient air boundary, and receptors. TAP modeling was conducted for the 14 operational modeling scenarios, consistent with the NAAQS analyses. Modeling Scenario W5 was eliminated from the arsenic modeling, as discussed in Section 5.8 of this *Modeling Review Attachment*.

The meteorological dataset processed using McCall, Idaho, cloud cover data was used for analyses in the *TAP Addendum*. Impacts were not assessed using the dataset processed using the Bulk Richardson (BULKRN) method for boundary layer parameter calculations. EPA considers both methods to be acceptable. Although modeled impacts tend to be somewhat larger when using meteorological data processed by the BULKRN method, DEQ contends that the impact analyses are still largely conservative compared to actual impacts anticipated. Conservative aspects include: continual operation of the worst-case operational scenario; operation at maximum allowable rates for the averaging period; no reduction in winter-time emissions from fugitive sources, accounting for emission suppression effects of increased moisture.

5.3 TAP Modeling Applicability

Table 1 provides a comparison between applicable facility-wide maximum potential TAP emissions for the highest-emitting scenario (W3) and TAP screening emission levels (ELs) from *Idaho Air Rules* Sections 585 (for non-carcinogens) and 586 (for carcinogens). Note that TAPs also classified as HAPs

emitted from sources "addressed" or "covered" by NSPS or NESHAP were not required to be evaluated for compliance with TAP increments in accordance with *Idaho Air Rules* Section 210.20. Furthermore, PRI has determined that the West End Development Rock Storage Facility will not be constructed. This change eliminated Modeling Scenario W5 (the highest-emitting scenario described in the main body of the DEQ *Modeling Review Memorandum*) as a potential operating scenario. After eliminating Modeling Scenario W5, it was determined that Modeling Scenario W3 is the highest-emitting scenario for all TAPs.

Table 1. TAP MODELING APPLICABILITY DETERMINATION (HIGHEST-EMITTING MODELING SCENARIO: W3).

HAP/TAP	Emissions (lb/hr)			EL (lb/hr)		Determination

Table 1. TAP MODELING APPLICABILITY DETERMINATION (HIGHEST-EMITTING MODELING SCENARIO: W3).						
HAP/TAP	Emissions (lb/hr)			EL (lb/hr)		Determination
	(a)	(b)	Total	(c)	(d)	
Thallium	8.1E-3	5.2E-4	8.7E-3	7.0E-3	--	Non-carcinogenic EL exceeded
Uranium	8.1E-3	5.2E-4	8.7E-3	1.3E-2	--	EL not exceeded
Vanadium	2.3E-2	8.4E-4	2.4E-2	3.0E-3	--	Non-carcinogenic EL exceeded
Trimethyl Benzene	--	1.1E-2	1.1E-2	8.2E+0	--	EL not exceeded
Tungsten	8.1E-3	5.2E-4	8.7E-3	3.3E-1	--	EL not exceeded
Zinc	2.9E-2	2.2E-3	3.1E-2	6.7E-1	--	EL not exceeded

a. Total HAP/TAP emissions for EL evaluation from mining (i.e., pits, blasting, haul roads, stockpiles and DRSF, tailings storage facility, access road, and underground exploration) and leaching. Emissions from sources covered/addressed by NSPS/NESHAP are not included in the evaluation for modeling applicability.

b. Total HAP/TAP emissions for EL evaluation from processing and production (i.e., ore processing [crushers and transfer, prill silos], ore concentration and refining [autoclave, electrowinning cells and pregnant solution tank, retort, furnace, carbon kiln], process heating [POX boiler, carbon regeneration kiln, propane vaporizer, solution heater], lime production [limestone crushers, screens, mill, transfers, lime kiln, kiln feed, lime mill, pebble lime silo, lime silos, lime mill crushing], aggregate production [portable crushers, screens, transfers], concrete production [central mixer, cement silos, aggregate bin], HVAC [heaters], emergency power [emergency generators, fire pump], fuel storage [gasoline fuel and tanks]). Emissions from sources covered/addressed by NSPS/NESHAP are not included in the evaluation for modeling applicability.

c. Non-carcinogenic EL from *Idaho Air Rules* Section 585.

d. Carcinogenic EL from *Idaho Air Rules* Section 586.

Table 1 shows that the SGP facility-wide potential TAP emissions exceed the respective EL for arsenic, beryllium, cadmium, cyanide, formaldehyde, manganese, nickel, phosphorus, aluminum, barium, calcium carbonate, calcium oxide, iron, sulfuric acid, thallium, and vanadium. Therefore, modeling was required for these 16 TAPs (11 non-carcinogenic and five carcinogenic TAPs) to demonstrate compliance with Acceptable Ambient Concentrations of Non-Carcinogens (AACs) and AACCs.

5.4 TAP Modeled Emission Rates

Table 2 lists the source-specific modeled emission rates for all 11 non-carcinogenic TAPs that required modeling (worst-case modeling scenario for all non-carcinogenic TAPs: W5). Table 3 lists the source-specific modeled emission rates for all five carcinogenic TAPs that required modeling (worst-case impacts for arsenic are associated with modeling scenario W2; worst-case impacts for all other carcinogenic TAPs are associated with modeling scenario W1). Note that all source-specific emission rates listed in Tables 2 and 3 were extracted by DEQ's modeling staff from the submitted modeling input files.

The total modeled emission rates for all non-carcinogenic TAPs are equal to the total facility-wide HAP/TAP emissions as stated in the permitting emissions inventory (excluding sources addressed by NSPS/NESHAP), evaluated at 180,000 T/day (see last two rows of Table 2). However, for carcinogenic TAPs, modeling was performed using an emission inventory that included T-RACT controls, long-term mining production limits, and other emission inventory refinements, as described in Section 4.0 of this *Modeling Review Attachment* (see last three rows of Table 3).

Table 2. MODELED EMISSION RATES FOR NON-CARCINOGENIC TAPS (WORST-CASE MODELING SCENARIOS).

a. Arsenic (worst-case modeling scenario: W2).
b. Pounds per hour.
c. Beryllium (worst-case modeling scenario: W1).
d. Cadmium (worst-case modeling scenario: W1).
e. Formaldehyde (worst-case modeling scenario: W1).
f. Nickel (worst-case modeling scenario: W1).
g. The Haul Road was represented in the model as a series of volume sources. The emission rates listed in this table represent each individual volume source.
h. Total T-RACT emission rates – calculated based on T-RACT controls, long-term mining production limits, and other emission inventory refinements, as described in Section 4.0 of this *Modeling Review Attachment* – are derived from Tables B-W2 (for Arsenic) and B-W1 (for Beryllium, Cadmium, Formaldehyde, and Nickel) in Appendix B of the *TAP Addendum*.
i. Total emission rates at 180,000 tons per day were derived from Worksheet "TblA" in the emission inventory dated October 5, 2021. The total emission rates in this row represent all facility-wide HAP/TAP emission sources from mining, leaching, and processing and production (excluding emissions from sources "addressed" or "covered" by NSPS/NESHAP).

5.5 Cyanide Modeling Emission Source Parameters

Modeling analyses for cyanide introduced two new emission sources that were not previously evaluated by DEQ: tailings storage facility (model ID: TSF) and mill tanks (model ID: MILLTANKS).

1. The tailings storage facility was modeled by Air Sciences as a surface-based (zero release height above ground-level and zero initial vertical dimension) AREA source. The easterly and northerly lengths were calculated as square-root of the TSF area (easterly length = northerly length = $\sqrt{1{,}338{,}158\ square\ meters}$ = 1,157 meters).

2. The mill tanks were grouped and modeled by Air Sciences as a single VOLUME source. The tanks sit on the ground, so the release height was set to the average tank height of 12.2 meters (40 feet). The initial lateral dispersion (σ_y) was calculated as the equivalent diameter of the combined (18) tank area divided by the single VOLUME source coefficient of 4.3:

$$\sigma_{y(MILLTANKS)} = \frac{Equivalent\ diameter}{4.3} = \frac{\sqrt{\Sigma(d)^2}}{4.3} = 42.8\ feet$$

The individual tank diameters (d) are: two tanks at 40 feet, four tanks at 52 feet, six tanks at 54 feet, and six tanks at 20 feet.

DEQ typically requires that tailings storage facilities be modeled as an AREAPOLY source with an outline that follows the contour of the emission source, and that mill tanks be represented in the model as individual volume sources; but, given that the maximum modeled concentration for cyanide is safely below the AAC (0.08%), DEQ's modeling team accepted the modeling analysis submitted by Air Sciences and concluded that it confidently demonstrates that the cyanide AAC will not be exceeded.

5.6 Deposition Modeling

Air Sciences applied particle deposition algorithms in the impact modeling for particulate TAPs. The particulate deposition parameters used in the NAAQS compliance analysis were derived for PM_{10} and $PM_{2.5}$ (see Tables 22 and 23 in the main body of the DEQ *Modeling Review Memorandum*). Dust-related metal TAP emissions include total particulates (all size fractions of particulate matter [PM] up to PM_{30}). Therefore, the deposition parameters for PM were calculated using the same methodology and EPA references used for PM_{10} and $PM_{2.5}$ in the NAAQS compliance demonstration analyses. The PM deposition parameters are provided below in Table 4. The same density values were used as in the previous TAPs modeling analysis. However, an additional deposition characterization bin was added to better handle deposition of 10 µm to 30 µm particulates; mass fractions were adjusted accordingly.

Table 4. PARTICULATE MATTER DEPOSITION PARAMETERS BY SOURCE CATEGORY.

Source Category	Parameter	PM

[a.] See Table 23 in the main body of the DEQ *Modeling Review Memorandum*.

5.7 Carcinogenic TAP Modeling Lifetime Exposure Adjustment

Maximum modeled concentrations for carcinogenic TAPs were adjusted to account for the life-of-mine production limits, which affects the lifetime exposure.

PRI evaluated the highest modeled annual carcinogenic TAP concentration from each of the 14 modeling scenarios for lifetime exposure as follows:

$$Lifetime\ exposure\ \left(\frac{\mu g}{m^3}\right) = \frac{Highest\ annual\ concentration\ \left(\frac{\mu g}{m^3}\right) \times 16\ (mine\ operation\ years)}{70\ (years, lifetime\ exposure)}$$

This equation assumes that the highest annual concentration from the 14 modeling scenarios is repeated for 16 years of mining operation. This was then averaged over 70 years to calculate the 70-year lifetime exposure.

PRI and Air Sciences contend that calculating lifetime exposure based on 16 years of mining operation is conservative. The annual emissions for carcinogenic TAP modeling are based on 135,000 tons/day (see Section 5.1 of this *Modeling Review Attachment*) and 365 days per year. Over 16 years, this equates to a potential mining production of 788.4 million tons:

$$\frac{135{,}000\ \left(\frac{tons}{day}\right) \times 365\ \left(\frac{days}{year}\right) \times 16\ years}{1{,}000{,}000\ \left(\frac{tons}{million\ ton}\right)} = 788.4\ million\ tons$$

The actual life-of-mine total production as described in the SGP *Refined Proposed Action* (*ModPRO2*) mine plan is only 402.86 million tons (Perpetua 2021), which is 51.1% of the potential life-of-mine production represented in the above equation and related emission evaluations.

5.8 Arsenic Compliance Demonstration for Modeling Scenarios W1-W4

To demonstrate compliance with the AACC for arsenic, PRI applied two additional operating limitations:

- The removal of Modeling Scenario W5 as a potential operating scenario
- Limiting the West End Pit's life-of-mine potential mining production to 50% of the total life-of-mine potential mining production of 788.4 million tons: 50% * 788.4 million tons = 394.2 million tons

PRI has determined that the West End Development Rock Storage Facility (DRSF) will not be constructed. This change eliminated Modeling Scenario W5 from the arsenic modeling evaluation. The remaining four West End Pit modeling scenarios (W1–W4) are evaluated using the 70-year lifetime exposure equation from Section 5.7 and adjusting for the proposed West End Pit life-of-mine production limit of 50% of the total production as follows:

$$LifeExpose_{Wi,j,n} = \left[\left(WEPExpose_{Wi,n}\right)(50\%) + \left(nonWEPExpose_{Sj,n}\right)(50\%)\right]\left[\frac{16\ year\ LOM}{70\ year\ exposure}\right]$$

where:

W*i*	=	West End Pit scenario, where *i* = 1 to 4.
S*j*	=	non West End Pit scenario, where *j* = B1, B2, H1, H2, H3, H4, Y1, Y2, and Y3.
n	=	specific receptor.
$LifeExpose_{Wi,j,n}$	=	lifetime exposure in µg/m³ for West End Pit scenario *i*, non West End Pit scenario *j*, at receptor *n*.
$WEPExpose_{Wi,n}$	=	annual maximum impact in µg/m³ for West End Pit scenario *i* at receptor *n*.
$nonWEPExpose_{Sj,n}$	=	annual maximum impact in µg/m³ for non West End Pit scenario *j* at receptor *n*.
16 year LOM	=	maximum life-of-mine.
70 year exposure	=	Lifetime exposure used for development of AACCs in *Idaho Air Rules*.

The above equation was used to calculate the lifetime arsenic exposure from the West End Pit scenarios (W1–W4) on a receptor-by-receptor basis. Combining the concentrations from Modeling Scenarios W1–W4 with the highest concentration from the remaining non-West End Pit scenarios (B1, B2, H1, H2, H3, H4, Y1, Y2, or Y3) conservatively ensures that the maximum potential impacts from applicable sources are evaluated and remain below AACCs.

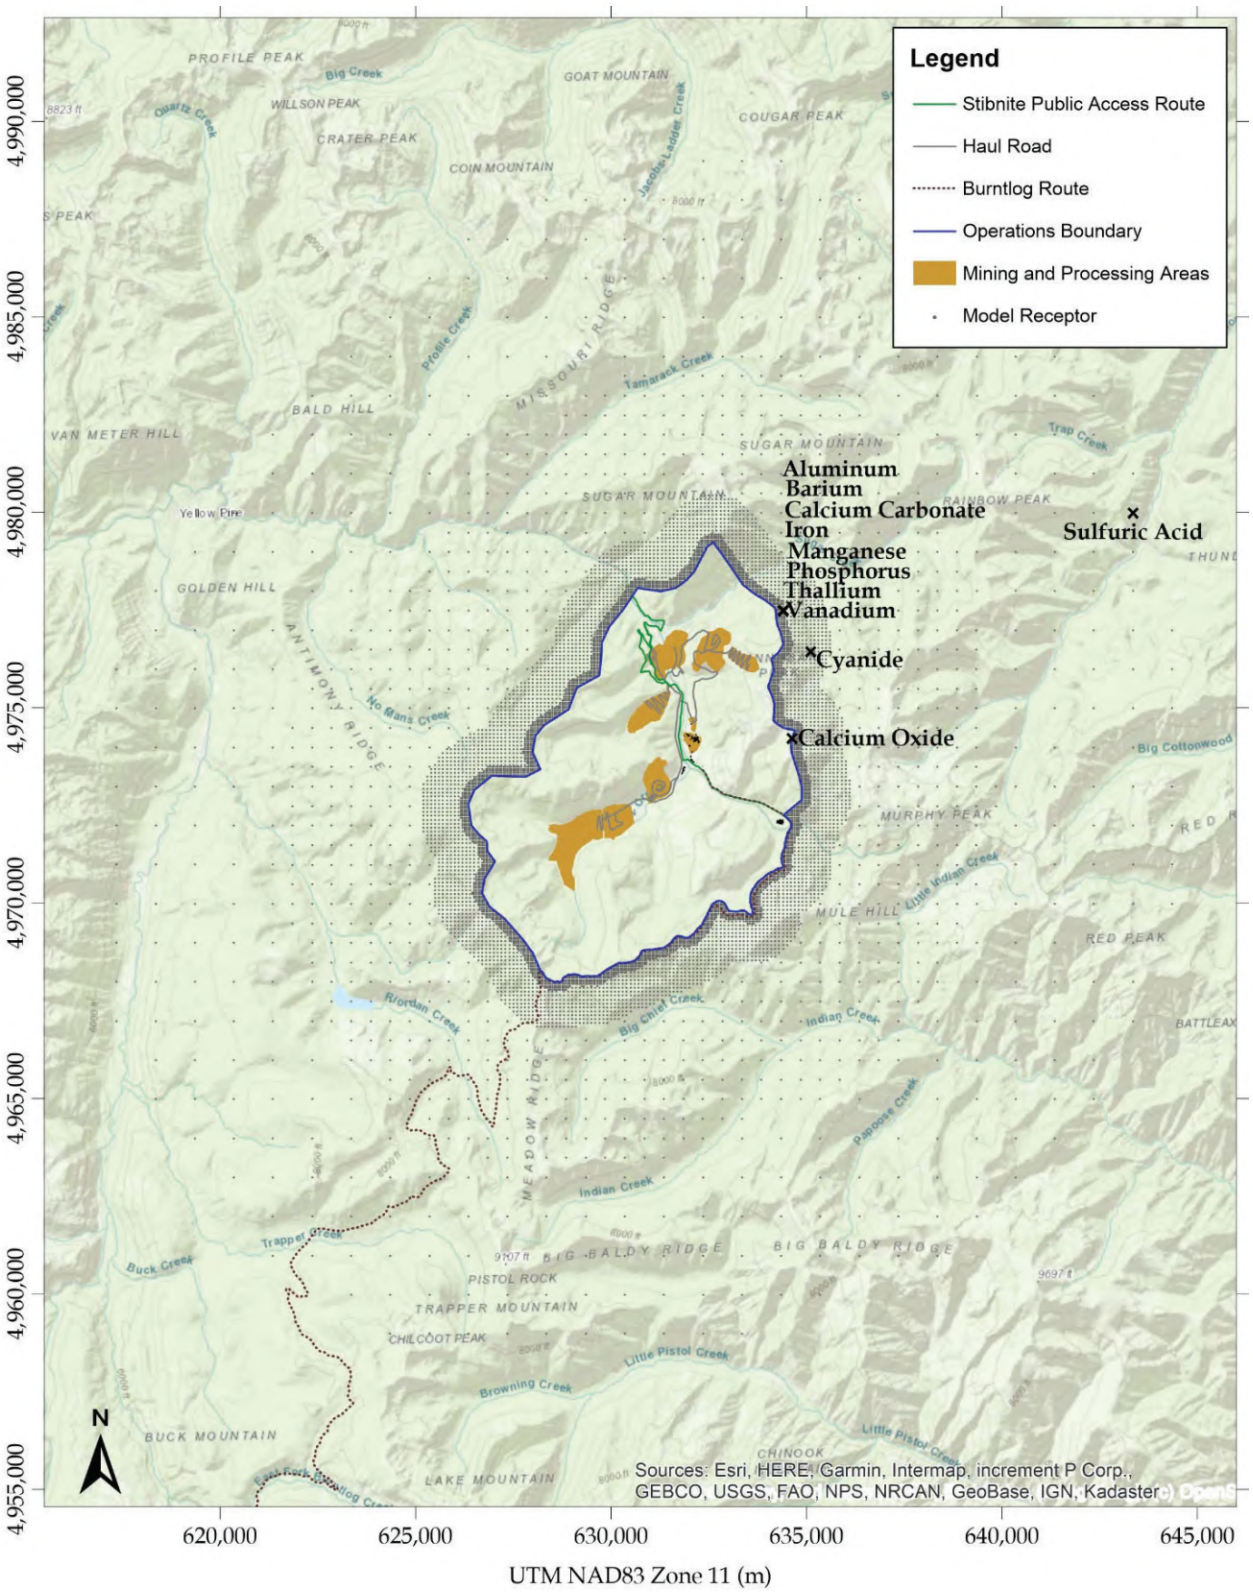
PRI contends that calculating lifetime arsenic exposure based on the proposed West End Pit life-of-mine production limit of 50% of the total production is conservative. The actual life-of-mine total production from the West End Pit as described in the ModPRO2 mine plan is only 198.26 million tons (Perpetua 2021), which is 50.3% of the proposed West End Pit life-of-mine production limit of 394.2 million tons.

6.0 Impact Results

TAP impact analysis results, as submitted in the *TAP Addendum* and as further assessed by DEQ, are discussed in this section. The effect of various operational refinements also reduced PM_{10} and $PM_{2.5}$ impacts, and this is discussed in Section 6.2.

6.1 TAP Impact Analyses Results

This section describes the revised TAP impact analyses and demonstrates that applicable TAP emissions resulting from operation of the SGP will not result in increased impacts that exceed AACs or AACCs.



6.1.1 Modeling Non-Carcinogenic TAPs

The non-carcinogenic TAPs subject to impact modeling requirements to demonstrate compliance with AACs of *Idaho Air Rules* Section 585 were modeled at the emission levels shown in Table 1 above. The maximum 24-hour modeled concentration for each of the 14 modeling scenarios demonstrates compliance with the applicable AAC, as summarized below in Table 5. PRI elected to include Scenario W5 in the modeling analysis for non-carcinogenic TAPs. Figure 1 illustrates the locations of the maximum impacts for each non-carcinogenic TAP.

Table 5. RESULTS FOR TAPS IMPACT ANALYSES FOR NON-CARCINOGENIC TAPS.					
Toxic Air Pollutant	**Averaging Time**	**Maximum Modeled Concentration ($\mu g/m^3$)[a]**	**Model Scenario**	**AAC[b] ($\mu g/m^3$)**	**Percent of AAC**
Aluminum	24-hour	6.17	W5	500	1.23%
Barium	24-hour	0.07	W5	25	0.28%
Calcium carbonate	24-hour	1.22	W5	500	0.24%
Calcium oxide	24-hour	0.15	All	100	0.15%
Cyanide	24-hour	0.20	All	250	0.08%
Iron	24-hour	1.58	W5	50	3.16%
Manganese	24-hour	0.03	W5	250	0.01%
Phosphorus	24-hour	0.06	W5	5	1.20%
Sulfuric acid	24-hour	0.41	All	50	0.82%
Thallium	24-hour	0.001	W5	5	0.02%
Vanadium	24-hour	0.002	W5	2.5	0.08%

a. Micrograms per cubic meter.
b. Acceptable Ambient Concentration of a Non-carcinogenic TAP.

Figure 1. SGP NON-CARCINOGENIC MAXIMUM TAP IMPACT LOCATIONS.

6.1.2 Modeling Carcinogenic TAPs

The carcinogenic TAPs subject to impact modeling requirements to demonstrate compliance with AACCs of *Idaho Air Rules* Section 586 were modeled using an emission inventory that includes the T-RACT controls, long-term mining production limits, and other emission inventory refinements, as described in Section 4.0 and 5.0 of this *Modeling Review Attachment*.

The maximum modeled impact for each of the 14 modeling scenarios demonstrated compliance with the T-RACT AACC, as summarized below in Table 6. The SGP maximum concentrations were adjusted to account for the life-of-mine production limits, which affect the lifetime exposure, and to account for the elimination of Modeling Scenario W5. See Sections 5.7 and 5.8 of this *Modeling Review Attachment* for more detail. The locations of the maximum impacts for each carcinogenic TAP are presented in Figure 2. Arsenic concentrations are considerably lower in areas away from the location of maximum impact as shown in Figure 3.

Table 6. RESULTS FOR TAPS IMPACT ANALYSES FOR CARCINOGENIC TAPS.

Toxic Air Pollutant	Averaging Time	Maximum Modeled Lifetime Exposure Concentration ($\mu g/m^3$)[a,b]	Model Scenario	AACC[c] ($\mu g/m^3$)	T-RACT[d] AACC	Percent of T-RACT AACC
Arsenic	Annual	0.00095	W2	0.00023	0.0023	41.30%
Beryllium	Annual	0.00001	W1	0.0042	0.042	0.02%
Cadmium	Annual	0.000002	W1	0.00056	0.0056	0.04%
Formaldehyde	Annual	0.00007	W1	0.077	0.77	0.01%
Nickel	Annual	0.00001	W1	0.042	0.42	<0.01%

a. Micrograms per cubic meter.
b. The lifetime exposure concentrations are based on the proposed restrictions discussed in Sections 5.7 and 5.8 of this *Modeling Review Attachment*.
c. Acceptable Ambient Concentration of a Carcinogenic TAP.
d. Toxic Air Pollutant Reasonably Available Control Technology allows the AACCs to be increased by a factor of ten per *Idaho Air Rules* Section 210.12(b).

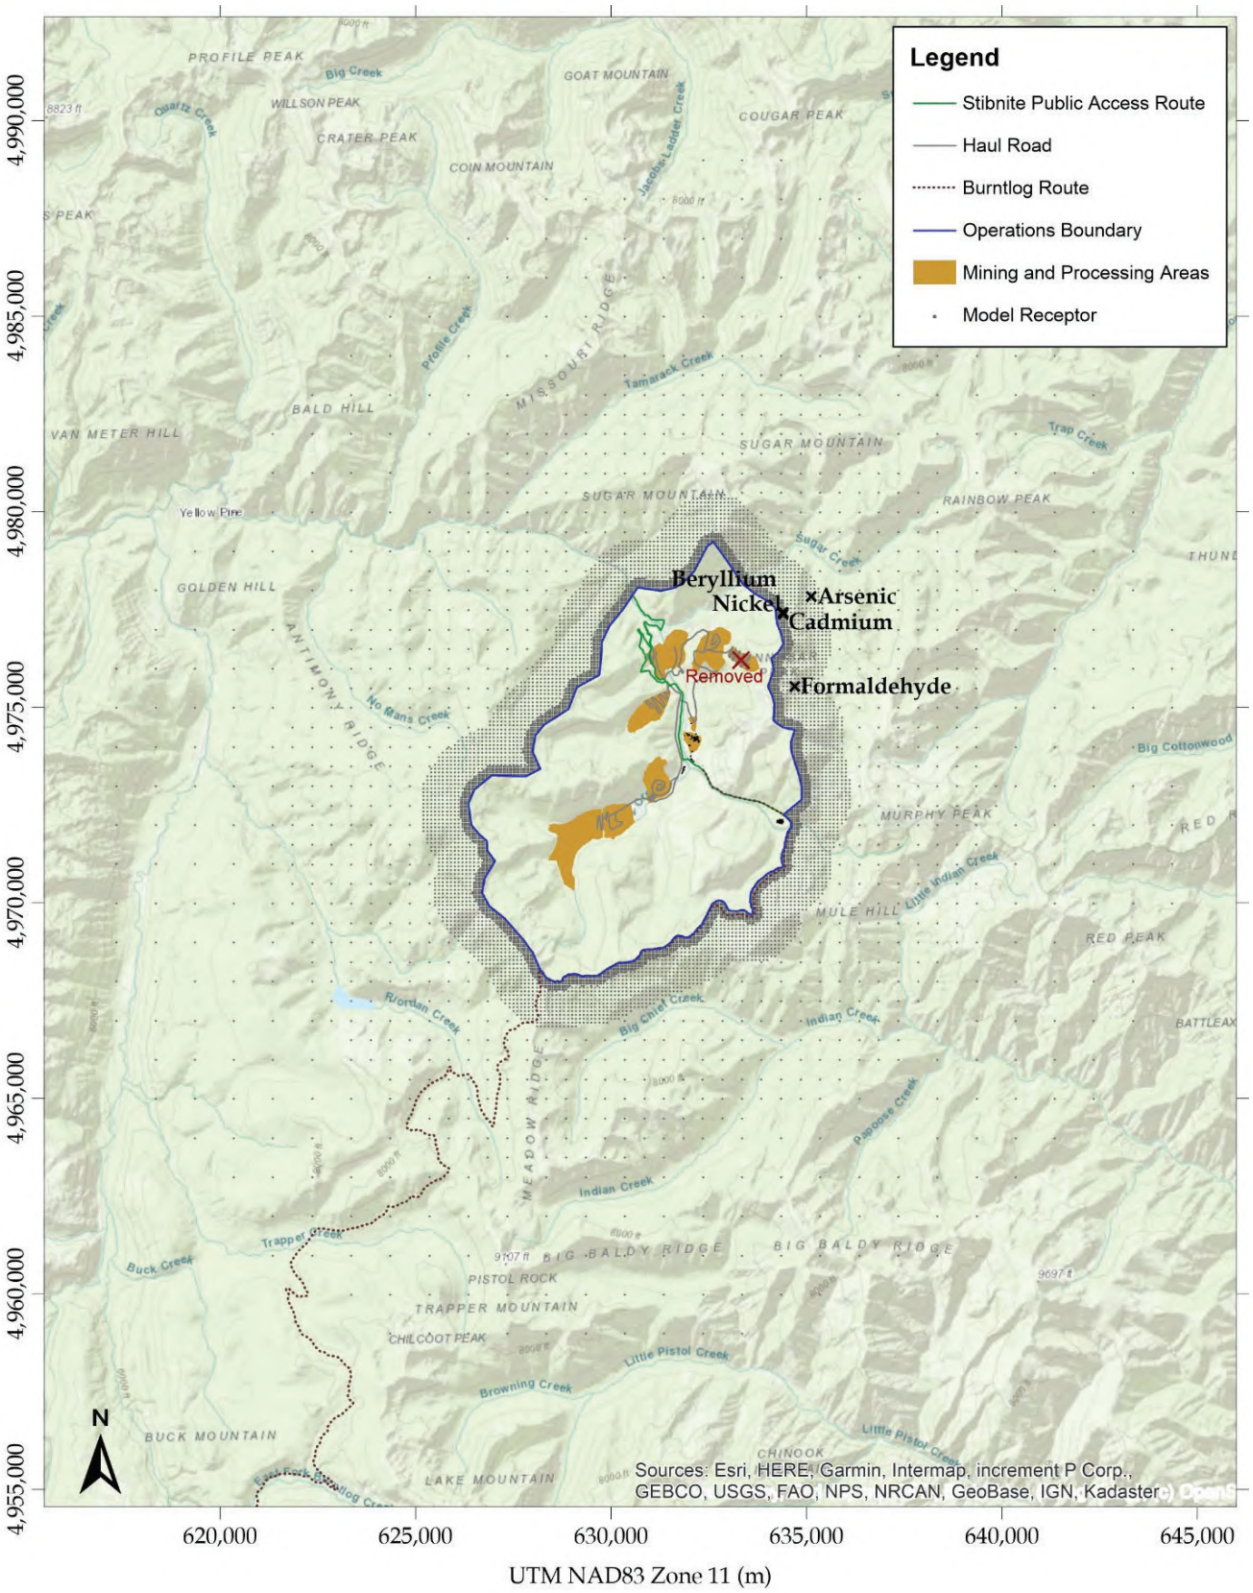

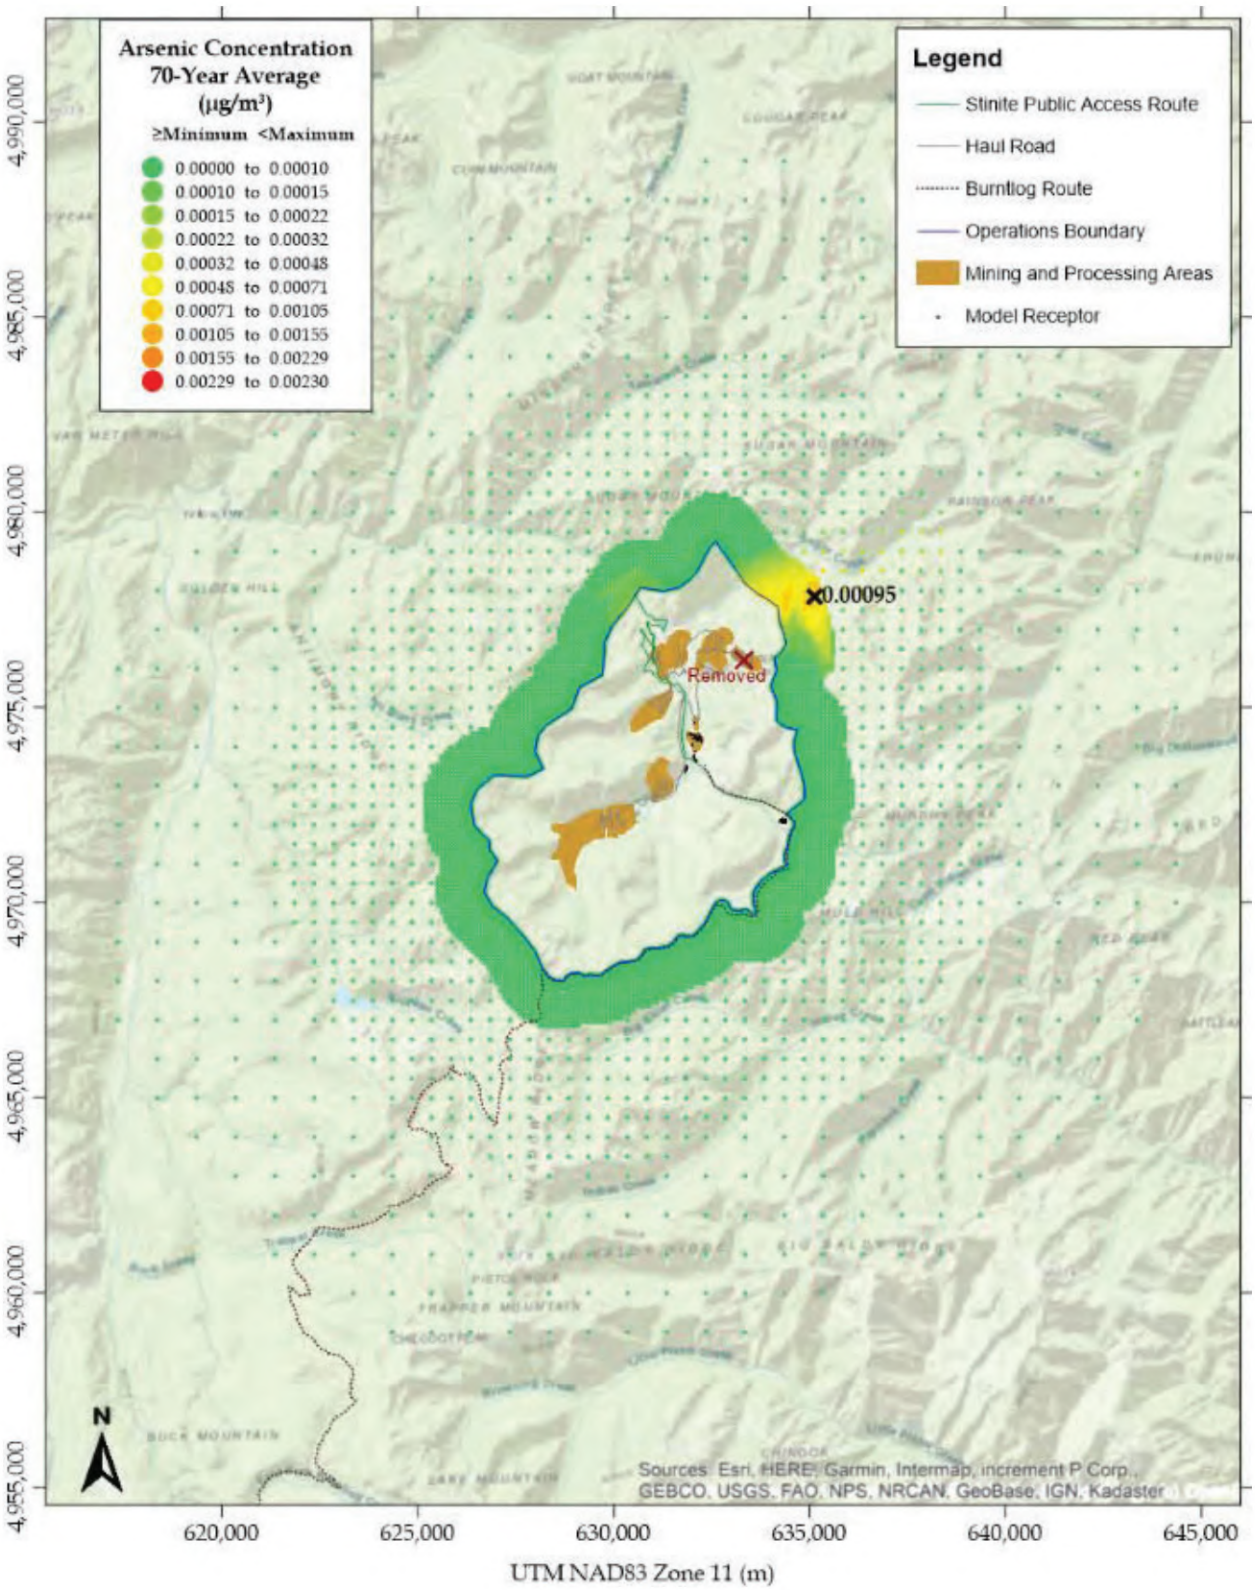

Figure 3. SGP CONTOURS OF LIFETIME ARSENIC IMPACTS.

6.2 *Effect of Changes to Modeled PM_{10} Results*

PRI has determined that the West End Development Rock Storage Facility will not be constructed. This change eliminated Modeling Scenario W5 as a potential operating scenario. In Section 4.1.4 in the main body of the DEQ *Modeling Review Memorandum*, DEQ identified PM_{10} NAAQS exceedances at four hotspot receptors when using the BULKRN meteorological dataset for Modeling Scenario W5 (the highest PM_{10} impact modeling scenario). When Modeling Scenario W5 is removed, the highest modeled impacts are predicted to occur for Modeling Scenario W3, which represents the transport of development rock from the West End Pit to the Hangar Flats Development Rock Storage Facility.

Table 7 presents results for the cumulative NAAQS impact analyses for Scenario W3. Results still exceed the 24-hour PM_{10} NAAQS even when Modeling Scenario W5 is eliminated. However, there is only one hotspot receptor exceeding NAAQS. The modeled violation is also predicted to occur during winter. This is a critical consideration because during winter, not only are fugitive emissions minimized because of the higher moisture content of material handled or driven over, but background concentrations in such remote areas are also generally much lower because of the absence of wildfires and dust-generating sources.

Table 7 also lists the results when using temporally varying backgrounds, instead of a single-value background, in the cumulative NAAQS impact analysis (using the "SEASON" and "MONTH" options in AERMOD). The highest daily average PM_{10} concentrations measured at Stibnite for every season and month in 2014 were used as inputs in the model. Table 7 shows that the SGP facility *safely* demonstrates compliance with the 24-hour PM_{10} NAAQS when temporally varying backgrounds (both seasonal and monthly) are used instead of the single-value background. Summing modeled design values with a single-value background that is on the upper end of the distribution results in a very conservative estimate of total impacts. DEQ strongly believes that using temporally varying backgrounds that respect seasonality is appropriate for the SGP facility, and that using the highest value in the period interval is very conservative.

TABLE 7. RESULTS FOR 24-HOUR PM_{10} CUMULATIVE NAAQS IMPACT ANALYSES FOR MODELING SCENARIO W3.

Backgrounds Scenario	Max. Conc.[a] ($\mu g/m^3$)[b]	Model Scenario	Back. Conc.[c] ($\mu g/m^3$)	Total Conc.[d] ($\mu g/m^3$)	NAAQS ($\mu g/m^3$)	Percent of NAAQS
Single-Value Background	116.9	W3	34.0	150.9[e]	150	100.6%
Seasonally Varying Backgrounds	123.5[f]	W3	*Seasonal*	123.5[f]		82.3%
Monthly Varying Backgrounds	123.5[f]	W3	*Monthly*	123.5[f]		82.3%

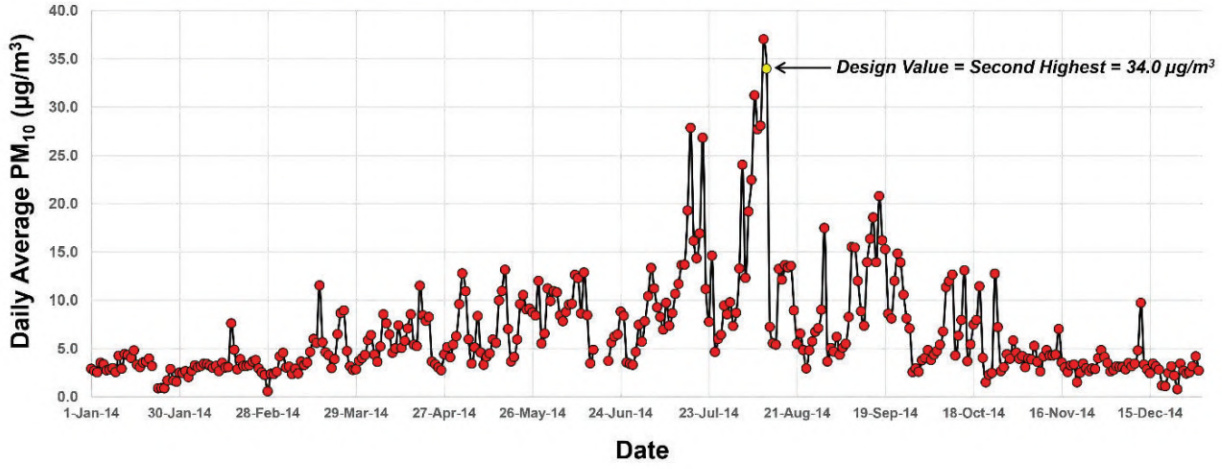
a. Max. Conc. = maximum modeled design concentration.
b. Micrograms per cubic meter.
c. Back. Conc. = background concentration.
d. Total Conc. = total (modeled + background) concentration.
e. One hotspot receptor exceeds NAAQS.
f. The maximum modeled design concentration already incorporates the seasonal and monthly background values.

The time series plot in Figure 4 and the box-and-whiskers plot in Figure 5 illustrate the variability in daily average PM_{10} concentrations collected at the Stibnite Site in 2014. Figures 4 and 5 confirm that the highest concentrations from the modeled and monitored datasets do *not* occur simultaneously. Highest modeled impacts are predicted to occur during winter while the highest background concentrations were measured at Stibnite during summer. Therefore, the summation method, where total impacts are

calculated by summing modeled design values with a background concentration that is also consistent in form with the regulatory design value, results in a very conservative estimate of the total impact for comparison to NAAQS. DEQ concludes that use of temporally varying (i.e., seasonal and monthly) backgrounds for SGP is justified. DEQ is highly confident that operation of the SGP will not cause or contribute to a violation of NAAQS.

PM_{10} and $PM_{2.5}$ NAAQS compliance was previously demonstrated prior to refinements and adjustments proposed in the submitted *TAP Addendum*. The main body of the DEQ *Modeling Review Memorandum* discussed and considered results from both modeling with meteorological data processed using the BULKRN method and modeling with data processed using cloud cover data, and DEQ concluded that NAAQS compliance was demonstrated with a high degree of confidence. The adjustments and refinements described in the *TAP Addendum* further increase DEQ's confidence in NAAQS compliance.

Figure 4. TIME SERIES OF DAILY AVERAGE PM_{10} CONCENTRATIONS MEASURED AT STIBNITE IN 2014.



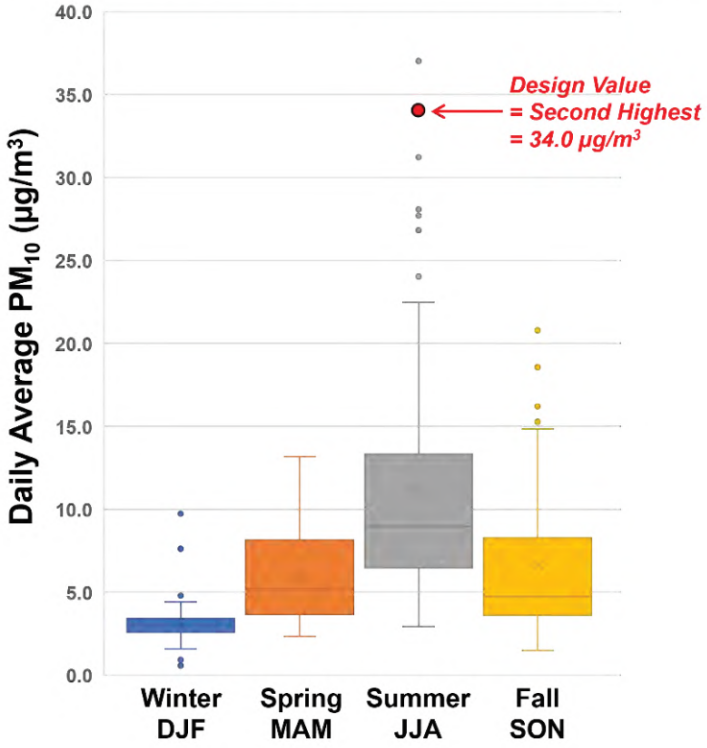


Figure 5. BOX-AND-WHISKERS PLOT FOR SEASONAL PM_{10} BACKGROUND CONCENTRATIONS MEASURED AT STIBNITE IN 2014.

In Figure 5 the middle line of each box represents the median. The "x" in the box represents the mean. The bottom and the top lines of the box represent the 1st quartile (25th percentile) and the 3rd quartile (75th percentile), respectively. The whiskers extend to the minimum and maximum values not considered outliers. Outliers are plotted individually.

7.0 Conclusions

This section provides conclusions of the *TAP Addendum* and DEQ's review of the *TAP Addendum*.

7.1 Conclusions of Revised TAP Analyses

The revised and refined TAP analyses:

- Revised TAP-applicable sources at the SGP facility.
- Proposed additional emission control measure and adjusted operations to reduce TAP emissions.
- Refined the approach used to demonstrate compliance with TAP regulations.

The submitted application, with the adjustments and refinements to analyses as described in the *TAP Addendum*, demonstrated to DEQ's satisfaction that the emissions of applicable TAPs will not result in impacts to ambient air that exceed TAP increments of *Idaho Air Rules* Section 585 and 586.

7.2 Effects of Adjustments/Revisions on NAAQS Compliance Demonstrations

The submitted application, prior to the *TAP Addendum*, demonstrated compliance with NAAQS to DEQ's satisfaction; and the operational measures proposed in the *TAP Addendum* will only further reduce estimated emissions. Eliminating Modeling Scenario W5 impacts, with the elimination of the West End Development Rock Storage Facility, affects the 24-hour PM_{10} impact modeling analysis for SGP. Modeling Scenario W3 is now the scenario producing the highest modeled impacts, and NAAQS compliance is easily demonstrated when using temporally varying background PM_{10} values, which were obtained from onsite monitoring data.

7.3 Conservatism of Permitting Analyses

Emissions and locations from which emissions occur are highly dynamic at mining facilities. This presents unique challenges for permit development because permits must include limits and operational requirements that ensure air quality standards are not violated. Permitting rules require that air impacts be assessed using maximum potential emissions as limited by either the capacity of the unit/operation or as limited by enforceable permit provisions. A permit where actual emissions are nearly representative of maximum allowable emissions, through imposing permit limits, would be exceedingly complex and require overly burdensome monitoring and record-keeping requirements. To avoid this, applicants typically calculate allowable emissions and perform impact analyses based on simplistic operational scenarios that largely overstate emissions estimated to occur from the facility.

PRI and Air Sciences have asserted that the submitted emission estimates, operational scenarios, and air impact analyses associated with the permit application greatly overstate best-estimated values. This point is evident when comparing the permit application materials and analyses with those presented in ModPRO2, PRI's revised mine plan and associated impacts. ModPRO2 is used in support of the Environmental Impact Statement (EIS).

EXHIBIT B

order to effectively implement 161, the department developed a policy that set emission limits for certain toxic air pollutants. Idaho industry requested that the policy be implemented in rule (instead of a policy) to provide greater certainty and transparency for industry. Through many discussions with industry and the public, a rule was developed that was responsibly protective of environmental quality while being reasonably permissive of industrial activity. As noted in Section 203.03, by complying with the TAPs rules developed in sections 210, 585 and 586, a facility adequately demonstrated compliance with 161.

Because TAPs are generally known to be hazardous to human health (EPA 1991), the federal government also implemented rules to control emissions of TAPs through National Emission Standards for Hazardous Air Pollutants (NESHAPs). EPA first tried to implement risk based standards according to the Clean Air Act (CAA) amendments of 1970. Between 1970 and 1990, EPA was only able to implement standards for 8 pollutants (asbestos, benzene, beryllium, coke oven emissions, inorganic arsenic, mercury, radionuclides, and vinyl chloride). Because of EPA's inability to address air toxics in a timely and efficient manner, Congress revised the CAA in 1990 to develop a program to control a list of hazardous air pollutants (HAPs) through technology standards for specific industries. Congress itself developed the list of 188 HAPs. They also prescribed maximum achievable control (MACT) standards for large (major) sources of HAPs and generally achievable control technology (GACT) standards for smaller (area) sources. The area source NESHAPs also only focused on a subset of 30 HAPs that were identified as being the most problematic in urban areas. Congress's intent was to address the major risks associated with TAPs by focusing on the most toxic pollutants and most significant source categories. The original list of 188 HAPs was based on the list of pollutants subject to the Emergency Planning and Community Right-to-Know Act (EPCRA). After the HAPs list was created in the early 1990's, the list of pollutants subject to EPCRA has doubled, while the list of HAPs has remained essentially unchanged.

The Idaho TAPs rules were developed to complement the federal NESHAPs, thus the rules are not more stringent than federal law. IDAPA 58.01.01.210.20 specifically states that if a facility is subject to a federal NESHAP, they have met the requirements of our state air toxics rules. These rules do regulate an activity not regulated by the federal government. They are a uniquely Idaho solution of addressing air toxics emissions. An argument could be made that the rules are broader in scope than federal law, as they do regulate an activity not regulated by federal law.

(2) To the degree that a department action is based on science, in proposing any rule or portions of any rule subject to this section, the department shall utilize:

(a) The best available peer reviewed science and supporting studies conducted in accordance with sound and objective scientific practices; and

The Idaho TAPs rules were developed to protect public health by developing risk based standards that would apply to new or modified industrial sources only. There are two lists of pollutants that facilities need to consider, but only if the facility is not subject to a federal air toxics standard.

The first list of pollutants are non-carcinogens (do not cause cancer) in IDAPA 58.01.01.585. They may cause adverse health effects based on short term (24-hour) exposures. Examples include methyl isocyanate, chlorine, cyanide and xylene. The acceptable ambient levels for non-carcinogens are based on occupational exposure levels from the American Conference of Government Industrial Hygienists (ACGIH) threshold limit values (TLV). (ACGIH 2019). The TLV is typically an 8 hour time weighted average concentration and it is the concentration to which workers may be repeatedly exposed during a 40 hour work week without adverse effect. Two safety factors were applied to the TLV value: 1) to extrapolate the 8 hour exposure level to a 24 hour public exposure, and 2) to extrapolate from the relatively healthy mostly male working population to a general population that included women, children and the elderly. Thus the TAP increment values are 1/20th the TLV values.

Because ambient monitoring values can sometimes be difficult to determine, the department also developed stack emission screening levels (ELs) for easier analysis (in pounds/hour). These were based on a conservative stack modeling analysis.

The second list of pollutants are carcinogens (i.e., have been determined to cause cancer over a lifetime of exposure) in IDAPA 58.01.01.586. Examples include formaldehyde, benzene, and polycyclic aromatic hydrocarbons. The acceptable ambient levels for carcinogens are based on the cancer unit risk values from the Environmental Protection Agency and correspond to a one in a million cancer risk. (EPA 2019). An EL was also determined for

Case Docket No. 0101-22-01
OAH Case No. 23-245-01

EXPERT DECLARATION OF KEVIN LEWIS

PERPETUA RESOURCES EXHIBIT
200

I, Kevin Lewis, hereby declare and affirm as follows:

1. I am currently a Principal Air Quality Engineer at Air Sciences Inc. (Air Sciences). I have prepared this declaration in support of the Permit to Construct (PTC) issued for the Stibnite Gold Project (SGP) on June 17, 2022. Perpetua Resources Idaho, Inc. (Perpetua) received the PTC that was challenged in this proceeding, Case Docket No. 0101-22-01; OAH Case No. 23-245-01.

A. Qualifications and Experience

2. I earned a Bachelor of Science (BS) degree in Chemical Engineering from the University of Wisconsin, Madison, in 1990.

3. From 1990 to 1992, I worked at the Wisconsin Department of Natural Resources, where I wrote air quality permits for toxic pollutants and conducted compliance inspections.

4. In 1993, I joined Air Sciences, became an owner in 1996, and served as President from 2011 to 2021. Air Sciences is a consulting firm specializing in ambient air quality analyses, permitting, and compliance.

5. With over 33 years of experience in air quality, I have conducted air quality analyses for permits across more than 25 states and internationally. At Air Sciences, I focus primarily on air permitting for the gold mining industry. In collaboration with the Nevada Mining Association and the U.S. Environmental Protection Agency (EPA), I compiled, analyzed, and summarized technical data to help develop the National Emissions Standard for Hazardous Air Pollutants (NESHAP): Gold Mine Ore Processing and Production Area Source Category rules under 40 CFR Part 63, Subpart EEEEEEE, which applies to the SGP.

6. During my time at Air Sciences, I developed air quality analyses for hundreds of air permits, renewals, and modifications. I also provided technical support to state agencies throughout the technical review, permit drafting, and public comment phases.

7. I led the modeling and permit development for Perpetua, ensuring compliance with ambient air quality standards while achieving project objectives. This included using reliable emissions data and appropriate modeling techniques to reflect permit conditions.

8. I began working with Perpetua as an air quality consultant in 2017, and I continue to provide consultancy services to this day.

B. Scope of Review

9. I reviewed the in the *Final Order* issued by the Board of Environmental Quality (Board) on May 9, 2024 in the Matter of Air Quality Permit to Construct P-2019.0047 (Final Order), which remanded "this matter back for the development of further evidence regarding ambient air concentrations of arsenic that will be produced by the SGP and whether those levels comply with the Air Rules." Final Order at 23. Based on my review of the Final Order the Board found the following issues to be addressed on remand:

a. DEQ did not act reasonably in using a five-year rolling average for T-RACT that was not properly supported by permit conditions.

b. There was insufficient evidence to support the T-RACT analysis limiting the non-West End pit production limit.

c. DEQ did not act reasonably and in accordance with law when it applied the 16/70 calculation to the ambient arsenic air concentration analysis.

10. I will address items (a), (b) and (c) in this declaration.

C. Documents Reviewed

11. I have reviewed the permitting record in this case, the expert declarations of Theresa Lopez, Norka Paden, and Kevin Schilling, and documents referenced below and attached as an exhibit to this declaration.

D. Summary of Opinions

12. Based on my expertise and multi-state permitting experiences:

a. DEQ properly established a five-year rolling average compliance demonstration in the PTC for ambient arsenic concentrations from the SGP.

b. DEQ sufficiently supported the permitting for the non-West End Pit activities.

c. DEQ correctly applied the provisions of IDAPA[1] 586 to perform an "apples to apples" toxic air pollutant (TAP) risk evaluation using an adjusted arsenic concentration and exposure duration to compare to the T-RACT Acceptable Ambient Concentration for Carcinogens (AACC).

Following rigorous analyses of Perpetua's application, as well as addressing repeated comments from stakeholders, DEQ prepared a thorough and conservative record in support of the PTC.

E. General Permitting and Modeling Context

13. With over thirty years of experience as an air permit consultant, including the development and review of hundreds of permits, I have identified two key objectives in the permitting process:

a. The permittee must submit a thorough and complete permit application.

[1] The Rules for the Control of Air Pollution in Idaho (Air Rules), IDAPA 58.01.01, provide for the control of air pollution in Idaho and govern issuance of air quality permits, including permits to construct. For brevity, citations to the Air Rules are abbreviated "IDAPA," followed by the specific section of IDAPA 58.01.01.

b. The permitting agency must issue a permit that includes operating restrictions and monitoring requirements to ensure compliance with air quality regulations.

14. Integral to these objectives is the creation of accurate emissions data and modeling to support compliance with ambient air quality standards.

15. To obtain a permit in Idaho, an applicant must satisfy for DEQ that the proposal will comply with all applicable state or federal emission standards, will not cause or contribute to a violation of the National Ambient Air Quality Standards, and using the methods provided in IDAPA 210, the emissions of toxic air pollutants will not injure or unreasonably affect human or animal life or vegetation as required by IDAPA 161. IDAPA 202.01, 202.02, 202.03.

16. Compliance with all applicable toxic air pollutant carcinogenic increments demonstrates preconstruction compliance with IDAPA 161 with regards to the pollutants listed in IDAPA 586: the Ambient Air Concentrations for Carcinogenic increments. IDAPA 202.03.

17. Modeling is necessary to meet the requirements of IDAPA 202.02 and 202.03. Specifically, the project proponent must determine the ambient concentrations of relevant toxic air pollutants from the project and compare these concentrations to the AACC.

18. Perpetua and DEQ took a conservative approach throughout the process of demonstrating compliance with IDAPA 202. Specifically, the analyses included arsenic emissions from fugitive dust related to mining activities. This is significant because fugitive dust is the primary source of arsenic emissions from the project. Furthermore, fugitive dust emissions of arsenic are "addressed" by NESHAP Subpart EEEEEEE and therefore would normally be

excluded from the analysis per IDAPA 210.20. *See* Statement of Basis, Permit to Construct No. P-2019.0047 at 28 (Feb. 18, 2021) (Proposed for Public Comment).[2]

19. Modeling of arsenic emissions from the SGP to comply with the Air Rules included fugitive dust from mining activities and involved the following steps: (1) quantifying annual arsenic emissions from all sources while accounting for process scenarios and emission control measures, (2) inputting the emissions data, emission locations, and initial dispersion parameters into the model, and (3) running the model with one year of onsite meteorological data to determine the annual average concentration at specific receptors located at and beyond the ambient air boundary.

20. The results of the modeling performed by Air Sciences and DEQ contain multiple layers of conservatism.

21. First, the model itself is conservative. EPA's evaluation studies for the type of modeling conducted for the SGP showed that the model, specifically AERMOD, over predicts pollutant concentrations by 1.41 to 3.21 times. REC 1834

22. Second, the quantification of arsenic emissions from the SGP was conservative. For haul road dust, the largest source of arsenic emissions, we used the higher of the two published emission factors in the emissions calculations. The emission factor used is five times greater than the lower factor. REC 1834

23. Third, the control and reduction in arsenic emissions from haul road dust was calculated conservatively. We used a control efficiency of 90% for chemical suppressants; the actual range is 90-99%. We also used a control efficiency of 33% for watering dust; the actual range is 75-95%. REC 1834

[2] The 2021 Statement of Basis, along with selected appendices, is attached hereto as Attachment 1.

24. Finally, we conducted fourteen modeling scenarios, each using conservative process and operating assumptions. Each scenario assumed mining activity in a single deposit and hauling to a single location year-round at the maximum permitted production level to maximize predicted arsenic impacts. Actual operation will be more varied in location and rates resulting in significantly lower arsenic impacts.

25. These analyses led to predicted arsenic impacts that are one to two orders of magnitude higher than the actual impacts will be.

26. In my experience, applying multiple layers of conservatism in the permitting review process is standard practice across all air quality permitting agencies, and DEQ's process is no exception. The goal is always to ensure compliance with air quality regulations under all circumstances.

27. DEQ also provided extra opportunities for public involvement. DEQ provided the most robust opportunity for public participation in the SGP permitting process that I've encountered in my 33 years of permitting experience. DEQ afforded commenters unprecedented accommodations that responded to public input. All comments, suggestions, and challenges were thoroughly reviewed. DEQ addressed each comment and, in some instances, conducted additional, more conservative analyses in response to the comments submitted.

F. Opinions

The IDAPA 586 AACC Annual Averaging Period is Not the Compliance Period.

28. As an expert on the relationship between air quality regulations and air quality modeling, I have a comprehensive understanding of the meaning and purpose of IDAPA 586 that reads "The AACC in this section are annual averages."

29. This text led the Board to infer that "the rule specifies compliance on an annual basis." Final Order at 19. This inference incorrectly conflates the AACC *averaging period* specified in IDAPA 586 with the *compliance period* described in IDAPA 006.125.[3]

30. Regulations often differentiate between the averaging period and the compliance period for health-based air contaminant concentration standards, especially when assessing long-term health risks.[4]

31. Treatment of the AACC as requiring compliance on an annual basis introduces an improper compliance period into IDAPA 586 and overlooks the adopted rules defining the methods and EPA scientific principles for determining cancer risk probability.

32. Within the full context of IDAPA 586, "The AACC in this section are annual averages" describes the annual average concentration that will result in a 1-in-1,000,000 excess cancer risk probability assuming constant lifetime exposure (70 years) to that concentration of ambient air emissions.

33. The AACC values listed in IDAPA 586 encompass three components:

a. The ***annual average*** concentration (0.00023 µg/m³ for arsenic) that correlates to

b. The ***1-in-1,000,000*** cancer risk probability as defined by the URF in IDAPA 586 over

c. A ***70-year*** exposure duration or compliance period per IDAPA 006.125.

---

[3] Definition from Air Rules in effect during the PTC application review: "**Toxic Air Pollutant Carcinogenic Increments**. Those ambient air quality increments based on the probability of developing excess cancers over a seventy (70) year lifetime exposure to one (1) microgram per cubic meter (1 ug/m3) of a given carcinogen and expressed in terms of a screening emission level or an acceptable ambient concentration for a carcinogenic toxic air pollutant. They are listed in Section 586."

[4] For example, the new $PM_{2.5}$ National Ambient Air Quality Standard of 9.0 µg/m³ specifies an averaging period as the "annual arithmetic mean" (or annual average) per 40 CFR 50.20(a), while the compliance period is defined as a three-year average according to 40 CFR Part 50, Appendix N. *See* 89 Fed. Reg. 16202, 16203 (Mar. 6, 2024).

34. Neglecting any of these components when assessing the cancer risk probability, such as the 70-year exposure duration, not only conflicts with the rule, but fundamentally alters the rule itself and ignores the EPA scientific principles underlying the rule.

35. When comparing modeling results to the AACC values listed in IDAPA 586, all three components must align for a correct comparison:

a. The model output must be expressed as an ***annual average*** in $\mu g/m^3$;

b. The target cancer risk probability must be ***1-in-1,000,000;*** and

c. The exposure duration must occur or be permitted to occur over a ***70-year*** period.

36. The Final Order's statement that "the rule specifies compliance on an annual basis," Final Order at 19, rewrites one of the three essential components of the AACC, namely the exposure duration. Under the Board's interpretation, a project with a 5-year operational permit limit would pose the same risk as a project without a limit. Limiting the exposure duration reduces the cancer risk, as demonstrated by the EPA's risk calculation methods. Declaration of Norka Paden (Paden Decl.) ¶¶ 4, 13.

37. If the project proposal includes a different actual exposure duration that is less than the 70-year lifetime default or the project proposal includes a different target risk (like the 1-in-100,000 T-RACT), then either the model output concentration, the AACC itself, or both must be adjusted according to EPA's methods to ensure all components align.

38. Adjustment for actual project facts is necessary for a correct assessment of cancer risk. Failing to adjust components of the AACC is inconsistent with the rule and contrary to the EPA scientific principles upon which the rule is based.

DEQ Properly Established a Five-Year Rolling Average Compliance Demonstration Period.

39. The IDAPA 586 "annual average" does not represent the compliance period for project emissions; it represents the annual average concentration of emissions that presents a 1-in-1,000,000 (or 1-in-100,000 T-RACT) cancer risk probability assuming constant exposure over a 70-year lifetime.

40. The Final Order stated that "there was no evidence in the record explaining how the five-year rolling average comports with the annual AACC limits." This conclusion conflated the averaging period specified in IDAPA 586 with the notion of a compliance period.

41. The AACC value is defined as a lifetime of exposure, specifically 70 years. This means that cumulative exposure over this 70-year period must not exceed levels that would result in a cancer risk probability of 1-in-1,000,000, or 1-in-100,000 for T-RACT sources.

42. DEQ imposed a daily production limit of 135,000 tons per day (T/day) because production generates arsenic emissions (primarily from fugitive dust emissions). Limiting production proportionally reduces arsenic emissions, concentrations and exposure.

43. DEQ correctly established a compliance demonstration period of 5 years for the 135,000-T/day limit using a 5-year rolling average. The 5-year rolling average represents a more conservative (shorter) timeframe than the exposure duration of 70 years inherent in the AACC. The 5-year rolling average is also a more conservative (shorter) timeframe than the T-RACT AACC exposure duration for the SGP of 16 years.

44. A five-year rolling average production limit in Permit Condition 3.5 is appropriate because "any permit limits must only assure that concentrations in ambient air over the total duration of the project do not cause a potential exposure concentration associated with a 1-in

1,000,000 [AACC] or a 1-in-100,000 [T-RACT] cancer risk." Declaration of Kevin Schilling (Schilling Decl.) ¶ 25.

45. The Board asserted that a "five-year rolling average allows considerable daily and annual increases in exposures which are contrary to limits set forth in the Air Rules." As explained by Theresa Lopez in her Declaration, the T-RACT AACC represents the lifetime probability of cancer risk from a ***cumulative*** dose of arsenic over a specific period of exposure. During the 16-year SGP project life, the ***cumulative*** dose is unaffected by variability in exposures (daily or annual) that may occur over the 5-year averaging period. In addition, Kevin Schilling states, "any daily and annual variability is inconsequential to the exposure concentration and resulting risk." Schilling Decl. ¶ 26.

46. The notion that the Air Rules prohibit daily variability in exposure, and therefore, a daily production limit with a daily compliance demonstration is needed to protect public health, is inaccurate. Limiting daily production activity does not eliminate exposure variability. The modeled output emissions concentration is inherently variable due to a multitude of factors unrelated to production and emissions. For example, for a given day when the wind blows from northeast to southwest, the predicted concentration (and exposure) at the northeast side of the ambient air boundary will be zero, regardless of the production and emissions.

DEQ Sufficiently Justified the Permitting for the Non-West End Pit Activities.

47. The permit imposes a total mining production limit of 788.4 million tons for the life of the project (Permit Condition 3.6). This limit applies to the aggregate amount of mining from all deposits, whether from a single deposit or a combination of deposits, ensuring that the total does not exceed 788.4 million tons over the life of the mine.

48. During permit development, Air Sciences performed 14 different model runs reflecting 14 different operating scenarios to assess arsenic concentrations based on production activity from each of the deposits individually

49. The modeling analysis for arsenic emissions from the Non-West End Pit (non-WEP) deposit scenarios demonstrated that mining activities at the non-WEP deposits result in ambient arsenic concentrations at or below the T-RACT adjusted AACC, even when the full 788.4 million tons of production comes from any one of those deposits. Schilling Decl. ¶¶ 28, 30.

50. The modeling analyses for arsenic emissions from the West End Pit (WEP) deposit scenarios resulted in proportionally higher impacts. This is attributed to the WEP's proximity to the northeastern ambient air boundary and prevailing wind patterns, as illustrated in Figure 1, attached as Exhibit A.

51. To address these elevated arsenic impacts associated with mining at the WEP, DEQ imposed an additional specific production limit for WEP activity. The limit is set at 394.2 million tons over the life of the project (Permit Condition 3.6), which represents 50% of the total mining production limit of 788.4 million tons.

52. Two life-of-mine production limits effectively constrain operations as follows:

a. Total mining from WEP and non-WEP locations cannot exceed 788.4 million tons.

b. Mining at the WEP cannot exceed 394.2 million tons.

c. Mining at non-WEP locations cannot exceed 788.4 million tons minus any mining at the WEP.

53. These restrictions work together as follows: A + B = C, where A represents WEP mining, B represents non-WEP mining, and C represents total mining. There is no need to

establish another limit for non-WEP mining because B can only be the difference between the total (788.4 million) and the volume from the WEP (limited to 394.2 million) as set forth in Permit Condition 3.6. Imposing an additional production limit for non-WEP activity would not offer any further protection of public health or the environment.

DEQ Correctly Applied the Permit Conditions Limiting the Project Life to 16 Years to the Analysis of Compliance with the T-RACT AACC

54. Based on my extensive multi-state permitting experience, DEQ's interpretation and analyses of the cancer risk associated with arsenic from the SGP followed sound permitting practices and scientific methods for TAPs evaluations.

55. In specific, DEQ correctly interpreted that "annual average" referred to in IDAPA 586 is simply the output of the air dispersion model that will result in a **1-in-1,000,000** excess cancer risk probability assuming the emissions impact will occur ***each year for 70 years***. Schilling Decl. ¶ 20.

56. The air dispersion model, specifically EPA's AERMOD, predicts ambient air concentrations as annual averages. For assessing long-term health impacts, such cancer risk probability (the AACC), the annual average output from the model serves as the default long-term averaging period. Defining the AACC as "annual averages" is consistent with the model's output and informs the compliance demonstration. It does not negate the other components of the AACC essential to properly assessing the cancer risk from the project's arsenic emissions.

57. Again, the AACC values in IDAPA 586 encompass three components: (1) the annual average concentration (0.00023 $\mu g/m^3$ for arsenic), (2) a cancer risk probability of 1-in-1,000,000, and (3) a 70-year exposure duration. For a proper comparison of modeling results all three components must align.

58. The annual average output concentration from the model can only be compared directly to AACC values in IDAPA 586 under the following conditions: 1) a target risk of ***1-in-1,000,000*** and 2) an emissions impact duration (or exposure duration) of ***70 years***. If one or both conditions are adjusted, then an adjustment to either the AACC and/or the annual average model output concentration must also be made for an "apple-to-apples" comparison.

59. For example, the annual average concentration for a 5-year project cannot be compared to the listed AACC because the exposure durations differ: five (5) years for the actual project and 70 years for the listed AACC. This example is found in IDAPA 210.15. To adjust for exposure duration, the example found in IDAPA 210.15 prompts the AACC to be multiplied by 10 to adjust for the shorter duration of the project. See Schilling Decl. ¶ 19.

60. DEQ properly applied these principles in the arsenic analysis for the SGP. The listed AACC was adjusted in accordance with IDAPA 210.12 to reflect the permit conditions establishing T-RACT. Per IDAPA 210.12 the AACC was multiplied by 10 to represent a risk of ***1-in-100,000*** for an emissions impact duration of ***70 years***; this is the T-RACT AACC. Then the annual average output concentration from the model was adjusted for the life-of-mine permit condition to reflect a 16-year exposure duration. This is shown mathematically by multiplying the modeled concentration by 16/70. This adjustment represents the equivalent modeled concentration over a 70-year period, known as the Exposure Concentration (EC). Detailed explanations are provided in the declarations of Norka Paden (¶¶ 4, 13) and Kevin Schilling (¶¶ 6.c, 18, 20).

61. With the AACC adjusted to the T-RACT AACC and the modeled annual average concentration adjusted to the EC, DEQ established a scientifically appropriate comparison to

determine acceptable risk. If the EC is less than the T-RACT AACC, as in the case of the SGP, then the risk of the project is less than ***1-in-100,000***.

62. As described in the declarations of Kevin Schilling and Norka Paden, DEQ applied these adjustments properly in their analyses of the SGP arsenic emissions impacts. Not applying these adjustments would be contrary to DEQ's toxic air pollutant rule and contrary to EPA's scientific approach and risk factors used for calculating excess risk probability adopted by the rule.

I declare under penalty of perjury under the laws of the United States that the foregoing is true and correct to the best of my knowledge, information, and belief.

DATED: August 30, 2024.

Kevin Lewis, Air Sciences Inc.

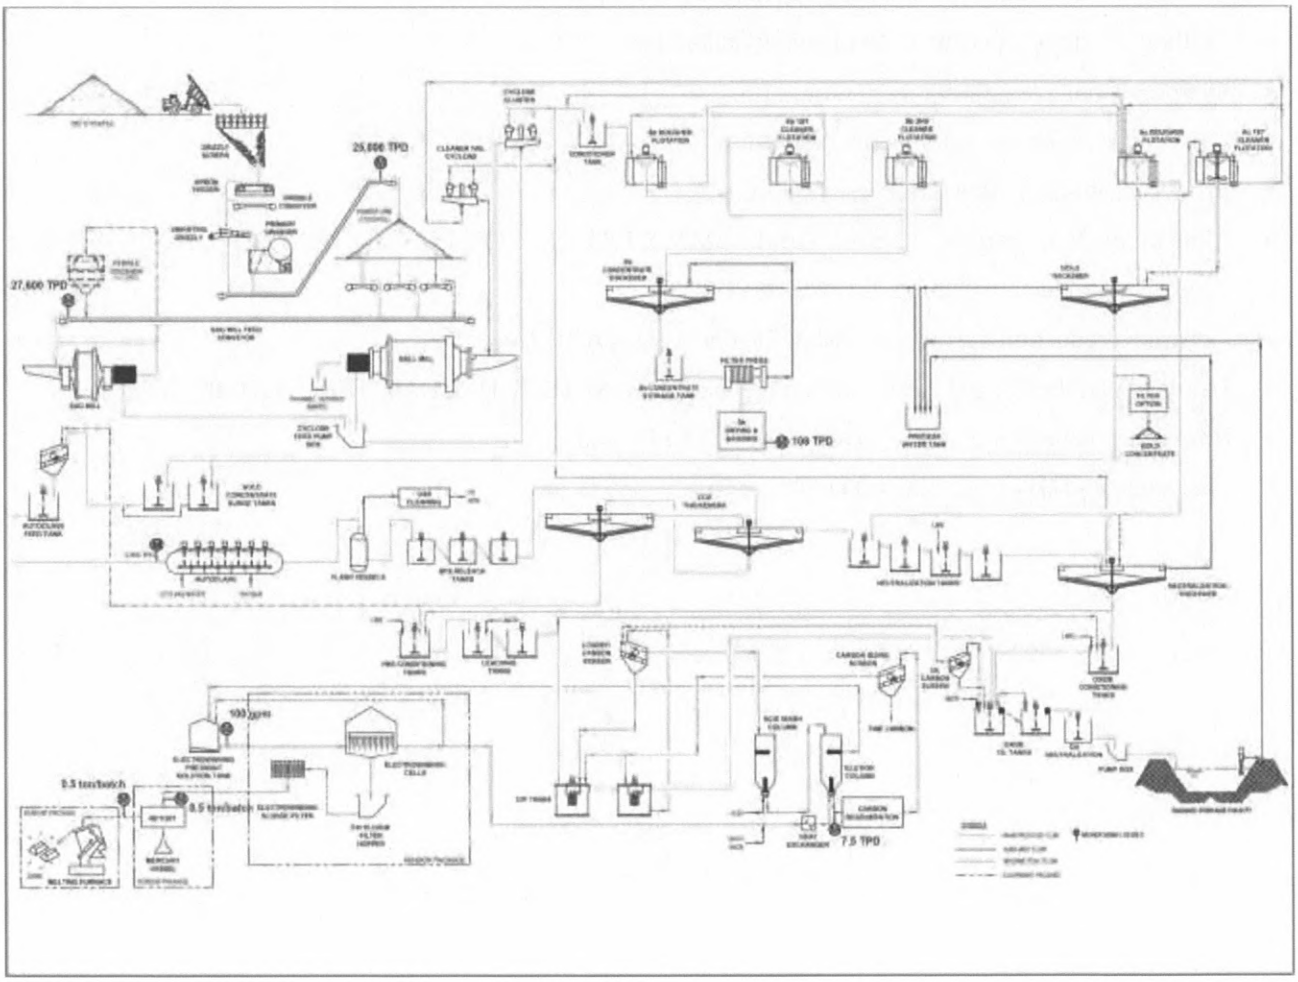
FACILITY INFORMATION

Description

Midas Gold Idaho, Inc. (Midas Gold) proposes to construct and operate the Stibnite Gold Project (SGP), consisting of conventional open-pit mining, ore preparation, and gold extraction operations.

SGP is to be located in Valley County at the intersection Forest Service roads NF-374 and NF-412 (Stibnite Road), approximately 10 miles east of Yellow Pine. The proposed Burntlog Route access road will provide year-round access to the site. The project comprises a combination of public national forest and private lands. The mining operations boundary within which public access will be excluded is defined in Figure 1. This operations boundary also defines the ambient air boundary used in all ambient air quality impact analyses.

Figure 1 PROJECT AREA OF OPERATIONS



SGP will require the construction of significant infrastructure, including a power transmission line, a primary mine site access road, onsite haul roads, an ore processing facility, onsite workspaces, employee housing and recreation, water storage and distribution facilities, and sewage disposal facilities.

Conventional open-pit mining methods including drilling, blasting, excavating, and hauling will be used to extract ore and waste rock, termed development rock (DR). Hydraulic shovels and front-end loaders will be used to load ore and DR into haul trucks. DR will be used for construction, restoration, and backfilling, or hauled to the dedicated development rock storage facilities (DRSF). Approximately 340 million tons of DR will be handled over the life of the mine.

The SGP will include three years of pre-mining development and construction activities, followed by an operating mine life of approximately 12 years. Mining will occur in three open pits: Yellow Pine Pit (YPP), Hangar Flats pit (HFP), and West End pit (WEP). Although there will be overlap in mine development construction and operations, the general sequence of mining will be the YPP deposit, followed by the HFP and WEP deposits. Legacy tailings from the Meadow Creek valley (Bradley Tailings [BT]) will also be reclaimed and reprocessed during the initial project schedule. Surface exploration drilling will occur within the pits and within the Scout Prospect decline (underground exploration) throughout the mine operation period. Restoration and reclamation of other legacy mining features will occur prior to mining, throughout the life of the mine, and as part of the mine closure.

Figure 2 DIAGRAM OF PROCESS FLOWS

Ore will be hauled to the primary crusher area, where it will be fed directly into the crusher dump pocket or stockpiled. The ore crushing plant will be designed to operate at a maximum rate of 25,000 tons per calendar day (T/day). Approximately 100 million tons of ore will be mined from the three pits over the life of the project. The metal-recovery process from ore will include conventional crushing and grinding, followed by froth-flotation circuits that will generate separate gold-silver and antimony-silver concentrates. The antimony-silver concentrate will be shipped offsite for refining, whereas additional onsite processing of the gold-silver concentrate will include pressure oxidation, carbon-in-leach circuits, and refining processes to recover gold and minor amounts of silver. The finely ground leftover ore material from the mineral-recovery process, termed tailings, will be neutralized, thickened, and transported via a pipeline to the tailings storage facility. A diagram of ore processing and ore concentration and refining process flows is provided in Figure 2.

Permitting History

This is the initial PTC for a new facility, thus there is no permitting history.

Application Scope

This permit is the initial PTC for this facility.

The applicant has proposed to conduct mining operations and to install and operate ore processing, ore concentration and refining, and ancillary equipment:

- Drilling, blasting, excavating, and hauling operations;
- Ore processing operations (OC1–OC13, PS);
- Ore concentration and refining operations (AC, EW, MR, MF, CKD);
- Process heating (ACB, CKB, PV, HS, LKC);
- Lime production operations (LS1–LS12, LSBM, LS-L/U, LK, LCR, LS1-L/U, MillS2-L/U, ACS1–ACS4);
- Aggregate production operations (PCSP1, PCSP2);
- Concrete production operations (CM; CS1–CS2-L/U, CA-L/U);
- Heating, Ventilation, and Air Conditioning heaters (H1M–H2M, HM, HAC, HR, HA, HMO, HTS, HW);
- Emergency generator engines (EDG1–EDG3, EDFP); and
- Fuel storage (TG1–TG2, TD3—TD10).

Application Chronology

August 20, 2019	DEQ received an application and an application fee.
August 29 – September 13, 2019	DEQ provided an opportunity to request a public comment period on the application and proposed permitting action.
September 19, 2019	DEQ determined that the application was incomplete.
October 4, 2019	DEQ received a preliminary response and supplemental information from the applicant, including a request to delegate authority of responsible official.
October 9, 2019	DEQ approved the request to delegate authority of responsible official.
October 15, 2019	DEQ met with the applicant to review and discuss the preliminary response.
October 22, 2019	DEQ determined that the application remained incomplete while the applicant prepared a response to the remaining items previously identified (9/19/19), and included a summary of recommendations provided at the meeting (10/15/19).
November 8, 2019	DEQ requested additional information from the applicant via email, relating to items previously identified (9/19/19).
November 21, 2019	DEQ received a request from the applicant for extension until November 27, 2019 to respond.
November 27, 2019	DEQ received supplemental information from the applicant, including a revised application with updated emissions inventories and modeling analyses.
December 24, 2019	DEQ determined that the application was incomplete.
January 8, 2020	DEQ received a request from the applicant for extension until February 7, 2020 to respond.
January 31, 2020	DEQ requested additional information from the applicant via email, relating to items previously identified (12/24/19).
February 5, 2020	DEQ received supplemental information from the applicant, including a revised application with updated emissions inventories and modeling analyses.
March 6, 2020	DEQ determined that the application was incomplete.
April 2, 2020	DEQ received a request from the applicant for extension until April 15, 2020 to respond.
April 15, 2020	DEQ received supplemental information from the applicant, including updated modeling analyses.
May 15, 2020	DEQ determined that the application was complete.
June 24, 2020	DEQ received the final application including all updates.
July 6, 2020	DEQ made available the draft permit and statement of basis for peer and regional office review.
July 14, 2020	DEQ made available the draft permit and statement of basis for applicant review.
July 31, 2020	DEQ made available an updated draft statement of basis Appendix B for applicant review.

August 3 and 13, 2020	DEQ received comments from the applicant on the draft permit and statement of basis.
August 20, 2020	DEQ received the permit processing fee.
September 10 – October 12, 2020	DEQ provided a public comment period on the proposed action.
October 12, 2020	DEQ received a request to extend the public comment period.
October 13 – November 11, 2020	DEQ extended the public comment period on the proposed action.
October 27, 2020	DEQ provided an information meeting during the extended public comment period.
November 20, 2020	DEQ requested additional information from the applicant to address substantive public comments received, including missing TAP and HAP emission estimates.
November 25 and December 11, 2020	DEQ extended the response to public comment period until February 22, 2021 to allow additional time for the applicant and DEQ to respond to substantive public comments.
December 17, 2020	DEQ received a response to the request for additional information from the applicant.[1]
December 18 and 21, 2020	DEQ received supplemental information from the applicant, including a response and HAP/TAP addendum to the application,[2] updated HAP and TAP emissions estimates,[3] updated TAP modeling analyses,[4] and supporting references.[5]
January 28, 2021	DEQ received updated modeling files with corrections for formaldehyde and sulfuric acid, and an updated figure showing TAP modeled impacts.
February XX – March XX, 2021	DEQ provided a public comment period on the proposed action as updated to address the HAP and TAP addendum and updates.
February XX, 2020	DEQ provided an information meeting during the public comment period.
DRAFT February 18, 2021	DEQ issued the final permit, statement of basis, and response to public comments.

TECHNICAL ANALYSIS

Emissions Units and Control Equipment

Table 1 lists all sources of regulated emissions for informational purposes.

Table 1 EMISSIONS UNIT AND CONTROL EQUIPMENT INFORMATION

Source ID No.	Source	Control Equipment	Maximum Process Rate
Mining			
	Drilling activities	Reasonable control and Fugitive Dust Control Plan (FDCP)	1,200 holes/day
	Blasting activities	Reasonable control & FDCP	2 blasts/day
	Excavating and hauling activities	Reasonable control & FDCP – Chemical suppression and water sprays Control efficiency: 93.3% for PM/PM_{10} (haul roads)	180,000 T/day
	Rock dumps and storage piles	Reasonable control & FDCP	n/a
PS1–2-L/U	(2) Prill Silos #1-2 Maximum capacity: 100 T (each)	Loading – None Unloading – None	200 T/day and 9,000 T/yr (combined)
Ore Processing			
OC1	Loader Transfer of Ore to Grizzly	Reasonable control & FDCP – Water sprays and moisture carryover	25,000 T/day
OC2	Grizzly to Apron Feeder		
OC3	Conveyor – Apron Feeder to Dribble		
OC4	Conveyor – Apron Feeder to Grizzly		
OC5	Conveyor – Dribble to Grizzly		
OC6	Grizzly to Primary Crusher or Coarse Ore Stockpile Feed		
OC7	Primary Crusher	Reasonable control & FDCP – Water sprays and moisture carryover	
OC8	Conveyor – Coarse Ore Stockpile Feed Transfer to Stockpile		
OC9	Stockpile Transfer to Reclaim Conveyors	Reasonable control & FDCP – Below-grade of storage piles Control efficiency: 80% for PM/PM_{10}	27,600 T/day
OC10	Conveyor – Reclaim Conveyors to SAG Mill Feed Conveyor		
OC11	Conveyor – SAG Mill Feed Transfer to SAG Mill	Reasonable control & FDCP – Enclosure Control efficiency: 80% for PM/PM_{10}	
OC12	Pebble Crusher	Reasonable control & FDCP – Water sprays and moisture carryover	
OC13	Pebble Discharge to SAG Mill Feed		
Ore Concentration and Refining			
CIP Leach 1–4	Carbon-in-Pulp Leach Tanks	Chemical treatment (lime, caustic soda, hydrogen peroxide, copper sulfate, etc.)	125 g/m^3 CN, 10.25 pH, and 1,700 T/yr PAX
CIL 1–6	Carbon-in-Leach Tanks	Chemical treatment	
CIP 1–6	Carbon-in-Pulp Tanks	Chemical treatment	
CN Detox 1–2	Cyanide Detox Tanks	Chemical treatment	25 g/m^3 CN, and 8.5 pH

Table 1 EMISSIONS UNIT AND CONTROL EQUIPMENT INFORMATION

Source ID No.	Source	Control Equipment	Maximum Process Rate
AC	Autoclave (AC)	Venturi Scrubber (VS1) Vent Gas Cleaning Tower (ST1) Vent Gas Steam Condensation Tower (CT1) Carbon Filter (CA5) Type: sulfur-impregnated activated carbon Form: granulated	6,960 T/day
EW	Electrowinning Cells and Pregnant Solution Tank	Shared Carbon Filter (CA2) Type: sulfur-impregnated activated carbon Form: granulated	100 gpm
MR	Mercury Retort	Condenser Carbon Filter (CA3) Type: sulfur-impregnated activated carbon Form: granulated	1,000 lb/batch and 21 T/yr
MF	Induction Melting Furnace	Baghouse (BH2) Carbon Filter (CA4) Type: sulfur-impregnated activated carbon Form: granulated	
CKD	Carbon Regeneration Kiln (Drum)	Wet Scrubber (WS2) Carbon Filter (CA1) Type: sulfur-impregnated activated carbon Form: granulated	7.2 T/day
	Tailings and Maintenance Pond activities	Chemical treatment, reasonable control & FDCP	1 g/m^3 CN
Process Heating			
ACB	POX Boiler (for AC) Maximum capacity: 17 MMBtu/hr Fuel: propane	None	operation is limited to AC startup only
HS	Strip Circuit Solution Heater Maximum capacity: 5 MMBtu/hr Fuel: propane	None	n/a
CKB	Carbon Regeneration Kiln Burners Maximum capacity: 2.255 MMBtu/hr Fuel: propane	None	(n/a)
PV	Propane Vaporizer Maximum capacity: 0.1 MMBtu/hr Fuel: propane	None	n/a
LKC	PFR Shaft Lime Kiln Combustion Maximum capacity: 22.0 MMBtu/hr Fuel: propane	None	n/a

Table 1 EMISSIONS UNIT AND CONTROL EQUIPMENT INFORMATION

Source ID No.	Source	Control Equipment	Maximum Process Rate
Lime Production			
LS1	Limestone transfer to Primary Crusher Hopper	None	1,130 T/day
LS2	Primary Crusher Maximum capacity: 1,130 T/day	None	
LS3	Primary Screen	None	
LS4	Secondary Crusher	None	
LS5	Secondary Screen	None	
LS6	Conveyor – Limestone to Ball Mill Feed Bin	None	
LS7	Conveyor – Limestone to Ball Mill Feed	None	
LS8	Conveyor – Ball Mill Feed to Ball Mill	None	
LSBM	Limestone Ball Mill	Baghouse (BH3)	
LS9	Conveyor – Limestone to Kiln Feed Bin	None	267 T/day
LS10	Conveyor – Limestone to Lime Kiln Feed	None	
LS11	Fines Screen	None	
LS12	Conveyor – Kiln Feed to PFR Shaft Lime Kiln	None	
LK	Parallel Flow Regenerative (PFR) Shaft Kiln	Baghouse (BH4)	169 T/day and 52,377 T/yr
LCR	Lime Mill Crusher	Baghouse (BH5)	
LS-L/U	Bucket Elevator – Pebble Lime Silo Loading	Loading – Bin Vent Filter	
	Pebble Lime Silo discharge to Lime Slaker	Unloading – Wet Scrubber (WS3)	
LS1-L/U	SAG Mill Lime Silo #1 Maximum capacity: 250 T/day	Loading – Bin Vent Filter Unloading – None	4,000 T/day and 70,000 T/yr (combined)
MillS2-L/U	SAG Mill Lime Silo #2 Maximum capacity: 250 T/day	Loading – Bin Vent Filter Unloading – None	
ACS1	AC Lime Silo #1 Maximum capacity: 1,000 T/day	Loading – Bin Vent Filter Unloading – None	
ACS2	AC Lime Silo #2 Maximum capacity: 1,000 T/day	Loading – Bin Vent Filter Unloading – None	
ACS3	AC Lime Silo #3 Maximum capacity: 1,000 T/day	Loading – Bin Vent Filter Unloading – None	
ACS4	AC Lime Silo #4 Maximum capacity: 500 T/day	Loading – Bin Vent Filter Unloading – None	
Aggregate Production			
PCSP1	Portable Crushing and Screening Plant 1 Crushers, screens, and conveyors	Reasonable control & FDCP – water sprays and moisture carryover	2,000 T/day (aggregate)
PCSP2	Portable Crushing and Screening Plant 2 Crushers, screens, and conveyors	Reasonable control & FDCP – water sprays and moisture carryover	2,000 T/day (aggregate)
Concrete Production			
CM	Central Mixer Loading Maximum capacity: 120 T/hr	Reasonable control & FDCP – Controls may include water sprays, enclosures, hoods, curtains, shrouds, movable and telescoping chutes, and central duct collection systems.	2,480 T/day and 560,000 T/yr (cement + aggregate)
CS1-L/U	Cement/Shotcrete Silo #1 Maximum capacity: 80 T	Loading – Bin Vent Filter Unloading – None	
CS2-L/U	Cement/Shotcrete Silo #2 Maximum capacity: 80 T	Loading – Bin Vent Filter Unloading – None	
CA-L/U	Aggregate Bin Maximum capacity: 2,400 T	Loading – None Unloading – None	

Table 1 EMISSIONS UNIT AND CONTROL EQUIPMENT INFORMATION

Source ID No.	Source	Control Equipment	Maximum Process Rate
Heating, Ventilation, and Air Conditioning (HVAC)			
H1M	Mine Air Heater #1 Maximum capacity: 4 MMBtu/hr Fuel: propane	None	n/a
H2M	Mine Air Heater #2 Maximum capacity: 4 MMBtu/hr Fuel: propane	None	n/a
HM	(4) Mill HVAC Heaters #1-4 Maximum capacity: 1.0 MMBtu/hr (each) Fuel: propane	None	n/a
HAC	Autoclave HVAC Heater Maximum capacity: 0.25 MMBtu/hr Fuel: propane	None	n/a
HR	Refinery HVAC Heater Maximum capacity: 0.25 MMBtu/hr Fuel: propane	None	n/a
HA	Admin HVAC Heater Maximum capacity: 0.25 MMBtu/hr Fuel: propane	None	n/a
HMO	(2) Mine Ops. HVAC Heaters Maximum capacity: 0.25 MMBtu/hr (each) Fuel: propane	None	n/a
HTS	(2) Truck Shop HVAC Heaters Maximum capacity: 1.0 MMBtu/hr (each) Fuel: propane	None	n/a
HW	(3) Warehouse HVAC Heaters Maximum capacity: 1.0 MMBtu/hr (each) Fuel: propane	None	n/a

Table 1 EMISSIONS UNIT AND CONTROL EQUIPMENT INFORMATION

Source ID No.	Source	Control Equipment	Maximum Process Rate
Emergency Power Generation and Fire Suppression			
EDG1	Camp Emergency Generator Date of construction: 2007 or later Maximum capacity: 1,000 bkW Maximum operation: 100 hr/yr (non-emergency) Fuel: ultra-low sulfur diesel (ULSD) Displacement: <10 L/cyl	EPA Tier 2 technologies	1 hr/day and 100 hr/yr
EDG2	Plant Emergency Generator #1 Date of construction: 2007 or later Maximum capacity: 1,000 bkW Maximum operation: 100 hr/yr (non-emergency) Fuel: ULSD Displacement: <10 L/cyl	EPA Tier 2 technologies	1 hr/day and 100 hr/yr
EDG3	Plant Emergency Generator #2 Date of construction: 2007 or later Maximum capacity: 1,000 bkW Maximum operation: 100 hr/yr (non-emergency) Fuel: ULSD Displacement: <10 L/cyl	EPA Tier 2 technologies	1 hr/day and 100 hr/yr
EDFP	Mill Fire Pump Date of construction: 2009 or later Maximum capacity: 200 bkW Maximum operation: 100 hr/yr (non-emergency) Fuel: ULSD Displacement: <10 L/cyl	None	1 hr/day and 100 hr/yr
Fuel Storage			
TG1–TG2	Mine Site Gasoline Tanks (#1 through #2) Maximum capacity: 5,000 gal each	Lids or other appropriate closure with gasketed seal and submerged filling	<100,000 gal/mo
TD3–TD10	Mine Site Diesel Tanks (#3 through #10)	Lids or other appropriate closure	n/a

Emissions Inventories

Potential to Emit

IDAPA 58.01.01 defines Potential to Emit (PTE) as the maximum capacity of a facility or stationary source to emit an air pollutant under its physical and operational design. Any physical or operational limitation on the capacity of the facility or source to emit an air pollutant, including air pollution control equipment and restrictions on hours of operation or on the type or amount of material combusted, stored or processed, shall be treated as part of its design if the limitation or the effect it would have on emissions is state or federally enforceable. Secondary emissions did not count in determining the PTE of a facility or stationary source.

Using this definition of PTE, an emissions inventory was developed for the SGP (see Appendix A). Emissions estimates of criteria pollutant and hazardous air pollutant (HAP) PTE were based on project-specific activity rates (e.g., continuous operation with the exception of the POX Boiler and emergency generator engines, design production rates, material haul rates, blasting agent usage rates, reagent usage rates, etc.), process design (e.g., open-pit mining, process concentration and pH, parallel flow regenerative lime production, central mix concrete production, haul fleet, etc.), emission abatement techniques (e.g., dust suppressant, chemical treatment, carbon filter, baghouse, bin vent filtration, wet scrubber, venturi scrubber, vent gas cleaning tower, and vent gas steam condensation tower control equipment), material characteristics (e.g., moisture content, road silt content, haul route distances, etc.), site conditions (onsite meteorological data, precipitation, etc.), and emission factors based on AP-42,[6] representative source test emissions data, and representative emission limits. Estimated emissions from the autoclave and the carbon regeneration kiln relied on emissions data from representative source test emissions data, scaled to the proposed equipment capacity. Estimated emissions from fuel storage tanks relied on TANKS[7] emission estimation software and projected annual gasoline and ULSD usage rates. Estimated emissions from the emergency generator engines relied on the use of certified engine emission factors.

Uncontrolled PTE

Using the definition of PTE, uncontrolled PTE is then defined as the maximum capacity of a facility or stationary source to emit an air pollutant under its physical and operational design. Any physical or operational limitation on the capacity of the facility or source to emit an air pollutant, including air pollution control equipment and restrictions on hours of operation or on the type or amount of material combusted, stored or processed, shall **not** be treated as part of its design **since** the limitation or the effect it would have on emissions **is not** state or federally enforceable.

The uncontrolled PTE is used to determine if a facility is a "synthetic minor" source of emissions. Synthetic minor sources are facilities that have an uncontrolled PTE for regulated air pollutants or HAP above an applicable major source threshold without permit limits.

For Midas Gold, uncontrolled PTE was based upon a worst-case for operation of the facility of continuous operation at proposed maximum material throughput and fuel input rates (Table 1), without consideration of control equipment. For batch operations, the number of operations necessary to achieve the proposed daily throughput rates was assumed in estimating emissions (MR, MF). Silo loading and unloading operations were assumed to occur at most once per day (LS1-L/U, MillS2-L/U, LS-L/U, PS-L/U, ACS1–ACS4-L/U, CS1–CS2-L/U, CA-L/U). Fuel storage was based on estimated facility-wide fuel usage rates (TG1, TG2 and TD3—TD10). For the purposes of maintenance and testing, emergency power generation operations were assumed to occur 1 hour per day and 100 hours per year (EDG1–EDG3, EDFP). With the exception of the POX Boiler in which operation is limited to AC startup only, continuous operation at maximum fuel input rates was assumed for all process heating and HVAC equipment.

Although not explicitly calculated, it was confirmed by Midas Gold in the response to a request for additional information[1] that the uncontrolled HAP PTE for SGP is estimated to exceed 25 tons per year (T/yr) without application of the specified control equipment (Table 1). Arsenic HAP PTE from haul roads at a controlled emission rate of 0.464 pounds per hour (lb/hr) and accounting for 93.3% control efficiency exceeds 20 T/yr, supporting that uncontrolled HAP PTE exceeds 10 T/yr of single HAP and 25 T/yr of total HAP.

Pre-Project PTE

Pre-project PTE is used to establish the change in emissions at a facility as a result of this project. Because this is a new facility, pre-project emissions are set to zero for all criteria pollutants.

Post-Project PTE

Post-project PTE is used in determining the change in emissions at a facility and in determining the facility's classification as a result of this project. Post-project PTE includes all permit limits resulting from this project.

In addition to assuming continuous operation of the facility at the proposed material throughput and fuel input rates, post-project emissions estimates account for the use of dust suppressant, chemical treatment, carbon filter, baghouse, bin vent filtration, wet scrubber, venturi scrubber, vent gas cleaning tower, and vent gas steam condensation tower control equipment.

A variety of factors impact emissions from unpaved roadways, and it was recognized that accurate determination of site-specific parameters characterizing road conditions and vehicle traffic was critical to estimating particulate matter emissions and ambient air impacts. Midas Gold provided site-specific information to support parameters such as silt content, mean vehicle weight, and dust suppressant control efficiencies, and provided an analysis evaluating the conservatism of the resulting emission factor (AP-42).[8] To ensure operation consistent with these parameters and to reasonably control fugitive emissions, compliance with requirements identified in the FDCP is

[8] Appendix A – Model Parameter / Assumption / Data Level of Conservatism IDEQ Forms to the Stibnite Gold Project Permit to Construct Application, Midas Gold, revised June 23, 2020 (2020AAG1078).

required by the permit. Further discussion of the sensitivity of predicted air quality impacts is provided in the Ambient Air Quality Impact Analyses section.

The following table presents the post-project PTE for criteria pollutants from all emissions units at the facility as determined by DEQ staff. Because this is a new facility, the post-project PTE is equivalent to the facility-wide PTE. Refer to Appendix A for a summary of the calculations and the assumptions used to determine emissions from each source, and the Facility Classification section for a review of facility classifications based on uncontrolled and controlled PTE.

a) Controlled average emission rate in tons per year is an annual average, based on the proposed annual operating scenarios and annual limits.

b) Estimated emissions from the "W3" scenario resulted in the most emissions across most activities, with the exception of material load/unload and wind erosion activities, which occurred in the Y1, H1, W1, and B1 scenarios. Totals reported are for the "W3" scenario.

c) In the response to a request for additional information, Midas Gold confirmed that antimony process dryer and bagging operation emission sources (Sb1 and Sb2) initially proposed would be replaced by a dewatering/packaging circuit. As a result, these emission sources have been removed from the permit and post-project PTE.

Fourteen operational scenarios were evaluated by the applicant and verified by DEQ in order to estimate maximum hourly, daily, and annual potential emissions from sources. These scenarios encompassed all feasible origin and destination location combinations for locating ore and development rock. A summary of these scenarios is provided in Table 4. Although drilling, blasting, excavating, and hauling activities are not expected to be confined to a single scenario in practice, emissions in each scenario were conservatively estimated at the maximum daily proposed processing rate (180,000 of ore and rock) to allow for maximum operational flexibility, and to evaluate potential air quality impacts. Scenarios having the greatest potential emissions (i.e., the top seven) were those with the longest origin-to-destination distances, which resulted in increased emissions evident in onsite hauling and material loading and unloading activities. Consequently, the W3 scenario having the maximum origin-to-destination distance (16,415 daily vehicle miles traveled) is representative of maximum potential emissions.

Table 4 OPERATING SCENARIOS

Scenario	Origin [a]	Destination [a]
Y1	YPP	STKP
Y2	YPP	FDRSF
Y3	YPP	HFDRSF
H1	HFP	STKP
H2	HFP	FDRSF
H3	HFP	HFDRSF
H4	HFP	YPDRSF
W1	WEP	STKP
W2	WEP	FDRSF
W3	WEP	HFDRSF
W4	WEP	YPDRSF
W5	WEP	WEDRSF
B1	BT	STKP
B2	BT	HFDRSF

a) Where ore and rock origin and destination locations as depicted in Figure 1 are abbreviated as follows:
YPP = Yellow Pine Pit, HFP = Hangar Flats pit, WEP = West End pit,
BT = Bradley Tailings, STKP = Primary Crusher Stockpile,
FDRSF = Fiddle DRSF, HFDRSF = Hangar Flats DRSF,
YPDRSF = Yellow Pine DRSF, WEDRSF = West End DRSF, and
DRSF = development rock storage facilities.

There are numerous sources of fugitive dust emissions at the facility, including drilling and blasting activities, crushing and ore handling equipment, ore and rock storage piles, and unpaved roadways. Calculated at maximum daily processing rates, emissions from these sources would tend to be conservatively estimated. But it is also recognized that uncertainties exist in some of the emission factors used, and that predicted modeled impacts may be sensitive to emissions from such sources. In particular, it may prove challenging to consistently and continuously achieve the targeted level of fugitive dust control for emissions from traffic on unpaved roadways, with over 55 miles of haul truck routes within the mining operations boundary, a fleet of 32 haul trucks weighing between 37 and 357 tons, and a targeted dust control efficiency of 93.3% accomplished by application of both dust suppressant and water controls. Based on this, and the scale of operations, a detailed Fugitive Dust Control Plan (FDCP) was required (Permit Conditions 2.6). It is noted that Midas Gold projected actual annual production at approximately 42.7 million T/yr, or 65% of the permitted annual production limit of 65.7 million T/yr (Permit Condition 3.5), and that as a result actual emissions are expected to be lower than presented.

Change in PTE

The change in facility-wide PTE is used to determine if a public comment period may be required and to determine the processing fee per IDAPA 58.01.01.225. The following table presents the facility-wide change in the potential to emit for criteria pollutants, which for a new source is equivalent to the facility-wide and post-project PTE.

Table 5 CHANGES IN PTE FOR REGULATED AIR POLLUTANTS

Source	PM	PM_{10}	$PM_{2.5}$	CO	NO_x	VOC	SO_2
	T/yr [a]	T/yr [a]	T/yr [a]	T/yr [a]	T/yr [a]	T/yr [a]	T/yr [a]
Pre-Project PTE	0.00	0.00	0.00	0.00	0.00	0.00	0.00
Post-Project PTE	86.6	55.7	35.8	29.5	36.2	4.7	6.3
Changes in Potential to Emit	**86.6**	**55.7**	**35.8**	**29.5**	**36.2**	**4.70**	**6.30**

a) Controlled average emission rate in tons per year is an annual average, based on the proposed annual operating scenarios and annual limits.

Controlled Hazardous and Toxic Air Pollutant Emissions

A summary of the estimated PTE for hazardous air pollutants (HAP) and emissions increases (PTE) for non-carcinogenic and carcinogenic toxic air pollutants (TAP) and for potential is provided in the following table (Table 6). This table and the Ambient Air Quality Impact Analyses were updated to include new and updated TAP emission estimates from additional emission sources identified in public comments and in a response and HAP/TAP addendum to the application provided by Midas Gold.[2,3]

All permitted fugitive and point emission sources were evaluated in the new HAP and TAP emission estimates. In Table 6 below, HAP and TAP PTE emissions estimates are for the highest emissions year Scenario "W3" referenced from Table B1-W3 of Appendix B to the HAP/TAP addendum and 'TblB1' worksheet in the supporting spreadsheet. Process and production activities include ore processing; ore concentration and refining; process heating; aggregate production; concrete production; heating, ventilation, and air conditioning (HVAC); emergency power generation and fire suppression; and fuel storage. Mining and leaching activities include drilling, blasting, excavating, hauling, prill silos, rock dumps and storage piles, and tailings. Metal HAP and TAP emissions from process materials were based on metal concentration profiles from onsite core samples of ore and limestone materials, including 98 samples of SGP limestone[9] and over 55,000 samples of SGP ore.[10,11] As a conservative assumption, the limestone profile was also used for emissions from aggregate materials. Mercury emissions from the LK were estimated by assuming all mercury in the limestone feed is volatilized and emitted. For each non-mercury metal HAP and TAP, emissions from the LK were calculated as PM emissions multiplied by the median metal concentration measured. Elemental analysis of core samples was complemented with an evaluation of whether each result represented a regulated HAP and/or TAP substance (element or compound) in Table 2 of the HAP/TAP addendum.[2]

TAP also classified as HAP emitted from sources addressed by New Source Performance Standards (NSPS) or National Emission Standards for Hazardous Air Pollutants (NESHAP) were not required to be evaluated for compliance with TAP increments in accordance with IDAPA 58.01.01.210.20 (Subsection 210.20). Guidance and clarification of Subsection 210.20 source exemptions were included in the Subsection 210.20 (IDAPA 58.01.01.210.20) section and in the response to public comments document that is part of the final permit package for this permitting action. Some of the screening levels for non-carcinogenic and carcinogenic TAP were exceeded as a result of this project and required modeling. Modeling was required for aluminum, barium, calcium carbonate, calcium oxide, iron, sulfuric acid, thallium, and vanadium because the 24-hour average non-carcinogenic screening emission levels (EL) in IDAPA 58.01.01.585 were exceeded. Modeling was required for arsenic, cadmium, formaldehyde, and nickel because the annual average carcinogenic EL in IDAPA 58.01.01.586 were exceeded. Refer to the Ambient Air Quality Impact Analyses section and Appendix B for additional discussion.

a) HAP and TAP PTE emissions estimates are for the highest emissions year Scenario W3, referenced from Table B1-W3 of Appendix B to the HAP/TAP addendum and 'TblB1' worksheet in the supporting spreadsheet. Process and production activities include ore processing; ore concentration and refining; process heating; aggregate production; concrete production; heating, ventilation, and air conditioning (HVAC); emergency power generation and fire suppression; and fuel storage. Mining and leaching activities include drilling, blasting, excavating, hauling, prill silos, rock dumps and storage piles, and tailings.

b) Controlled average emissions rates in pounds per hour (lb/hr). Emissions rates for non-carcinogens are daily averages, based on the proposed daily operating scenarios and limits. Emissions rates for carcinogens are annual averages, based on the proposed annual operating scenarios and limits.

c) Controlled average emissions rates in tons per year (T/yr) are annual averages, based on the proposed annual operating scenarios and annual limits.

d) Adjusted TAP emissions and screening emission levels (EL) as specified in IDAPA 58.01.01.585-586 for purposes of TAP preconstruction compliance demonstrations. For TAP, adjusted emissions do not include sources addressed by NSPS and NESHAP in accordance with IDAPA 58.01.01.210.20Table 8.

e) Carcinogenic TAP as identified in IDAPA 58.01.01.586.

f) Polycyclic aromatic hydrocarbon (PAH). The group of seven PAH with a single EL are regulated as polycyclic organic matter (POM) equivalent in potency to benzo(a)pyrene as specified in IDAPA 58.01.01.586.

g) Adjusted mercury emissions (which are not TAP) are reported in pounds per year (lb/yr) and do not include fugitive sources and sources addressed by NESHAP 40 CFR 63 for comparison to the Mercury Emission Standard threshold of 25 lb/yr. Facility-wide mercury PTE emission rates were calculated as annual average based on federally-enforceable NESHAP Subpart EEEEEEE limits, and exceed values referenced from Table B1-W3 of Appendix B to the HAP/TAP addendum and 'TblB1' worksheet in the supporting spreadsheet (which account for the proposed mercury control devices for refinery process sources AC, EW, MR, MF, CKD).

h) Total hazardous air pollutant (HAP) emissions from all permitted sources and activities (combined). The maximum potential emissions of any single HAP is hydrogen chloride.

i) Toxic air pollutant that is not also a hazardous air pollutant (i.e., non-HAP TAP) and is not included in HAP totals.

j) Dichlorobenzene is regulated as both the ortho- and para- isomers (o-dichlorobenzene and 1,4-dichlorobenzene). For the purposes of TAP compliance, the lowest EL (and therefore most conservative) is listed.

HAP and TAP particulate metals are indirectly regulated via facility-wide fugitive dust requirements for particulate matter (PM) (Permit Conditions 2.1–2.8, 3.9, 5.9), material throughput and operational limits (Permit Conditions 3.3–3.8, 4.7–4.12, 5.4–5.8, 6.2), PM emission limits (Permit Conditions 4.3, 5.3), control device requirements (Permit Conditions 3.10, 4.13–4.17, 5.9–5.15), and associated testing, monitoring, recordkeeping, and reporting requirements. Because usage of process reagents were not correlated to material throughput rates and not otherwise inherently limited, HAP emissions limits and usage limits were established for potassium amyl xanthate (PAX) and sodium cyanide (Permit Conditions 4.4–4.6). Cyanide emissions were sensitive to leachant concentration and basicity, and monitoring of these parameters was established (Permit Condition 4.5) to ensure compliance with the emission limit. Monitoring of these limits and process parameters also ensure compliance with the major threshold for each individual HAP of 10 tons per year (T/yr).

Ambient Air Quality Impact Analyses

The applicant has demonstrated preconstruction compliance to DEQ's satisfaction that emissions from this facility will not cause nor significantly contribute to a violation of any ambient air quality standard. The applicant has also demonstrated preconstruction compliance to DEQ's satisfaction that the emissions increase due to this permitting action will not exceed any acceptable ambient concentration (AAC) or acceptable ambient concentration for carcinogens (AACC) for toxic air pollutants (TAP). A summary of the Ambient Air Impact Analysis for TAP is provided in Appendix B.

As presented in the modeling memorandum in Appendix B, the estimated emission rates of PM_{10}, $PM_{2.5}$, SO_2, CO, NO_x, and certain TAP from this project exceeded applicable screening emission levels (EL) and published DEQ modeling thresholds established in IDAPA 58.01.01.585-586 and in the State of Idaho Air Quality Modeling Guideline.[12] The facility-wide emission rate of lead (Pb) was determined to be below the "below regulatory concern" (BRC) threshold level of less than 10% of the "significant" emission rate defined in IDAPA 58.01.01.006 (i.e., less than 0.06 T/yr) and therefore modeling was not required.[12] Refer to the Emissions Inventories section for additional information concerning the emissions inventories.

New and updated TAP increment compliance demonstrations[4] were provided after evaluation of fugitive particulate TAP emissions from emission sources (Table 6) as identified in public comments and in a response and HAP/TAP addendum to the application provided by Midas Gold.[2] For non-HAP TAP, all sources were evaluated for TAP compliance by comparison of facility-wide emissions to applicable screening emission levels (EL). After exclusion of sources addressed by NSPS and NESHAP (Table 8), applicable concrete production and HVAC emission sources were evaluated for HAP TAP compliance by comparison of adjusted emissions to applicable EL. Refer to the Emissions Inventories section for estimates of HAP and TAP emissions (as summarized in Table 6) and to the Subsection 210.20 (IDAPA 58.01.01.210.20) section for relevant guidance and discussion of sources addressed by NSPS and NESHAP. With the exception of 12 TAP, estimated emission increases of non-carcinogenic and carcinogenic TAP demonstrated preconstruction compliance with TAP standards in accordance with IDAPA 58.01.01.210.07 using controlled average emission rates. Modeling analyses conducted in the development of TAP rules supports that if controlled average emission rates do not exceed applicable screening emission levels (EL) in IDAPA 58.01.01.585–586, controlled ambient concentrations are expected to be below the applicable acceptable ambient concentration (AAC/AACC).

Estimated emission increases of aluminum, arsenic, barium, cadmium, calcium carbonate, calcium oxide, formaldehyde, iron, nickel, sulfuric acid, thallium, and vanadium (12 TAP) demonstrated preconstruction compliance with TAP standards in accordance with IDAPA 58.01.01.210.08 for controlled ambient concentrations. Modeling analyses demonstrated preconstruction compliance with the acceptable ambient concentrations for these TAP (AAC/AACC) in IDAPA 58.01.01.585–586. Emission limits (Permit Condition 4.3), operational and material throughput limits (Permit Conditions 3.3–3.8, 4.5–4.12, and 5.4–5.8), fugitive dust control requirements (Permit Conditions 2.1–2.8), and control equipment requirements (Permit Conditions 2.6, 3.9–3.11, 4.13–4.17, and 5.9–5.15) limit these TAP emissions in accordance with IDAPA 58.01.01.210.08.c, limit Pb to BRC, and limit PM, PM_{10} ,and $PM_{2.5}$ to below the emission rates relied upon in the NAAQS evaluation of ambient air impacts in the modeling analyses.

Arsenic represented the single greatest HAP TAP emission; adjusted arsenic HAP TAP emissions at 5.7E-06 pounds per hour (lb/hr) did not exceed 2% of the applicable EL. Iron (Fe) represented the greatest single non-HAP TAP emission at over 15 lb/hr, which did not exceed 15% of the applicable EL. Any uncertainties in metal TAP emission estimates are not expected to affect compliance with TAP provisions.

It was recognized that accurately defining the mining operations boundary and controlling public access within that boundary was critical to estimating ambient air impacts. To ensure operation consistent with the defined mining operations boundary, site-specific access control measures will be employed. Midas Gold has committed

[12] Criteria pollutant thresholds in Table 2, State of Idaho Guideline for Performing Air Quality Impact Analyses, Doc ID AQ-011, September 2013, criteria pollutant BRC thresholds as provided in IDAPA 58.01.01.221.01, and DEQ guidance pertaining to BRC (2014ACF3).

to identifying and complying with these site-specific access control measures in an Access Management Plan (AMP, as required by Permit Condition 2.7).[13] Refer to Appendix E for a description and discussion of the mining operations boundary and control measures that may be included in this plan.

An ambient air quality impact analyses document has been crafted by DEQ based on a review of the modeling analysis submitted in the application. That document is part of the final permit package for this permitting action (refer to Appendix B). Refer to the Emissions Inventories section and Appendix A for additional information concerning development of the emissions inventories.

REGULATORY ANALYSIS

Attainment Designation (40 CFR 81.313)

The facility is located in Valley County, which is designated as attainment or unclassifiable for $PM_{2.5}$, PM_{10}, SO_2, NO_2, CO, and Ozone. Refer to 40 CFR 81.313 for additional information.

Facility Classification

The AIRS/AFS facility classification codes are as follows:

For HAP (hazardous air pollutants) only:

A = Use when any one HAP has permitted emissions > 10 T/yr or if the aggregate of all HAP (Total HAP) has permitted emissions > 25 T/yr.

SM80 = Use if a synthetic minor (uncontrolled HAP emissions are > 10 T/yr or if the aggregate of all uncontrolled HAP (Total HAP) emissions are > 25 T/yr and permitted emissions fall below applicable major source thresholds) and the permit sets limits > 8 T/yr of a single HAP or ≥ 20 T/yr of Total HAP.

SM = Use if a synthetic minor (uncontrolled HAP emissions are > 10 T/yr or if the aggregate of all uncontrolled HAP (Total HAP) emissions are > 25 T/yr and permitted emissions fall below applicable major source thresholds) and the permit sets limits < 8 T/yr of a single HAP and/or < 20 T/yr of Total HAP.

B = Use when the potential to emit (i.e. uncontrolled emissions and permitted emissions) are below the 10 and 25 T/yr HAP major source thresholds.

UNK = Class is unknown.

For All Other Pollutants:

A = Use when permitted emissions of a pollutant are > 100 T/yr.

SM80 = Use if a synthetic minor for the applicable pollutant (uncontrolled emissions are > 100 T/yr and permitted emissions fall below 100 T/yr) and permitted emissions of the pollutant are ≥ 80 T/yr.

SM = Use if a synthetic minor for the applicable pollutant (uncontrolled emissions are > 100 T/yr and permitted emissions fall below 100 T/yr) and permitted emissions of the pollutant are < 80 T/yr.

B = Use when the potential to emit (i.e. uncontrolled emissions and permitted emissions) are below the 100 T/yr major source threshold.

UNK = Class is unknown.

[13] Attachment 2 – Stibnite Road Access Management Plan to the Stibnite Gold Project Permit to Construct Application, Midas Gold, revised June 23, 2020 (2020AAG1078).

Table 7 REGULATED AIR POLLUTANT FACILITY CLASSIFICATION

Pollutant	Uncontrolled PTE (T/yr)	Permitted PTE (T/yr)	Major Source Thresholds (T/yr)	AIRS/AFS Classification
PM	560	86.6	100	SM80
PM_{10}	337	55.7	100	SM
$PM_{2.5}$	164	35.8	100	SM
SO_2	6.27	6.3	100	B
NO_x	36.16	36.2	100	B
CO	29.47	29.5	100	B
VOC	4.68	4.7	100	B
HAP (single)	>20	3.666	10	SM
Total HAP	>25	12.68	25	SM

Based on the uncontrolled PTE summarized in Table 2 and controlled PTE summarized above and in Table 3, Table 6, and Appendix A, the permittee will be a "synthetic minor" source of PM, PM_{10}, $PM_{2.5}$, and HAP emissions for new source review and Title V (Tier I) permitting purposes. The uncontrolled PTE for the remaining criteria pollutants (SO_2, NO_x, CO, VOC) confirm Midas Gold will be a natural minor source for these emissions.

Permit to Construct (IDAPA 58.01.01.201)

The permittee has requested that a PTC be issued to the facility for the proposed new emission sources. Therefore, a permit to construct is required in accordance with IDAPA 58.01.01.201. This permitting action was processed in accordance with the procedures of IDAPA 58.01.01.200-228.

Tier II Operating Permit (IDAPA 58.01.01.401)

IDAPA 58.01.01.401 ..... Tier II Operating Permit

The application was submitted for a permit to construct (refer to the Permit to Construct (IDAPA 58.01.01.201) section), and an optional Tier II operating permit has not been requested. Therefore, the procedures of IDAPA 58.01.01.400–410 were not applicable to this permitting action.

Subsection 210.20 (IDAPA 58.01.01.210.20)

IDAPA 58.01.01.210.20..... NSPS and NESHAP Sources

No demonstration of compliance with the TAP provisions is required to obtain a PTC or to demonstrate PTC exemption criteria for a new source or for modification of an existing source if the TAP is also a listed HAP from:

- *The equipment or activity covered by a NSPS or NESHAP; or*
- *The source category of equipment or activity addressed by a NSPS or NESHAP even if the equipment or activity is not subject to compliance requirements under the federal rule.*

Emission sources covered or addressed by NSPS or NESHAP are identified in the following table, and guidance on interpretation of "addressed" is provided in Appendix F. Each emission source and activity listed in the table is addressed by the corresponding NSPS and NESHAP. For the sources identified, emissions of TAP that are also HAP (HAP TAP) were excluded from TAP compliance demonstrations (i.e., excluded from comparison to TAP EL and from modeling to demonstrate compliance with TAP AAC/AACC, as discussed in the Ambient Air Quality Impact Analyses).

Table 8 NSPS and NESHAP Sources

NESHAP / NSPS	Source Category Subject & Addressed	Sources
NESHAP Subpart ZZZZ [a] NSPS Subpart IIII	Any industry using a stationary internal combustion engine	*Emergency Power Generation* EDG1, EDG2, EDG3, EDFP
NESHAP Subpart AAAAA [a] NSPS Subpart HH	Any lime manufacturing plant	*Lime Production* LK, LKC, LS1–LS12, LSBM, LS-L/U, LCR, LS1-L/U, MillS2-L/U, and ACS1-4-L/U
NESHAP Subpart DDDDD [a] NESHAP Subpart JJJJJJ [a] NSPS Subpart Dc etc.	Any facility using a boiler or process heater (indirect fire)	*Process Heating* ACB, CKB, PV, HS [b]
NESHAP Subpart CCCCCC [a]	Any gasoline dispensing facility Includes any operation that transfers and stores gasoline	*Gasoline Fuel Storage and Dispensing* TG1–TG2
NESHAP Subpart EEEEEEE [a]	Gold ore mining Includes an establishment engaged in developing the mine site, mining, and/or beneficiating ores valued chiefly for their gold content, or in transformation of gold into bullion or doré bar in combination with mining activities	*Mining* drilling, blasting, excavating, hauling, prill silos, rock dumps and storage piles, tailings *Ore Processing* OC1–OC13 [b] *Ore Concentration and Refining* CIP Leach 1–4, CIL 1–6, CIP 1–6, CN Detox 1–2, AC, EW, MR, MF, CKD *Process Heating* ACB, CKB, PV, HS [b]
NSPS Subpart LL	Any metallic mineral plant Includes any combination of equipment that extracts aluminum, copper, gold, iron, lead, molybdenum, silver, titanium, tungsten, uranium, zinc, and zirconium	*Ore Processing* OC1–OC13 [b]
NSPS Subpart OOO	Any nonmetallic mineral plant Includes plants processing crushed and broken stone, crushed and broken limestone, lime plants, sand and gravel, clay, etc.	*Aggregate Production* PCSP1, PCSP2 *Concrete Production* CA-L/U *Lime Production* LK, LKC, LS1–LS12, LSBM, LS-L/U, LCR, LS1-L/U, MillS2-L/U, and ACS1-4-L/U [b]
Source category that may not be subject to and may not be addressed by NSPS or NESHAP		*Concrete Production* CM, CS1-L/U, CS2-L/U *Heating, Ventilation, and Air Conditioning* H1M–H2M, HM, HAC, HR, HA, HMO, HTS, HW

a) NESHAP in 40 CFR 63
b) Ore Processing emission sources are addressed by both the gold ore mining and metallic mineral plant source categories, Process Heating emission sources are addressed by both the gold ore mining and boiler/process heater source categories, and Lime Production emission sources are addressed by both the lime production and nonmetallic mineral processing plant source categories.

After exclusion of sources addressed by NSPS and/or NESHAP, concrete production (central mixer, cement/shotcrete silos, aggregate bin) and heating, ventilation, and air conditioning (HVAC) units comprise the remaining sources that are applicable to compliance with TAP provisions. Emissions of each TAP from these sources (non-NESHAP-addressed) were estimated and compared to the applicable screening emission level (as summarized in Table 6).

Mercury Emission Standard (IDAPA 58.01.01.215)

IDAPA 58.01.01.215..... Mercury Emission Standard for New or Modified Sources

No owner or operator may commence construction or modification of a stationary source or facility that results in an increase in annual potential emissions of mercury of 25 pounds or more unless the owner or operator has obtained a PTC under Sections 200–228 of the Rules. The PTC application shall include an MBACT analysis for the new or modified source or sources for review and approval by DEQ. A determination of applicability under Section 215 shall be based upon the best available information.

Fugitive emissions shall not be included in a determination of applicability under Section 215.

New or modified stationary sources within a source category subject to 40 CFR 63 are exempt from the requirements of Section 215.

IDAPA 58.01.01.215 sets requirements for mercury emissions. For this standard, fugitive emissions and sources in a source category subject to 40 CFR 63 are exempt. As identified in Table 8, emission sources within a source category subject to NESHAP 40 CFR 63, including Subpart ZZZZ, Subpart AAAAA, Subpart CCCCCC, and Subpart EEEEEEE were therefore exempt from this standard. Although non-applicable to area sources of HAP such as Midas Gold, as a source category lime manufacturing plants are subject to NESHAP 40 CFR 63, Subpart AAAAA and associated sources (identified in Table 8) therefore exempt from this standard. Fugitive emissions from drilling, blasting, excavating, roadways (hauling), dozing, grading, storage piles, tailings and other fugitive and mobile emission sources were also exempt from this standard. Refer to the MACT/GACT Applicability (40 CFR 63) section for regulatory applicability analysis. No mercury emissions are expected from fuel storage, emergency power generation, and fire suppression sources.

After exclusion of sources within a source category subject to an area source NESHAP (40 CFR 63), aggregate production (crushers, screens, and conveyors), concrete production (aggregate bin), and heating, ventilation, and air conditioning (HVAC) units comprise the remaining sources that are applicable to the Mercury Emission Standard. Mercury emissions from these sources (non-fugitive and non-NESHAP-addressed) were estimated at less than 0.041 pounds per year (lb/yr), below the level at which MBACT review is required. Mercury emissions from propane combustion in HVAC sources are uncontrolled. Mercury emissions from materials processed in aggregate production and concrete production are controlled via water sprays and moisture carryover. As such controls are required for the portable crushing and screening plant, central mixer, and cement/shotcrete silos (Permit Conditions 2.1–2.8, 5.9, 5.10, and 5.15).

For the autoclave, electrowinning cells and pregnant solution tank, mercury retort, and induction melting furnace refinery sources (AC, EW, MR, MF) with enforceable NESHAP Subpart EEEEEEE mercury emission limits, potential emissions estimates (PTE) calculated consistent with these limits were included in the facility-wide mercury emission totals in Table 6. These values were substituted in lieu of the controlled emission estimates referenced from Table B1-W3 of Appendix B to the HAP/TAP addendum and 'TblB1' worksheet in the supporting spreadsheet. Although the mercury emissions from these sources are ultimately not included in the adjusted mercury emission totals for the purposes of the Mercury Emission Standard, these were used for the purposes of estimating HAP PTE consistent with enforceable limits.

Particulate Matter – New Equipment Process Weight Limitations (IDAPA 58.01.01.701)

IDAPA 58.01.01.701 ..... Particulate Matter – New Equipment Process Weight Limitations

IDAPA 58.01.01.700 through 703 set PM emission limits for process equipment based on when the piece of equipment commenced operation and the piece of equipment's process weight (PW) in pounds per hour (lb/hr). IDAPA 58.01.01.701 establishes PM emission limits for equipment that commenced operation on or after October 1, 1979.

For equipment commencing operation on or after October 1, 1979, the PM allowable emission rate (E) is based on one of the following equations:

IDAPA 58.01.01.701.01.a: If PW is $< 9{,}250$ lb/hr; $E = 0.045\ (PW)^{0.60}$

IDAPA 58.01.01.701.01.b: If PW is $\geq 9{,}250$ lb/hr; $E = 1.10\ (PW)^{0.25}$

For the new ore processing, ore concentration and refining, lime production, aggregate production, and concrete production equipment sources (Table 1) emissions (E) were calculated at the proposed maximum throughput rates (Table 1), and estimated emissions from all sources demonstrated compliance with this requirement. Compliance with operational and material throughput limits (Permit Conditions 3.3–3.8, 4.5–4.12, and 5.4–5.8) and control equipment requirements (Permit Conditions 2.6, 3.9–3.11, 4.13–4.17, and 5.9–5.15) assure compliance with this standard, resulting in much lower emission rates.

Title V Classification (IDAPA 58.01.01.300, 40 CFR Part 70)

IDAPA 58.01.01.301 ..... Requirement to Obtain Tier I Operating Permit

Any source subject to 40 CFR 63, Subpart EEEEEEE is a Tier I source as defined in IDAPA 58.01.01.006.122.c. In accordance with IDAPA 58.01.01.313.01.b., the permittee must submit a complete application to DEQ for an initial Tier I operating permit within 12 months of becoming a Tier I source.

Midas Gold has committed to applying for a Tier I permit. Detailed federal regulatory applicability were provided in the PTC application, and specific federally-applicable requirements will be incorporated into the Tier I. Refer to the NSPS Applicability (40 CFR 60), NESHAP Applicability (40 CFR 61), and MACT/GACT Applicability (40 CFR 63) sections below for additional information regarding applicable requirements.

Post-project facility-wide emissions from this facility do not have a PTE greater than 100 tons per year for criteria pollutants or 10 tons per year for any one HAP or 25 tons per year for all HAP combined as demonstrated previously in the Emissions Inventories section of this analysis. Although not a major facility as defined in IDAPA 58.01.01.008.10, any source subject to 40 CFR 63, Subpart EEEEEEE is a Tier I source as defined in IDAPA 58.01.01.006.122.c. In accordance with IDAPA 58.01.01.313.01.b., the permittee must submit a complete application to DEQ for an initial Tier I operating permit within 12 months of becoming a Tier I source. Refer to the NESHAP Applicability (40 CFR 61) section for additional discussion of Subpart EEEEEEE applicability.

Permit Condition 2.24 incorporates the requirement to obtain a Tier I permit in accordance with IDAPA 58.01.01.313.01.b.

PSD Classification (40 CFR 52.21)

40 CFR 52.21 ..... Prevention of Significant Deterioration of Air Quality

The facility is not a major stationary source as defined in 40 CFR 52.21(b)(1), nor is it undergoing any physical change at a stationary source not otherwise qualifying under paragraph 40 CFR 52.21(b)(1) as a major stationary source which would constitute a major stationary source by itself as defined in 40 CFR 52. PSD requirements were therefore not applicable to this permitting action in accordance with 40 CFR 52.21(a)(2).

The facility includes a lime manufacturing plant (LMP) that uses a Parallel Flow Regenerative Shaft Kiln (LK, LKC) to produce lime product from limestone by calcination, which is a designated facility as defined in 40 CFR 52.21(b)(1)(i)(a). For each criteria pollutant, LMP emissions do not exceed 100 T/yr and facility-wide emissions do not exceed 250 T/yr.

NSPS Applicability (40 CFR 60)

The permittee has affected facilities subject to New Source Performance Standards (NSPS). The POX Boiler (ACB) meets the definition of process heater rather than steam generating unit, and the use of a rotary lime kiln has not been proposed in the production of lime; therefore Subpart Dc and Subpart HH are not applicable. Initial regulatory applicability analyses and determinations are provided below; detailed analyses and explicit incorporation of applicable requirements is left to the required Tier I permit action as discussed in the Title V Classification (IDAPA 58.01.01.300, 40 CFR Part 70) section.

- Standards of Performance for New Stationary Sources (NSPS) 40 CFR 60, Subpart A – General Provisions. DEQ is delegated this Subpart.

- NSPS 40 CFR 60, Subpart LL – Standards of Performance for Metallic Mineral Processing Plants. DEQ is delegated this Subpart. Each crusher, conveyor belt transfer point, and truck unloading station is an affected facility.
- NSPS 40 CFR 60, Subpart OOO – Standards of Performance for Nonmetallic Mineral Processing Plants. DEQ is delegated this Subpart. Each crusher, grinding mill, screening operation, belt conveyor, and storage bin is an affected facility.
- NSPS 40 CFR 60, Subpart IIII – Standards of Performance for Stationary Compression Ignition Internal Combustion Engines. DEQ is delegated this Subpart. Each emergency generator engine and fire pump is an affected facility.

Emission sources regulated by Subpart LL, Subpart OOO, and Subpart IIII are identified in the incorporation of federal requirements condition (Permit Condition 2.22)

40 CFR 60, Subpart A ..... General Provisions

§60.1 ..... Applicability

(a) Except as provided in subparts B and C, the provisions of this part apply to the owner or operator of any stationary source which contains an affected facility, the construction or modification of which is commenced after the date of publication in this part of any standard (or, if earlier, the date of publication of any proposed standard) applicable to that facility.

(b) Any new or revised standard of performance promulgated pursuant to section 111(b) of the Act shall apply to the owner or operator of any stationary source which contains an affected facility, the construction or modification of which is commenced after the date of publication in this part of such new or revised standard (or, if earlier, the date of publication of any proposed standard) applicable to that facility.

Because the permittee will own or operate NSPS affected facilities, which have been proposed to commence construction after the date of publication of the relevant applicable NSPS standards (as listed above), general provisions in Subpart A are applicable.

40 CFR 60, Subpart A is incorporated by reference into Permit Condition 2.22, and specific applicable requirements will be incorporated into the Tier I operating permit.

40 CFR 60, Subpart Dc ..... Standards of Performance for Small Industrial-Commercial-Institutional Steam Generating Units

§60.40c ..... Applicability and delegation of authority.

(a) Except as provided in paragraphs (d), (e), (f), and (g) of this section, the affected facility to which this subpart applies is each steam generating unit for which construction, modification, or reconstruction is commenced after June 9, 1989 and that has a maximum design heat input capacity of 29 megawatts (MW) (100 million British thermal units per hour (MMBtu/h)) or less, but greater than or equal to 2.9 MW (10 MMBtu/h).

§60.41c ..... Definitions.

As used in this subpart, all terms not defined herein shall have the meaning given them in the Clean Air Act and in subpart A of this part.

...

Heat input *means heat derived from combustion of fuel in a steam generating unit and does not include the heat derived from preheated combustion air, recirculated flue gases, or exhaust gases from other sources (such as stationary gas turbines, internal combustion engines, and kilns).*

Heat transfer medium *means any material that is used to transfer heat from one point to another point.*

...

Process heater *means a device that is primarily used to heat a material to initiate or promote a chemical reaction in which the material participates as a reactant or catalyst.*

...

Steam generating unit *means a device that combusts any fuel and produces steam or heats water or heats any heat transfer medium. This term includes any duct burner that combusts fuel and is part of a combined cycle system. This term does not include process heaters as defined in this subpart.*

Although the Pressure Oxidation Boiler (POX Boiler) is between 10 and 100 MMBtu/hr in design heat input capacity (17 MMBtu/hr) and is proposed for construction after June 9, 1989, it meets the definition of process heater rather than steam generating unit, and therefore is not applicable to this subpart. The POX Boiler (ACB) is a device used to directly heat ore material via steam injection into the autoclave, to promote chemical oxidation reactions in which the heated ore participates as a reactant. DEQ is delegated this Subpart.

40 CFR 60, Subpart HH ..... Standards of Performance for Lime Manufacturing Plants

§60.340 ..... Applicability and designation of affected facility.

(a) The provisions of this subpart are applicable to each rotary lime kiln used in the manufacture of lime.

(b) The provisions of this subpart are not applicable to facilities used in the manufacture of lime at kraft pulp mills.

(c) Any facility under paragraph (a) of this section that commences construction or modification after May 3, 1977, is subject to the requirements of this subpart.

§60.341 ..... Definitions.

As used in this subpart, all terms not defined herein shall have the same meaning given them in the Act and in the General Provisions.

(a) Lime manufacturing plant *means any plant which uses a rotary lime kiln to produce lime product from limestone by calcination.*

(b) Lime product *means the product of the calcination process including, but not limited to, calcitic lime, dolomitic lime, and dead-burned dolomite.*

(c) Positive-pressure fabric filter *means a fabric filter with the fans on the upstream side of the filter bags.*

(d) Rotary lime kiln *means a unit with an inclined rotating drum that is used to produce a lime product from limestone by calcination.*

(e) Stone feed *means limestone feedstock and mill scale or other iron oxide additives that become part of the product.*

The use of a rotary lime kiln has not been proposed in the production of lime, and therefore the requirements of Subpart HH are not applicable. DEQ is delegated this Subpart.

40 CFR 60, Subpart LL ..... Standards of Performance for Metallic Mineral Processing Plants

§60.380 ..... Applicability and designation of affected facility.

(a) The provisions of this subpart are applicable to the following affected facilities in metallic mineral processing plants: Each crusher and screen in open-pit mines; each crusher, screen, bucket elevator, conveyor belt transfer point, thermal dryer, product packaging station, storage bin, enclosed storage area, truck loading station, truck unloading station, railcar loading station, and railcar unloading station at the mill or concentrator with the following exceptions. All facilities located in underground mines are exempted from the provisions of this subpart. At uranium ore processing plants, all facilities subsequent to and including the beneficiation of uranium ore are exempted from the provisions of this subpart.

(b) An affected facility under paragraph (a) of this section that commences construction or modification after August 24, 1982, is subject to the requirements of this part.

Because the permittee will own or operate a metallic mineral processing plant with a crusher at an open-pit mine; with crushers, conveyor belt transfer points, and truck unloading stations at the mill or concentrator; and because these are proposed to commence construction after August 24, 1982, requirements in Subpart LL are applicable.

40 CFR 60, Subpart LL is incorporated by reference into Permit Condition 2.22, and specific applicable requirements will be incorporated into the Tier I operating permit.

40 CFR 60, Subpart OOO ..... Standards of Performance for Nonmetallic Mineral Processing Plants

§60.670 ..... Applicability and designation of affected facility.

(a)(1) Except as provided in paragraphs (a)(2), (b), (c), and (d) of this section, the provisions of this subpart are applicable to the following affected facilities in fixed or portable nonmetallic mineral processing plants: each crusher, grinding mill, screening operation, bucket elevator, belt conveyor, bagging operation, storage bin, enclosed truck or railcar loading station. Also, crushers and grinding mills at hot mix asphalt facilities that reduce the size of nonmetallic minerals embedded in recycled asphalt pavement and subsequent affected facilities up to, but not including, the first storage silo or bin are subject to the provisions of this subpart.

(2) The provisions of this subpart do not apply to the following operations: All facilities located in underground mines; plants without crushers or grinding mills above ground; and wet material processing operations (as defined in §60.671).

(b) An affected facility that is subject to the provisions of subparts F or I of this part or that follows in the plant process any facility subject to the provisions of subparts F or I of this part is not subject to the provisions of this subpart.

(c) Facilities at the following plants are not subject to the provisions of this subpart:

(1) Fixed sand and gravel plants and crushed stone plants with capacities, as defined in §60.671, of 23 megagrams per hour (25 tons per hour) or less;

(2) Portable sand and gravel plants and crushed stone plants with capacities, as defined in §60.671, of 136 megagrams per hour (150 tons per hour) or less; and

(3) Common clay plants and pumice plants with capacities, as defined in §60.671, of 9 megagrams per hour (10 tons per hour) or less.

(d)(1) When an existing facility is replaced by a piece of equipment of equal or smaller size, as defined in §60.671, having the same function as the existing facility, and there is no increase in the amount of emissions, the new facility is exempt from the provisions of §§60.672, 60.674, and 60.675 except as provided for in paragraph (d)(3) of this section.

(2) An owner or operator complying with paragraph (d)(1) of this section shall submit the information required in §60.676(a).

(3) An owner or operator replacing all existing facilities in a production line with new facilities does not qualify for the exemption described in paragraph (d)(1) of this section and must comply with the provisions of §§60.672, 60.674 and 60.675.

(e) An affected facility under paragraph (a) of this section that commences construction, modification, or reconstruction after August 31, 1983, is subject to the requirements of this part.

(f) Table 1 of this subpart specifies the provisions of subpart A of this part 60 that do not apply to owners and operators of affected facilities subject to this subpart or that apply with certain exceptions.

Because the project contains crushers, grinding mills, screening operations, belt conveyors, and storage bins in a fixed or portable nonmetallic mineral processing plant, which are proposed to commence construction after August 31, 1983, requirements in Subpart OOO are applicable. The portable crushing and screening plants (PCSP1, PCSP2) will be rated at below 150 tons per hour (T/hr), and are therefore not subject to the provisions of Subpart OOO.

40 CFR 60, Subpart OOO is incorporated by reference into Permit Condition 2.22, and specific applicable requirements will be incorporated into the Tier I operating permit.

40 CFR 60, Subpart IIII..... Standards of Performance for Stationary Compression Ignition Internal Combustion Engines

§60.4200..... Am I subject to this subpart?

(a) The provisions of this subpart are applicable to manufacturers, owners, and operators of stationary compression ignition (CI) internal combustion engines (ICE) and other persons as specified in paragraphs (a)(1) through (4) of this section. For the purposes of this subpart, the date that construction commences is the date the engine is ordered by the owner or operator.

(1) Manufacturers of stationary CI ICE with a displacement of less than 30 liters per cylinder where the model year is:

(i) 2007 or later, for engines that are not fire pump engines;

(ii) The model year listed in Table 3 to this subpart or later model year, for fire pump engines.

(2) Owners and operators of stationary CI ICE that commence construction after July 11, 2005, where the stationary CI ICE are:

(i) Manufactured after April 1, 2006, and are not fire pump engines, or

(ii) Manufactured as a certified National Fire Protection Association (NFPA) fire pump engine after July 1, 2006.

(3) Owners and operators of any stationary CI ICE that are modified or reconstructed after July 11, 2005 and any person that modifies or reconstructs any stationary CI ICE after July 11, 2005.

(4) The provisions of §60.4208 of this subpart are applicable to all owners and operators of stationary CI ICE that commence construction after July 11, 2005.

(b) The provisions of this subpart are not applicable to stationary CI ICE being tested at a stationary CI ICE test cell/stand.

(c) If you are an owner or operator of an area source subject to this subpart, you are exempt from the obligation to obtain a permit under 40 CFR part 70 or 40 CFR part 71, provided you are not required to obtain a permit under 40 CFR 70.3(a) or 40 CFR 71.3(a) for a reason other than your status as an area source under this subpart. Notwithstanding the previous sentence, you must continue to comply with the provisions of this subpart applicable to area sources.

(d) Stationary CI ICE may be eligible for exemption from the requirements of this subpart as described in 40 CFR part 1068, subpart C (or the exemptions described in 40 CFR part 89, subpart J and 40 CFR part 94, subpart J, for engines that would need to be certified to standards in those parts), except that owners and operators, as well as manufacturers, may be eligible to request an exemption for national security.

(e) Owners and operators of facilities with CI ICE that are acting as temporary replacement units and that are located at a stationary source for less than 1 year and that have been properly certified as meeting the standards that would be applicable to such engine under the appropriate nonroad engine provisions, are not required to meet any other provisions under this subpart with regard to such engines.

Because the permittee will own or operate compression ignition (CI) internal combustion engines (ICE) which are proposed to commence construction after July 11, 2005 and which will be ordered after April 1, 2006 for the emergency generator engines, and which will be ordered after July 1, 2006 for the fire pump engine, requirements in Subpart IIII are applicable. The permittee has not requested or qualified for exemption pursuant to §60.4200(b), (d), or (e).

40 CFR 60, Subpart IIII is incorporated by reference into Permit Condition 2.22, and specific applicable requirements will be incorporated into the Tier I operating permit.

NESHAP Applicability (40 CFR 61)

The facility is not subject to any NESHAP requirements in 40 CFR 61.

MACT/GACT Applicability (40 CFR 63)

The permittee has proposed to operate as a minor source of hazardous air pollutant (HAP) emissions, and has affected facilities subject to the following National Emission Standards for Hazardous Air Pollutants (NESHAP). The lime manufacturing plant is proposed at an area source of HAP, and therefore is not applicable to Subpart AAAAA. The process boiler is at an area source of Applicability determinations and regulatory analyses are provided below.

- National Emission Standards for Hazardous Air Pollutants for Source Categories (NESHAP) 40 CFR 63, Subpart A – General Provisions. DEQ is delegated this Subpart for Tier I sources.
- NESHAP 40 CFR 63, Subpart ZZZZ – National Emission Standards for Hazardous Air Pollutants for Stationary Reciprocating Internal Combustion Engines (RICE). DEQ is delegated this Subpart. The emergency generator and fire pump engines (EDG1, EDG2, EDG3, and EDFP) are affected sources.
- NESHAP 40 CFR 63, Subpart CCCCCC – National Emission Standards for Hazardous Air Pollutants for Source Category: Gasoline Dispensing Facilities. DEQ is delegated this Subpart for Tier I sources. The gasoline fuel storage tanks (TG1, TG2) are affected sources.
- NESHAP 40 CFR 63, Subpart EEEEEEE – National Emission Standards for Hazardous Air Pollutants: Gold Mine Ore Processing and Production Area Source Category. DEQ is delegated this Subpart for Tier I sources. The collection of ore pretreatment processes and the carbon process with mercury retort are affected sources. Ore pretreatment processes include the autoclave (AC). Carbon processes with mercury retort include the electrowinning cells and pregnant solution tank (EW), the mercury retort (MR), induction melting furnace (MF), and the carbon regeneration kiln (CKD).

Emission sources regulated by Subpart EEEEEEE, Subpart CCCCCC, and Subpart ZZZZ are identified in the incorporation of federal requirements condition (Permit Condition 2.22)

40 CFR 63, Subpart A ..... General Provisions

§63.1 ..... Applicability.

(a) General. *(1) Terms used throughout this part are defined in §63.2 or in the Clean Air Act (Act) as amended in 1990, except that individual subparts of this part may include specific definitions in addition to or that supersede definitions in §63.2.*

(2) This part contains national emission standards for hazardous air pollutants (NESHAP) established pursuant to section 112 of the Act as amended November 15, 1990. These standards regulate specific categories of stationary sources that emit (or have the potential to emit) one or more hazardous air pollutants listed in this part pursuant to section 112(b) of the Act. This section explains the applicability of such standards to sources affected by them. The standards in this part are independent of NESHAP contained in 40 CFR part 61. The NESHAP in part 61 promulgated by signature of the Administrator before November 15, 1990 (i.e., the date of enactment of the Clean Air Act Amendments of 1990) remain in effect until they are amended, if appropriate, and added to this part.

(3) No emission standard or other requirement established under this part shall be interpreted, construed, or applied to diminish or replace the requirements of a more stringent emission limitation or other applicable requirement established by the Administrator pursuant to other authority of the Act (section 111, part C or D or any other authority of this Act), or a standard issued under State authority. The Administrator may specify in a specific standard under this part that facilities subject to other provisions under the Act need only comply with the provisions of that standard.

(4)(i) Each relevant standard in this part 63 must identify explicitly whether each provision in this subpart A is or is not included in such relevant standard.

(ii) If a relevant part 63 standard incorporates the requirements of 40 CFR part 60, part 61 or other part 63 standards, the relevant part 63 standard must identify explicitly the applicability of each corresponding part 60, part 61, or other part 63 subpart A (General) provision.

(iii) The General Provisions in this subpart A do not apply to regulations developed pursuant to section 112(r) of the amended Act, unless otherwise specified in those regulations.

...

(b) Initial applicability determination for this part. *(1) The provisions of this part apply to the owner or operator of any stationary source that—*

(i) Emits or has the potential to emit any hazardous air pollutant listed in or pursuant to section 112(b) of the Act; and

(ii) Is subject to any standard, limitation, prohibition, or other federally enforceable requirement established pursuant to this part.

(2) [Reserved]

(3) An owner or operator of a stationary source who is in the relevant source category and who determines that the source is not subject to a relevant standard or other requirement established under this part must keep a record as specified in §63.10(b)(3).

Because the permittee will own or operate stationary sources that emit HAP which are subject to standards, limitations, prohibitions, or other federally-enforceable requirements established pursuant to NESHAP, provisions in Subpart A are applicable.

40 CFR 63, Subpart A is incorporated by reference into Permit Condition 2.22, and specific applicable requirements will be incorporated into the Tier I operating permit.

40 CFR 63, Subpart ZZZZ..... National Emissions Standards for Hazardous Air Pollutants for Stationary Reciprocating Internal Combustion Engines

§63.6580..... What is the purpose of subpart ZZZZ?

Subpart ZZZZ establishes national emission limitations and operating limitations for hazardous air pollutants (HAP) emitted from stationary reciprocating internal combustion engines (RICE) located at major and area sources of HAP emissions. This subpart also establishes requirements to demonstrate initial and continuous compliance with the emission limitations and operating limitations.

§63.6585..... Am I subject to this subpart?

You are subject to this subpart if you own or operate a stationary RICE at a major or area source of HAP emissions, except if the stationary RICE is being tested at a stationary RICE test cell/stand.

(a) A stationary RICE is any internal combustion engine which uses reciprocating motion to convert heat energy into mechanical work and which is not mobile. Stationary RICE differ from mobile RICE in that a stationary RICE is not a non-road engine as defined at 40 CFR 1068.30, and is not used to propel a motor vehicle or a vehicle used solely for competition.

(b) A major source of HAP emissions is a plant site that emits or has the potential to emit any single HAP at a rate of 10 tons (9.07 megagrams) or more per year or any combination of HAP at a rate of 25 tons (22.68 megagrams) or more per year, except that for oil and gas production facilities, a major source of HAP emissions is determined for each surface site.

(c) An area source of HAP emissions is a source that is not a major source.

(d) If you are an owner or operator of an area source subject to this subpart, your status as an entity subject to a standard or other requirements under this subpart does not subject you to the obligation to obtain a permit under 40 CFR part 70 or 71, provided you are not required to obtain a permit under 40 CFR 70.3(a) or 40 CFR 71.3(a) for a reason other than your status as an area source under this subpart. Notwithstanding the previous sentence, you must continue to comply with the provisions of this subpart as applicable.

(e) If you are an owner or operator of a stationary RICE used for national security purposes, you may be eligible to request an exemption from the requirements of this subpart as described in 40 CFR part 1068, subpart C.

(f) The emergency stationary RICE listed in paragraphs (f)(1) through (3) of this section are not subject to this subpart. The stationary RICE must meet the definition of an emergency stationary RICE in §63.6675, which includes operating according to the provisions specified in §63.6640(f).

(1) Existing residential emergency stationary RICE located at an area source of HAP emissions that do not operate or are not contractually obligated to be available for more than 15 hours per calendar year for the purposes specified in §63.6640(f)(2)(ii) and (iii) and that do not operate for the purpose specified in §63.6640(f)(4)(ii).

(2) Existing commercial emergency stationary RICE located at an area source of HAP emissions that do not operate or are not contractually obligated to be available for more than 15 hours per calendar year for the purposes specified in §63.6640(f)(2)(ii) and (iii) and that do not operate for the purpose specified in §63.6640(f)(4)(ii).

(3) Existing institutional emergency stationary RICE located at an area source of HAP emissions that do not operate or are not contractually obligated to be available for more than 15 hours per calendar year for the purposes specified in §63.6640(f)(2)(ii) and (iii) and that do not operate for the purpose specified in §63.6640(f)(4)(ii).

Because the permittee will own or operate stationary RICE at an area source of HAP which are subject to standards, limitations, prohibitions, or other federally-enforceable requirements established pursuant to NESHAP, requirements in Subpart ZZZZ are applicable.

40 CFR 63, Subpart ZZZZ is incorporated by reference into Permit Condition 2.22, and specific applicable requirements will be incorporated into the Tier I operating permit.

40 CFR 63, Subpart AAAAA..... National Emission Standards for Hazardous Air Pollutants for Lime Manufacturing Plants

§63.7080..... What is the purpose of this subpart?

This subpart establishes national emission standards for hazardous air pollutants (NESHAP) for lime manufacturing plants. This subpart also establishes requirements to demonstrate initial and continuous compliance with the emission limitations.

§63.7081..... Am I subject to this subpart?

(a) You are subject to this subpart if you own or operate a lime manufacturing plant (LMP) that is a major source, or that is located at, or is part of, a major source of hazardous air pollutant (HAP) emissions, unless the LMP is located at a kraft pulp mill, soda pulp mill, sulfite pulp mill, beet sugar manufacturing plant, or only processes sludge containing calcium carbonate from water softening processes.

(1) An LMP is an establishment engaged in the manufacture of lime product (calcium oxide, calcium oxide with magnesium oxide, or dead burned dolomite) by calcination of limestone, dolomite, shells or other calcareous substances.

(2) A major source of HAP is a plant site that emits or has the potential to emit any single HAP at a rate of 9.07 megagrams (10 tons) or more per year or any combination of HAP at a rate of 22.68 megagrams (25 tons) or more per year from all emission sources at the plant site.

(b) [Reserved]

§63.7143..... What definitions apply to this subpart?

Terms used in this subpart are defined in the Clean Air Act, in §63.2, and in this section as follows:

...

Lime manufacturing plant (LMP) *means any plant which uses a lime kiln to produce lime product from limestone or other calcareous material by calcination.*

Lime product *means the product of the lime kiln calcination process including, calcitic lime, dolomitic lime, and dead-burned dolomite.*

Limestone *means the material comprised primarily of calcium carbonate (referred to sometimes as calcitic or high calcium limestone), magnesium carbonate, and/or the double carbonate of both calcium and magnesium (referred to sometimes as dolomitic limestone or dolomite).*

...

The lime manufacturing plant is proposed at an area source of HAP, and therefore is not subject to this Subpart.

40 CFR 60, Subpart CCCCCC..... National Emission Standards for Hazardous Air Pollutants for Source Category: Gasoline Dispensing Facilities

§63.11110..... What is the purpose of this subpart?

This subpart establishes national emission limitations and management practices for hazardous air pollutants (HAP) emitted from the loading of gasoline storage tanks at gasoline dispensing facilities (GDF). This subpart also establishes requirements to demonstrate compliance with the emission limitations and management practices.

§63.11111..... Am I subject to the requirements in this subpart?

(a) The affected source to which this subpart applies is each GDF that is located at an area source. The affected source includes each gasoline cargo tank during the delivery of product to a GDF and also includes each storage tank.

(b) If your GDF has a monthly throughput of less than 10,000 gallons of gasoline, you must comply with the requirements in §63.11116.

(c) If your GDF has a monthly throughput of 10,000 gallons of gasoline or more, you must comply with the requirements in §63.11117.

(d) If your GDF has a monthly throughput of 100,000 gallons of gasoline or more, you must comply with the requirements in §63.11118.

(e) An affected source shall, upon request by the Administrator, demonstrate that their monthly throughput is less than the 10,000-gallon or the 100,000-gallon threshold level, as applicable. For new or reconstructed affected sources, as specified in §63.11112(b) and (c), recordkeeping to document monthly throughput must begin upon startup of the affected source. For existing sources, as specified in §63.11112(d), recordkeeping to document monthly throughput must begin on January 10, 2008. For existing sources that are subject to this subpart only because they load gasoline into fuel tanks other than those in motor vehicles, as defined in §63.11132, recordkeeping to document monthly throughput must begin on January 24, 2011. Records required under this paragraph shall be kept for a period of 5 years.

(f) If you are an owner or operator of affected sources, as defined in paragraph (a) of this section, you are not required to obtain a permit under 40 CFR part 70 or 40 CFR part 71 as a result of being subject to this subpart. However, you must still apply for and obtain a permit under 40 CFR part 70 or 40 CFR part 71 if you meet one or more of the applicability criteria found in 40 CFR 70.3(a) and (b) or 40 CFR 71.3(a) and (b).

(g) The loading of aviation gasoline into storage tanks at airports, and the subsequent transfer of aviation gasoline within the airport, is not subject to this subpart.

(h) Monthly throughput is the total volume of gasoline loaded into, or dispensed from, all the gasoline storage tanks located at a single affected GDF. If an area source has two or more GDF at separate locations within the area source, each GDF is treated as a separate affected source.

(i) If your affected source's throughput ever exceeds an applicable throughput threshold, the affected source will remain subject to the requirements for sources above the threshold, even if the affected source throughput later falls below the applicable throughput threshold.

(j) The dispensing of gasoline from a fixed gasoline storage tank at a GDF into a portable gasoline tank for the on-site delivery and subsequent dispensing of the gasoline into the fuel tank of a motor vehicle or other gasoline-fueled engine or equipment used within the area source is only subject to §63.11116 of this subpart.

(k) For any affected source subject to the provisions of this subpart and another Federal rule, you may elect to comply only with the more stringent provisions of the applicable subparts. You must consider all provisions of the rules, including monitoring, recordkeeping, and reporting. You must identify the affected source and provisions with which you will comply in your Notification of Compliance Status required under §63.11124. You also must demonstrate in your Notification of Compliance Status that each provision with which you will comply is at least as stringent as the otherwise applicable requirements in this subpart. You are responsible for making accurate determinations concerning the more stringent provisions, and noncompliance with this rule is not excused if it is later determined that your determination was in error, and, as a result, you are violating this subpart. Compliance with this rule is your responsibility and the Notification of Compliance Status does not alter or affect that responsibility.

§63.11132..... What definitions apply to this subpart?

As used in this subpart, all terms not defined herein shall have the meaning given them in the Clean Air Act (CAA), or in subparts A and BBBBBB of this part. For purposes of this subpart, definitions in this section supersede definitions in other parts or subparts.

Dual-point vapor balance system *means a type of vapor balance system in which the storage tank is equipped with an entry port for a gasoline fill pipe and a separate exit port for a vapor connection.*

Gasoline *means any petroleum distillate or petroleum distillate/alcohol blend having a Reid vapor pressure of 27.6 kilopascals or greater, which is used as a fuel for internal combustion engines.*

Gasoline cargo tank *means a delivery tank truck or railcar which is loading or unloading gasoline, or which has loaded or unloaded gasoline on the immediately previous load.*

Gasoline dispensing facility (GDF) *means any stationary facility which dispenses gasoline into the fuel tank of a motor vehicle, motor vehicle engine, nonroad vehicle, or nonroad engine, including a nonroad vehicle or nonroad engine used solely for competition. These facilities include, but are not limited to, facilities that dispense gasoline into on- and off-road, street, or highway motor vehicles, lawn equipment, boats, test engines, landscaping equipment, generators, pumps, and other gasoline-fueled engines and equipment.*

Monthly throughput *means the total volume of gasoline that is loaded into, or dispensed from, all gasoline storage tanks at each GDF during a month. Monthly throughput is calculated by summing the volume of gasoline loaded into, or dispensed from, all gasoline storage tanks at each GDF during the current day, plus the total volume of gasoline loaded into, or dispensed from, all gasoline storage tanks at each GDF during the previous 364 days, and then dividing that sum by 12.*

Motor vehicle *means any self-propelled vehicle designed for transporting persons or property on a street or highway.*

Nonroad engine *means an internal combustion engine (including the fuel system) that is not used in a motor vehicle or a vehicle used solely for competition, or that is not subject to standards promulgated under section 7411 of this title or section 7521 of this title.*

Nonroad vehicle *means a vehicle that is powered by a nonroad engine, and that is not a motor vehicle or a vehicle used solely for competition.*

Submerged filling *means, for the purposes of this subpart, the filling of a gasoline storage tank through a submerged fill pipe whose discharge is no more than the applicable distance specified in §63.11117(b) from the bottom of the tank. Bottom filling of gasoline storage tanks is included in this definition.*

Vapor balance system *means a combination of pipes and hoses that create a closed system between the vapor spaces of an unloading gasoline cargo tank and a receiving storage tank such that vapors displaced from the storage tank are transferred to the gasoline cargo tank being unloaded.*

Vapor-tight *means equipment that allows no loss of vapors. Compliance with vapor-tight requirements can be determined by checking to ensure that the concentration at a potential leak source is not equal to or greater than 100 percent of the Lower Explosive Limit when measured with a combustible gas detector, calibrated with propane, at a distance of 1 inch from the source.*

Vapor-tight gasoline cargo tank *means a gasoline cargo tank which has demonstrated within the 12 preceding months that it meets the annual certification test requirements in §63.11092(f) of this part.*

Because the permittee will own or operate a gasoline dispensing facility (GDF) at an area source of HAP, requirements in Subpart CCCCCC are applicable. Because the permittee has committed to loading and dispensing of less than 100,000 gallons of gasoline per month (gal/mo), the requirements of 40 CFR 63.11117 will become applicable in accordance with 40 CFR 63.11111(b) and (c). Gasoline loading and dispensing is limited by Permit Condition 2.18 to avoid requirements applicable to GDF exceeding 100,000 gal/mo, and requires recordkeeping in accordance with 40 CFR 63.11111(e).

40 CFR 63, Subpart CCCCCC is incorporated by reference into Permit Condition 2.22, and specific applicable requirements will be incorporated into the Tier I operating permit.

40 CFR 63, Subpart EEEEEEE..... National Emission Standards for Hazardous Air Pollutants: Gold Mine Ore Processing and Production Area Source Category

§40 CFR 63.11640..... Am I subject to this subpart?

(a) You are subject to this subpart if you own or operate a gold mine ore processing and production facility as defined in §63.11651, that is an area source.

(b) This subpart applies to each new or existing affected source. The affected sources are each collection of "ore pretreatment processes" at a gold mine ore processing and production facility, each collection of "carbon processes with mercury retorts" at a gold mine ore processing and production facility, each collection of "carbon processes without mercury retorts" at a gold mine ore processing and production facility, and each collection of "non-carbon concentrate processes" at a gold mine ore processing and production facility, as defined in §63.11651.

(1) An affected source is existing if you commenced construction or reconstruction of the affected source on or before April 28, 2010.

(2) An affected source is new if you commenced construction or reconstruction of the affected source after April 28, 2010.

(c) This subpart does not apply to research and development facilities, as defined in section 112(c)(7) of the Clean Air Act (CAA).

(d) If you own or operate a source subject to this subpart, you must have or you must obtain a permit under 40 CFR part 70 or 40 CFR part 71.

§40 CFR 63.11651..... What definitions apply to this subpart?

Terms used in this subpart are defined in the Clean Air Act, in §63.2, and in this section as follows:

Autoclave *means a pressure oxidation vessel that is used to treat gold ores (primarily sulfide refractory ore) and involves pumping a slurry of milled ore into the vessel which is highly pressurized with oxygen and heated to temperatures of approximately 350° to 430 °F.*

Calomel-based mercury control system *means a mercury emissions control system that uses scrubbers to remove mercury from the gas stream of a roaster or combination of roasters by complexing the mercury from the gas stream with mercuric chloride to form mercurous chloride (calomel). These scrubbers are also referred to as "mercury scrubbers."*

Carbon adsorber *means a control device consisting of a single fixed carbon bed, multiple carbon beds or columns, carbon filter packs or modules, and other variations that uses activated carbon to remove pollutants from a gas stream.*

Carbon kiln *means a kiln or furnace where carbon is regenerated by heating, usually in the presence of steam, after the gold has been stripped from the carbon.*

Carbon processes with mercury retorts *means the affected source that includes carbon kilns, preg tanks, electrowinning cells, mercury retorts, and melt furnaces at gold mine ore processing and production facilities that use activated carbon, or resins that can be used as a substitute for activated carbon, to recover (adsorb) gold from the pregnant cyanide solution.*

Carbon processes without mercury retorts *means the affected source that includes carbon kilns, preg tanks, electrowinning cells, and melt furnaces, but has no retorts, at gold mine ore processing and production facilities that use activated carbon, or resins that can be used as a substitute for activated carbon, to recover (adsorb) gold from the pregnant cyanide solution.*

Concentrate *means the sludge-like material that is loaded with gold along with various other metals (such as silver, copper, and mercury) and various other substances, that is produced by electrowinning, the Merrill-Crowe process, flotation and gravity separation processes. Concentrate is measured as the input to mercury retorts, or for facilities without mercury retorts, as the input to melt furnaces before any drying takes place. For facilities without mercury retorts or melt furnaces, concentrate is measured as the quantity shipped.*

Deviation *means any instance where an affected source subject to this subpart, or an owner or operator of such a source:*

(1) Fails to meet any requirement or obligation established by this subpart, including but not limited to any emissions limitation or work practice standard;

(2) Fails to meet any term or condition that is adopted to implement an applicable requirement in this subpart and that is included in the operating permit for any affected source required to obtain such a permit; or

(3) Exceeds any operating limit established under this subpart.

Electrowinning *means a process that uses induced voltage on anode and cathode plates to remove metals from the continuous flow of solution, where the gold in solution is plated onto the cathode. Steel wool is typically used as the plating surface.*

Electrowinning Cells *means a tank in which the electrowinning takes place.*

Gold mine ore processing and production facility *means any industrial facility engaged in the processing of gold mine ore that uses any of the following processes: Roasting operations, autoclaves, carbon kilns, preg tanks, electrowinning, mercury retorts, or melt furnaces. Laboratories (see CAA section 112(c)(7)), individual prospectors, and very small pilot scale mining operations that processes or produces less than 100 pounds of concentrate per year are not a gold mine ore processing and production facility. A facility that produces primarily metals other than gold, such as copper, lead, zinc, or nickel (where these metals other than gold comprise 95 percent or more of the total metal production) that may also recover some gold as a byproduct is not a gold mine ore processing and production facility. Those facilities whereby 95 percent or more of total mass of metals produced are metals other than gold, whether final metal production is onsite or offsite, are not part of the gold mine ore processing and production source category.*

Melt furnace *means a furnace (typically a crucible furnace) that is used for smelting the gold-bearing material recovered from mercury retorting, or the gold-bearing material from electrowinning, the Merrill-Crowe process, or other processes for facilities without mercury retorts.*

Mercury retort *means a vessel that is operated under a partial vacuum at approximately 1,100° to 1,300 °F to remove mercury and moisture from the gold bearing sludge material that is recovered from electrowinning, the Merrill-Crowe process, or other processes. Mercury retorts are usually equipped with condensers that recover liquid mercury during the processing.*

Merrill-Crowe process *means a precipitation technique using zinc oxide for removing gold from a cyanide solution. Zinc dust is added to the solution, and gold is precipitated to produce a concentrate.*

Non-carbon concentrate processes *means the affected source that includes mercury retorts and melt furnaces at gold mine ore processing and production facilities that use the Merrill-Crowe process or other processes and do not use carbon (or resins that substitute for carbon) to recover (adsorb) gold from the pregnant cyanide solution.*

Ore dry grinding *means a process in which the gold ore is ground and heated (dried) prior to additional preheating or prior to entering the roaster.*

Ore preheating *means a process in which ground gold ore is preheated prior to entering the roaster.*

Ore pretreatment processes *means the affected source that includes roasting operations and autoclaves that are used to pre-treat gold mine ore at gold mine ore processing and production facilities prior to the cyanide leaching process.*

Pregnant solution tank (or preg tank) *means a storage tank for pregnant solution, which is the cyanide solution that contains gold-cyanide complexes that is generated from leaching gold ore with cyanide solution.*

Pregnant cyanide solution *means the cyanide solution that contains gold-cyanide complexes that are generated from leaching gold ore with a dilute cyanide solution.*

Quenching *means a process in which the hot calcined ore is cooled and quenched with water after it leaves the roaster.*

Roasting operation *means a process that uses an industrial furnace in which milled ore is combusted across a fluidized bed to oxidize and remove organic carbon and sulfide mineral grains in refractory gold ore. The emissions points of the roasting operation subject to this subpart include ore dry grinding, ore preheating, the roaster stack, and quenching.*

Because the permittee will own or operate a gold mine ore processing and production facility at an area source of HAP, requirements in Subpart EEEEEEE are applicable. The collection of ore pretreatment processes and the carbon process with mercury retort are affected sources. Ore pretreatment processes include the autoclave (AC). Carbon processes with mercury retort include the electrowinning cells and pregnant solution tank (EW), the mercury retort (MR), induction melting furnace (MF), and the carbon regeneration kiln (CKD).

Any source subject to 40 CFR 63, Subpart EEEEEEE is a Tier I source as defined in IDAPA 58.01.01.006.122.c. In accordance with IDAPA 58.01.01.313.01.b., the permittee must submit a complete application to DEQ for an initial Tier I operating permit within 12 months of becoming a Tier I source.

This subpart includes mercury emissions limits for the collection of new ore pretreatment processes and for the new carbon processes with mercury retort. This subpart also requires weight measurement devices for measuring ore throughput for the autoclave (AC) and mineral-bearing solution throughput for the electrowinning cells and pregnant solution tank (EW). Requires monitoring of mercury emissions, and monitoring of either inlet gas temperature for each process unit with a carbon filter (EW, MR, MF, CKD) or both water flow and pressure drop for each process unit with a wet scrubber not followed by a carbon filter (AC).

40 CFR 63, Subpart EEEEEEE is incorporated by reference into Permit Condition 2.22, and specific applicable requirements will be incorporated into the Tier I operating permit.

Permit Conditions Review

This section describes the permit conditions for this initial permit.

Permit Conditions 1.1–1.2 describe the purpose of this permitting action and the emission sources and the control equipment regulated by this permit. This reflects information presented in the application and relied upon in the development of emissions inventories, and in the evaluation of ambient air impacts in the modeling analyses. Refer to the Emissions Inventories and the Ambient Air Quality Impact Analyses sections for additional information concerning these analyses.

Because specific vendor and manufacturer information was unavailable at the time of permitting, documentation and testing requirements were included (Permit Condition 2.20) to verify consistency with the information specified in the application. Production values and limits were based on process flow diagrams and engineering design information provided.

Permit Conditions 2.1–2.8 incorporate fugitive dust emission limits and control requirements as required by IDAPA 58.01.01.650-651. Compliance is ensured by implementing reasonable control precautions and corrective actions when appropriate, excluding public access to operations, and complying with inspection, monitoring, recordkeeping, and notification requirements. Specific precautions are identified and required in the fugitive dust control plan (FDCP), and specific measures to control public access within the operations boundary are identified in and required by the Access Management Plan (AMP; Permit Conditions 2.6 and 2.7, respectively). A trigger level for haul roads was also established requiring employment of control measures (Permit Condition 2.5).

Reduction of PM emissions from each of the identified conveyors by 80% was supported by assuming location of these material transfers at below grade (OC9, OC10) or enclosure on all sides (OC11). Reduction of PM emissions from haul roads by a combined 93.3% was supported by assuming appropriate application of water and magnesium chloride dust suppression; DEQ is cognizant that to consistently achieve this level of control requires conscientious efforts, vigilant inspection and monitoring, and a comprehensive FDCP. Because continuous operation was proposed, suppression measures will need to account for and accommodate all weather conditions including diurnal and seasonal variability, and all traffic loads including mining and public traffic along publicly accessible roads. Conditions outside of what may normally be anticipated may require additional measures such as a reduction in vehicle speeds or selection of a more effective chemical dust suppressant. Although the FDCP specifies a minimum of efforts required, additional operational limits and monitoring are to be considered moving forward and evaluated for incorporation into the FDCP. Certification of employees for visible emissions inspection, training and orientation of relevant employees, and periodic evaluation of FDCP requirements are also required.

Access control measures are described in the Ambient Air Boundary section of the application (Section 5.6), and address primary access points, secondary access points, and surveillance.

Permit Conditions 2.9–2.12 incorporate visible emission limits and control requirements (Permit Condition 2.9) in accordance with IDAPA 58.01.01.625. Compliance is ensured by implementing corrective actions when appropriate and complying with inspection, monitoring, and recordkeeping requirements. Certification of employees for visible emissions inspection is also required.

Permit Condition 2.13 incorporates PM emission limits for process equipment as defined in IDAPA 58.01.01.006, in accordance with IDAPA 58.01.01.700-703, which includes all ore processing, ore concentration and refining, lime production, aggregate production, and concrete production equipment (Table 1). Compliance with operational and material throughput limits (Permit Conditions 3.3–3.8, 4.5–4.12, and 5.4–5.8) and control equipment requirements (Permit Conditions 2.6, 3.9–3.11, 4.13–4.17, and 5.9–5.15) and associated monitoring were considered adequate to ensure compliance with process weight-based PM emission limitations.

Permit Conditions 2.14–2.15 incorporate odorous emission limits in accordance with IDAPA 58.01.01.776.01. Compliance is ensured by complying with monitoring and recordkeeping requirements, including corrective action when appropriate.

Permit Conditions 2.16–2.17 incorporate sulfur content limits for distillate fuel oil, in accordance with IDAPA 58.01.01.725. Compliance is ensured by complying with monitoring and recordkeeping requirements.

Permit Conditions 2.18–2.19 limit facility-wide gasoline fuel throughput. Limiting gasoline throughput limits PTE, ensures avoidance of Subpart CCCCCC requirements applicable to GDF exceeding 100,000 gal/mo, and requires recordkeeping in accordance with 40 CFR 63.11111(e). Compliance is ensured by complying with monitoring and recordkeeping requirements.

Permit Conditions 2.20–2.21 require developing and complying with the requirements of an O&M manual to ensure compliance with control equipment maintenance and operation general provisions (Permit Condition 7.2). Documentation of as-built process equipment specifications and control equipment performance guarantees and establishing control equipment operating parameters and procedures were required, since these were relied upon in the development of emissions inventories, and in the evaluation of ambient air impacts in the modeling analyses. Compliance is ensured by complying with monitoring and recordkeeping requirements.

Permit Condition 2.22 incorporates applicable general compliance, notification, recordkeeping, reporting, general provisions, and other federal requirements by reference in accordance with IDAPA 58.01.01.107.03 and 590-591. Compliance is ensured by complying with applicable federal testing, monitoring, recordkeeping, and reporting requirements. In the event there is a conflict between the subparts and/or emission sources listed (Permit Condition 2.22), the federal requirements shall apply.

With regard to permit conditions referenced in accordance with federal requirements (i.e., NSPS and NESHAP requirements), should there be a conflict between the language of the permit condition and the language of the requirement, the language of the requirement shall govern. Refer to NSPS Applicability (40 CFR 60) and MACT/GACT Applicability (40 CFR 63) sections for additional information concerning applicable requirements.

Permit Conditions 2.23–2.24 require notification upon becoming a Tier I source and require the permittee to obtain a Tier I operation permit within 12 months of commencement of operation of any ore concentration and refining equipment (i.e., NESHAP Subpart EEEEEEE-affected sources) in accordance with IDAPA 58.01.01.313.01.b.

Permit Condition 2.25 specifies recommended test methods to be used when performance testing is required, unless otherwise specified in the permit, in accordance with IDAPA 58.01.01.157. The permittee is required to comply with notification and reporting requirements and is encouraged to submit performance test protocol to DEQ for approval prior to any performance testing in accordance with the performance testing general provisions (Permit Condition 7.7–7.9).

Permit Condition 2.26 provides DEQ agency contact information.

Permit Conditions 3.1–3.2 describe mining and ore processing equipment and controls. This reflects information presented in the application and relied upon in the development of emissions inventories, and in the evaluation of ambient air impacts in the modeling analyses.

Permit Conditions 3.3–3.8 and 3.11–3.16 establish limits on material throughput and production. These limits were relied upon in the development of emissions inventories and in the evaluation of ambient air impacts in the modeling analyses. Overall mine throughput is limited by hauling and excavating limits (Permit Condition 3.5). Compliance is ensured by complying with monitoring and recordkeeping requirements (Permit Conditions 3.11–3.16).

Permit Conditions 3.9–3.10 require measures to include in the FDCP to control fugitive emissions. Use of reasonable controls were relied upon in the development of emissions inventories and in the evaluation of ambient air impacts in the modeling analyses. Compliance is ensured by complying with fugitive dust monitoring and recordkeeping requirements (Permit Conditions 2.1–2.8).

Permit Conditions 4.1–4.2 describe ore concentration and refining equipment and controls. This reflects information presented in the application and relied upon in the development of emissions inventories, and in the evaluation of ambient air impacts in the modeling analyses.

Permit Condition 4.3, and 4.33–4.34 establish emissions limits for ore concentration and refining equipment, consistent with estimates relied upon in the development of emissions inventories and in the evaluation of ambient air impacts in the modeling analyses for these sources. A sulfuric acid emission limit consistent with the modeled TAP emission rate from the autoclave was established in accordance with IDAPA 58.01.01.210.08. Compliance is ensured by complying with equipment operating and testing requirements (Permit Conditions 4.5–4.17, and 4.33–4.34).

Permit Conditions 4.4, 4.5–4.6, 4.7–4.12 and 4.18–4.25 limit operations of ore concentration and refining process equipment, consistent with the hours of operation, reagent usage, and material throughput assumptions relied upon in the development of emissions inventories and in the evaluation of ambient air impacts in the modeling analyses for these sources. Compliance is ensured by complying with monitoring and recordkeeping requirements (Permit Conditions 4.18–4.25). Cyanide is consumed, recycled, and destroyed in the process, and cyanide HAP emissions (and emission factors) dependent upon leachant concentration and basicity. Monitoring of these parameters was established to ensure that emissions do not exceed 10 T/yr of cyanide HAP to avoid classification as a HAP major source. Re-classification as a major source would affect NSPS and NESHAP applicability determinations, such as Subpart AAAAA as discussed in the NESHAP Applicability (40 CFR 61) section.

Permit Conditions 4.13–4.17 and 4.26–4.32 require control equipment for ore concentration and refining processes, consistent with controls relied upon in the development of emissions inventories and in the evaluation of ambient air impacts in the modeling analyses. Compliance is ensured by complying with monitoring and recordkeeping requirements (Permit Conditions 4.26–4.32).

Permit Condition 4.33 and 4.34 require testing of ore concentration and refining emission sources to demonstrate compliance with emissions limits (Permit Condition 4.3).

Permit Conditions 5.1–5.2 describe lime, aggregate, and concrete production equipment and controls. This reflects information presented in the application and relied upon in the development of emissions inventories, and in the evaluation of ambient air impacts in the modeling analyses.

Permit Condition 5.3 establishes emissions limits for lime, aggregate, and concrete production equipment, consistent with estimates relied upon in the development of emissions inventories and in the evaluation of ambient air impacts in the modeling analyses for these sources. Compliance is ensured by complying with equipment operating requirements (Permit Conditions 5.4–5.15).

Permit Conditions 5.4–5.8 and 5.16–5.20 limit operations of each lime, aggregate, and concrete production process equipment, consistent with material throughput assumptions relied upon in the development of emissions inventories and in the evaluation of ambient air impacts in the modeling analyses for these sources. Compliance is ensured by complying with monitoring and recordkeeping requirements (Permit Conditions 5.15–5.20).

Permit Conditions 5.9–5.10 require measures to include in the FDCP to control fugitive emissions. Use of water sprays, building enclosures, and reasonable controls were relied upon in the development of emissions inventories and in the evaluation of ambient air impacts in the modeling analyses. Compliance is ensured by complying with fugitive dust monitoring and recordkeeping requirements (Permit Conditions 2.1–2.8).

Permit Conditions 5.11–5.15 and 5.21–5.24 require control equipment for lime, aggregate, and concrete production processes, consistent with controls relied upon in the development of emissions inventories and in the evaluation of ambient air impacts in the modeling analyses. Compliance is ensured by complying with monitoring and recordkeeping requirements (Permit Conditions 5.21–5.24).

Permit Condition 6.1 describes the emergency power generation equipment. This reflects information presented in the application and relied upon in the development of emissions inventories, and in the evaluation of ambient air impacts in the modeling analyses.

Permit Conditions 6.2 and 6.3–6.4 limit operations of each emergency power generation engine, consistent with the purpose and hours of operation assumptions relied upon in the development of emissions inventories, in the determination of federal regulatory applicability, and in the evaluation of ambient air impacts in the modeling analyses for these sources. Compliance is ensured by complying with monitoring, recordkeeping, and notification requirements (Permit Conditions 6.3–6.4).

Permit Condition 7.1, the duty to comply general compliance provision, requires that the permittee comply with all of the permit terms and conditions pursuant to Idaho Code §39-101.

Permit Condition 7.2, the maintenance and operation general compliance provision, requires that the permittee maintain and operate all treatment and control facilities at the facility in accordance with IDAPA 58.01.01.211.

Permit Condition 7.3, the obligation to comply general compliance provision, specifies that no permit condition is intended to relieve or exempt the permittee from compliance with applicable state and federal requirements, in accordance with IDAPA 58.01.01.212.01.

Permit Condition 7.4, the inspection and entry provision, requires that the permittee allow DEQ inspection and entry pursuant to Idaho Code §39-108.

Permit Condition 7.5, the permit expiration construction and operation provision, specifies that the permit expires if construction has not begun within two years of permit issuance or if construction has been suspended for a year in accordance with IDAPA 58.01.01.211.02.

Permit Condition 7.6, the notification of construction and operation provision, requires that the permittee notify DEQ of the dates of construction and operation, in accordance with IDAPA 58.01.01.211.01 and 211.03.

Permit Condition 7.7, the performance testing notification of intent provision, requires that the permittee notify DEQ at least 15 days prior to any performance test to provide DEQ the option to have an observer present, in accordance with IDAPA 58.01.01.157.03.

Permit Condition 7.8, the performance test protocol provision, requires that any performance testing be conducted in accordance with the procedures of IDAPA 58.01.01.157 and encourages the permittee to submit a protocol to DEQ for approval prior to testing.

Permit Condition 7.9, the performance test report provision, requires that the permittee report any performance test results to DEQ within 60 days of completion, in accordance with IDAPA 58.01.01.157.04-05.

Permit Condition 7.10, the monitoring and recordkeeping provision, requires that the permittee maintain sufficient records to ensure compliance with permit conditions, in accordance with IDAPA 58.01.01.211.

Permit Condition 7.11, the excess emissions provision, requires that the permittee follow the procedures required for excess emissions events, in accordance with IDAPA 58.01.01.130-136.

Permit Condition 7.12, the certification provision, requires that a responsible official certify all documents submitted to DEQ, in accordance with IDAPA 58.01.01.123.

Permit Condition 7.13, the false statement provision, requires that no person make false statements, representations, or certifications, in accordance with IDAPA 58.01.01.125.

Permit Condition 7.14, the tampering provision, requires that no person render inaccurate any required monitoring device or method, in accordance with IDAPA 58.01.01.126.

Permit Condition 7.15, the transferability provision, specifies that this permit to construct is transferable, in accordance with the procedures of IDAPA 58.01.01.209.06.

Permit Condition 7.16, the severability provision, specifies that permit conditions are severable, in accordance with IDAPA 58.01.01.211.

PUBLIC REVIEW

Public Comment Opportunity

An opportunity for public comment period on the application was provided in accordance with IDAPA 58.01.01.209.01.c. During this time, there was a request for a public comment period on DEQ's proposed action. Refer to the Application Chronology for public comment opportunity dates.

Public Comment Period

Comment periods were made available to the public in accordance with IDAPA 58.01.01.209.01.c. An initial comment period and extension were provided to address the initial application and proposed action (i.e., permit and technical statement of basis), and a final comment period was provided to address updates to the proposed action resulting from a HAP/TAP application addendum[2] submitted by Midas Gold that included new HAP and TAP emission estimates, additional information and discussion supporting HAP and TAP emission estimates, new and updated TAP increment compliance demonstrations which included particulate TAP emissions from fugitive sources, and a source-by-source inventory of HAP and TAP emissions. During this time, comments were submitted in response to DEQ's proposed action. Refer to the Application Chronology for the dates of each public comment period.

A response to public comments document has been crafted by DEQ based on comments submitted during each public comment period. That document is part of the final permit package for this permitting action.

APPENDIX B – AMBIENT AIR QUALITY IMPACT ANALYSES REVIEW MEMORANDUM

MEMORANDUM

DATE: February 8, 2021

TO: Morrie Lewis, Permit Writer, Air Program

FROM: Pao Baylon, Modeling Review Analyst, Air Program
Through Kevin Schilling, Modeling Supervisor, Air Program

PROJECT: P-2019.0047 PROJ 62288, Permit for an Open-pit Gold Mine and On-site Ore Preparation and Gold Extraction Operation located in Valley County, Idaho.

SUBJECT: Demonstration of Compliance with IDAPA 58.01.01.203.02 (NAAQS) and 203.03 (TAPs) as it relates to air quality impact analyses.

Contents

YPP	Yellow Pine Pit
z_o	Surface Roughness Length
°F	Degrees Fahrenheit
$\mu g/m^3$	Micrograms per cubic meter of air
µm	Microns

1.0 Summary

Midas Gold Idaho, Inc. (Midas Gold) submitted a Permit to Construct (PTC) application to construct and operate the Stibnite Gold Project (SGP) in Valley County, Idaho. The SGP will consist of conventional open-pit mining operations and onsite ore preparation and gold extraction processes. The potential air emissions from the SGP are less than the applicable major source thresholds for both criteria and hazardous air pollutants (HAP), and therefore, the facility is designated as a minor source for Title V and New Source Review (NSR) requirements, and an area source for National Emission Standards for Hazardous Air Pollutants (NESHAP) applicability. Project-specific air quality analyses involving atmospheric dispersion modeling of estimated emissions associated with the facility were submitted to DEQ to demonstrate that applicable emissions do not result in violation of a National Ambient Air Quality Standard (NAAQS) or Toxic Air Pollutant (TAP) increment as required by the Idaho Administrative Procedures Act 58.01.01.203.02 and 203.03 (Idaho Air Rules Section 203.02 and 203.03). This memorandum provides a summary of the applicability assessment for analyses and air impact analyses used to demonstrate compliance with applicable NAAQS and TAP increments, as required by Idaho Air Rules Section 203.02 and 203.03.

Air Sciences, Inc. (Air Sciences), on behalf of Midas Gold, prepared the PTC application and performed ambient air impact analyses for this project. DEQ review of submitted data and DEQ analyses summarized by this memorandum addressed only the rules, policies, methods, and data pertaining to the air impact analyses used to demonstrate that estimated emissions associated with operation of the facility will not cause or significantly contribute to a violation of any applicable air quality standard. This review did not address/evaluate compliance with other rules or analyses not pertaining to the air impact analyses. Evaluation of emission estimates was the responsibility of the DEQ permit writer and is addressed in the main body of the DEQ Statement of Basis, and emission calculation methods were not evaluated in this modeling review memorandum.

Table 1 presents key assumptions and results to be considered in the development of the permit. Idaho Air Rules require air impact analyses be conducted in accordance with methods outlined in 40 Code of Federal Regulations (CFR) 51, Appendix W *Guideline on Air Quality Models* (Appendix W). Appendix W requires that air quality impacts be assessed using atmospheric dispersion models with emissions and operations representative of design capacity or as limited by a federally enforceable permit condition.

The submitted information and analyses: 1) utilized appropriate methods and models; 2) was conducted using reasonably accurate or conservative model parameters and input data (review of emission estimates was addressed by the DEQ permit writer); 3) adhered to established DEQ guidelines for new source review dispersion modeling; 4) showed either a) that estimated potential/allowable emissions are at a level defined as below regulatory concern (BRC) and do not require a NAAQS compliance demonstration; b) that predicted pollutant concentrations from emissions associated with the project as modeled were below Significant Impact Levels (SILs) or other applicable regulatory thresholds; or c) that predicted pollutant concentrations from emissions associated with the project, when appropriately combined with co-contributing sources and background concentrations, were below applicable NAAQS at ambient air locations where and when the project has a significant impact; 5) showed that TAP emission increases associated with the project will not result in increased ambient air impacts exceeding allowable TAP increments. This conclusion assumes that conditions in Table 1 are representative of facility design capacity or operations as limited by a federally enforceable permit condition. The DEQ permit writer should use Table 1 and other information presented in this memorandum to generate appropriate permit provisions/restrictions to assure emissions do not exceed applicable regulatory thresholds requiring further analyses and to assure the requirements of Appendix W are met regarding emissions representative of design capacity or permit allowable rates.

Table 1. KEY ASSUMPTIONS USED IN MODELING ANALYSES.	
Criteria/Assumption/Result	**Explanation/Consideration**
General Emission Rates. Emission rates used in the air impact analyses must represent maximum potential emissions as given by design capacity, inherently limited by the nature of the process or configuration of the facility, or as limited by the issued permit for the specific pollutant and averaging period.	Compliance has not been demonstrated for emission rates greater than those used in the air impact analyses.
Air Impact Analyses for Criteria Pollutant Emissions. Stibnite Gold Project (SGP) facility-wide maximum potential to emit are greater than the respective Level I thresholds for all criteria pollutants and averaging periods except for Lead. Therefore, modeling is triggered for applicable averaging periods for $PM_{2.5}$[a], PM_{10}[b], CO[c], NOx[d], and SO_2[e]. Modeling was not required for Lead.	Project-specific air impact analyses demonstrating compliance with NAAQS, as required by Idaho Air Rules Section 203.02, are required for pollutant increases above Below Regulatory Concern (BRC) thresholds, or for pollutants having an emissions increase that is greater than Level I modeling applicability thresholds (where the BRC exclusion cannot be used).
Air Impact Analyses for TAP Emissions. SGP facility-wide potential Toxic Air Pollutant (TAP) emissions exceed the respective screening emission levels (ELs) for arsenic, cadmium, formaldehyde, nickel, aluminum, barium, calcium carbonate, calcium oxide, iron, sulfuric acid, thallium, and vanadium. Therefore, air dispersion modeling was required for these 12 TAPs. TAPs also classified as Hazardous Air Pollutants (HAPs) emitted from sources addressed by New Source Performance Standards (NSPS) or National Emission Standards for Hazardous Air Pollutants (NESHAP) were not required to be evaluated for compliance with TAP increments in accordance with IDAPA 58.01.01.210.20.	A TAP increment compliance demonstration would be required for any TAPs with emissions above ELs. IDAPA 58.01.01.210.20 states that if TAP emissions from a specific source are addressed by NSPS or NESHAP, then a TAP impact analysis is not required for that TAP from that specific source.
Significant Impact Level Analysis Not Conducted. A Significant Impact Level (SIL) analysis was not conducted for the SGP facility.	Based on the magnitude of the facility-wide emissions and preliminary modeling analyses, it was determined that the impacts from the SGP emissions exceeded the SIL for most criteria pollutants. Therefore, SIL analyses were considered redundant and not performed for the project.
Multiple Modeling Scenarios. To evaluate the worst-case air impacts from the SGP facility, a total of 14 scenarios were modeled. These scenarios represent the hauling of material, which can be either ore or development rock (DR), from four possible origins (three pits and a tailings facility) to five possible destinations (ore will be hauled to the crushing area while DR will be hauled to one of four development rock storage facilities [DRSF]). Modeled design values listed in this modeling memo represent the worst-case modeling scenario for every modeled pollutant and averaging period.	Conventional open-pit methods will be used to extract ore and DR from four possible origins (Yellow Pine Pit [YPP], Hangar Flats Pit [HFP], West End Pit [WEP], and Bradley Tailings [BT]). Ore and DR will be hauled to five possible destinations (Stockpile [STKP], Yellow Pine DRSF [YPDRSF], Hangar Flats DRSF [HFDRSF], West End DRSF [WEDRSF], and Fiddle DRSF [FDRSF]). Only 14 of the 20 possible scenarios were modeled. Six scenarios were not feasible because the timing of the activity within the sequence of mine operations makes the scenarios logistically impossible. Modeled results listed in this memo represent worst-case modeling scenarios.
Modeling of Material Origin and Destination. Each material origin location (YPP, HFP, WEP, and BT) was modeled as an AREA source. Ore destination (STKP) was modeled as a VOLUME source. Each DR destination (YPDRSF, HFDRSF, WEDRSF, and FDRSF) was modeled as a VOLUME source.	Each material origin location comprised appropriate emissions from drilling, material loading, dozing, and surface exploration. Ore destination comprised ore unloading emissions. Each DR destination comprised appropriate emissions from DR unloading, dozing, and wind erosion. For the four AREA and five VOLUME sources, the dimensions were developed by reasonably fitting an equal-area rectangle within the actual footprint of each fugitive source. For the pit and DRSF fugitive activity locations, the release height was based on the haul truck height. The applicable initial lateral dispersion for each VOLUME source was calculated from the respective shorter dimension and EPA-specified methods. The applicable initial vertical dispersion for each AREA and VOLUME source was

Table 1. KEY ASSUMPTIONS USED IN MODELING ANALYSES.	
Criteria/Assumption/Result	**Explanation/Consideration**
	calculated from the respective vertical dimension and EPA-specified methods.
Modeling of Haul Roads. A representative haul road network for hauling material from inside the pit to various destinations was developed for each of the 14 modeling scenarios.	The haul road network was divided into 22 sections. Each section was further divided into multiple segments with a length equal to twice the adjusted haul road width. Each of the segments was characterized as an individual VOLUME source in the model. Material hauling emissions associated with each origin-destination route were assigned to each segment along the route based on estimated total emissions along the route and traffic distribution along each section.
Modeling of Blasting Emissions. Blasting emissions were represented by a VOLUME source inside a pit (YPPBL, HFPBL, and WEPBL). Blasting is not expected to occur in BT but was modeled (BTBL) in order to streamline the permitting process.	The blasting physical parameters were developed from dimensions based on blast area used in the emission calculation. The blasting release height was the midpoint of the blasting height. The initial lateral and vertical dispersion dimensions for blasting were calculated per methods specified in the AERMOD User's Guide.
Modeling of Burntlog Route Access Road. The access road portion within the operations boundary was characterized by a series of LINE sources laid along the actual route.	Emissions associated with the portion of the Burntlog Route mine access road that is within project boundary (from the south gate to the process area) are included in the SGP analyses. These include dust emissions generated from travel of maintenance equipment, light-duty pickup trucks and buses used for employee, visitor, and contractor transportation, and heavy-duty trucks used for cargo (including fuel, consumables, machine parts, ore processing supplies, ore concentrate, etc.) and services (including food supplies, trash, recyclables, etc.) transportation. Release parameters for the LINE sources were based on an estimated average vehicle height. The access road emissions were evenly distributed along the road by dividing the total access road emissions by its total area.
Control of Fugitive Dust from Roadways. Fugitive particulate emissions from roadways were assumed to be controlled above 93%, which is an aggressive level of control.	The high level of emission control was needed to demonstrate compliance with NAAQS. Compliance is not demonstrated for emissions greater than those associated with above 93% control.
NOx Chemistry and NO_2/NOx In-Stack Ratios. Ozone Limiting Method (OLM), a Tier 3 NO_2 screening method, was used to estimate the 1-hour and annual NO_2 impacts. The following NO_2/NOx In-Stack Ratios (ISR) were used in the modeling analyses: Blasting: 0.036 Diesel engines: 0.11 Propane heaters: 0.10	The OLM method requires an input of NO_2/NOx ISRs for each modeled source. The NO_2/NOx ratio for blasting was based on blasting plume measurements provided in published literature. The NO_2/NOx ratio for stationary diesel combustion sources was based on heavy-duty diesel trucks in the California Air Pollution Control Officers Association (CAPCOA) Guidance Document. This NO_2/NOx ratio (11 percent) is conservatively higher than the diesel combustion NO_2/NOx ratio provided in the EPA ISR database: 6 percent average, 9.8 percent maximum. The CAPCOA document and the EPA ISR database do not provide an NO_2/NOx ratio for propane boilers. The CAPCOA-recommended NO_2/NOx ratio for natural gas boilers was selected for the propane boilers. The natural gas boilers NO_2/NOx ratio is considered appropriate for the propane boilers because both are gaseous fuels with relatively similar combustion characteristics and are expected to have similar NO_2/NOx ratios. DEQ performed a sensitivity analysis using Tier 2 (Ambient Ratio Method 2), a more conservative NO_2 screening method, and found that the facility is safely below the 1-hour and annual NO_2 NAAQS.

Table 1. KEY ASSUMPTIONS USED IN MODELING ANALYSES.	
Criteria/Assumption/Result	**Explanation/Consideration**
Alternate Meteorological Data Processed Using Cloud Cover. An alternative meteorological dataset was processed without using the Bulk Richardson (BULKRN) method. This alternate processing (NON-BULKRN) used upper air data from Boise airport, supplemented with the cloud-cover data collected at the National Weather Service station in McCall, Idaho.	Meteorological data processing with and without BULKRN are considered acceptable regulatory options by EPA. The NON-BULKRN meteorological data yielded lower modeled design values than the meteorological data processed using the BULKRN method.
Ambient Air Boundary. Midas Gold will legally control the SGP, an active industrial site where mining activities will occur, such as heavy equipment operation. Most areas of the mine will require strict safety protocols and controlled access. Midas Gold has established an operations boundary to identify the area where public access will be excluded. Public access inside the operations boundary will be restricted for the life of the mine by physical barriers at points of potential access, including the current Stibnite Road point of entry and proposed site access via the Burntlog Route, as well as natural features of the landscape that prevent access.	Ambient air is defined in Section 006 of the Idaho Air Rules as "that portion of the atmosphere, external to buildings, to which the general public has access." Receptors must be placed at any portion of the atmosphere that is considered ambient air.
Onsite Background $PM_{2.5}$ and PM_{10} Concentrations. The following background $PM_{2.5}$ and PM_{10} concentrations were measured at SGP in 2014 and used in the cumulative NAAQS impact analysis: Annual $PM_{2.5}$: 3.5 $\mu g/m^3$ (weighted average of quarterly means) 24-hour $PM_{2.5}$: 15.0 $\mu g/m^3$ (98^{th} percentile/8^{th} high) 24-hour PM_{10}: 37.0 $\mu g/m^3$ (highest 1^{st} high)	Midas Gold developed an onsite monitoring program to collect site-specific meteorological parameters and determine ambient particulate matter ($PM_{2.5}$ and PM_{10}) concentrations at its Stibnite monitoring station. $PM_{2.5}$ and PM_{10} background concentrations were based on calendar year 2014 instead of the complete dataset (November 2013 through June 2015). For 24-hour PM_{10}, the design value is the *second-highest* 24-hour average concentration in a given year. However, the background value that was used in the modeling analyses represents the *first-highest* 24-hour average concentration measured in 2014. Therefore, using a larger background concentration adds a layer of conservatism to the calculated total impact for 24-hour PM_{10}.
NW AIRQUEST Background CO, NO_2, and SO_2 Concentrations. The following background concentrations for CO, NO_2, and SO_2 were used in the cumulative NAAQS impact analysis: 1-hour CO: 1,740 $\mu g/m^3$ 8-hour CO: 1,110 $\mu g/m^3$ 1-hour NO_2: 4.3 $\mu g/m^3$ Annual NO_2: 0.9 $\mu g/m^3$ 1-hour SO_2: 12.3 $\mu g/m^3$ 3-hour SO_2: 16.8 $\mu g/m^3$	Gaseous pollutant background concentrations were determined using the Northwest International Air Quality Environmental Science and Technology Consortium (NW AIRQUEST) online tool. The NW AIRQUEST tool uses regional scale modeling of pollutants in Washington, Oregon, and Idaho, with model results adjusted according to available monitoring data.
Medium-Traffic Background Concentrations. To provide additional information regarding the relative contribution of traffic emissions, background concentrations were obtained from NW AIRQUEST for the road section between mile markers 143 and 144 on Highway 55 passing through the town of McCall.	The McCall location is approximately 38 miles west of the SGP. The annual average daily traffic count for this road section is over 10,000 vehicles per day. Although the background concentrations at McCall are not representative of the rural SGP area, they provide additional information regarding the relative contribution of traffic emissions.
Weight-of-Evidence Analyses for 24-hour PM_{10}. PM_{10} modeling with meteorological dataset processed using the site-specific BULKRN method shows up to five hotspot receptors for Scenario W5 (the highest PM_{10} modeling scenario) that exceed NAAQS. All modeled violations occur during winter when the average snow depth and average precipitation at the project site are 21-68 inches and 6.0 inches, respectively. Therefore, fugitive road dust emissions during high-modeled impact hours could be overestimated. PM_{10} modeling simulation was based on a mining production rate of 180,000 ton/day of development rock (65,700,000 ton/year, which is more conservative than the	Meteorological data processing with and without BULKRN are considered acceptable by EPA, with the BULKRN method utilizing more of the onsite collected meteorological parameters. However, the BULKRN-processed meteorological data yielded higher modeled design value impacts for the SGP facility than the meteorological data processed without the BULKRN method. DEQ's supplemental analyses suggest that when emissions are more-closely representative of typical daily mining production rates for a high-production period (everything else held constant), the SGP facility is able to demonstrate

REC 4202

TR 0887

Table 1. KEY ASSUMPTIONS USED IN MODELING ANALYSES.	
Criteria/Assumption/Result	**Explanation/Consideration**
expected peak production rate of 42,692,000 ton/year). To investigate the effect of a lower modeled mining production rate on design value concentrations, DEQ performed a modeling simulation where mining production rate was assumed to be 120,000 ton/day instead of 180,000 ton/day, but everything else was held constant. Maximum modeled concentration, when summed with the background concentration, is lower than the 24-hour PM_{10} NAAQS thereby demonstrating NAAQS compliance. DEQ's weight-of-evidence analyses conclude that, considering all the collective conservative layers of the modeling analyses, including the use of meteorological data processed by two different methods, there is a satisfactory level of confidence that operation of the project as described in the application will not cause or contribute to a violation of NAAQS.	compliance with 24-hour PM_{10} NAAQS at those few receptors showing a potential violation when using meteorological data processed with the BULKRN method.

Summary of Submittals and Actions

May 30, 2019	Modeling protocol was submitted to DEQ by Brown and Caldwell on behalf of the applicant.
June 27, 2019	Conditional modeling protocol approval was provided to Brown and Caldwell by DEQ.
August 21, 2019	Regulatory start date. PTC application and modeling report were prepared by Air Sciences on behalf of the applicant.
September 19, 2019	Application deemed incomplete by DEQ.
October 4, 2019	DEQ received a preliminary response and supplemental information from the applicant.
October 15, 2019	DEQ met with the applicant to review and discuss the preliminary response.
October 22, 2019	DEQ determined that the application remained incomplete while the applicant prepared a response to remaining items previously identified, and included a summary of recommendations provided at the meeting.
November 8, 2019	DEQ requested additional information from the applicant via e-mail, relating to items previously identified.
November 21, 2019	Applicant requested extension until November 27, 2019 to respond to incompleteness.
November 27, 2019	DEQ received supplemental information from the applicant, including a revised application with updated emission inventories and modeling analyses.

December 24, 2019	DEQ determined that the application was incomplete.
January 8, 2020	Applicant requested extension until February 7, 2020 to respond to incompleteness.
February 5, 2020	DEQ received supplemental information from the applicant, including a revised application with updated emission inventories and modeling analyses.
March 6, 2020	DEQ determined that the application was incomplete.
April 2, 2020	Applicant requested extension until April 15, 2020 to respond to incompleteness.
April 15, 2020	DEQ received supplemental information from the applicant, including updated modeling analyses.
May 15, 2020	DEQ determined that the application was complete.
June 24, 2020	DEQ received the final updated application.
July 14, 2020	DEQ made available the draft permit and statement of basis for applicant review.
July 31, 2020	DEQ made available an updated draft statement of basis for applicant review.
August 3 and 13, 2020	DEQ received comments from the applicant on the draft permit and statement of basis.
September 10 – October 12, 2020	DEQ provided a public comment period on the proposed action.
October 12, 2020	DEQ received a request to extend the public comment period.
October 13 – November 11, 2020	DEQ extended the public comment period.
November 20, 2020	DEQ requested additional information from the applicant to address substantive public comments received, including missing HAP and TAP emission estimates.
December 18, 2020	DEQ received supplemental information from the applicant, including a HAP/TAP addendum, updated HAP and TAP emission estimates, and updated TAP modeling analyses.
January 28, 2021	DEQ received updated modeling files with corrections for formaldehyde and sulfuric acid, and an updated figure showing TAP modeled impacts.

2.0 Background Information

This section provides background information applicable to the project and the site proposed for the facility. It also provides a brief description of the applicable air impact analyses requirements for the project.

REC 4204

TR 0889

2.1 Project Description

The SGP will require the construction of significant infrastructure, including a power transmission line, a primary mine site access road, onsite haul roads, an ore processing facility, onsite workspaces, employee housing and recreation, water storage and distribution facilities, and sewage disposal facilities.

The SGP will include three years of pre-mining development and construction activities, followed by an operating mine life of approximately 12 years. Mining will occur in three open pits: Yellow Pine Pit (YPP), Hangar Flats Pit (HFP), and West End Pit (WEP). The general sequence of mining will be the YPP deposit, followed by the HFP and WEP deposits. Legacy tailings from the Meadow Creek valley (Bradley Tailings [BT]) also will be reclaimed and reprocessed during the initial project schedule. Surface exploration drilling will continue within the pits and the Scout Prospect decline (underground exploration) throughout the mine operation period. Restoration and reclamation of other legacy mining features will occur prior to mining, throughout the life of the mine, and as part of the mine closure.

Conventional open-pit methods including drilling, blasting, excavating, and hauling will be used to extract ore and waste rock, termed development rock (DR). Hydraulic shovels and front-end loaders will be used to load ore and DR into haul trucks. DR will be used for construction, restoration, and backfilling, or hauled to the dedicated development rock storage facilities (DRSF). Approximately 340 million tons of DR will be handled over the life of the mine. Ore will be hauled to the primary crusher area, where it will be fed directly into the crusher dump pocket or stockpiled. The ore crushing plant will be designed to operate at a maximum rate of 25,000 tons per day (ton/day). Approximately 100 million tons of ore will be mined from the three pits over the life of the project.

The metal-recovery process from ore will include conventional crushing and grinding, followed by froth-flotation circuits that will generate separate gold-silver and antimony-silver concentrates. The antimony-silver concentrate will be shipped offsite for refining, whereas additional onsite processing of the gold-silver concentrate will include pressure oxidation, carbon-in-leach circuits, and refining processes to recover gold and minor amounts of silver. The finely ground leftover ore material from the mineral-recovery process, termed tailings, will be neutralized, thickened, and transported via a pipeline to the tailings storage facility (TSF).

Lime used in the ore processing will either be purchased or manufactured onsite from limestone available at the site. In addition, certain construction and maintenance activities during operations may require sized aggregate. To allow for the operational flexibility to produce construction aggregate onsite, the application included two portable crushing and screening plants.

The following air pollutants are expected from operations at the SGP facility:

- Criteria air pollutants: carbon monoxide (CO), oxides of nitrogen (NOx), particulate matter less than 2.5 microns (μm) and 10 μm ($PM_{2.5}$ and PM_{10}), sulfur dioxide (SO_2), lead (Pb), and ozone (O_3) precursor volatile organic compounds (VOC)
- Hazardous air pollutants (HAP), including mercury (Hg)
- Other non-HAP toxic air pollutants (TAP)
- Greenhouse gases

Based on the uncontrolled potential to emit (PTE) and controlled PTE, the SGP facility will be a "synthetic minor" source of PM, PM_{10}, $PM_{2.5}$, and HAP emissions for new source review (NSR) and Title V (Tier I) permitting purposes. The uncontrolled PTE for the remaining criteria pollutants (SO_2, NOx,

CO, VOC) confirm that the SGP facility will be a natural minor source for these emissions. Facility classification is reviewed by the permit writer. Detailed calculations and explanations are provided in the DEQ Statement of Basis.

The PTC addresses all air pollutant-emitting activities associated with the facility.

2.2 Facility Location and Area Classification

The SGP is located in the Stibnite-Yellow Pine Mining District in Valley County, central Idaho (Northing: 4,973,751 meters [m]; Easting: 632,038 m; UTM Zone 11), approximately 100 miles northeast of Boise, 38 miles east of McCall, and approximately 10 miles east of Yellow Pine. A facility location map for the SGP is presented in Figure 1. This figure also shows the proposed Burntlog Route (access road) that will provide a year-round safe access to the site. The SGP site layout is presented in Figure 2.

The Stibnite-Yellow Pine Mining District is characterized by historic mining activities and unpatented (federal land) and patented (private land) mining claims that include deposits of gold, silver, tungsten, and antimony. The district lies in both Boise National Forest (BNF) and Payette National Forest (PNF), but is administered by the PNF's Krassel Ranger District (Midas Gold 2017a). The project area terrain is characterized by narrow valleys 6,000 to 6,600 feet above mean sea level (amsl), surrounded by steep mountains ranging over 8,500 feet amsl. The main drainage basin in the project area is the East Fork of the South Fork of the Salmon River (EFSFSR).

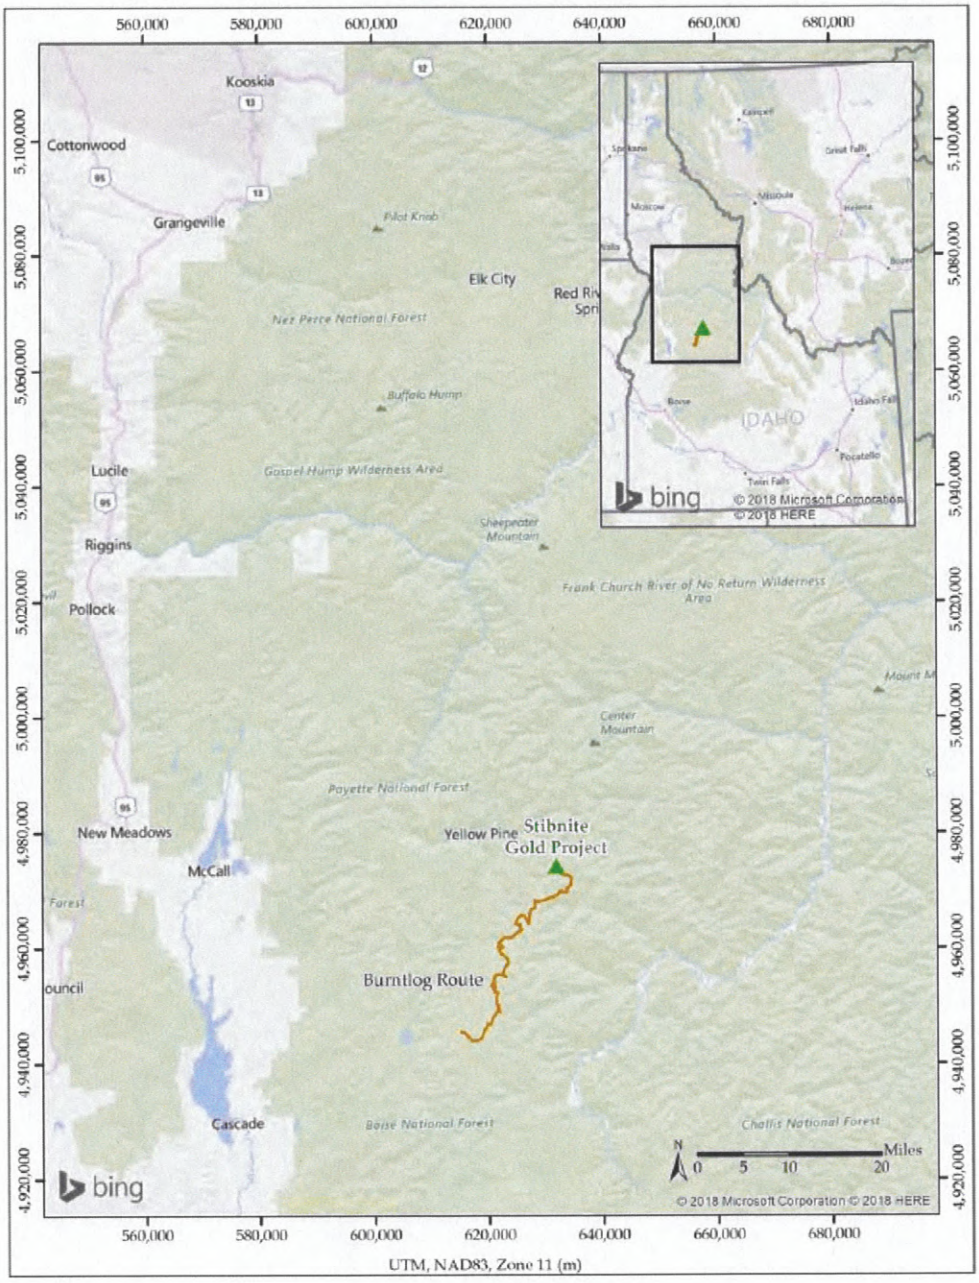
The EFSFSR joins Johnson Creek 16 miles downstream, near the village of Yellow Pine. The project area is encompassed by the watersheds of EFSFSR tributaries, including Sugar Creek, Meadow Creek, Johnson Creek, Riordan Creek, Burntlog Creek, Midnight Creek, and Trout Creek. Primary commercial activity in the area comprises mineral exploration, mining, logging, and dispersed recreation.

This area is designated as an attainment or unclassifiable area for SO_2, NO_2, CO, Lead, O_3, PM_{10}, and $PM_{2.5}$. The area is not classified as non-attainment for any criteria pollutants.

REC 4206

TR 0891

Figure 1. SGP FACILITY LOCATION MAP.



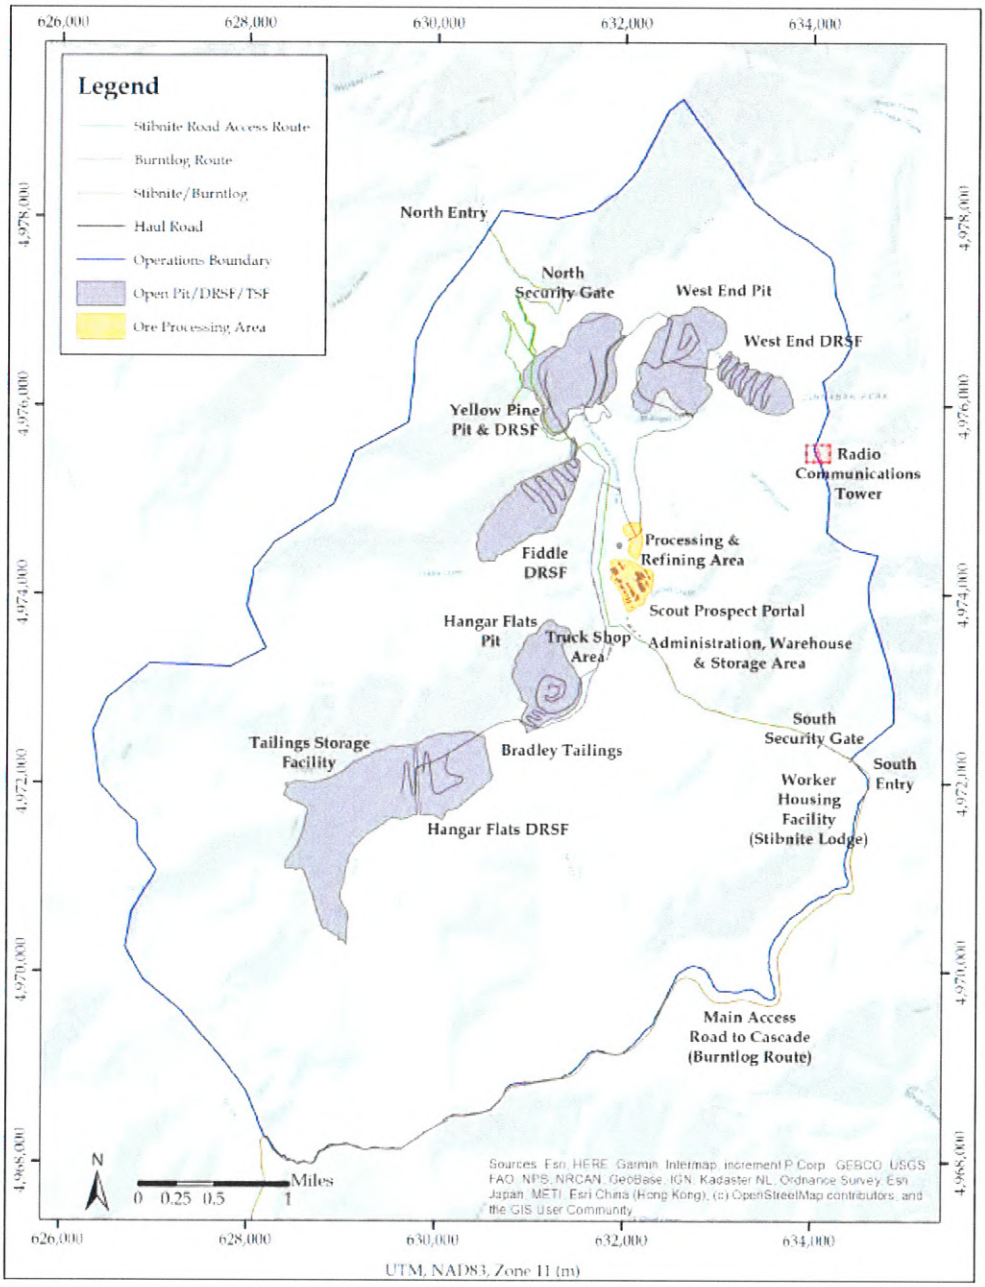


Figure 2. SGP SITE LAYOUT AND STIBNITE ROAD ACCESS ROUTE.

2.3 *Air Impact Analyses Required for All Permits to Construct*

Idaho Air Rules Sections 203.02 and 203.03:

> *No permit to construct shall be granted for a new or modified stationary source unless the applicant shows to the satisfaction of the Department all of the following:*

***02. NAAQS**. The stationary source or modification would not cause or significantly contribute to a violation of any ambient air quality standard.*

***03. Toxic Air Pollutants.** Using the methods provided in Section 210, the emissions of toxic air pollutants from the stationary source or modification would not injure or unreasonably affect human or animal life or vegetation as required by Section 161. Compliance with all applicable toxic air pollutant carcinogenic increments and toxic air pollutant non-carcinogenic increments will also demonstrate preconstruction compliance with Section 161 with regards to the pollutants listed in Sections 585 and 586.*

Atmospheric dispersion modeling, using computerized simulations, is used to demonstrate compliance with both NAAQS and TAPs. Idaho Air Rules Section 202.02 states:

***02. Estimates of Ambient Concentrations**. All estimates of ambient concentrations shall be based on the applicable air quality models, data bases, and other requirements specified in 40 CFR 51 Appendix W (Guideline on Air Quality Models).*

2.4 Significant Impact Level and Cumulative NAAQS Impact Analyses

If specific criteria pollutant emission increases associated with the proposed permitting project cannot qualify for a BRC exemption as per Idaho Air Rules Section 221, then the permit cannot be issued unless the application demonstrates that applicable emission increases will not cause or significantly contribute to a violation of NAAQS, as required by Idaho Air Rules Section 203.02.

The first phase of a NAAQS compliance demonstration is to evaluate whether the proposed facility/project could have a significant impact to ambient air. Section 3.1.1 of this memorandum describes the applicability evaluation of Idaho Air Rules Section 203.02. The Significant Impact Level (SIL) analysis for a new facility or proposed modification to a facility involves modeling estimated criteria air pollutant emissions from the facility or modification to determine the potential impacts to ambient air. Air impact analyses are required by Idaho Air Rules to be conducted in accordance with methods outlined in Appendix W. Appendix W requires that facilities be modeled using emissions and operations representative of design capacity or as limited by a federally enforceable permit condition.

A facility or modification is considered to have a significant impact on air quality if maximum modeled impacts to ambient air exceed the established SIL listed in Idaho Air Rules Section 006 (referred to as a "significant contribution" in Idaho Air Rules) or as incorporated by reference as per Idaho Air Rules Section 107.03.b. Table 2 lists the applicable SILs.

Table 2. APPLICABLE REGULATORY LIMITS.

Pollutant	Averaging Period	Significant Impact Levels[a] ($\mu g/m^3$)[b]	Regulatory Limit[c] ($\mu g/m^3$)	Modeled Design Value Used[d]
PM_{10}[e]	24-hour	5.0	150[f]	Maximum 6th highest[g]
$PM_{2.5}$[h]	24-hour	1.2	35[i]	Mean of maximum 8th highest[j]
	Annual	0.2	12[k]	Mean of maximum 1st highest[l]
Carbon monoxide (CO)	1-hour	2,000	40,000[m]	Maximum 2nd highest[n]
	8-hour	500	10,000[m]	Maximum 2nd highest[n]
Sulfur Dioxide (SO_2)	1-hour	3 ppb[o] (7.8 $\mu g/m^3$)	75 ppb[p] (196 $\mu g/m^3$)	Mean of maximum 4th highest[q]
	3-hour	25	1,300[m]	Maximum 2nd highest[n]
Nitrogen Dioxide (NO_2)	1-hour	4 ppb (7.5 $\mu g/m^3$)	100 ppb[s] (188 $\mu g/m^3$)	Mean of maximum 8th highest[t]
	Annual	1.0	100[r]	Maximum 1st highest[n]
Lead (Pb)	3-month[u]	NA	0.15[r]	Maximum 1st highest[n]

	Quarterly	NA	1.5[r]	Maximum 1st highest[n]
Ozone (O_3)	8-hour	40 TPY VOC[v]	70 ppb[w]	Not typically modeled

a. Idaho Air Rules Section 006 (definition for significant contribution) or as incorporated by reference as per Idaho Air Rules Section 107.03.b.
b. Micrograms per cubic meter.
c. Incorporated into Idaho Air Rules by reference, as per Idaho Air Rules Section 107.
d. The maximum 1st highest modeled value is always used for the significant impact analysis unless indicated otherwise. Modeled design values are calculated for each ambient air receptor.
e. Particulate matter with an aerodynamic diameter less than or equal to a nominal 10 micrometers.
f. Not to be exceeded more than once per year on average over 3 years.
g. Concentration at any modeled receptor when using five years of meteorological data.
h. Particulate matter with an aerodynamic diameter less than or equal to a nominal 2.5 micrometers.
i. 3-year mean of the upper 98th percentile of the annual distribution of 24-hour concentrations.
j. 5-year mean of the 8th highest modeled 24-hour concentrations at the modeled receptor for each year of meteorological data modeled. For the SIL analysis, the 5-year mean of the 1st highest modeled 24-hour impacts at the modeled receptor for each year.
k. 3-year mean of annual concentration.
l. 5-year mean of annual averages at the modeled receptor.
m. Not to be exceeded more than once per year.
n. Concentration at any modeled receptor.
o. Interim SIL established by EPA policy memorandum.
p. 3-year mean of the upper 99th percentile of the annual distribution of maximum daily 1-hour concentrations.
q. 5-year mean of the 4th highest daily 1-hour maximum modeled concentrations for each year of meteorological data modeled. For the significant impact analysis, the 5-year mean of 1st highest modeled 1-hour impacts for each year is used.
r. Not to be exceeded in any calendar year.
s. 3-year mean of the upper 98th percentile of the annual distribution of maximum daily 1-hour concentrations.
t. 5-year mean of the 8th highest daily 1-hour maximum modeled concentrations for each year of meteorological data modeled. For the significant impact analysis, the 5-year mean of maximum modeled 1-hour impacts for each year is used.
u. 3-month rolling average.
v. An annual emissions rate of 40 ton/year of VOCs is considered significant for O_3.
w. Annual 4th highest daily maximum 8-hour concentration averaged over three years.

If modeled maximum pollutant impacts to ambient air from the emission sources associated with a new facility or modification exceed the SILs, then a cumulative NAAQS impact analysis is necessary to demonstrate compliance with NAAQS and Idaho Air Rules Section 203.02.

A cumulative NAAQS impact analysis for attainment area pollutants involves assessing ambient impacts (typically the design values consistent with the form of the standard) from potential/allowable emissions resulting from the project and emissions from any nearby co-contributing sources (including existing emissions from the facility that are unrelated to the project), and then adding a DEQ-approved background concentration value to the modeled result that is appropriate for the criteria pollutant/averaging-period at the facility location and the area of significant impact. The resulting pollutant concentrations in ambient air are then compared to the NAAQS listed in Table 2. Table 2 also specifies the modeled design value that must be used for comparison to the NAAQS. NAAQS compliance is evaluated on a receptor-by-receptor basis for the modeling domain.

If the cumulative NAAQS impact analysis indicates an exceedance of NAAQS, a culpability analysis can determine if this exceedance is due to emissions from the proposed project. The permit may not be issued if the proposed project has a significant contribution (exceeding the SIL) to the modeled violation. If project-specific impacts are below the SIL, then the project does not have a significant contribution to the specific violations.

Compliance with Idaho Air Rules Section 203.02 is generally demonstrated if: a) applicable specific criteria pollutant emission increases are at a level defined as BRC, using the criteria established by DEQ regulatory interpretation (DEQ 2014); or b) all modeled impacts of the SIL analysis are below the

REC 4210

TR 0895

applicable SIL or other level determined to be inconsequential to NAAQS compliance; or c) modeled design values of the cumulative NAAQS impact analysis (modeling all emissions from the facility and co-contributing sources, and adding a background concentration) are less than applicable NAAQS at receptors where impacts from the proposed facility/modification exceeded the SIL or other identified level of consequence; or d) if the cumulative NAAQS analysis showed NAAQS violations, the impact of proposed facility/modification to any modeled violation was inconsequential (typically assumed to be less than the established SIL) for that specific receptor and for the specific modeled time when the violation occurred.

2.5 Toxic Air Pollutant Analyses

Emissions of toxic substances are generally addressed by Idaho Air Rules Section 161:

> *Any contaminant which is by its nature toxic to human or animal life or vegetation shall not be emitted in such quantities or concentrations as to alone, or in combination with other contaminants, injure or unreasonably affect human or animal life or vegetation.*

Permitting requirements for toxic air pollutants (TAPs) from new or modified sources are specifically addressed by Idaho Air Rules Section 203.03 and require the applicant to demonstrate to the satisfaction of DEQ the following:

> *Using the methods provided in Section 210, the emissions of toxic air pollutants from the stationary source or modification would not injure or unreasonably affect human or animal life or vegetation as required by Section 161. Compliance with all applicable toxic air pollutant carcinogenic increments and toxic air pollutant non-carcinogenic increments will also demonstrate preconstruction compliance with Section 161 with regards to the pollutants listed in Sections 585 and 586.*

Per Section 210, if the total project-wide emission increase of any TAP associated with a new source or modification exceeds screening emission levels (ELs) of Idaho Air Rules Section 585 or 586, then the ambient impact of the emission increase must be estimated. If ambient impacts are less than applicable Acceptable Ambient Concentrations (AACs) for non-carcinogens of Idaho Air Rules Section 585 and Acceptable Ambient Concentrations for Carcinogens (AACCs) of Idaho Air Rules Section 586, then compliance with TAP requirements has been demonstrated.

TAPs also classified as HAPs emitted from sources addressed by New Source Performance Standards (NSPS) or National Emission Standards for Hazardous Air Pollutants (NESHAP) were not required to be evaluated for compliance with TAP increments in accordance with IDAPA 58.01.01.210.20 (Subsection 210.20). The DEQ permit writer evaluates the applicability of specific TAPs to the Subsection 210.20 exclusion. Guidance and clarification of Subsection 210.20 source exemptions are included in the DEQ Statement of Basis.

IDAPA 58.01.01.215 sets requirements for mercury emissions. For this standard, fugitive emissions and sources in a source category subject to 40 CFR 63 are exempt. The DEQ permit writer evaluates the applicability of mercury emissions to the exemption criteria. Details are provided in the DEQ Statement of Basis. Adjusted mercury emissions from non-fugitive and non-NESHAP-addressed sources were below the level (25 pounds per year) at which Mercury Best Available Control Technology (MBACT) review is required.

TR 0896

3.0 Analytical Methods and Data

This section describes the methods and data used in the analyses to demonstrate compliance with applicable air quality impact requirements. The DEQ Statement of Basis provides a discussion of the methods and data used to estimate criteria and TAP emission rates.

3.1 Emission Source Data

Emissions of criteria pollutants and TAPs resulting from operation of the SGP facility were estimated by Air Sciences for various applicable averaging periods. The calculation of potential emissions is the responsibility of the DEQ permit writer, and the representativeness and accuracy of emission estimates is not addressed in this modeling memorandum. DEQ air impact analysts are responsible for assuring that potential emission rates provided in the emission inventory are properly used in the model. The rates listed must represent the maximum allowable rate as averaged over the specified period.

Emission rates used in the impact modeling applicability analyses and any modeling analyses, as listed in this memorandum, should be reviewed by the DEQ permit writer and compared with those in the final emission inventory. All modeled criteria air pollutant and TAP emission rates must be equal to or greater than the facility's potential emissions calculated in the PTC emission inventory or proposed permit allowable emission rates.

Emissions from unpaved roads were calculated based on a control efficiency of 90% from chemical application and 33% from watering (combined control efficiency above 93%). Emission controls and emission calculations are not reviewed in this modeling memorandum. However, it is critical for NAAQS compliance that this high level of control be achieved.

Activity-specific (e.g., drilling, blasting, material crushing and conveying, refining, and other ancillary sources) emissions were estimated based on maximum activity rates, coupled with applicable emission estimation techniques. Maximum emissions were calculated on a short-term (hourly and daily) and long-term (annual) basis for ore processing and mining operations, as discussed below.

The ore-processing rate will range from 20,000 ton/day to 25,000 ton/day at full production. Therefore, maximum potential daily ore processing emissions were based on the maximum design rate of 25,000 ton/day. Maximum potential annual emissions were based on potential daily emissions multiplied by 365 days per year.

Emissions from mining operations (drilling, blasting, material extraction and movement, mobile mine machinery use, and other ancillary sources) vary for each year of the life of the mine (LOM). However, for the modeling analyses, the mining operation potential emissions were estimated using conservatively high maximum activity rates provided in Table 3.

Table 3. MINING ACTIVITY RATES FOR POTENTIAL EMISSION CALCULATIONS.

Activity	Maximum Rate		Comments
Drilling	600	holes per blast	--
Blasting	2	blasts per day	--
	1	blast per hour	--
Material extraction and hauling	180,000	tons per day	Ore or DR
Onsite dozing	144	hours per day	6 dozers operating continuously
Onsite grading	72	hours per day	3 graders operating continuously
Onsite water trucking	48	hours per day	2 trucks operating continuously

The potential hourly emission rates for ore processing and mining operation activities were calculated by dividing the daily rate by the 24 hour-per-day operation schedule, and annual rates were calculated by multiplying maximum daily emissions with 365 days per year. This is conservative because the mine is expected to operate for only 355 days per year.

The maximum mine production rate is approximately 42.7 million (MM) tons per year (ton/yr); however, a maximum daily production rate of 180,000 ton/day used for potential emission calculations results in a conservatively higher production rate of approximately 65.7 MMton/yr, approximately 50 percent higher than the projected production rate.

Midas Gold will employ newer model year mining and maintenance machines (excavators, shovels, haul trucks, dozers, graders, portable light plants, etc.) that are expected to meet or exceed applicable regulatory emission standards. Non-road mobile equipment engines are exempt from permitting requirements; therefore, the tailpipe emissions resulting from fuel combustion in the non-road mobile equipment are not quantified for the SGP facility. Background concentrations from McCall, 38 miles west of the SGP, were used in the cumulative NAAQS impact analyses (Section 4.1.2) to conservatively account for the impact contribution of traffic emissions.

The approximately 38-mile long Burntlog Route mine access road will be outside the project ambient air boundary and open to the public. Traffic emissions on public roads generally are considered to be part of background concentrations. Therefore, emissions on the Burntlog Route mine access road that are outside of the project boundary are not included in the SGP analyses. However, the emissions associated with the portion of the Burntlog Route mine access road that is within project boundary (from the south gate to the process area) are included in the SGP analyses. These include dust emissions generated from travel of maintenance equipment, light-duty pickup trucks and buses used for employee, visitor, and contractor transportation, and heavy-duty trucks used for cargo (including fuel, consumables, machine parts, ore processing supplies, ore concentrate, etc.) and services (including food supplies, trash, recyclables, etc.) transportation.

3.1.1 Criteria Pollutant Modeling Applicability and Modeled Emission Rates

If project-specific emission increases for criteria pollutants would qualify for a BRC permit exemption as per Idaho Air Rules Section 221 if it were not for potential emissions of one or more pollutants exceeding the BRC threshold of 10 percent of emissions defined by Idaho Air Rules as significant, then a NAAQS compliance demonstration may not be required for those pollutants with emissions below BRC levels. DEQ's regulatory interpretation policy of exemption provisions of Idaho Air Rules is that: "*A DEQ NAAQS compliance assertion will not be made by the DEQ modeling group for specific criteria pollutants having a project emissions increase below BRC levels, provided the proposed project would have qualified for a Category I Exemption for BRC emissions quantities except for the emissions of another criteria pollutant*" (DEQ 2014). The interpretation policy also states that the exemption criteria of uncontrolled potential to emit (PTE) not to exceed 100 ton/year (Idaho Air Rules Section 220.01.a.i) is not applicable when evaluating whether a NAAQS impact analyses is required. A permit will be issued limiting PTE below 100 ton/year, thereby negating the need to maintain calculated uncontrolled PTE under 100 ton/year. The BRC exemption cannot be used to exempt a project from a pollutant-specific NAAQS compliance demonstration in most cases where a PTC is required for the action regardless of emission quantities, such as the modification of an existing emission or throughput limit.

A NAAQS compliance demonstration must be performed for pollutant increases that would not qualify for the BRC exemption from the requirement to demonstrate compliance with NAAQS.

REC 4213

TR 0898

Site-specific air impact modeling analyses may not be necessary for some pollutants, even where such emissions do not qualify for the BRC exemption. DEQ has developed modeling applicability thresholds, below which a site-specific modeling analysis is not required. DEQ generic air impact modeling analyses that were used to develop the modeling thresholds provide a conservative SIL analysis for projects with emissions below identified threshold levels. Project-specific modeling applicability thresholds are provided in the *Idaho Air Modeling Guideline* (DEQ 2013). These thresholds were based on assuring an ambient impact of less than the established SIL for specific pollutants and averaging periods.

If total project-specific emission rate increases of a pollutant are below Level I Modeling Applicability Thresholds, then project-specific air impact analyses are not necessary for permitting. Use of Level II Modeling Applicability Thresholds is conditional, requiring DEQ approval. DEQ approval is based on dispersion-affecting characteristics of the emission sources such as stack height, stack gas exit velocity, stack gas temperature, distance from sources to ambient air, presence of elevated terrain, and potential exposure to sensitive public receptors.

For the SGP analyses, several modeling scenarios were considered to evaluate the worst-case air impacts from the SGP facility. The different modeling scenarios are discussed in Section 3.1.3. Table 4 provides a comparison between facility-wide maximum PTE for the highest-emitting scenario (W3) and modeling applicability thresholds. The short-term and long-term PTE emissions are equal to the sum of process and ancillary emissions and mining fugitive emissions. It is important to note that the process and ancillary source emissions remain the same for each modeling scenario discussed in Section 3.1.3.

Table 4. SITE-SPECIFIC CRITERIA POLLUTANT MODELING APPLICABILITY.

Source Category	Carbon Monoxide (CO)	Nitrogen Oxides (NOx)		$PM_{2.5}$[a]		PM_{10}[b]	Sulfur Dioxide (SO_2)		Lead (Pb)
	lb/hr[c]	ton/yr[d]	lb/hr	ton/yr	lb/hr	lb/hr	ton/yr	lb/hr	lb/month[e]
Process and ancillary	33.5	37.9	55.4	36.4	13.4	21.7	6.5	1.88	0.0437
Mining fugitive	1,742.0	17.1	46.8	98.9	22.5	224.7	0.03	0.09	--
Total	1,775.5	55.0	102.2	135.3	35.9	246.4	6.5	1.97	0.0437
Level I threshold	15.0	1.2	0.2	0.35	0.054	0.22	1.2	0.21	14.0
Modeling required	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	No

[a] Particulate matter with an aerodynamic diameter less than or equal to a nominal 2.5 micrometers.
[b] Particulate matter with an aerodynamic diameter less than or equal to a nominal 10 micrometer.
[c] Pounds per hour.
[d] Tons per year.
[e] Pounds per month.

As indicated in Table 4, the SGP facility-wide maximum PTE are greater than the respective Level I thresholds for all criteria pollutants and averaging periods except for Pb. Therefore, modeling is triggered for applicable averaging periods for CO, NOx, $PM_{2.5}$, PM_{10}, and SO_2. Modeling is not required for Pb. The use of Level II modeling thresholds was not approved by DEQ for this project.

Tables 5-7 list criteria pollutant emission rates used in the cumulative NAAQS impact analyses for the worst-case modeling scenarios. Significant Impact Level (SIL) analyses were not performed. Based on the magnitude of the facility-wide emissions and preliminary modeling analyses, it was determined that the impacts from the SGP emissions exceeded the SIL for most criteria pollutants. Therefore, SIL

REC 4214

TR 0899

analyses were considered redundant and not performed for this report. Table 5 lists the source-specific modeled emission rates for 24-hour and annual $PM_{2.5}$ and 24-hour PM_{10} (worst-case modeling scenario: W5). Table 6 lists the source-specific modeled emission rates for 1-hour and 8-hour CO and annual NO_2 (worst-case modeling scenario: W1). Table 7 lists the source-specific modeled emission rates for 1-hour NO_2 and 1-hour and 3-hour SO_2 (worst-case modeling scenario: B1). Modeling scenarios are discussed in Section 3.1.3. For 1-, 3-, and 8-hour averaging times, hourly emission rates provided in pounds per hour were used. For 24-hour averaging time, daily emission rates provided in pounds per day were used. For the annual averaging time, annual emission rates provided in tons per year were used. All modeled emission rates in Tables 5-7 are listed in units of pounds per hour (lb/hr). The total modeled input emission rates (highest emission scenario) are listed in Table 8.

a. Pounds per hour.

Table 8. CRITERIA POLLUTANT TOTAL MODELED EMISSION RATES (WORST-CASE MODELING SCENARIOS).

Pollutant	Averaging Time	Emissions[a]
CO	8 hours	1,775.50 lb/hr
	1 hour	1,775.50 lb/hr
NO_2	1 year	54.93 ton/yr
	1 hour	58.07 lb/hr
$PM_{2.5}$	1 year	135.23 ton/yr
	24 hours	781.69 lb/day
PM_{10}	24 hours	5,768.93 lb/day
SO_2	3 hours	1.97 lb/hr
	1 hour	1.97 lb/hr

a. Combined process, ancillary, and fugitive emissions modeled. Fugitive emissions vary by pit scenario. Maximum pit scenario emissions are shown.

Ozone (O_3) differs from other criteria pollutants in that it is not typically emitted directly into the atmosphere. O_3 is formed in the atmosphere through reactions of VOCs, NOx, and sunlight. Atmospheric dispersion models used in stationary source air permitting analyses cannot be used to estimate O_3 impacts resulting from VOC and NOx emissions from an industrial facility. O_3 concentrations resulting from area-wide emissions are predicted by using more complex airshed models such as the Community Multi-Scale Air Quality (CMAQ) modeling system. Use of the CMAQ model is very resource-intensive and DEQ asserts that performing a CMAQ analysis for a particular permit application is not typically a reasonable or necessary requirement for air quality permitting.

Addressing secondary formation of O_3 within the context of permitting a new stationary source has been somewhat addressed in EPA regulation and policy. As stated in a letter from Gina McCarthy of EPA to Robert Ukeiley, acting on behalf of the Sierra Club (letter from Gina McCarthy, Assistant Administrator, United States Environmental Protection Agency, to Robert Ukeiley, January 4, 2012):

. . . footnote 1 to sections 51.166(I)(5)(I) of the EPA's regulations says the following: "No de minimis air quality level is provided for ozone. However, any net emission increase of 100 tons per year or more of volatile organic compounds or nitrogen oxides subject to PSD would be required to perform an ambient impact analysis, including the gathering of air quality data."

"The EPA believes it unlikely a source emitting below these levels would contribute to such a violation of the 8-hour ozone NAAQS, but consultation with an EPA Regional Office should still be conducted in accordance with section 5.2.1.c. of Appendix W when reviewing an application for sources with emissions of these ozone precursors below 100 TPY."

DEQ determined it was not appropriate or necessary to require a quantitative source-specific O_3 impact analysis because allowable emission estimates of VOCs and NOx are below the 100 tons/year threshold.

3.1.2 TAPs Modeling Applicability and Modeled Emission Rates

A comparison of the applicable non-carcinogenic and carcinogenic screening emission levels (EL) for the TAP from IDAPA 58.01.01, Sections 585 and 586, respectively, with applicable facility-wide maximum potential TAP emissions for the highest-emitting scenario (W3) is provided in Table 9. Note that TAPs also classified as HAPs emitted from sources addressed by NSPS or NESHAP were not required to be evaluated for compliance with TAP increments in accordance with IDAPA 58.01.01.210.20.

Table 9. TAP MODELING APPLICABILITY DETERMINATION.

HAP/TAP	Emissions (lb/hr)			EL (lb/hr)		Determination
	(a)	(b)	Total	(c)	(d)	
1,3-Butadiene	--	--	--	--	2.4E-5	EL not exceeded

Calcium Oxide	--	7.0E-1	7.0E-1	1.3E-1	--	Non-carcinogenic EL exceeded
Copper	4.1E-3	5.3E-4	4.6E-3	6.7E-2	--	EL not exceeded
Cyclohexane	--	1.0E-3	1.0E-3	7.0E+1	--	EL not exceeded
Hydrogen Sulfide	--	9.0E-1	9.0E-1	9.3E-1	--	EL not exceeded
Iron	14.8	2.1E-1	15.0	6.7E-2	--	Non-carcinogenic EL exceeded
Molybdenum	8.1E-4	4.7E-4	1.3E-3	3.3E-1	--	EL not exceeded
Pentane	--	1.2E-1	1.2E-1	1.2E+2	--	EL not exceeded
Silver	4.1E-4	4.1E-4	8.2E-4	7.0E-3	--	EL not exceeded
Sulfuric Acid	--	2.03	2.03	6.7E-2	--	Non-carcinogenic EL exceeded
Thallium	8.1E-3	5.2E-4	8.7E-3	7.0E-3	--	Non-carcinogenic EL exceeded
Uranium	8.1E-3	5.2E-4	8.7E-3	1.3E-2	--	EL not exceeded
Vanadium	2.3E-2	8.4E-4	2.4E-2	3.0E-3	--	Non-carcinogenic EL exceeded
Trimethyl Benzene	--	1.1E-2	1.1E-2	8.2E+0	--	EL not exceeded
Tungsten	8.1E-3	5.2E-4	8.7E-3	3.3E-1	--	EL not exceeded
Zinc	2.9E-2	2.2E-3	3.1E-2	6.7E-1	--	EL not exceeded

a. Total HAP/TAP emissions for EL evaluation from mining (i.e., pits, blasting, haul roads, stockpiles and DRSF, access road, and underground exploration) and leaching. Emissions from sources addressed by NSPS/NESHAP are not included in the evaluation for modeling applicability.

b. Total HAP/TAP emissions for EL evaluation from processing and production (i.e., ore processing, ore concentration and refining, process heating, lime production, aggregate production, concrete production, HVAC, emergency power, fuel storage). Emissions from sources addressed by NSPS/NESHAP are not included in the evaluation for modeling applicability.

c. Non-carcinogenic EL from IDAPA 58.01.01 Section 585.

d. Carcinogenic EL from IDAPA 58.01.01 Section 586.

e. Polycyclic aromatic hydrocarbon (PAH). The group of seven PAH with a single EL are regulated as polycyclic organic matter (POM) equivalent in potency to benzo(a)pyrene as specified in IDAPA 58.01.01.586.

Table 9 shows that the SGP facility-wide potential TAP emissions exceed the respective EL for arsenic, cadmium, formaldehyde, nickel, aluminum, barium, calcium carbonate, calcium oxide, iron, sulfuric acid, thallium, and vanadium. Therefore, modeling was required for these 12 TAPs.

Table 10 lists the source-specific modeled emission rates for all 12 TAPs (worst-case modeling scenario: W5).

3.1.3 Modeling Scenarios

As discussed in Section 2.1, conventional open-pit methods will be used to extract ore and DR from three pits: YPP, HFP, and WEP, and legacy tailings from BT. Ore will be hauled to the crushing area, and the DR will be moved to four DRSF: Yellow Pine (YPDRSF), Hangar Flats (HFDRSF), West End (WEDRSF), and Fiddle (FDRSF). The SGP site layout provided later in Figure 4 shows these locations.

Midas Gold plans for an up to three-year construction schedule to build mine site facilities and infrastructure, as well as the power transmission line, followed by 12 years of mining operations (i.e., LOM Years 1 through 12). Depending on the mine design and operating schedule, mining activity rates will vary temporally and spatially during the 12 years of mine production and operation. For example, ore production varies from approximately 6.8 MMton in LOM Year 1 (67% in YPP, 26% in WEP, and 7% in BT) to 9 MMton in LOM 3 (78% in YPP, 10% in BT, 7% in WEP, and 5% in HFP). Similarly, DR production varies from approximately 4.8 MMton in LOM Year 12 (100% in WEP) to 34 MMton in each of LOM Years 4 through 9, with varying distribution among the four DRSF for each LOM Year. The total material (ore and DR) production varies from approximately 12.5 MMton in LOM Year 12 to 42.7 MMton in LOM Year 4.

Similar to the material production, the distribution and hauling of DR to the four destinations (YPDRSF, HFDRSF, WEDRSF, FDRSF) also will vary for each LOM year. Depending on the material origin (pits and BT) and destination (crushing area and DRSF), material hauling distances also will vary for each LOM year.

Therefore, depending on material production rates and origin, DR destination, and hauling distances, mining emissions will vary spatially and temporally throughout the mine life. For permitting purposes, Midas Gold used a maximum production rate of 180,000 tons of material (ore and/or DR) per day, for an annual production rate of 65.7 MMton/yr. This annual production rate is more than 50% higher than the estimated maximum total material production rate of 42.7 MMton/yr.

In order to allow Midas Gold with operation flexibility and to capture variability in material origin and destination in the air quality analyses, several pit scenarios were developed for the SGP air quality analyses. Each pit scenario uses the maximum production rate of 180,000 ton/day in a single pit and uses a single material destination. Each pit has a dedicated ore scenario that assumes all material produced is ore and is hauled to the crusher area; and depending on mine design multiple DR destination scenarios each assuming all material produced is DR and is transported to a single DRSF. For example, most of the DR from HFP will be moved to HFDRSF and during LOM Years 2 through 10, but a fraction of this rock will be moved to FDRSF during LOM Years 3 and 8, and a fraction to YPDRSF during LOM Year 9. Therefore, in order to evaluate all hauling scenarios originating from HFP, the following four (one for ore hauling, three for DR hauling) HFP scenarios were modeled:

1. HFP Scenario 1 – 180,000 ton/day of ore produced and hauled to the crusher area
2. HFP Scenario 2 – 180,000 ton/day of DR produced and hauled to the FDRSF
3. HFP Scenario 3 – 180,000 ton/day of DR produced and hauled to the HFDRSF
4. HFP Scenario 4 – 180,000 ton/day of DR produced and hauled to the YPDRSF

Overall, 14 scenarios were modeled for $PM_{2.5}$ and PM_{10} analyses to cover all possible origin and destination combinations. Each modeling scenario included processing and ancillary source potential emissions. The multiple scenarios modeled for $PM_{2.5}$ and PM_{10} analyses are presented in Table 11. This table also shows the six origin/destination options that are not applicable to the SGP Project as denoted by

REC 4225

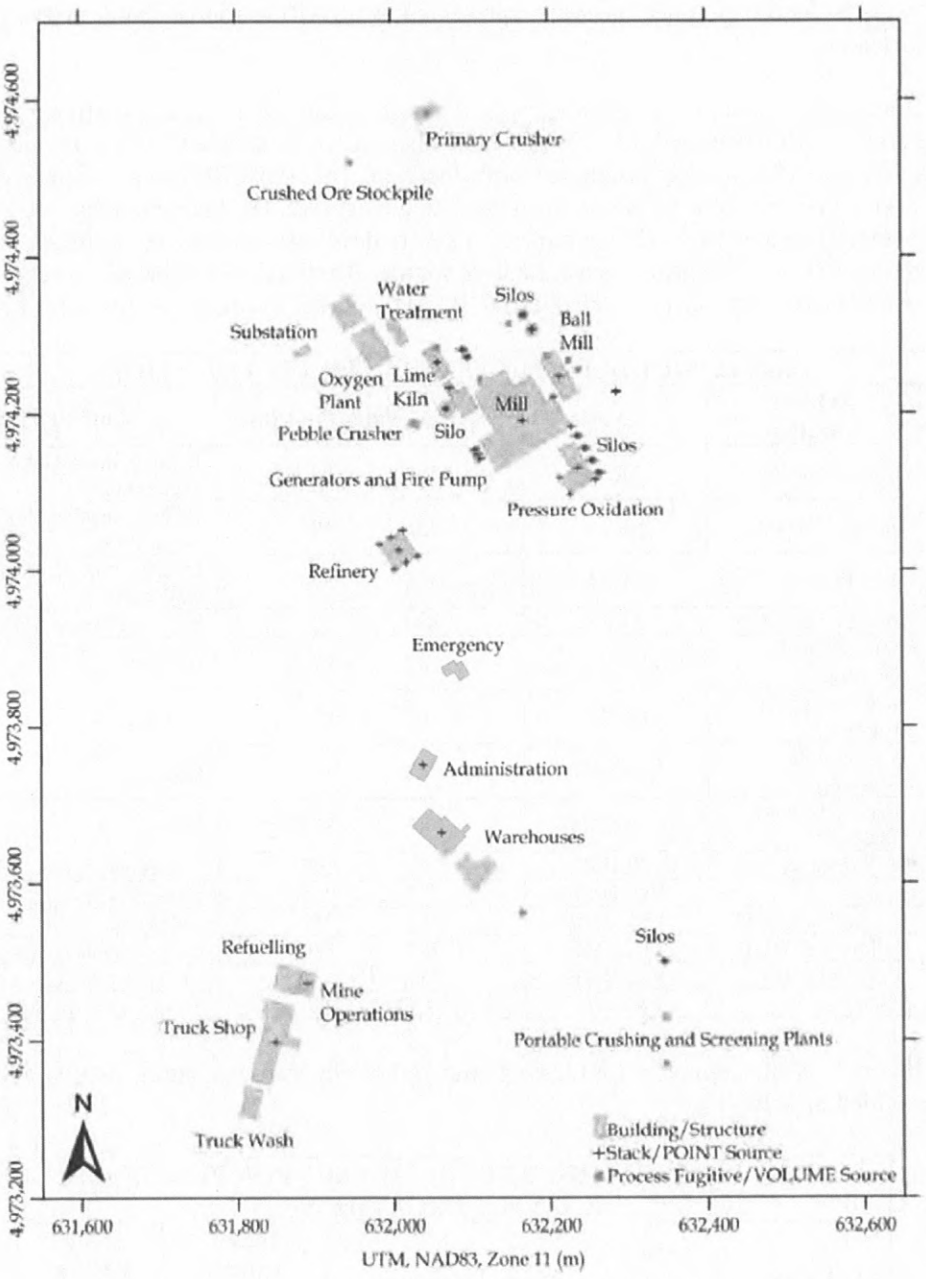
TR 0910

"0 ton/day." These six scenarios are not feasible because the timing of the activity within the sequence of mine operations makes the scenarios logistically impossible.

Table 11. MODELING SCENARIOS FOR $PM_{2.5}$ AND PM_{10} ANALYSES.

Pit Scenario	Pit/Origin (ton/day)				Ore Destination (ton/day)	DR Destination (ton/day)			
	YPP	HFP	WEP	BT	STKP	FDRSF	HFDRSF	YPDRSF	WEDRSF
Y1	180,000	--	--	--	180,000	--	--	--	--
Y2	180,000	--	--	--	--	180,000	--	--	--
Y3	180,000	--	--	--	--	--	180,000	--	--
Y4	0	--	--	--	--	--	--	0	--
Y5	0	--	--	--	--	--	--	--	0
H1	--	180,000	--	--	180,000	--	--	--	--
H2	--	180,000	--	--	--	180,000	--	--	--
H3	--	180,000	--	--	--	--	180,000	--	--
H4	--	180,000	--	--	--	--	--	180,000	--
H5	--	0	--	--	--	--	--	--	0
W1	--	--	180,000	--	180,000	--	--	--	--
W2	--	--	180,000	--	--	180,000	--	--	--
W3	--	--	180,000	--	--	--	180,000	--	--
W4	--	--	180,000	--	--	--	--	180,000	--
W5	--	--	180,000	--	--	--	--	--	180,000
B1	--	--	--	180,000	180,000	--	--	--	--
B2	--	--	--	180,000	--	--	180,000	--	--
B3	--	--	--	0	--	0	--	--	--
B4	--	--	--	0	--	--	--	0	--
B5	--	--	--	0	--	--	--	--	0

Scenario Y4 is not applicable because the YPDRSF and the YPP are in the same area; therefore, the pit cannot be backfilled with development rock until after mining of the pit is completed. Scenarios Y5 and H5 are not applicable because the WEDRSF will only be utilized by the WEP because of its proximity; it is only accessible from the WEP. Scenarios B3, B4 and B5 are not applicable because the development rock from the BT will only be hauled to the HFDRSF because of its proximity. All other development rock storage facilities are significantly farther away from BT.



The fugitive CO, NO_2, and SO_2 emissions are limited to pits only, and they do not vary by ore and/or DR hauling and destinations. Therefore, for these pollutants, one scenario for each pit, including processing and ancillary source potential emissions, was modeled, i.e., scenarios Y1, H1, W1, and B1.

The TAP emissions are limited to processing and ancillary sources, so a single scenario was modeled for each applicable TAP analysis.

3.1.4 Processing, Refining, and Ancillary Sources

The processing, refining, and ancillary sources with exhaust stacks, such as baghouse-equipped sources, generators, process and building heaters, autoclave, retort, smelting furnace, carbon kiln, lime kiln, etc., were modeled as POINT sources. The process sources without exhaust stacks, such as material transfers, ore screening and crushing, etc., were modeled as VOLUME sources. A plot plan showing the processing and refining area buildings and sources is provided in Figure 3. Process and ancillary source model input parameters are provided later in Tables 15 and 16.

Figure 3. PROCESSING AND REFINING AREA BUILDING AND SOURCE LAYOUT.

3.1.5 Fugitive Sources: Blasting, Material Origin and Destination, and Underground Exploration Emissions

Blasting emissions were represented by a VOLUME source located inside a pit. Each material origin location (YPP, HFP, WEP, BT) was modeled as an AREA source and comprised appropriate emissions from drilling, material loading, dozing, and surface exploration. Ore destination (crusher area) was modeled as a VOLUME source and comprised ore unloading emissions. Each DR destination (FDRSF,

HFDRSF, YPDRSF, WEDRSF) was modeled as a VOLUME source comprising appropriate emissions from DR unloading, dozing, and wind erosion. Emissions from underground core sampling drilling (UGEXP) in the Scout prospect decline were represented by an AREA source characterized by the portal opening dimensions.

Model input physical characteristics for blasting and possible material origin and destination locations, and Scout portal are presented in Table 12. This table also shows the source type and associated dimensions for each of the modeled fugitive source/location. The VOLUME source dimensions for blasting provided in Table 12 were based on an estimated blast area. For the remaining AREA and VOLUME sources listed in Table 12, the dimensions were developed by reasonably fitting an equal-area rectangle within the actual footprint of each fugitive source. Blasting is not expected to occur in BT. However, blasting emissions were modeled in BT (BTBL) in order to streamline the permitting process.

Table 12. MODELED FUGITIVE ACTIVITY LOCATIONS.

Model ID	Activity Location	Type	Lateral Dimensions (m)	Emission Sources
YPP	Yellow Pine Pit	AREA	882 × 882	Drilling, loading, dozing, surface exploration
HFP	Hangar Flats Pit	AREA	491 × 491	Drilling, loading, dozing, surface exploration
WEP	West End Pit	AREA	376 × 376	Drilling, loading, dozing, surface exploration
BT	Bradley Tailings	AREA	820 × 420	Loading, dozing, wind erosion
YPPBL	Yellow Pine Pit (Blasting)	VOLUME	87 × 87	Blasting
HFPBL	Hangar Flats Pit (Blasting)	VOLUME	87 × 87	Blasting
WEPBL	West End Pit (Blasting)	VOLUME	87 × 87	Blasting
BTBL	Bradley Tailings (Blasting)	VOLUME	87 × 87	Blasting
STKP	PC Stockpile	VOLUME	229 × 229	Unloading, dozing, wind erosion
FDRSF	Fiddle DRSF	VOLUME	775 × 775	Unloading, dozing, wind erosion
HFDRSF	Hangar Flats DRSF	VOLUME	752 × 752	Unloading, dozing, wind erosion
YPDRSF	Yellow Pine DRSF	VOLUME	784 × 784	Unloading, dozing, wind erosion
WEDRSF	West End DRSF	VOLUME	533 × 533	Unloading, dozing, wind erosion
UGEXP	Scout Portal	AREA	4.9 × 4.9	Sample core drilling

The model input physical parameters for blasting, material origin and destination locations, and Scout portal are provided in Table 13.

Table 13. MODEL INPUT PARAMETERS FOR FUGITIVE ACTIVITY LOCATIONS.

Model ID	Base Elevation (m)	Release Height (m)	Initial Lateral Dispersion (m)	Initial Vertical Dispersion (m)
YPP	1,832.4	4.7	N/A	4.4
HFP	1,993.3	4.7	N/A	4.4
WEP	2,191.8	4.7	N/A	4.4
BT	2,011.7	4.7	N/A	4.4
YPPBL	1,717.2	15.0	20.2	7.0
HFPBL	1,890.6	15.0	20.2	7.0
WEPBL	1,994.0	15.0	20.2	7.0

BTBL	2,011.7	15.0	20.2	7.0
STKP	1,979.8	4.7	53.3	4.4
FDRSF	2,115.2	4.7	180.2	4.4
HFDRSF	2,079.8	4.7	174.8	4.4
YPDRSF	1,904.1	4.7	182.2	4.4
WEDRSF	2,376.5	4.7	124.1	4.4
UGEXP	2,018.0	0	N/A	0

The blasting physical parameters were developed from dimensions (provided in Table 12) based on blast area used in the emission calculation. The blasting release height is the midpoint of the blasting height (30 m).

The initial lateral and vertical dispersion dimensions for blasting were calculated per methods specified in (EPA 2018c) for a volume source not on or adjacent to a building, as:

$$Initial\ Lateral\ Dispesion = \frac{Width\ (87\ m)}{4.3}$$

$$Initial\ Vertical\ Dispesion = \frac{Height\ (30\ m)}{4.3}$$

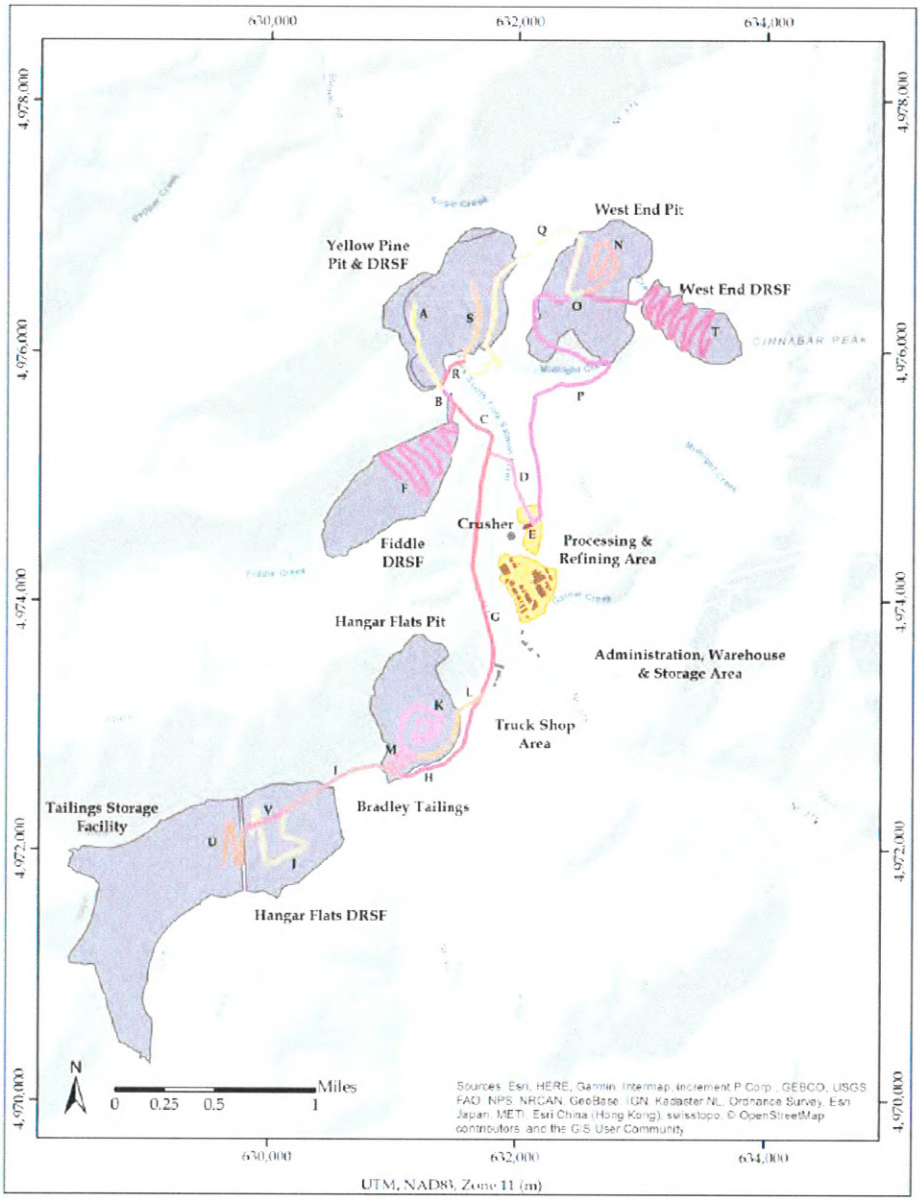
For the pit and DRSF fugitive activity locations listed in Table 12, i.e., YPP, HFP, WEP, BT, FDRSF, HFDRSF, and WEDRSF, the release height was based on the haul truck height (weighted based on model-specific usage) and calculated using the recommendations provided in the Haul Road Workgroup Report (EPA 2012), as:

$$Release\ Height = \frac{Plume\ Top\ (Weighted\ Truck\ Height \times 1.7)}{2}$$

The applicable initial lateral dispersion for each VOLUME source was calculated from the respective shorter dimension and EPA-specified methods (EPA 2018c) (EPA 2016) as follows:

$$Initial\ Lateral\ Dispesion = \frac{Short\ Lateral\ Dimension}{2.15}$$

The applicable initial vertical dispersion for each AREA and VOLUME source was calculated from the respective vertical dimension and EPA-specified methods (EPA 2018c) (EPA 2016) as follows:



$$Initial\ Vertical\ Dispersion = \frac{Plume\ Top\ (Weighted\ Truck\ Height \times 1.7)}{2.15}$$

Scout portal was modeled as a surface-based AREA source with zero release height.

3.1.6 Fugitive Sources: Haul Roads

A representative haul road network for hauling material from inside the pit (or origin) to various destinations was developed for each pit scenario provided in Table 11. The haul road network is presented in Figure 4.

Figure 4. HAUL ROAD NETWORK AND SECTIONS.

As shown in Figure 4, the haul road network was divided into 22 sections, A through V. Each section was further divided into multiple segments with a length equal to twice the adjusted haul road width of 32.5 m (26 m road width plus 6 m (EPA 2012)). Each of the segments was characterized as an individual VOLUME source in the model, with a release height of 4.75 m (weighted-average truck height times 1.7, divided by 2 (EPA 2012)), an initial lateral dispersion of 15.1 m (adjusted road width divided by 2.15 (EPA 2012)), and an initial vertical dispersion of 4.42 m (weighted-average top-of-plume height divided by 2.15 (EPA 2012)). Material hauling emissions associated with each origin-destination route were assigned to each segment along the route based on estimated total emissions along the route and traffic distribution along each section, as provided in Table 14 for the four HFP scenarios.

Table 14. HAUL ROAD EMISSION DISTRIBUTION GRID FOR HFP SCENARIOS.					
Pit Scenario		**H1**	**H2**	**H3**	**H4**

U	19	--	--	--	--
V	7	--	--	--	--

The top row in Table 14 shows the pit scenarios, and the next two rows show hauling route and the associated segment emission denominator (SED) used to distribute segment emissions along each route. The remainder of Table 14 presents the number of segments for each road section (shown in Figure 4) and the associated traffic distribution factor for each route. The emission distribution for each applicable segment is illustrated in the following example.

For route: HFP–STKP (Hangar Flats pit to crusher stockpile), Figure 4 shows that material from HFP will be hauled to the crusher area following the route along Sections K, L, G, and D. All (100%) of the ore from HFP will travel on each of these sections; therefore, each of these sections has a traffic distribution factor of 1.0 for this route.

The SED for each route is the sum-product of the number of segments and traffic distribution for the applicable sections. The SED for the HFP–STKP route is calculated as:

$$SED_{(HFP-STKP)} = (28 \times 1) + (16 \times 1) + (38 \times 1) + (14 \times 1) = 96$$

Emissions for each section-segment were estimated by dividing the total emissions along the route by its SED and multiplying by the section distribution factor. For example, the emission rate for each of the 28 segments along Section K was calculated as:

$$Emission\ Rate - Section\ K_{(Segments\ 1-28)} = \frac{Total\ Emissions_{(HFP-STKP)}}{96} \times 1$$

3.1.7 Fugitive Sources: Burntlog Route Access Road

The access road portion within the operations boundary was characterized by a series of LINE sources laid along the actual route. Emissions associated along this access road include dust emissions generated from travel of maintenance equipment, light-duty pickup trucks and buses used for employee, visitor, and contractor transportation, and heavy-duty trucks used for cargo and services transportation. These sources were assigned a release height of 3 m and an initial vertical dispersion of 2.8 m. These release parameters were based on an estimated average vehicle height of 3.5 m, which is representative of an overall approximation of anticipated vehicle heights (grader – 3.7 m, heavy-duty truck – 3.6 m, and pickup truck – 3.2 m) and the AREA source parameterization recommendations provided in the Haul Road Workgroup Report (EPA 2012). The AERMOD emission input units for AREA source are grams per meter square. The access road emissions were evenly distributed along the road by dividing the total access road emissions by its total area, i.e., the Burntlog Route section within the operations boundary (2,950 m) multiplied by the road width (6.1 m).

3.1.8 Emission Release Parameters

Table 15 lists the emission release parameters, including stack height, exhaust temperature, exhaust velocity, and stack diameter for SGP's process and ancillary point sources in metric units (English units are in parentheses). Table 16 lists the emission release parameters for SGP's process and ancillary volume sources in metric units (English units are in parentheses). Emission release parameters were based on information provided in the application. Justification for emission release parameters is summarized in the next section.

Table 15. PROCESS AND ANCILLARY POINT SOURCE EMISSION RELEASE PARAMETERS IN METRIC UNITS (ENGLISH UNITS IN PARENTHESES).

Release Point	Description	UTM[a] Coordinates		Stack Height in m (ft)[c]	Stack Exhaust Temp. in K (°F)[d]	Stack Exhaust Velocity in m/sec (fps)[e]	Stack Diameter in m (ft)	Orient. Of Release[f]
		Easting-X in m[b]	Northing-Y in m					
LS1L	Mill Lime Silo #1 Loading	632,095	4,974,272	13.3 (43.7)	0.0 (-459.7)	18.1 (59.4)	0.15 (0.49)	D
MillS2L	Mill Lime Silo #2 Loading	632,090	4,974,282	13.3 (43.7)	0.0 (-459.7)	18.1 (59.4)	0.15 (0.49)	D
SB1	Sb Dryer (2.72 MMBtu/hr Propane-Fired)	632,231	4,974,183	45.7 (150.0)	455.4 (360.0)	6.9 (22.8)	0.30 (0.98)	D
SB2	Sb Bagging	632,208	4,974,221	45.7 (150.0)	0.0 (-459.7)	6.5 (21.2)	0.30 (0.98)	D
AC	Autoclave	632,229	4,974,096	23.5 (77.0)	364.3 (196.1)	7.4 (24.3)	1.52 (4.99)	D

3.1.9 Emission Release Parameter Justification

Modeled Process and Ancillary Point Sources

The pneumatic transfer silo loadings and bin transfers (LS1L, MillS2L, ACS1L, ACS2L, ACS3L, ACS4L, PSL, CS1L, CS2L, LS6, LSBM, LS9, LSL) were modeled as POINT sources with a 3-foot bin vent above standard silo height as release height. Exit velocity was estimated using the standard stack diameter and flow rates for similar sources (NDEP 2019) or 0.001 meter per second for horizontal exhaust. These sources were modeled with ambient exhaust temperature.

For propane-fired process (Sb1, ACB, CKB, PV, HS) and building heaters (H1M, H2M, HM, HAC, HR, HA, HMO, HTS, HW), exhaust flow rates were calculated using EPA Method 9 with 3% oxygen content and 15% moisture content. Standard stack diameters were selected based on the heater rating. The process heaters were modeled with a 10-foot stack above the building, whereas the building heaters were modeled with a release height of 1 foot above the respective buildings.

Similar source exhaust temperature, flow, and diameter from (NDEP 2017) were used for refinery sources, including the carbon regeneration kiln (CKD), electrowinning cells (EW), mercury retort (MR),

and induction furnace (MF). Each of these sources was modeled with a 10- foot stack above the refinery building.

For emergency generators (EDG1, EDG2, EDG3) and the fire pump (EDFP), the exhaust flow rates were calculated using EPA Method 9 with 9% oxygen content and 8% moisture content. Standard stack diameters were selected based on engine rating. Each engine was modeled with a 7-foot-high stack.

Antimony bagging (Sb2), autoclave (AC), lime kiln (LK) (common stack with kiln burner (LKC)), and lime crushing (LCR) were characterized with similar source parameters from (NDEP 2015b), (APT 2013), and (NDEP 2010). Each of these sources was modeled with a 10-foot stack above its respective building.

Release parameters for the process and ancillary point sources were appropriately documented and justified. DEQ's source-group analysis (Table 29 in Section 4.1.4) suggests that the process and ancillary point sources contribute a small amount to the modeled design concentrations.

Modeled Process and Ancillary Volume Sources

For the following VOLUME source characterization discussion, release height was estimated as half of the vertical length (for example, building height), initial vertical dispersion was calculated by dividing the vertical length by the applicable EPA-recommended constant (EPA 2018c) for a single VOLUME source (4.3), and initial lateral dispersion was determined using the lesser lateral dimension (for example, building width) divided by the applicable EPA-recommended constant (EPA 2018c) for the surface source or elevated source with a building (2.15).

The sources associated with the primary crusher building, including loader transfer (OC1), grizzly feeder (OC2), apron feeders (OC3, OC4), ore transfers (OC5, OC6), and primary crusher (OC7), were characterized by the primary crusher building dimensions: 128' high and 52.9' wide.

The stockpile height (71.6') and the conveyor width (3') were used to determine the VOLUME source parameters for the stockpile feed conveyor (OC8).

Tunnel exit dimensions (8' high and 8' wide) were used to estimate the VOLUME release parameters for the stockpile transfer points (OC9, OC10). The SAG mill feed conveyor transfer (OC11) was characterized by a building opening (4' high and 4' wide) at the mid-height (70') of the mill building.

Pebble crusher building dimensions (20' high and 32.7' wide) were used to characterize the pebble crusher-associated sources (OC12, OC13).

Silo/bin unloading sources (LS1U, Mill2SU, ACS1U, ACS2U, ACS3U, ACS42U, PSU) were characterized by a typical screw discharge feeder characteristic, i.e., 5' above the ground with a 1' diameter.

Aggregate transfer and handling sources (CS1U, CS2U, CAL, CAU, CM) were characterized by the aggregate stockpile dimensions: 20' high and 72.2' wide.

Each portable crushing and screening plant was characterized by typical portable crushing and screening plant dimensions: 14' high and 185' wide.

Sources associated with limestone crushing (LS1, LS2, LS3, LS4, LS5) were characterized by the associated crusher building dimensions: 22.6' high and 22.6' wide.

The crushed limestone/pebble lime transfers (LS7, LS10, LSU) were characterized by a typical screw discharge to a conveyor characteristic, i.e., 5' above the ground, 3' drop, and a 1' diameter.

The limestone ball mill feed discharge (LS8) was characterized by a building opening (4' high and 4' wide) at the mid-height (30') of the ball mill building.
The limestone fines screening (LS11) was characterized by screen dimensions: 5' drop and 8' wide.

The limestone kiln feed (LS12) was characterized by a building opening (4' high and 4' wide) at the mid-height (70') of the kiln building.

Model input source characterization for fugitive emissions is described in Sections 3.1.5 and 3.1.6. Fugitive activity locations and their respective dimensions are provided in Table 12 and associated release parameters are listed in Table 13.

Release parameters for the process and ancillary volume sources were appropriately documented and justified. DEQ's source-group analysis (Table 29 in Section 4.1.4) suggests that the process and ancillary volume sources contribute a small amount to the modeled design concentrations.

3.2 Background Concentrations

Background concentrations are used if a cumulative NAAQS impact analysis is needed to demonstrate compliance with applicable NAAQS.

3.2.1 Onsite Particulate Monitoring

To establish background ambient air conditions for the SGP area, Midas Gold developed an onsite monitoring program to collect site-specific meteorological parameters and determine ambient particulate matter ($PM_{2.5}$ and PM_{10}) concentrations at its Stibnite monitoring station.

In September 2015, Midas Gold submitted the data collected at the Stibnite monitoring station for the period of November 2013 through June 2015 to DEQ. After reviewing the data and associated quality control procedures, DEQ concluded that the $PM_{2.5}$ and PM_{10} data collected at the Stibnite monitoring station satisfied the applicable regulatory requirements and approved the data to be used for background concentrations in the SGP air quality analyses (DEQ 2015). In its conclusions, DEQ recommended that the $PM_{2.5}$ and PM_{10} background concentrations should be based on calendar year 2014 instead of the complete dataset (November 2013 through June 2015).

DEQ-approved $PM_{2.5}$ and PM_{10} background concentrations, in units of micrograms per cubic meter ($\mu g/m^3$), are provided in Table 17. For 24-hour PM_{10}, the design value is the *second-highest* 24-hour average concentration in a given year. However, review of the Meteorological and Air Quality Data Summary for the SGP Monitoring Network (Midas Gold 2015) indicates that the DEQ-approved background for 24-hour PM_{10} (37.0 $\mu g/m^3$) is the *first-highest* 24-hour average concentration measured in 2014 (DEQ 2015). Therefore, using the first-high instead of the second-high as background adds a layer of conservatism to the cumulative NAAQS impact analyses for 24-hour PM_{10}.

Table 17. DEQ-APPROVED $PM_{2.5}$ AND PM_{10} BACKGROUND CONCENTRATIONS FOR SGP.			
Pollutant	**Averaging Time**	**Background Concentration ($\mu g/m^3$)**	**Design Value Rank**
$PM_{2.5}$	1 year	3.5	Weighted average of quarterly means
	24 hours	15.0	98th percentile/8th high
PM_{10}	24 hours	37.0	Highest 1st high

3.2.2 Gaseous Pollutant Background Concentrations

With a few exceptions of very large facilities or facilities located in nonattainment areas, regulatory agencies do not require the collection of gaseous criteria pollutants, including CO, NOx (and/or nitrogen dioxide [NO_2]), O_3, and SO_2. For these gaseous pollutants, data collected at government-regulated monitoring stations located in settings similar to the project area in terms of terrain, land use, and proximity of emission sources are typically used to establish background concentrations.

To determine representative background concentrations of CO, NOx, O_3, and SO_2 for the SGP site, which is located in a remote rural area, the DEQ-maintained ambient monitoring network was reviewed by Air Sciences. This review revealed that DEQ only conducts limited trace monitoring for CO, NOx, O_3, and SO_2 in the Boise metropolitan area along the Interstate 84 corridor. Thus, the data collected at these monitors are exposed to high emissions from industrial, urban, and transportation sources (DEQ 2015a) (DEQ 2018). For this reason, the gaseous pollutant concentrations recorded at these urban monitoring locations were not considered to be representative of a rural area, like the SGP site.

The EPA-maintained monitoring stations (EPA 2018a) in Idaho and surrounding states also were reviewed by Air Sciences to determine representative gaseous pollutant background concentrations for the SGP site. This review also did not identify any representative monitoring station to establish background gaseous pollutant concentrations for the SGP site.

The DEQ-recommended (DEQ 2019) CO, NOx, O_3, and SO_2 background concentrations for the SGP air quality analyses in units of parts per billion (ppb) and $\mu g/m^3$, are provided in Table 18. These background concentrations were obtained from the Northwest International Air Quality Environmental Science and Technology Consortium (NW AIRQUEST; https://arcg.is/1jXmHH) online tool using the project site coordinates. These background air pollutant levels are based on regional-scale air pollution modeling of pollutants in Washington, Oregon, and Idaho, with modeling results adjusted according to available monitoring data.

Table 18. DEQ-RECOMMENDED GASEOUS POLLUTANT BACKGROUND CONCENTRATIONS FOR SGP.				
Pollutant	**Averaging Time**	**Background Concentration**		**Reference**
		(ppb)	**($\mu g/m^3$)**	
CO	8 hours	970	1,110	NW AIRQUEST, 2014-2017 design value
	1 hour	1,520	1,740	
NO_2	1 year	0.5	0.9	
	1 hour	2.3	4.3	
O_3 (for NO_2 modeling)	8 hours	55	107.9	
SO_2	3 hours	6.4	16.8	
	1 hour	4.7	12.3	

3.2.3 Medium-Traffic Pollutant Background Concentrations

REC 4239

TR 0924

For additional information, background concentrations were obtained from NW AIRQUEST for the road section between mile markers 143 and 144 on Highway 55 passing through the town of McCall. This site (latitude 44.906° N, longitude 116.098° W) is approximately 38 miles west of the SGP. The annual average daily traffic count for this road section is over 10,000 vehicles per day. Table 19 provides the background concentrations for this medium-traffic site. Although these concentrations are not representative of the rural SGP area, they do provide additional information regarding the relative contribution of traffic emissions.

Table 19. MEDIUM-TRAFFIC BACKGROUND CONCENTRATIONS.

Pollutant	Averaging Time	Background Concentration		Reference
		(ppb)	($\mu g/m^3$)	
CO	8 hours	1,000	1,145	NW AIRQUEST, 2014-2017 design value, near McCall, ID (44.91°N, 116.10°W)

	1 hour	4.7	12.3	

3.3 Impact Modeling Methodology

This section describes the modeling methods used by the applicant/consultant to demonstrate preconstruction compliance with applicable air quality standards.

3.3.1 General Overview of Impact Analyses

Air Sciences performed the project-specific air pollutant emission inventory and air impact analyses that were submitted with the application. The submitted information/analyses, in combination with results from DEQ's air impact analyses, demonstrate compliance with applicable air quality standards to DEQ's satisfaction, provided the facility is operated as described in the submitted application and in this memorandum.

Table 20 provides a brief description of parameters used in the modeling analyses.

Table 20. MODELING PARAMETERS.

Parameter	Description/Values	Documentation/Addition Description
General Facility Location	Stibnite, Idaho	The area is an attainment or unclassified area for all criteria pollutants.
Model	AERMOD	AERMOD with the PRIME downwash algorithm, version 19191.
Meteorological Data	Onsite and McCall, Idaho surface data; Boise, Idaho upper air data	See Section 3.3.5 of this memorandum for additional details of the meteorological data.
Terrain	Considered	1/3 arc second National Elevation Dataset (NED) was acquired from the USGS for the surrounding area. AERMAP version 18081 was used to process terrain elevation data for all buildings and receptors. See Section 3.3.6 for more details.
Building Downwash	Considered	Plume downwash was considered for the structures associated with the facility. BPIP-PRIME was used to evaluate building dimensions for consideration of downwash effects in AERMOD. See Section 3.3.7.
NOx Chemistry	Ozone Limiting	See Section 3.3.8.

	Method	
Receptor Grid	**SIL Analysis** A SIL analysis was not performed.	
	Cumulative NAAQS Impact Analysis The selection of receptors for use in the cumulative NAAQS impact analysis is as follows (see Section 3.3.12):	
	Boundary	25-meter (m) spacing
	Grid 1	50-m spacing, 0.25 kilometers (km) out
	Grid 2	100-m spacing, 0.25 km to 1.25 km out
	Grid 3	500-m spacing, 1.25 km to 5 km out
	Grid 4	1,000-m spacing, 5 km to 10 km out
	Hotspot	25-m spacing, 200-m × 200-m around highest model impacts
	TAPs Analysis The receptor network used in the cumulative NAAQS impact analysis was also used in the TAPs analysis.	

3.3.2 Modeling Protocol

A modeling protocol for the SGP analyses was submitted to DEQ prior to the application, on May 30, 2019. The protocol was submitted by Brown and Caldwell on behalf of Midas Gold. Conditional DEQ protocol approval was provided to Brown and Caldwell on June 27, 2019.

3.3.3 Modeling Methodology

Project-specific modeling and other required impact analyses were generally conducted using data and methods described in the *Idaho Air Quality Modeling Guideline* (DEQ 2013).

3.3.4 Model Selection

Idaho Air Rules Section 202.02 requires that estimates of ambient concentrations be based on air quality models specified in Appendix W. The refined, steady-state, multiple-source, Gaussian dispersion model AERMOD was promulgated as the replacement model for ISCST3 in December 2005. AERMOD retains the single straight-line trajectory of ISCST3, but it includes more advanced algorithms to assess turbulent mixing processes in the planetary boundary layer for both convective and stable stratified layers.

AERMOD version 19191 was used by Air Sciences for the modeling analyses to evaluate impacts of the facility. This version was the current version at the time the application was received by DEQ.

3.3.5 Meteorological Data

AERMOD requires an input of hourly meteorological data to estimate pollutant concentrations in ambient air resulting from modeled source emissions. These data are commonly obtained from National Weather Service (NWS) stations at airports throughout the state. Applicants select data from an airport site that is determined to be reasonably representative of the permitted site location. Collection of meteorological data from the permitted site is not typically required by DEQ for minor source permit applications. The collection of one year of onsite data is required for permitting projects subject to the Prevention of Significant Deterioration (PSD) program, which is triggered by larger non-fugitive emission quantities.

Site-specific hourly surface meteorological data were collected and used in air impact analyses for this project, as described in the submitted modeling report. These data were collected from January 1, 2014 through December 31, 2014 at the Stibnite monitoring station. They were collected for analyses supporting an Environmental Impact Statement (EIS) and the Idaho DEQ minor source permit.

The site-specific surface data were supplemented with the twice-daily upper-air data (all levels) collected at the National Weather Service (NWS) station in Boise, Idaho (WBAN 24131).

These meteorological datasets were processed with the most recent version (19191) of the AERMOD meteorological pre-processor, AERMET, to produce AERMOD-input-ready hourly surface and profile meteorological files. The default option of adjusted surface friction velocity (ADJ_U*) and the Bulk Richardson (BULKRN) method for boundary layer parameter calculations was used for this meteorological data processing.

Additionally, an alternative meteorological dataset was processed without using the BULKRN method (NON-BULKRN). This alternate processing used the onsite and upper air datasets discussed above, supplemented with the cloud-cover data collected at the NWS station in McCall, Idaho (WBAN 94182).

Both processing methods (BULKRN and NON-BULKRN) are considered default for regulatory modeling analyses. EPA Region X Regional Modeling Contact, Jay McAlpine, PhD, was consulted for guidance on which data processing procedure to require for the analyses supporting the Idaho PTC. The BULKRN method was used for air impact analyses supporting the EIS after consultation with EPA, DEQ, and the US Forest Service. EPA recommended (June 18, 2019, email from Jay McAlpine, EPA, to Kevin Schilling, DEQ) using the BULKRN method since "use of the onsite data best fulfills the Guidance, and ensures consistency with the EIS, but this should be looked upon as technical advice only and not a requirement of the EPA."

Compliance with all NAAQS was easily demonstrated using meteorological data processed by the NON-BULKRN method; however, a small number of receptors showed 24-hour PM_{10} violations when the meteorological data processed with BULKRN method was used. DEQ performed a weight of evidence analyses (see Section 4.1.4 of this memorandum) to further evaluate the confidence of NAAQS compliance, using sensitivity analyses of various model input variables and the meteorological data processed using the BULKRN method.

AERMET requires the input of three surface boundary layer parameters: midday Bowen ratio (B_o), midday albedo (r), and surface roughness length (z_o). These parameters are dependent on the land use and vegetative cover of the area being evaluated. The EPA-recommended model, AERSURFACE, was used to estimate these surface parameters for the Stibnite meteorological data processing. AERSURFACE uses 1992 National Land Cover Data to determine these surface characteristics.

The determination of B_o is dependent on ambient moisture conditions (i.e., wet, average, or dry). For this purpose, historic 30-year (1985–2014) precipitation data from the Taylor Ranch station in Idaho (the closest station from which this type of data is available) were used.

The 70th and 30th percentile values estimated from the 30-year precipitation data were used to assign a moisture class to each calendar month per the following scheme: monthly precipitation greater than the 70th percentile was considered "wet"; between the 70th and 30th percentiles was considered "average"; and less than the 30th percentile was considered "dry." The monthly season and moisture classifications and estimated r and B_o for 2014 Stibnite meteorological data processing are presented in Table 21.

Table 21. 2014 MONTHLY SEASON AND MOISTURE CLASSIFICATION, AND CALCULATED *r* AND B_O.

Month	Season	*r*	30-Year Precipitation	2014 Precipitation	Moisture Classification	*Bo*

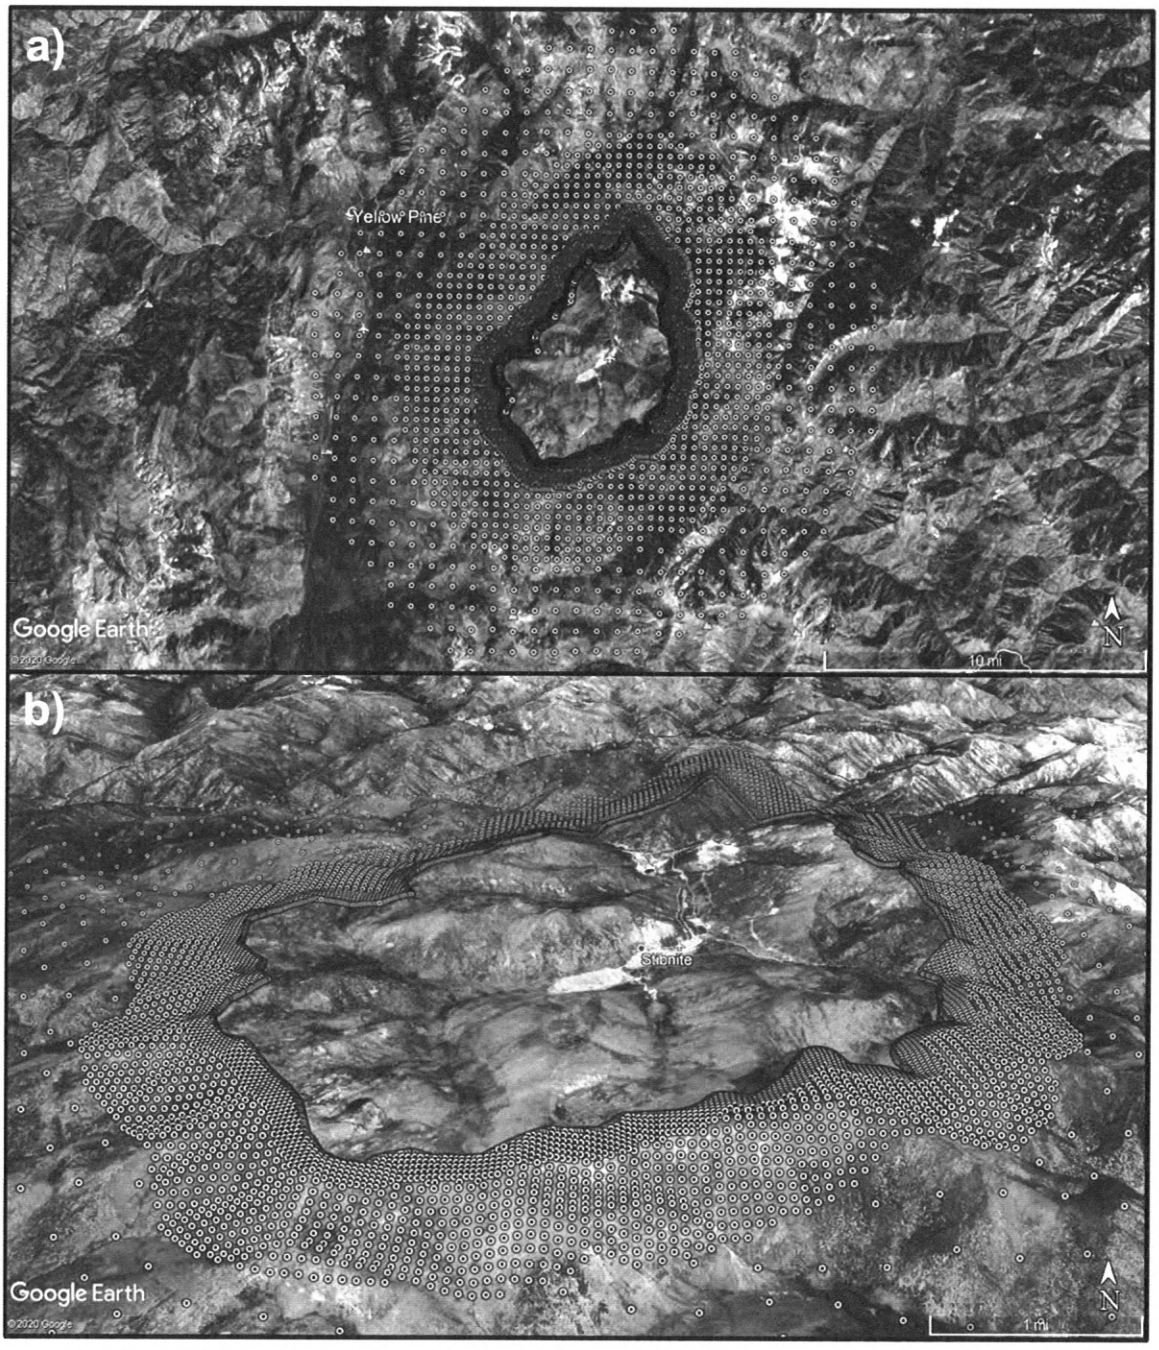
Met File Type: AERMET SFC
File: STIBNITE_2014U.SFC

Figure 6. METEOROLOGICAL STATION LOCATIONS FOR SGP MODELING.



3.3.6 Effects of Terrain on Modeled Impacts

Submitted ambient air impact analyses used terrain data extracted from United States Geological Survey (USGS) National Elevation Dataset (NED) files.

The terrain preprocessor AERMAP version 18081 was used by Air Sciences to extract the elevations from the NED files and assign them to receptors in the modeling domain in a format usable by AERMOD. AERMAP also determined the hill-height scale for each receptor. The hill-height scale is an

elevation value based on the surrounding terrain which has the greatest effect on that individual receptor. AERMOD uses those heights to evaluate whether the emission plume has sufficient energy to travel up and over the terrain or if the plume will travel around the terrain. Figure 7a depicts the full receptor grid used in the modeling analyses and Figure 7b illustrates a close-up of Figure 7a, overlaid on a terrain image from Google Earth.

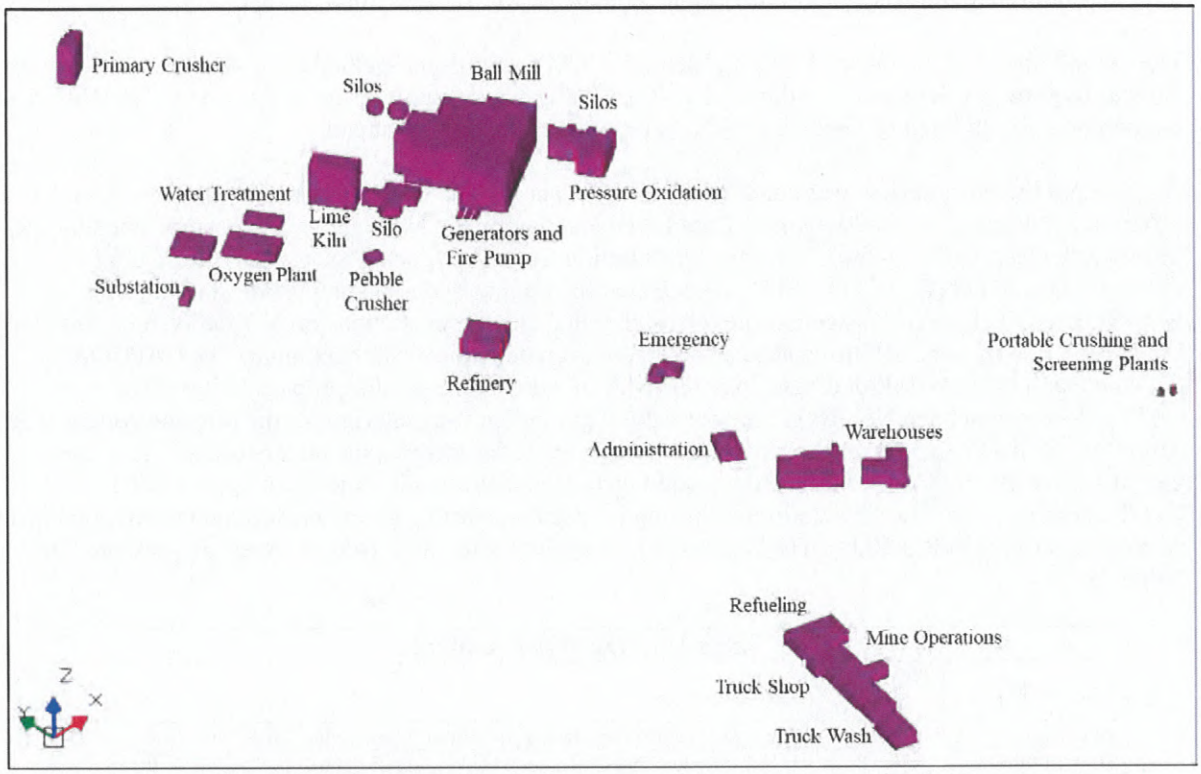


Figure 7. RECEPTOR GRID CENTERED AT THE SGP FACILITY.

3.3.7 Facility Layout and Downwash

Figure 3 shows the processing and refining area buildings and sources at the SGP facility. Figure 8 below depicts a three-dimensional view of Figure 3, as viewed from the southwest.

Figure 8. THREE-DIMENSIONAL VIEW OF PROCESSING AND REFINING AREA BUILDINGS AND SOURCES AT THE SGP FACILITY AS VIEWED FROM THE SOUTHWEST.

DEQ verified proper identification of the site location and the ambient air boundary by comparing a graphical representation of the modeling input file to aerial photographs on Google Earth (available at https://www.google.com/earth).

Potential downwash effects on emission plumes were accounted for in the model by using building dimensions and locations (locations of building corners, base elevation, and building heights). Dimensions and orientation of proposed buildings were used as input to the Building Profile Input Program for the Plume Rise Model Enhancements downwash algorithm (BPIP-PRIME version 04274) to calculate direction-specific dimensions and Good Engineering Practice (GEP) stack height information for input to AERMOD.

3.3.8 NOx Chemistry

The atmospheric chemistry of NO, NO_2, and O_3 complicates accurate prediction of NO_2 impacts resulting from NOx emissions. The conversion of NO to NO_2 can be conservatively addressed through the use of

several methods as outlined in a *2014 EPA NO_2 Modeling Clarification Memorandum* (EPA 2014). The guidance outlines a three-tiered approach:

- Tier 1 – assume full conversion of NO to NO_2 where total NOx emissions are modeled and modeled impacts are assumed to be 100 percent NO_2.
- Tier 2 – use an ambient ratio to adjust impacts from the Tier 1 analysis.
- Tier 3 – use a detailed screening method to account for $NO/NO_2/O_3$ chemistry such as the Ozone Limiting Method (OLM) or the Plume Volume Molar Ratio Method (PVMRM).

The default option of the Ozone Limiting Method (OLM), a third-tier method from 40 CFR 51, Appendix W, was used by Air Sciences to estimate the NO_2 1-hour and annual impacts for these analyses. The OLM method requires an input of in-stack NO_2/NOx ratio for each modeled source.

An in-depth literature review was conducted by Air Sciences to identify reasonable NO_2/NOx ratios for different combustion source categories. Based on this research, the NO_2/NOx ratio recommended for the heavy-duty diesel trucks in the California Air Pollution Control Officers Association (CAPCOA) Guidance Document (CAPCOA 2011) was selected for stationary diesel combustion sources. This NO_2/NOx ratio (11 percent) is conservatively higher than the diesel combustion NO_2/NOx ratio provided in the EPA ISR (In-Stack Ratio) database: 6 percent average, 9.8 percent maximum. The CAPCOA document and the EPA ISR database do not provide an NO_2/NOx ratio for propane boilers. The CAPCOA-recommended NO_2/NOx ratio for natural gas boilers was selected for the propane boilers. The natural gas boilers NO_2/NOx ratio is considered appropriate for the propane boilers because both are gaseous fuels with relatively similar combustion characteristics and are expected to have similar NO_2/NOx ratios. The NO_2/NOx ratio for blasting is based on blasting plume measurements provided in an Australian study (CSIRO 2008). The NO_2/NOx ratios used for the SGP NO_2 analyses are presented in Table 23.

Table 23. NO_2/NOx RATIOS.

Source Type	NO_2/NOx Ratio	Reference
Blasting	0.036	Commonwealth Scientific and Industrial Research Organization (CSIRO 2008)
Diesel Engines	0.11	CAPCOA Guidance Document, heavy-duty diesel trucks (CAPCOA 2011)
Propane Heaters	0.10	CAPCOA Guidance Document, natural gas boilers (CAPCOA 2011)

DEQ performed a sensitivity analysis using a Tier 2 screening method (ARM2), which is more conservative than OLM, and found that the SGP facility is safely below the 1-hour and annual NO_2 NAAQS. Results are summarized in Section 4.1.3.

3.3.9 Particulate Deposition

For $PM_{2.5}$ and PM_{10} analyses, default particulate modeling methods, including deposition (Method 1, to account for depletion due to particulate settling), were used. To account for particulate settling, AERMOD requires the following source-specific variables:

1. Mass-mean aerodynamic particle diameter (PARTDIAM) for each particle size bin
2. Mass fraction (MASSFRAX) for each particle size bin
3. Particle density (PARTDENS) for each particle size bin

REC 4248

TR 0933

A list of references that were used to develop the broad source category particle size bins and associated mass fractions was provided in the application. Midas Gold (Midas Gold 2017b) provided the ore and DR material densities. The diesel and propane combustion particulate densities were adopted from technical literature (UMN 2002) and (Khalizov et al. 2012), respectively. Densities for the remaining materials were obtained from the Engineering Toolbox (https://www.engineeringtoolbox.com/density-materials-d_1652.html). An average density was used when a material-specific density range was available.

For sources that were aggregated and modeled as activity locations, deposition parameters were selected for the dominant source within the activity location. For open-pits (YPP, HFP, WEP), approximately 90% of emissions were associated with drilling; therefore, drilling deposition parameters were assigned to these sources. Similarly, emissions from dozing accounted for over 70% of emissions in the DRSF (FDRSF, HFDRSF, WEDRSF) and BT; therefore, these sources were assigned deposition parameters based on a dozing particulate profile.

The deposition parameters including mass fractions, mass mean diameters, and densities for the different source categories/groups are provided in Table 24.

Table 24. DEPOSITION PARAMETERS BY SOURCE CATEGORY.

	Mass Mean Diameter (μm)	2.50	10.00	--	--	2.50	--
	Density (g/cm^3) (Ore or DR)	Pit-specific, see Table 25.					
Dozing	Bin Upper Diameter (μm)	2.50	10.00	--	--	2.50	--
	Mass Fraction	0.55	0.45	--	--	1.00	--
	Mass Mean Diameter (μm)	2.50	10.00	--	--	2.50	--
	Density (g/cm^3) (DR)	Pit-specific, see Table 25.					

In order to account for variability in ore and DR densities for different pits, pit-specific densities were used for the ore and DR for each modeling scenario, with the following exception – for haul roads, access roads, and portable crushers, the average DR density from YPP, HFP, and WEP was used. Note that the BT density was excluded from those sources because the BT material will not be used for roads or construction. The pit-specific ore and DR densities are provided in Table 25.

Table 25. PIT-SPECIFIC ORE AND DEVELOPMENT ROCK DENSITIES FOR DEPOSITION.

3.3.10 Ambient Air Boundary

Ambient air is defined in Section 006 of the Idaho Air Rules as "that portion of the atmosphere, external to buildings, to which the general public has access."

Midas Gold will legally control the SGP, an active industrial site where mining activities will occur, such as heavy equipment operation. Most areas of the mine will require strict safety protocols and controlled access. Midas Gold has established an operations boundary to identify the area where public access will be excluded. Public access inside the operations boundary will be restricted for the life of the mine by physical barriers at points of potential access, including the current Stibnite Road point of entry and proposed site access via the Burntlog Route, as well as natural features of the landscape that prevent access. Consistent with the guidance provided in the EPA's draft revised policy on ambient air (EPA 2018b), public access control will include the following measures:

- Primary Access Points: The Stibnite Road (north) and Burntlog Route (south) access points will include locked gates. Guard shacks will be located at each gate to monitor all vehicle ingress/egress. Each gate also will include appropriate adjacent barriers (i.e., fencing, bollards, boulders, or other barriers) to prevent any vehicle from circumventing the gate and gaining site access. These primary access points are also controlled by adjacent natural features, such as streams and creeks, steep topography, and areas of thick vegetation and undergrowth that serve as natural barriers or impediments to access.

- Secondary Access Points: Other potential access points, such as secondary roadways and trails, will include posted signs warning the public against entry into the site. At these locations, boulders will be placed across the trail and at an appropriate width adjacent to the trail to prevent any vehicle from circumventing the barrier. These secondary access points also incorporate adjacent natural features, such as streams and creeks, steep topography, and areas of thick vegetation and undergrowth that serve as natural barriers or impediments to access. Some mine features, such as the TSF and process plant areas, will include perimeter fencing.

- Surveillance: Midas Gold security personnel will routinely patrol mine facilities and roadways for unauthorized individuals. In addition, all onsite personnel will be trained on the necessity of restricting public access to areas within the operations boundary. Any suspected trespassing by unauthorized individuals will be reported immediately to security, and trespassers will be escorted off the site.

In response to comments from local community citizens, Midas Gold will manage an access route to provide the general public with limited access through the SGP site between Stibnite Road at Sugar Creek and Thunder Mountain Road at Meadow Creek (shown in Figure 2). This route will be managed in accordance with the Stibnite Road Access Management Plan which is summarized as follows:

The proposed Stibnite Road access route through the SGP site is meant to provide controlled through-site access that is safe, provides travel-time comparable to current conditions and is consistent with the United States Forest Service travel management plan. The Stibnite Road access route extends from the north entry point southward to the Administration, Warehouse and Storage Area. Continuing southward, the Stibnite Road access route incorporates the Burntlog access road segment that occurs within the operations area and extends to the south entry point as shown on Figure 2. Midas Gold has the legal authority to control access to the Stibnite Road access route and would provide seasonal (non-winter conditions) access only. At the discretion of Midas Gold, additional access controls may occur during various phases of construction, during mine operations that present potential safely hazards such as blasting, due to inclement weather, or under any other circumstances that may present a threat to the protection of public or employee health and safety. Midas Gold has the legal and practical ability to

enforce its control over roadway access and to monitor traffic passing through the SGP site. Signage will be placed at the North Security Gate (near the bridge over Sugar Creek) and the South Security Gate (near the Stibnite Lodge) to provide information to travelers, and guard shacks will be located at each gate to monitor all vehicle ingress/egress. Persons wishing to traverse the SGP site on the Stibnite Road access route will be required to check in at the security gate to receive a safety briefing and to alert mine staff of their presence. Travelers will be required to check out upon exiting the site to ensure passage through the site in a safe and timely manner. Travelers will not be allowed to stop or loiter while traveling though the operations area. Along its full length, the Stibnite Road access route would have appropriate signage to direct travelers and would be separated from mine haul roads and areas of mine operations by fencing, berms, or gates to prevent travelers from straying from the route. When possible and to the degree practicable, anticipated public access restrictions will be communicated to the public in a timely manner so that they may plan appropriately. Receptors on the Stibnite Road access route were not included in the SGP air quality analyses as this road is not considered ambient air.

The worker housing facility will be located within the project operations boundary, near the south access security gate. This housing facility will be used strictly for accommodating employees, contractors, and official visitors, and it will not be accessible to the general public. Therefore, the atmosphere over the land occupied by the worker housing facility is not considered ambient air, and receptors were not placed at this location for the air quality analyses.

The operations boundary, shown in Figure 2 above and Figure 9 below, was used to define the ambient air boundary for air dispersion modeling purposes.

3.3.11 Nearby Co-Contributing Sources

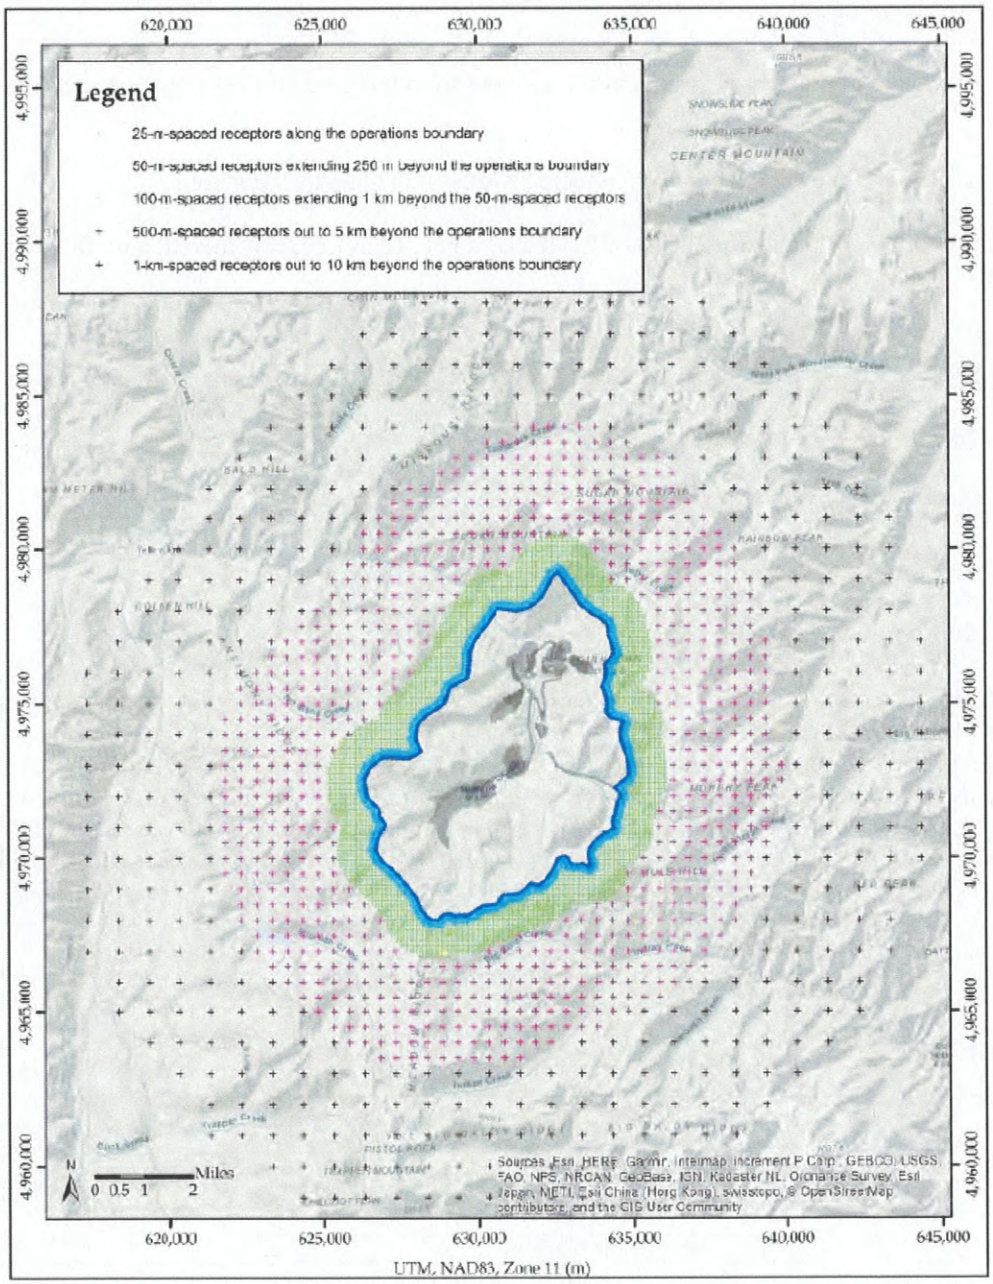
If impacts of neighboring emission sources on receptors showing a significant impact from the sources subject to the permitting action are not adequately accounted for by the background concentration used, then emissions from those sources must be modeled. The nearest significant permitted facility to SGP is Tamarack Mill, located more than 75 kilometers (km) west. This facility is located too far away to cause a significant concentration gradient along the periphery of the SGP and was therefore not included in the cumulative impact analyses for SGP.

3.3.12 Receptor Network

DEQ determined that the receptor grid used in the submitted modeling analyses was adequate to resolve maximum modeled impacts.

The SGP air quality analyses were performed using the following receptor spacing and extents (Table 20):

- 25-m-spaced receptors placed along the ambient air boundary;
- 50-m-spaced receptors extending 250 m beyond the ambient air boundary;
- 100-m-spaced receptors extending 1 km beyond the 50-m-spaced receptors;
- 500-m-spaced receptors extending 5 km beyond the ambient air boundary; and
- 1-km-spaced receptors extending 10 km beyond the ambient air boundary.



In addition, each highest modeled impact was evaluated further by performing a hot-spot analysis using a finer 25-m-spacing receptor grid. The modeling receptor grid is shown below in Figure 9. The full grid, along with the fenceline receptors, includes a total of 9,631 receptors. A SIL analysis was not conducted. The full receptor grid was used in the cumulative NAAQS impact and TAPs impact analyses.

REC 4252

TR 0937

The receptor grid used in the submitted modeling analyses met the minimum recommendations specified in the *Idaho Air Quality Modeling Guideline* (DEQ 2013), and DEQ determined that the receptor network was effective in reasonably assuring compliance with applicable air quality standards at all ambient air locations.

Figure 9. SGP AMBIENT AIR BOUNDARY AND MODELING RECEPTOR GRID.

3.3.13 Good Engineering Practice Stack Height

An allowable good engineering practice (GEP) stack height may be established using the following equation in accordance with Idaho Air Rules Section 512.03.b:

H = S + 1.5L, where:

H = good engineering practice stack height measured from the ground-level elevation at the base of the stack.

S = height of the nearby structure(s) measured from the ground-level elevation at the base of the stack.

L = lesser dimension, height or projected width, of the nearby structure.

Sources from the SGP facility are below GEP stack height. Therefore, consideration of downwash caused by nearby buildings was required.

4.0 NAAQS and TAPs Impact Modeling Results

4.1 Results for NAAQS Analyses

4.1.1 Significant Impact Level Analyses

A SIL analysis was not performed for the SGP project.

4.1.2 Cumulative NAAQS Impact Analyses

Table 26 provides results (highest of 14 scenarios) for the cumulative NAAQS impact analysis. It provides the model-predicted maximum design concentration (including the hot-spot analyses) and the associated modeling scenario, the background concentration, and the estimated total concentration (SGP impact plus background) for each pollutant-averaging time combination. A comparison of the estimated total concentrations with the applicable NAAQS is also provided in this table. For each pollutant and averaging period, two modeled design concentrations are listed, each corresponding to the meteorological data processed with (BULKRN) and without (NON-BULKRN, grey shading) the Bulk Richardson method.

Table 26. RESULTS FOR CUMULATIVE NAAQS IMPACT ANALYSES.

		2.7	B1		15.0		7.7%

a. Max. Conc. = maximum modeled design concentration.
b. Micrograms per cubic meter.
c. Back. Conc. = background concentration.
d. Total Conc. = total (modeled + background) concentration.
e. The first Max. Conc. value for each pollutant and averaging time represents results using the BULKRN meteorological data.
f. The second (grey-shaded) Max. Conc. value for each pollutant and averaging time represents results using the NON-BULKRN meteorological data.
g. Particulate matter with an aerodynamic diameter less than or equal to a nominal 2.5 micrometers.
h. Particulate matter with an aerodynamic diameter less than or equal to a nominal 10 micrometers.
i. For 24-hour PM_{10}, the design value is the *second-highest* 24-hour average concentration in a given year. However, the background value that was used in the modeling analyses represents the *first-highest* 24-hour average concentration measured in 2014. Therefore, using a larger background concentration adds a layer of conservatism to the calculated total impact for 24-hour PM_{10}.
j. Results for 24-hour PM_{10} with meteorological data processed using BULKRN show up to five hotspot receptors that exceed NAAQS. Refer to Section 4.1.4 of this modeling memo for a weight-of-evidence analysis demonstrating NAAQS compliance.

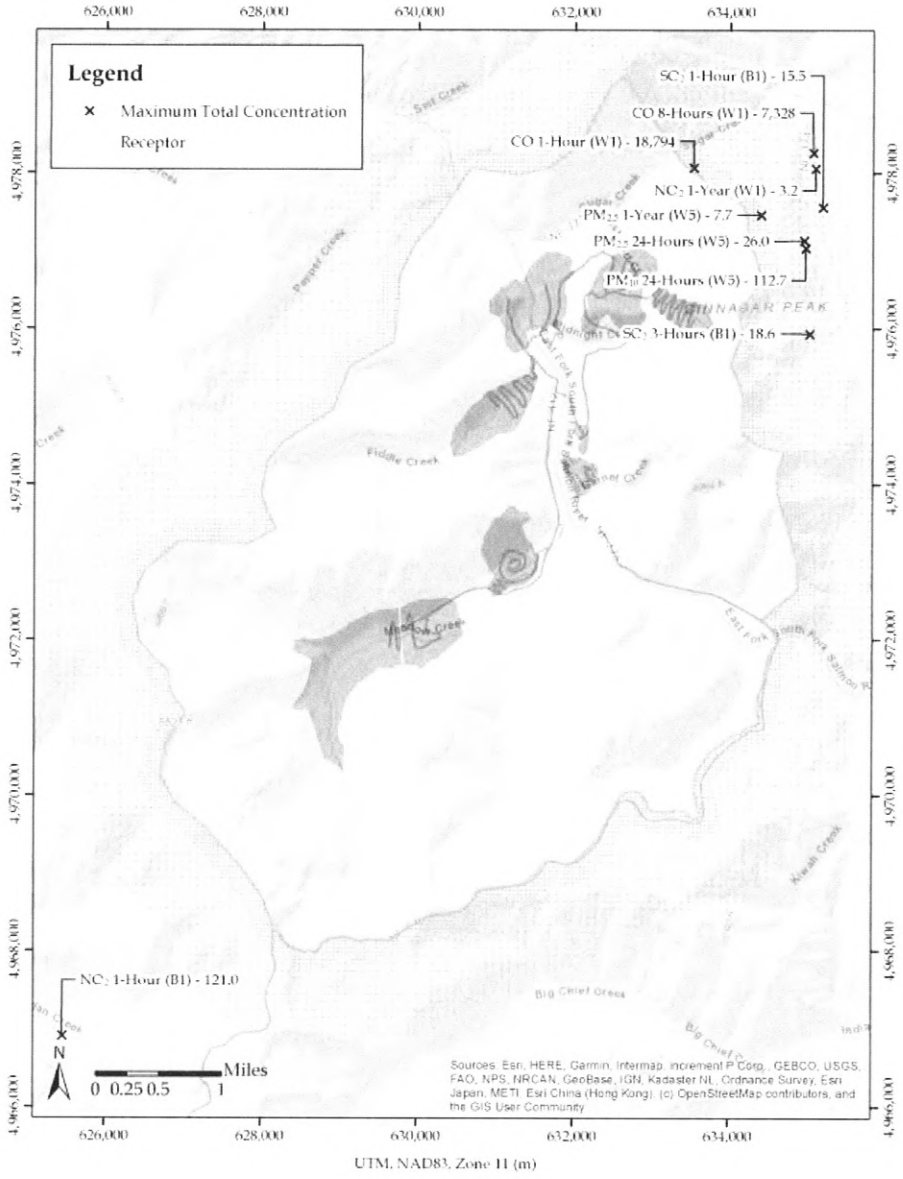

Table 26 shows that modeled concentrations derived using the BULKRN meteorological data are higher than the NON-BULKRN dataset. It also shows that the total (modeled + background) concentrations from the SGP cumulative impact analyses do not exceed the applicable NAAQS, except for when the BULKRN meteorological data are used in modeling 24-hour PM_{10} (total concentration is 105.7% of the 24-hour PM_{10} NAAQS).

PM_{10} modeling with the meteorological dataset processed with the BULKRN method shows up to five hotspot receptors for three modeling scenarios (W1, W3, and W5) with slight exceedance of NAAQS. Scenario W5 is the worst-case scenario, with a maximum total concentration of 158.5 $\mu g/m^3$ which exceeds the NAAQS of 150 $\mu g/m^3$. A weight-of-evidence analysis demonstrating PM_{10} NAAQS compliance is presented in Section 4.1.4 of this modeling memo.

The locations of the maximum impacts for each pollutant and averaging time are illustrated in Figure 10. The results presented in this figure include the hot-spot analyses conducted for each applicable pollutant-averaging time combination. For $PM_{2.5}$ and PM_{10}, the alternate meteorological data (NON-BULKRN) were used.

Modeling for ozone and secondary $PM_{2.5}$ were not performed for this minor stationary source. These analyses are typically associated with applications for major stationary sources. Nonetheless, taking the ratio of the VOC, NOx, and SO_2 emissions from the SGP facility by the emissions and resulting concentrations of O_3 and secondary $PM_{2.5}$ from EPA's modeled emission rates for precursors (MERPs) guidance yields estimated O_3 and secondary $PM_{2.5}$ concentrations of less than 1 ppb of O_3 and less than 0.1 $\mu g/m^3$ of $PM_{2.5}$ (24-hour and annual) for the SGP. These estimated concentrations have a negligible effect on compliance demonstration with the NAAQS.

Figure 10. SGP CUMULATIVE IMPACTS (µg/m³) AND LOCATIONS.

Higher background concentrations from McCall that include medium-traffic emissions provided in Section 3.2.3 were then combined with the SGP model-predicted maximum design concentrations to provide an additional level of conservatism in demonstrating compliance. These results are shown in Table 27. For $PM_{2.5}$ and PM_{10}, the alternate meteorological data (NON-BULKRN) were used. For the rest of the criteria pollutants, the BULKRN meteorological data were used.

4.1.3 DEQ's Sensitivity Analyses for 1-hour and annual NO_2

DEQ performed a sensitivity analysis for 1-hour and annual NO_2 using a Tier 2 (ARM2) screening method. Minimum and maximum NO_2/NOx ratios of 0.5 and 0.9, respectively, were used. Results from DEQ's cumulative NAAQS impact analyses, summarized below in Table 28, indicate that the SGP facility is safely below the 1-hour and annual NO_2 NAAQS even when using a more conservative NO_2 screening method.

4.1.4 DEQ's Weight-of-Evidence Analyses for 24-hour PM_{10}

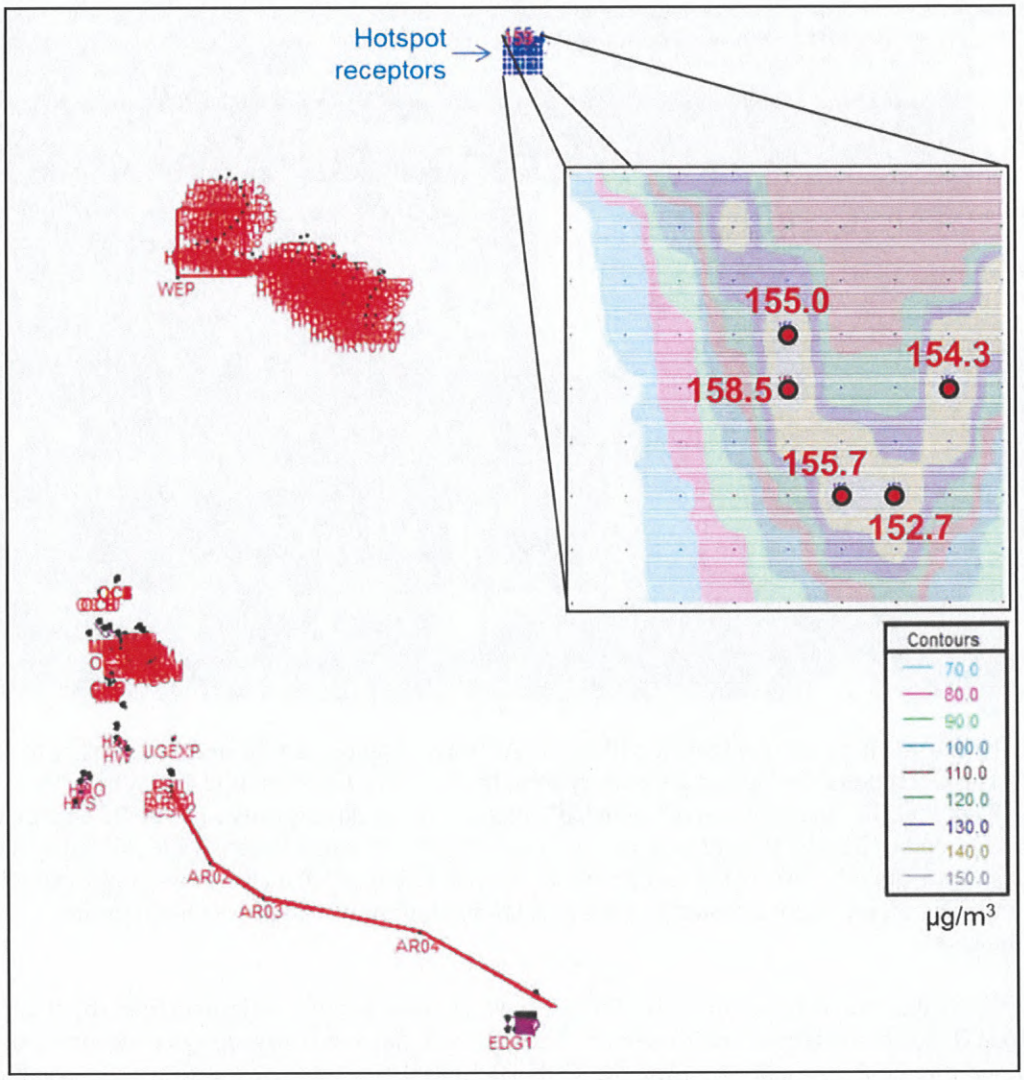
This section describes a weight-of-evidence analysis that provides additional analytical information to evaluate the degree of NAAQS compliance confidence for 24-hour PM_{10}. NAAQS compliance was demonstrated in the submitted application using meteorological data processed with an EPA-approved method using regional cloud cover to calculate stability parameters rather than site-specific monitored solar radiation and measured temperature differences with height. Both methods are considered default for regulatory purposes, and modeling using this dataset shows that the facility is well below NAAQS.

As described in Section 4.1.2, PM_{10} modeling with meteorological dataset processed using the site-specific BULKRN method shows up to five hotspot receptors for Scenario W5 (the highest PM_{10} modeling scenario) that exceed NAAQS (150 $\mu g/m^3$). The hotspot receptors have a 25-meter grid spacing. Hotspot receptors that exceed 24-hour PM_{10} NAAQS have total (modeled + background) concentrations of 152.7, 154.3, 155.0, 155.7, and 158.5 $\mu g/m^3$. Locations of these receptors are illustrated in Figure 11. Figure 12 shows these receptors overlaid on Google Earth. As noted in Section 3.2.1 of this modeling memorandum, the design value for 24-hour PM_{10} is the *second-highest* 24-hour average concentration in a given year. However, the background value that was used in the modeling analyses (37.0 $\mu g/m^3$) represents the *first-highest* 24-hour average concentration measured in 2014. Therefore, using a larger background concentration adds another layer of conservatism to the calculated total impact for 24-hour PM_{10}. If the *second-highest* 24-hour average concentration (34.0 $\mu g/m^3$) were used in the modeling analyses, the number of receptors that exceed the 24-hour PM_{10} NAAQS is reduced from five to four.

REC 4258

TR 0943

Figure 11. HOTSPOT RECEPTORS THAT EXCEED 24-HOUR PM_{10} NAAQS (SCENARIO W5, BULKRN METEOROLOGICAL DATA).



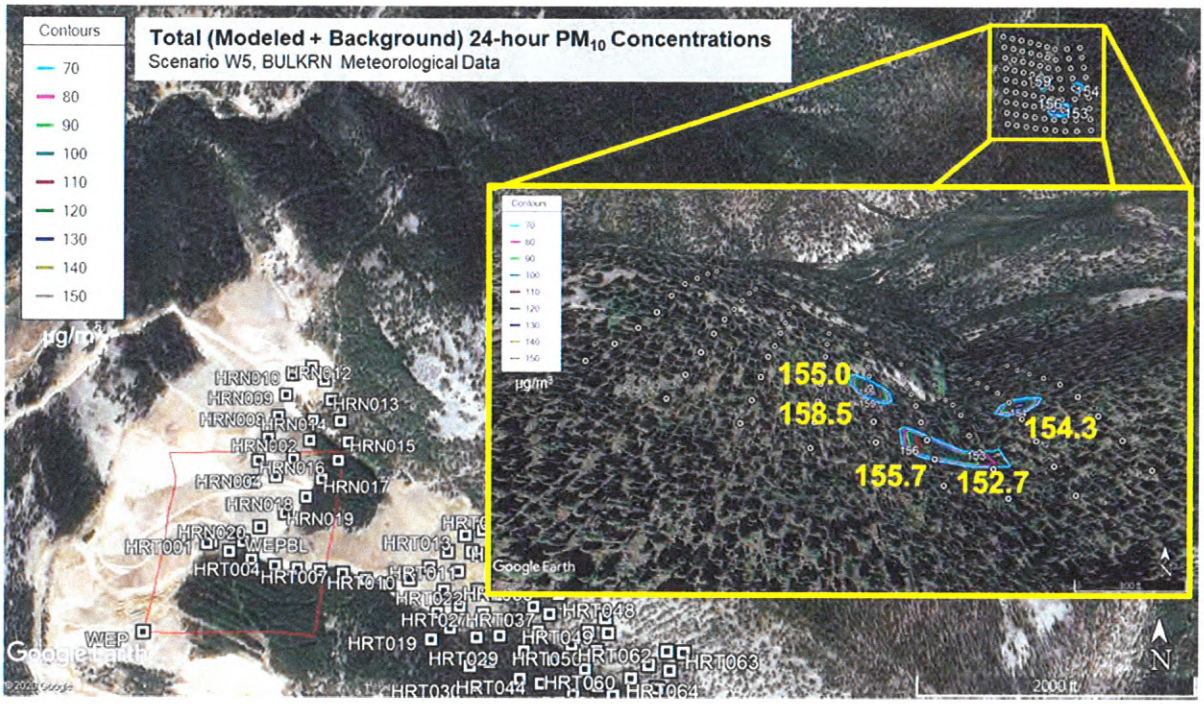


Figure 12. HOTSPOT RECEPTORS THAT EXCEED 24-HOUR PM_{10} NAAQS, OVERLAID ON GOOGLE EARTH IMAGE (SCENARIO W5, BULKRN METEOROLOGICAL DATA).

Figures 11 and 12 show that the modeled PM_{10} NAAQS exceedances are located northeast of the SGP facility. These receptors are located 2 km away from the center of the West End Pit (WEP). The AERMOD output files indicate that all modeled violations occur during winter (all modeled violations occur on December 23, 2014). Data provided in the SGP baseline study (Midas Gold 2017a) specify an average snow depth of 21-68 inches and an average precipitation of 6.0 inches at the project site during this period. Therefore, fugitive road dust emissions during high-modeled impact hours could be overestimated.

DEQ performed a source-group analysis (Table 29) which indicates that emissions from the WEP and the Haul Road (HR) are the largest contributors to the maximum modeled PM_{10} design concentrations. For comparison, source-group analyses using the NON-BULKRN meteorological data are also listed in Table 29.

Table 29. SOURCE-GROUP ANALYSES FOR 24-HOUR PM_{10} (SCENARIO W5).

Emission Source Group	Modeled Design Concentration (µg/m³)[a]	
	BULKRN	NON-BULKRN
ALL	121.5	75.7
West End Pit (WEP)	89.3	24.5
West End Pit Blasting (WEPBL)	1.94	1.81
West End Pit Development Rock Storage Facility (WEDRSF)	0.98	3.47
Haul Road (HR)	51.0	52.5
Access Road (ACCRD)	0.0064	0.0074
Underground Exploration (UGEXP)	0.00001	0.00001

Process & Ancillary Point Sources	0.23	0.76
Process & Ancillary Volume Sources	0.20	0.29

[a] Micrograms per cubic meter.

The six source groups listed in Table 29 that are related to mining activity and emissions (WEP, WEPBL, WEDRSF, HR, ACCRD, UGEXP) were examined further. Table 30 lists the daily modeled PM_{10} emissions (in pounds per day [lb/day]), grouped according to mining activity. Key assumptions for calculating the daily emissions are also listed in this table. Total modeled PM_{10} emission from mining activity for Scenario W5 is 3,336.76 lb/day. The contribution from each source group is listed in the second column of Table 30, and a pie chart is illustrated in Figure 13.

Table 30. KEY ASSUMPTIONS FOR CALCULATING DAILY MINING ACTIVITY EMISSIONS FOR 24-HOUR PM_{10} (SCENARIO W5).

Mining Activity	Emissions (lb/day)[a]
WEP (West End Pit)	**885.54**
Open Pit Drilling	
• Blasting 180,000 tons of material (DR) per day • Drilling 1,200 holes per day	811.20
Material Loading	
• Blasting 180,000 tons of material (DR) per day	18.00
Dozing	
• Dozers operating 144 hours per day • Surface material silt content of 6.9% • Material moisture content of 7.9%	54.20
Surface Exploration	
• Total wet drilling holes of 700 divided by 14 years • 50 holes per year	2.15
WEPBL (West End Pit Blasting)	**334.38**
Open Pit Blasting	
• Blasting 180,000 tons of material (DR) per day • Two blasts per day	334.38
WEDRSF (West End Pit Development Rock Storage Facility)	**57.12**
Material Unloading	
• Blasting 180,000 tons of material (DR) per day	2.88
Dozing	
• Six dozers operating 144 hours per day • Surface material silt content of 6.9% • Material moisture content of 7.9%	54.20
Wind Erosion	0.04
HR (Haul Road)	**2,050.34**
Onsite Hauling	
• Blasting 180,000 tons of material (DR) per day • One-way hauling distance of 3.07 miles • Total travel of 7,758 vehicle miles traveled (VMT) per day • Surface material silt content of 4% • Daily PM_{10} emission factor of 3.55 pounds per VMT • Control efficiency of 90% for chemical suppressant • Control efficiency of 33% for watering	1,842.97
Grading	
• Grader average speed of 6.5 mph • Three graders operating 72 hours per day • Control efficiency of 90% for chemical suppressant	60.51
Water Truck Travel	
• Two water trucks operating 48 hours per day	146.86

• Average truck speed of 15 mph • Surface material silt content of 4% • Daily PM_{10} emission factor of 3.04 pounds per VMT • Control efficiency of 90% for chemical suppressant • Control efficiency of 33% for watering	
ACCRD (Access Road) *Vehicle Travel* • Access road length of 1.6 miles (within project boundary) • Surface material silt content of 4% • Daily PM_{10} emission factor of 1.26 pounds per VMT • Control efficiency of 90% for chemical suppressant • Control efficiency of 33% for watering *Grading* • PM_{10} emission factor of 1.3 pounds per VMT • Control efficiency of 90% for chemical suppressant	**9.38** 9.17 0.21
UGEXP (Underground Exploration) *Underground Exploration* • Wet drilling 25 holes per year	**0.004** 0.004

[a] Pounds per day.

Figure 13. PIE CHART FOR DAILY MODELED PM_{10} EMISSIONS FROM MINING ACTIVITY (SCENARIO W5).

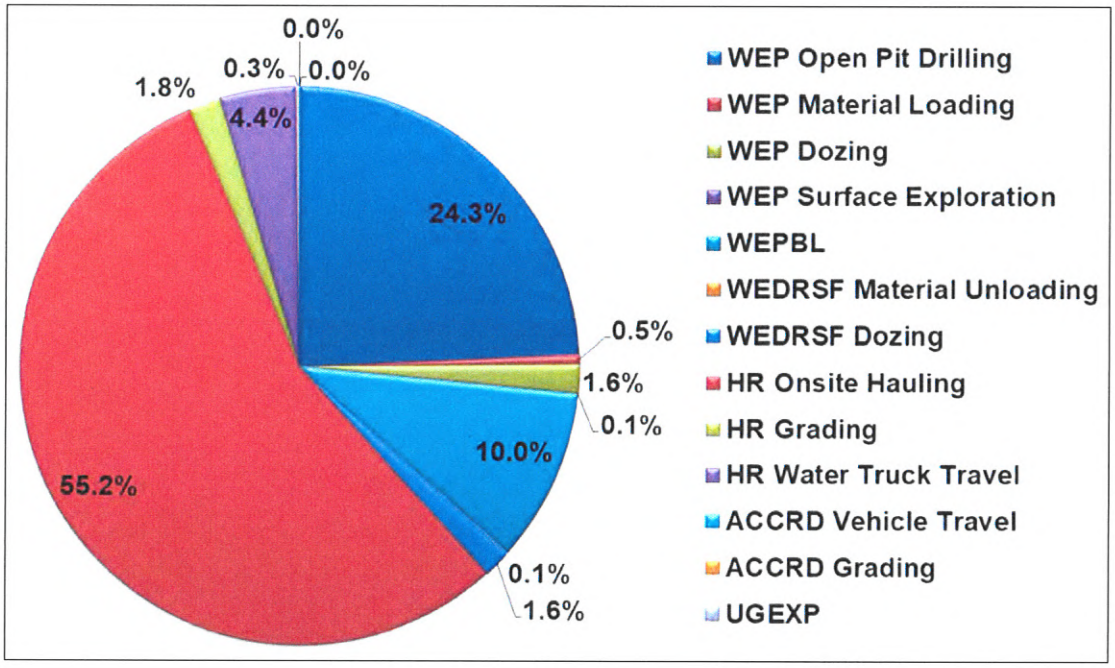

Figure 13 shows that onsite hauling on haul roads ("HR Onsite Hauling") accounts for 55.2% of the total daily PM_{10} emissions. Open pit drilling at the WEP ("WEP Open Pit Drilling") and blasting ("WEPBL") account for 24.3% and 10.0% of the daily PM_{10} emissions, respectively. Therefore, it is not surprising that HR, WEP, and WEPBL are associated with the highest modeled design concentrations in Table 29.

Table 31 shows the ten highest-ranked modeled 24-hour PM_{10} impacts from each emission source group. Note that for 24-hour PM_{10}, the design value is the *second-highest* 24-hour average concentration in a given year. Therefore, the second-high modeled value for source group ALL (121.5 $\mu g/m^3$) was summed

with the background concentration for comparison to NAAQS. The calculated total impact (modeled design value + background concentration) is conservative because the background value that was used in the cumulative NAAQS impact analyses (37.0 μg/m^3) represents the *first-highest* 24-hour average concentration measured in 2014.

Table 31. TEN HIGHEST-RANKED MODELED 24-HOUR PM_{10} IMPACTS IN μg/m^3 FROM DIFFERENT SOURCE GROUPS (SCENARIO W5, BULKRN METEOROLOGICAL DATA).

Given a background of 37.0 μg/m^3 and a NAAQS of 150 μg/m^3, the critical modeled concentration threshold for any 24-hour PM_{10} NAAQS violation is therefore 113.0 μg/m^3. Table 31 shows that the third-high modeled value for source group ALL (113.4 μg/m^3) barely exceeds NAAQS. Fourth-high (and lower-ranked) modeled impacts, when added to the background concentration, are below NAAQS.

As discussed earlier in this section, HR Onsite Hauling, WEP Open Pit Drilling, and WEP Blasting are the three largest components of the total daily PM_{10} emissions. Therefore, it is not surprising that HR, WEP, and WEPBL are associated with the highest modeled concentrations among all source groups.

To investigate the potential culpability of each source group to the modeled 24-hour PM_{10} NAAQS violation, DEQ performed a culpability analysis using the MAXIFILE output option in AERMOD. The MAXIFILE option provides the receptor location and date of an impact. DEQ performed two MAXIFILE runs. In the first MAXIFILE simulation, the model was run using source group ALL. A threshold value (113.0 μg/m^3) equal to the NAAQS minus background was set. The output file provided a list of the receptors where the NAAQS is exceeded. In the second MAXIFILE simulation, the model was run using only the receptors identified by the first MAXIFILE run. Source groups were included in the second modeling simulation. A threshold value equal to the 24-hour PM_{10} SIL (5.0 μg/m^3) was set. The output file provided a date stamp for any day when a source group exceeds the SIL and potentially contributes to a violation of the NAAQS. A significant contribution to a NAAQS violation would be predicted to occur if the date stamps for source group ALL (from the first MAXIFILE run) and for a specific source group (from the second MAXIFILE run) matched.

DEQ's culpability analyses confirm that emission source groups HR and WEP are culpable for the 24-hour PM_{10} NAAQS exceedances. The date stamps indicate NAAQS violations during the winter season (January 6, January 15, and December 23). We show next that when modeled emissions are more-closely

representative of typical daily mining production rates for a high-production period (everything else held constant), the SGP facility is able to demonstrate compliance with 24-hour PM_{10} NAAQS at those few receptors showing a potential violation when using meteorological data processed with the BULKRN method. We also discuss next the implication of NAAQS violations occurring during the winter season.

As listed in Table 30, PM_{10} modeling simulation for Scenario W5 was based on a mining production rate of 180,000 ton/day of development rock. This corresponds to 65,700,000 ton/year, which is more conservative than the expected peak production rate of 42,692,000 ton/year (116,964 ton/day). To investigate the effect of a lower modeled mining production rate on design value concentrations, DEQ performed a modeling simulation ("DEQ Run 1") where mining production rate was assumed to be 120,000 ton/day instead of 180,000 ton/day, but all other model variables were held constant. This adjustment lowered the modeled daily emission rates for WEP, WEDRSF, and HR, which are summarized in Table 32. Because the modeled emission rates were lower, the modeled design concentrations were also lower. Results for DEQ's sensitivity analyses are summarized in Table 33.

c. Back. Conc. = background concentration.
d. Total Conc. = total (modeled + background) concentration.
e. Particulate matter with an aerodynamic diameter less than or equal to a nominal 10 micrometers.
f. DEQ Run 1: mining production rate was modeled at 120,000 ton/day instead of 180,000 ton/day. Everything else was held constant.
g. For 24-hour PM_{10}, the design value is the *second-highest* 24-hour average concentration in a given year. However, the background value that was used in the modeling analyses represents the *first-highest* 24-hour average concentration measured in 2014. Therefore, using a larger background concentration adds a layer of conservatism to the calculated total impact for 24-hour PM_{10}.

Maximum modeled concentration for "DEQ Run 1", when summed with the background concentration, is lower than NAAQS thereby demonstrating NAAQS compliance. Total (modeled + background) concentrations for all hotspot receptors are depicted in Figure 14; maximum total impact is depicted by the red circle. The SGP facility complies with the 24-hour PM_{10} NAAQS when daily mining production rates closer to a more typical daily rate for a high-production period are used in the model, instead of a very conservative mining production rate, even when using site-specific BULKRN meteorological data.

Figure 14. RESULTS FOR DEQ'S SENSITIVITY ANALYSES SHOWING TOTAL (MODELED + BACKGROUND) 24-HOUR PM_{10} CONCENTRATIONS AT HOTSPOT RECEPTORS (SCENARIO W5, BULKRN METEOROLOGICAL DATA).

REC 4265

Meteorological data processing with and without BULKRN are considered acceptable by EPA. However, the BULKRN meteorological data yielded higher modeled design values for the SGP facility than the meteorological data processed without the BULKRN method. DEQ's analyses suggest that when daily mining production rates closer to a more typical daily rate for a high-production period are used (everything else held constant), the SGP facility is able to demonstrate compliance with 24-hour PM_{10} NAAQS at those few receptors showing a potential violation when using meteorological data processed with the BULKRN method.

Maximum modeled design value 24-hour PM_{10} impacts, even with the use of more reasonably expected daily production rates, are still just under the 150 $\mu g/m^3$ NAAQS. As noted earlier in this section, these high values were observed during the winter season. During this period, not only are fugitive emissions minimized because of the higher moisture content of material handled or driven over, but background concentrations in such remote areas are generally much lower because of the absence of wildfires and dust-generating sources.

To summarize, DEQ considered the following assumptions and results in its weight-of-evidence analyses:

a. All modeled impacts are below NAAQS for meteorological data with stability parameters calculated by regional cloud cover data.
b. Modeled impacts over the 24-hour PM_{10} NAAQS using BULKRN meteorological data are limited to a small area and limited period of time.
c. Modeled 24-hour PM_{10} NAAQS exceedances are limited to the winter season, where emissions and background levels are likely overestimated.
d. The model assumes maximum allowable operations/emissions.
e. The model assumes minimum allowable controls on emissions. The permit would require at least 93% control of maximum potential fugitive emissions, but the fugitive emissions may in fact be controlled by more than that, especially during winter and periods of precipitation.
f. Finally, 24-hour PM_{10} background concentrations represent the maximum 1st high (instead of the maximum 2nd high) which is on the higher end of the distribution.

DEQ's weight-of-evidence analyses show that, considering all the collective conservative layers of the modeling analyses, modeling efforts using both site-specific and alternative meteorological datasets show acceptable impacts. DEQ is highly confident that operation of the SGP will not cause or contribute to a violation of NAAQS. This is based on: (1) the submitted application materials and analyses; (2) DEQ's supplemental analyses; and (3) the assumption that the facility is constructed and operated as described in the application and limited by the PTC.

4.1.5 DEQ's Sensitivity Analyses for a Lower Fugitive Road Dust Control Efficiency

Fugitive particulate emissions from roadways were estimated by the applicant to be controlled above 93%, which is an aggressive level of control. The high level of emission control was needed to demonstrate compliance with NAAQS. To investigate the effect of lower unpaved road emission control efficiency, DEQ performed a modeling simulation ("DEQ Run 2") where the control efficiency was set to 90%. The daily mining production rate was assumed to be 120,000 ton/day instead of 180,000 ton/day, but everything else was held constant. These adjustments lowered the daily modeled emission rates for WEP and WEDRSF, but increased the daily modeled emission rate for HR and the Access Road (ACCRD) (Table 34). Five receptors exceed the 24-hour PM_{10} NAAQS. Figure 15 shows the locations of these receptors.

REC 4267

TR 0952

Figure 15. RESULTS FOR DEQ'S SENSITIVITY ANALYSES SHOWING HOTSPOT RECEPTORS THAT EXCEED 24-HOUR PM_{10} NAAQS, ASSUMING MINING PRODUCTION RATE OF 120,000 TONS PER DAY AND FUGITIVE ROAD DUST CONTROL EFFICIENCY OF 90% (SCENARIO W5, BULKRN METEOROLOGICAL DATA).

DEQ's sensitivity analyses suggest that a few hotspot receptors exceed the 24-hour PM_{10} NAAQS when the unpaved road control efficiency falls below 93% and the meteorological data processed with the BULKRN method is used. When the meteorological data processed without the BULKRN method is used, all the hotspot receptors demonstrate compliance with NAAQS at a 90% control efficiency and at both examined production levels:

- maximum impact at 120,000 ton per day: 73.9 $\mu g/m^3$ + 37.0 $\mu g/m^3$ = 110.9 $\mu g/m^3$.
- maximum impact at 180,000 ton per day: 84.6 $\mu g/m^3$ + 37.0 $\mu g/m^3$ = 121.6 $\mu g/m^3$.

While using alternative meteorological data processed without the BULKRN method safely demonstrates

compliance with NAAQS, using site-specific BULKRN meteorological data does not. Therefore, DEQ's modeling team recommends that the permit require an aggressive implementation of measures to achieve above 93% control efficiency for fugitive particulate emissions from roadways.

4.2 Results for TAPs Impact Analyses

The SGP TAP modeling results and their comparison with the applicable AACs/AACCs are provided in Table 35.

Table 35. RESULTS FOR TAPS IMPACT ANALYSES.

Toxic Air Pollutant	Averaging Time	Maximum Modeled Concentration ($\mu g/m^3$)[a]	Model Scenario	AAC[b] ($\mu g/m^3$)	AACC[c] ($\mu g/m^3$)	Percent of AAC/AACC
Arsenic	Annual	<1.00E-06	All	--	0.00023	<0.4%
Cadmium	Annual	0.00001	All	--	0.00056	1.8%
Formaldehyde	Annual	0.00064[d]	All	--	0.077	0.8%
Nickel	Annual	0.00002	All	--	0.042	0.05%
Aluminum	24-hour	27.454	W5	500	--	5.5%

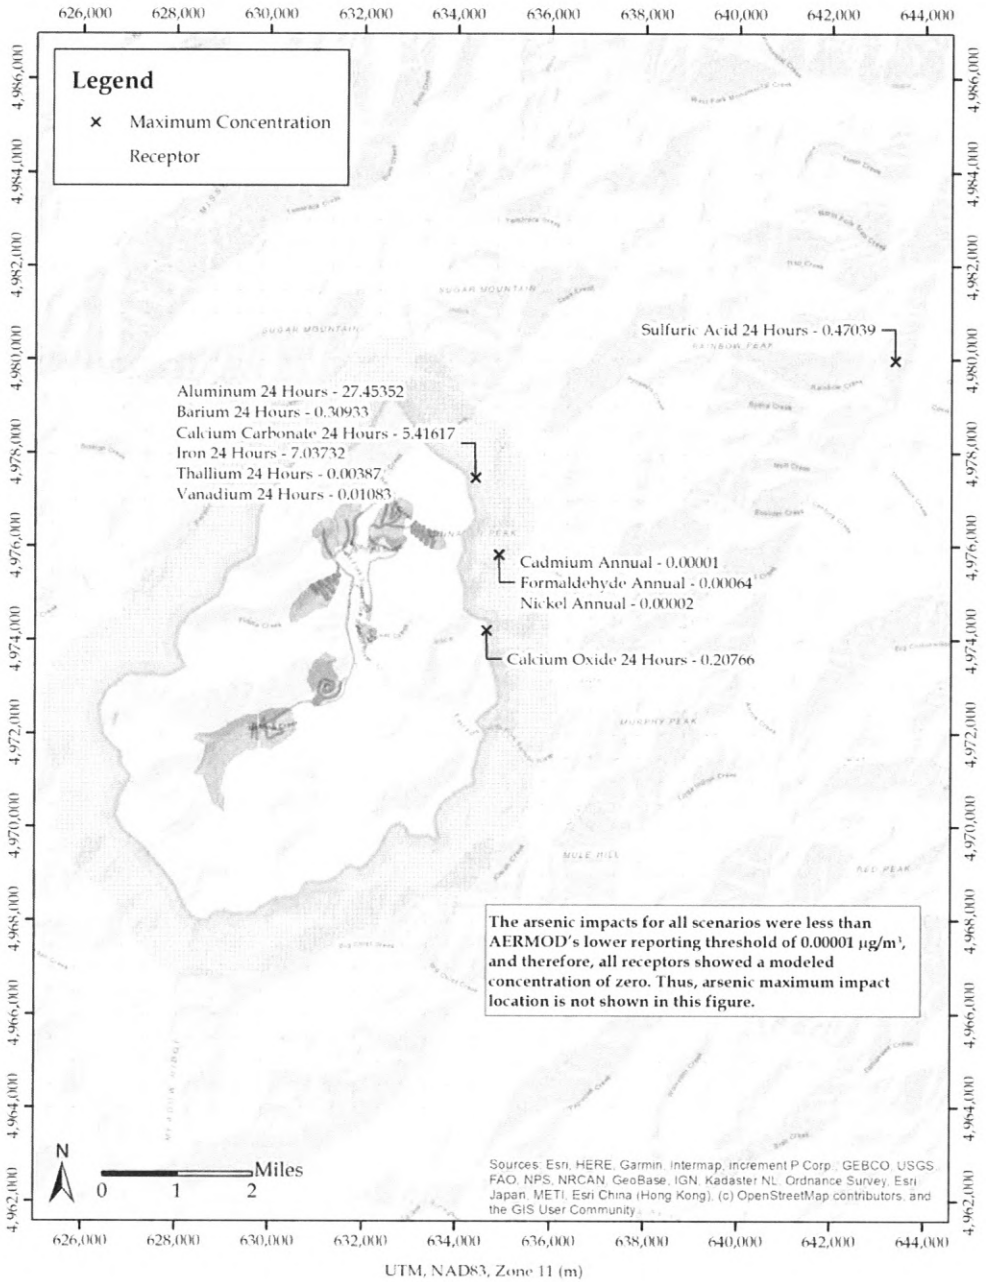
Vanadium	24-hour	0.0108	W5	2.5	--	0.4%



a. Micrograms per cubic meter.
b. Acceptable Ambient Concentration of a non-carcinogenic TAP.
c. Acceptable Ambient Concentration of a Carcinogenic TAP.
d. Deposition was not applied for formaldehyde and sulfuric acid (non-particulate TAPs).

Table 35 shows that the modeled TAP impacts from the SGP sources do not exceed the applicable AACs/AACCs. The locations of the maximum impacts for each TAP are presented in Figure 16.

REC 4269

TR 0954

Figure 16. SGP TAP IMPACTS (µg/m³) AND LOCATIONS.

To investigate the effect of deposition on modeled TAP impacts, DEQ performed a sensitivity analysis where deposition was not applied in the model (Table 36). Results show that modeled TAP impacts for non-carcinogens are higher than when deposition is applied (Table 35). However, modeled TAP impacts are still well below AACs/AACCs even when deposition is not applied in the model. This result illustrates that deposition is not a critical factor for demonstrating compliance with TAP increments.

Table 36. RESULTS FOR DEQ'S SENSITIVITY ANALYSES FOR TAPS IMPACT MODELING (WITHOUT DEPOSITION).						
Toxic Air Pollutant	**Averaging Time**	**Maximum Modeled Concentration ($\mu g/m^3$)[a]**	**Model Scenario**	**AAC[b] ($\mu g/m^3$)**	**AACC[c] ($\mu g/m^3$)**	**Percent of AAC/AACC**
Arsenic	Annual	<1.00E-06	All	--	0.00023	<0.4%

a. Micrograms per cubic meter.
b. Acceptable Ambient Concentration of a non-carcinogenic TAP.
c. Acceptable Ambient Concentration of a Carcinogenic TAP.

5.0 Conclusions

The information submitted with the PTC application, combined with DEQ's air impact analyses and the assumption that the facility is constructed and operated as described in the application and limited by the PTC, demonstrated to DEQ's satisfaction that emissions from the Stibnite Gold Project in Valley County, Idaho will not cause or significantly contribute to a violation of any applicable ambient air quality standard or TAP increment.

APPENDIX F – SUBSECTION 210.20 INTERPRETATION OF ADDRESSED

STATE OF IDAHO
DEPARTMENT OF
ENVIRONMENTAL QUALITY

1410 N Hilton Street, Boise, ID 83706
(208) 373-0502

Brad Little, Governor
Jess Byrne, Director

Examples of How DEQ Interprets the Word "Addressed" in Subsection 210.20

For example, 40 CFR 63 Subpart 6J - National Emission Standards for Hazardous Air Pollutants for Industrial, Commercial, and Institutional Boilers Area Sources regulates HAP emissions from coal, biomass, and oil-fired boilers. However, the subpart specifically exempts gas-fired (i.e. natural gas-fired) boilers because EPA determined that HAP emissions from these sources were too inconsequential to be regulated by the Subpart. DEQ interprets this to mean EPA did "address" natural gas boiler HAP emissions by choosing to exempt them. Thus, HAP emissions that are also TAP emissions from coal, biomass, oil-fired boilers, and natural gas-fired boilers are not required to demonstrate compliance with IDAPA 58.01.01.210 per section 210.20.

For example, 40 CFR 63 Subpart ZZZZ - National Emissions Standards for Hazardous Air Pollutants for Stationary Reciprocating Internal Combustion Engines regulates HAP emissions from IC engines by regulating CO emissions as a surrogate for HAP emissions. Therefore, HAP emissions from IC engines are not directly regulated by the Subpart. DEQ interprets this to mean EPA "addressed" HAP emissions by regulating CO emissions as a surrogate. Therefore HAP emissions that are also TAP emissions from IC engines are not required to demonstrate compliance with IDAPA 58.01.01.210 per section 210.20.

For example, HAP/TAP emissions from lumber drying kilns were evaluated in promulgating 40 CFR 63 Subpart DDDD - National Emission Standard for Hazardous Air Pollutants: Plywood and Composite Wood Products (PCWP). This Subpart regulates major sources of HAP emissions and includes lumber drying kilns at PCWP manufacturing facilities and "at any other kind of facility" as affected sources, even though this subpart does not include any substantive requirements to control or limit emissions from the kilns. In developing Subpart DDDD EPA stated "…we know of no other lumber kilns that are controlled for HAP, and we know of no cost effective HAP controls for lumber kilns…" (see Fed. Reg. /Vol 68, No. 6/Thursday, Jan 9, 2003/Proposed Rules page 1285). DEQ interprets this to mean EPA "addressed" HAPS that are also TAPS for both major and minor sources of HAP emissions; and therefore, lumber kilns are not required to demonstrate compliance with IDAPA 58.01.01.210, per section 210.20.

For example, when EPA regulated Phosphoric Acid Manufacturing for new sources, only the wet-process phosphoric acid line, superphosphoric acid process line, phosphate rock dryer, and the phosphate rock calciner have specific emissions limits in the rule. However, other emissions sources at facility were also looked at but they were determined by EPA to be insignificant and were not regulated in the rule. Therefore, when EPA looks at a source category to regulate, all emissions sources associated with the source category are "addressed" whether EPA establishes specific emissions limits for the emissions sources or not.
In sum, the term "addressed" is interpreted to mean EPA (1) specifically regulated, (2) specifically regulated by a surrogate, (3) reviewed, or (4) evaluated, the HAP emissions that are also TAPs.

Please note that in all cases it is presumed that EPA evaluated the 187 HAPs when developing the emission standards for new, modified or existing stationary sources regulated by 40 CFR Part 63 Subparts. Therefore, in all cases IDAPA Toxic Air Pollutants that are not one of the 187 Hazardous Air Pollutants will still need to be evaluated for compliance with IDAPA 58.01.01 Section 210.

EXPERT DECLARATION OF THERESA LOPEZ

PERPETUA RESOURCES EXHIBIT
201

I, Theresa Lopez, hereby declare and affirm as follows:

1. My name is Theresa Lopez. I am employed by Tetra Tech, Inc. as a Principal Toxicologist.

2. In addition to this Declaration, I have prepared a supporting memorandum that further elaborates on my testimony (Memorandum). A copy is attached.

A. Qualifications and Experience

3. My curriculum vitae is attached as Attachment C to the Memorandum.

4. I received a Master of Science degree in Public Health from the University of Colorado in 1991 and a Bachelor of Science degree in Nutritional Science with a minor in Zoology from the University of Florida in 1989. My relevant areas of expertise include chemical risk assessment, human health risk assessment, regulatory toxicology, and exposure assessments.

5. I worked extensively in the areas of public health, epidemiology, human health risk assessment, toxicology, and occupational health and safety, representing both the public and private sector for over 32 years with Tetra Tech.

6. My work included a variety of human health risk assessment projects at the federal and state levels, as well as international work. I led the investigation and assessment of chemical releases and environmentally compromised sites such as former nuclear weapons plants, active and closing naval bases, Superfund Sites, and mining, commercial, and school sites.

7. My work includes assisting in risk assessments and remediation of former mining sites with heavy metal, pesticides, petroleum compounds and other chemicals; and risk assessments for proposed mines, hazardous waste release sites, and petroleum remediation in the United States and Canada. I prepared human exposure assessments for schools and recreational settings and assessed clean-up goals and remediation strategies for closed industrial, mining,

redevelopment, and other sites. These sites often include the consideration of native and indigenous peoples. I provided exposure and dose reconstruction for Oak Ridge Associated Universities to quantify radiation doses to former nuclear weapons workers.

8. Recent relevant work includes review of human exposures, livestock exposures, plant, and food ingestion pathways for the development of water quality standards for the Navajo Nation; technical support for the Agency for Toxic Substances and Disease Registry (ATSDR) to provide scientific advise and education on public health assessment methodologies, review of toxicity data, and probabilistic risk assessment methodology, and primary experiments, for example to assess uptake measurements of metals and PFAS from soil to common food plants; and peer review of chemical assessments for the Consumer Product Safety Commission. I author and review reports for Health Canada related to Existing Substances Risk Assessment Bureau mandates. For these projects I am often designated as lead toxicologist.

B. Scope of Review

9. I have been retained as an expert witness by Perpetua Resources Idaho, Inc. (Perpetua) in the above-captioned case, to address issues raised in the Final Order issued by the Board of Environmental Quality on May 9, 2024 and to evaluate the risks presented by emissions of arsenic from the Stibnite Gold Project (SGP). Specifically, I have been asked to evaluate:

a. Whether the Idaho Department of Environmental Quality (DEQ) used appropriate risk assessment methodology by adjusting the maximum modeled lifetime arsenic emissions from the SGP by 16/70 to reflect the operational life of the SGP;

b. Whether, as conditioned by the Air Quality Permit to Construct (PTC) issued to Perpetua, arsenic emissions from the SGP present a greater than 1 in 100,000 cancer risk; and

c. Whether DEQ's use of a five-year rolling average production limit to demonstrate compliance with T-RACT is protective of public health and the environment.

C. Summary of Opinions

10. Based on my review of the permitting record in this matter, the Declarations of Norka Paden, Kevin Schilling, and Kevin Lewis, and the documents cited in, and attached to, my Memorandum, I conclude as follows:

a. I conclude that the 16/70 calculation was consistent with good scientific methodology for assessing cancer risk and consistent with the applicable rules. DEQ appropriately calculated, and considered, the exposure duration of 16 years of SGP operational life when evaluating the risk posed by arsenic emissions from the SGP. Cancer risk cannot be evaluated without taking into consideration the length of time a potential receptor will be exposed to carcinogen.

b. The Rules for the Control of Air Pollution in Idaho (Air Rules), IDAPA 58.01.01, provide a default formula for calculating cancer risk from carcinogen emissions from stationary sources. The Air Rules, specifically Section 586, adopted EPA risk assessment information and methodology, which inherently requires consideration of exposure duration.

c. The use of a 10-times adjustment to the Acceptable Ambient Concentration for Carcinogens (AACC) when a project will operate for five years or less is an example of an adjustment of exposure duration when evaluating cancer risk and does not preclude adjustment for exposure duration when a project will operate for less than 70 years.

d. I conclude that the incremental increase in cancer risk caused by arsenic emissions from the SGP is 1 in 240,000, which is less than the acceptable risk of 1

in 100,000. This conclusion is based on the maximum modeled annual concentration of arsenic predicted for SGP operations, the operational life of the SGP established by conditions in the PTC, and risk assessment methodology established by EPA.

e. I conclude that the use of a five-year rolling average production limit to demonstrate compliance with T-RACT is sufficiently protective to ensure that the ambient concentration of arsenic from the SGP will not cause a cancer risk above 1 in 100,000.

f. The PTC includes both daily production limits and limits production from the SGP to 135,000 tons per year based on a five-year rolling average. EPA's risk assessment methodology evaluates the incremental increase in cancer risk for each incremental increase in carcinogen dose over the exposure duration. Use of a five-year rolling average ensures that a receptor's total exposure to arsenic caused by the SGP will not exceed a 1 in 100,000 cancer risk. Although there may be short term increases in production, and the ambient concentration of arsenic, these short-term increases will not, alone, cause unacceptable cancer risk.

D. Background

11. Arsenic comes in several forms and occurs naturally in soil and minerals. Arsenic can enter the atmosphere from wind-blown dust. Arsenic concentrations in soil are variable across the country, and when soil is disturbed arsenic can become airborne and be carried with dust particles. Since arsenic is naturally in the environment, everyone is exposed to some arsenic by eating food, drinking water, or breathing air. People normally ingest small amounts of arsenic from breathing air, drinking water, and eating food. Indeed, food is considered the largest source of arsenic exposure for humans.

12. EPA analyzes the long-term, or carcinogenic, health effects of arsenic through animal and worker studies. The arsenic inhalation unit risk (IUR) published by EPA in the Integration Risk Information System (IRIS) reflects many years of research and evaluation and was developed using a linear extrapolation method that assumes that any level of exposure carries a risk. Under a linear risk extrapolation method, the dose is cumulative over the duration of exposure and cancer risk increases linearly as the cumulative total dose increases. Exposure is assumed to occur over a lifetime, assumed to be 70 years. See Memorandum, Figure 1.

13. All IURs (including for arsenic) are based on an incremental lifetime risk of 1 in one million from exposure to 1 $\mu g/m^3$ of a substance continuously (24 hours day and 365 days/ year) over a lifetime of exposure (assumed to be 70 years). Importantly, this is an incremental risk that does not consider other, unrelated risks present over a lifetime.

14. DEQ adopted EPA's cancer risk values and risk assessment methodology when it promulgated the Air Rules for toxic air pollutants from stationary sources. IDAPA 58.01.01.586; Memorandum at 5-7; Memorandum, Attachment A, Idaho DEQ 1993 at 33.

15. The unit risk factor (URF) of 4.3E-03$\mu g/m^3$ for arsenic that DEQ adopted in IDAPA 58.01.01.586 is the IUR developed by EPA and reflected in the IRIS.

16. Similarly, the AACC that DEQ adopted in IDAPA 58.01.01.586 is taken from the IRIS database and is referred to by EPA as the "Air Concentration at Specific Risk Levels." The AACC is calculated by dividing the acceptable lifetime risk (1 in 1,000,000) by the URF. See Memorandum, Figure 1.

17. The AACC in Section 586 of the Air Rules reflects the ambient concentration of arsenic to which a person could be exposed 24 hours a day, 365 days a year, for a 70-year lifetime before the cancer risk level exceeds 1 in 1,000,000 (AACC = 0.00023$\mu g/m^3$).

18. The AACC does not represent an annual emission limit; it is the concentration that a person may be exposed to for a lifetime continuously, with an incremental risk of cancer of 1 in 1,000,000. *See* Idaho DEQ 1993 at 32.

19. Both the URF and AACC are derived using a linear risk extrapolation method, meaning that cancer risk from arsenic exposure increases linearly as the dose or exposure duration increases. See Memorandum at 4. Therefore, although the URF and AACC are based on lifetime exposure, the ultimate determinate of cancer risk is the cumulative dose, regardless of the timeframe over which that dose is delivered.

E. Opinions

DEQ Appropriately Adjusted the Exposure Duration of SGP to 16 Years Consistent with Permit Conditions Limiting the Project Life.

20. When considering carcinogenic exposure, a critical factor to determine the cancer risk is the exposure duration. Although the AACC assumes a 70-year constant exposure, where the exposure duration is less than 70 years, the exposure duration must be adjusted for an accurate risk calculation. In the case of the SGP, the maximum exposure duration is 16 years. Therefore, the cancer risk from the ambient concentration of arsenic caused by the SGP cannot be compared to the AACC (that assumes 70 years) without adjusting for exposure duration.

21. Comparing unadjusted emissions to the AACC would result in an over-estimation of cancer risk because the dose will not continue for the 70-year lifetime exposure assumed

in the development of the AACC. For an "apples to apples" comparison, evaluation of SGP emissions must be adjusted for the shorter exposure duration.

22. EPA provides the following formula to compare the exposure concentration from a project that operates for less than 70 years to the lifetime exposure concentration that would cause a specified cancer risk (shaded notes are presented by author for clarification):

Cair-adj=Cair x ET x 1day/24 hours x EF x ED/AT

Where:
$C_{air-adj}$ = Air Concentration adjusted for exposure
C_{air} = Concentration of contaminant in air (mg/m^3) (this is the modeled or measured annual air concentration)
ET = Exposure time (hours/day) (this is assumed to be 24 hours/day)
EF = Exposure frequency (days/year) (this is assumed to be 365 days/year)
ED = Exposure duration (years) (this is 16 years – the life of operations)
AT = Averaging time (days) (this is lifetime – 70 years x 365 days/year; it never changes for any carcinogen)

See Memorandum at 9-10.

23. DEQ used this formula when it determined the acceptable risk from the ambient arsenic concentration caused by SGP operations.

24. Using the highest modelled annual average arsenic concentration from the project of 0.00414 $\mu g/m^3$ (REC 716) the calculation of the air concentration adjusted for exposure from the SGP is as follows:

$$\left[0.00414\,\frac{\mu g}{m3}\,x\,24\,\frac{hours}{day}\,x\,\frac{1\,day}{24\,hours}\,x\,365\,\frac{days}{year}\,x\,16\,years\right] / \left[365\,\frac{days}{year}\,x\,70\,years\right] = 0.00095\,\frac{\mu g}{m3}$$

25. Using EPA methodology, as adopted by DEQ, the adjusted lifetime-exposure concentration from the SGP is 0.00095$\mu g/m^3$. This is the correct project-specific arsenic

concentration to compare to the T-RACT AACC of 0.0023 µg/ m^3 for a cancer risk of 1:100,000. *See* REC 716.

The Cancer Risk Caused by Arsenic Emissions from the SGP is 1-in-240,000 -- Less than the Acceptable Risk of 1-in-100,000.

26. The highest air concentration of arsenic from the project is below the acceptable lifetime risk established by the T-RACT AACC.

27. Once the ambient arsenic concentration has been adjusted from a lifetime exposure to a project specific duration, to provide an "apples-to-apples" comparison to the AACC, then that ambient concentration is used to determine the cancer risk from arsenic from SGP.

28. Calculation of the incremental increase in cancer risk from SGP arsenic emissions is as follows:

$$\frac{1}{100{,}000} T\text{–}RACT\ Risk\ x\ 0.00095 \frac{\mu g}{m3} C_{air-adj} \,/\, 0.0023 \frac{\mu g}{m3}\ T\text{–}RACT\ AACC$$
$$= 4.1E\text{–}6\ or\ \frac{1}{240{,}000} Actual\ Risk$$

29. The incremental increase in cancer risk from SGP arsenic emissions is 1 in 240,000, meaning that if 240,000 people are exposed to the maximum ambient arsenic air concentration from the SGP continuously over 16 years, then one excess cancer would probabilistically be expected to develop over a lifetime. This is less than 1 excess cancer in 100,000 people, which is the acceptable risk limit in the T-RACT AACC for SGP.

30. DEQ utilized the formulas described in paragraphs 24 and 28 to compare the risk of exposure to arsenic emissions from the SGP. This analysis is consistent with EPA methodology and provides an "apples to apples" comparison of risk between SGP emissions of 16 years and the AACC concentration that assumes exposure over 70 years.

31. DEQ's assessment ensured that the PTC, and the conditions imposed on SGP, would ensure that the cancer risk from SGP emissions would be less than 1-in-100,000.

32. Section 210.15 of the Air Rules is an example of the proper adjustment for exposure duration and does not preclude this adjustment in other circumstances for an "apples to apples" comparison, where the project life is limited to less than 70 years.

33. In its analysis, DEQ analogized the SGP exposure duration adjustment to the short-term adjustment factor for sources that operate for 5 years or less in Section 210.15 of the Air Rules. The Final Order expressed concern that the Air Rules do not explicitly allow for an adjustment for sources that will operate for more than 5 years but less than 70 years.

34. Section 210.15 of the Air Rules is an example of an appropriate adjustment for exposure duration. This is consistent with EPA's methods for risk assessment and reliance on the URFs and AACCs. Sections 210.02 and 210.03 allow DEQ to develop analyses using project specific information, such as exposure duration. In my opinion these rules cannot be read to impede DEQ's use of EPA's methods and scientific practices to perform an appropriate risk assessment under the Air Rules.

35. Adjusting exposure duration is necessary and proper from a scientific and toxicological standpoint to apply the AACCs accurately. Omitting this adjustment is contrary to common scientific practice and the intent of the Air Rules as reflect DEQ documents. Memorandum Attachment A, References, Idaho DEQ 1992 and Idaho DEQ 1993.

36. This is particularly true when comparing project specific risk to the AACC because the AACC, and the URF upon which it is based, assumes a 70 year (lifetime) exposure.

37. The AACCs are not annual average air concentration limits or standards.

38. Treating the AACC as an annual emission limitation or annual limit on ambient exposure concentration is inconsistent with the purpose and development of the AACC. The

AACC is an ambient concentration that if emitted over time (default 70 years) could result in a risk of cancer response.

39. Treating the AACC as an annual emissions limitation significantly lowers acceptable risk. If the T-RACT AACC of 0.0023 $\mu g/m^3$ for arsenic were based on a one-year exposure, then the risk represented by that value would be about 1-in-7,000,000.

40. The URF and the AACC derived from it represent the upper-bound excess lifetime cancer risk estimated to result from continuous exposure to a contaminant over a lifetime at an air concentration of 1 $\mu g/m^3$.

41. In other words, the AACC and T-RACT AACC represent the chemical-specific airborne concentration at which the risk to an individual if exposed all day, every day for a lifetime is 1-in-1,000,000 (AACC) or 1-in-100,000 (T-RACT AACC). Any other interpretation defies fundamental toxicological science used by the EPA in the development of IURs (URFs).

42. The AACC and T-RACT AACC do not represent the risk of a cancer response following a single exposure.

The Use of a Five-Year Rolling Average Production Limit to Demonstrate Compliance with T-RACT is Sufficiently Protective to Ensure that the Ambient Concentration of Arsenic from the SGP Will Not Cause a Cancer Risk Above 1-in-100,000.

43. Finally, use of a 5-year rolling average production limit is as protective as an annual production limit, for purposes of determining an acceptable cancer risk.

44. Cancer risk increases from cumulative long-term exposure, not short-term annual emissions. Cancer risk is assessed based on total cumulative dose over the exposure duration, as demonstrated in the Memorandum, Figure 1, column D.

45. As shown in Figure 1, a total dose of 0.16 $\mu g/m^3$ of arsenic would cause an increased cancer risk of 1-in-100,000. The risk does not change if this total cumulative dose occurs in 1 year, 5 years, 16 years, or 70 years. Therefore, the 5-year rolling average is as protective as an annual production limit.

46. The 5-year average production limit ensures that if production is above the limit in one year, then future production must be reduced below the limit. This ensures that the cumulative ambient arsenic concentration does not exceed the acceptable ambient concentration level for the defined risk.

47. The 5-year average production limit in the PTC ensures that the ambient arsenic concentration from the SGP over the project life (exposure duration of 16 years) results in an acceptable cancer risk under the Air Rules.

I declare under penalty of perjury under the laws of the United States that the foregoing is true and correct to the best of my knowledge, information, and belief.

DATED: August 30, 2024.

Memorandum in Support of Declaration: DEQ's Review of Risk for the Stibnite Gold Project

TETRA TECH, INC.

Author:	Theresa Lopez MSPH Tetra Tech, Inc.
Date:	August 30, 2024
Subject:	Memorandum in Support of Declaration: DEQ's Review of Risk for the Stibnite Gold Project

I. INTRODUCTION

This memorandum and my opinions address certain of the issues remanded by the Idaho Board of Environmental Quality (Board) in *In re Matter of Air Quality Permit to Construct* P-2019.0047 regarding the Idaho Department of Environmental Quality's (DEQ) issuance on June 17, 2022 of a permit to construct (PTC) to Perpetua Resources Idaho, Inc. for the Stibnite Gold Project (SGP). This memorandum concludes that, as issued, the PTC for the SGP is protective of public health and establishes conditions that ensure a less than 1 in 100,000 cancer risk from worst-case exposure to arsenic, applying established toxicological principles. This memorandum confirms that the DEQ properly interpreted and applied the toxic air pollutant (TAPs) rules (including the ambient TAP carcinogenic increments and the acceptable risk represented by Sections 161, 210.12 and 586 of the Rules for the Control of Air Pollution in Idaho, IDAPA 58.01.01 (IDAPA or the Air Rules)) consistent with scientific methods and EPA guidelines.

II. STATEMENT OF QUALIFICATIONS

Attached hereto as Attachment C is a copy of my curriculum vitae.

III. DOCUMENTS REVIEWED

To form the opinions expressed in this memorandum, I reviewed the following documents:

- Board's Final Order
- PTC, issued June 17, 2022
- Statement of Basis (SOB) for the PTC issued June 17, 2022
- References listed in Attachment A
- Expert Declaration of Kevin Lewis (Filed Aug. 30, 2024)
- Expert Declaration of Kevin Schilling (Filed Aug. 13, 2024)
- Expert Declaration of Norka Paden (Filed Aug. 13, 2024)

IV. OVERVIEW OF ISSUES REMANDED BY THE BOARD AND ADDRESSED BY THIS MEMORANDUM

In its *Final Order* dated May 9, 2024, the Board remanded this case to the Hearing Officer for the development of further evidence related to DEQ's risk assessment for the Acceptable Ambient Concentration for Carcinogens (AACC) for arsenic as set forth in Section 586 of the Air Rules. Specifically, the Board directed that on remand, the Hearing Officer address the following:

- DEQ's application of the project exposure duration of 16 years when assessing compliance with the AACC. Specifically, the Board indicated that "DEQ did not provide sufficient evidence in the form of an expert opinion from a toxicologist or other qualified expert regarding the cancer risk associated with the 16/70 adjustment."
- DEQ's use of a five-year rolling average for T-RACT that the Board concluded was not supported by sufficient evidence.
- The T-RACT analysis limiting the non-West End Pit production limit.

This memorandum supports my expert opinion on the first two issues.

- This memorandum explains the role of exposure duration, including the current state of scientific methods for assessing risk from inhalation exposure and U.S. Environmental Protection Agency (EPA) directives on the use of toxicity values and risk assessment.
- This memorandum addresses the use by DEQ of a project specific adjustment factor of 16/70 to account for the operational life of the SGP.
- This memorandum addresses the use of a short-term adjustment factor, provided for in IDAPA 210.15 of the Air Rules, allowing a 10-times adjustment to the AACC for short-term projects. This is an example of the use of exposure duration in risk assessment, and adjustment for exposure duration in other risk assessments is also appropriate.
- This memorandum clarifies that AACCs are not annual average air concentration limits or standards.
- This memorandum explains why the use of a 5-year rolling average production limit is equally protective as an annual production limit.

V. TOXICOLOGY, THE TAPs RULES, AND ARSENIC

Toxicology is the study of the adverse effects (called "responses") of exposures to chemicals (as well as other compounds) on biological systems (called "doses"). In toxicology, dose-response is critical to characterizing risk of experiencing adverse effects. A dose-response assessment is a mathematical relationship between the extent of a biological response in an organism (if any) to a substance at varying levels of exposure (i.e., concentration) for varying periods of time (i.e., the duration of the exposure). The goal of a dose-response assessment is to define an exposure threshold above which a substance may cause adverse effects. In other words, the goal is to define the rate at which adverse effects may be experienced as the dose (concentration and exposure) increases.

EPA uses established dose-response assessments for various chemicals to characterize both non-cancer and cancer risks. For carcinogens, these assessments result in inhalation unit risk (IUR) values and are set forth in the EPA Integrated Risk Information System (IRIS). EPA uses the IUR to develop ambient concentrations that reflect cancer risk levels from continuous exposure over a 70-year lifetime. These concentrations can be found in the EPA IRIS.

Based on my review of the relevant documents, in my opinion, the foundation of the TAPs rules is consistent with the scientific principles underlying dose-response assessments that are established by EPA. IDAPA 586 reflects EPA risk assessment methodology that prompts adjustment of the exposure duration to assess the dose-response risk assessment properly. DEQ appropriately

considered exposure duration when applying the TAPs rules to the PTC, consistent with the EPA assessments on which they are based. In this PTC, DEQ applied the Air Rules consistent with the best available scientific practices in establishing cancer risk levels, and evaluating the environmental and health risks of exposure to arsenic from the SGP:

A. DEQ interpreted and applied the TAPs Rules consistent with EPA's risk assessment methodology including accepted scientific principles governing toxicity values, exposure evaluations, and cancer risk.
B. Based on EPA methods and DEQ policies and methodologies, DEQ appropriately adjusted the exposure duration to 16 years from the assumed 70 years reflecting conditions in the PTC that limit the project life to 16 years; this adjustment was necessary for a scientifically defensible "apples to apples" comparison with the AACC.
C. The highest air concentration projections modelled for arsenic emissions from SGP are below the acceptable lifetime risk established by the T-RACT AACC in IDAPA 586 and 210.12, and therefore, the PTC authorizes risks that are acceptable for human health and the environment.
D. IDAPA 210.15 allows for a 10-times adjustment to the AACC when a project will operate for 5 years or less. This is an example of applying exposure duration when evaluating cancer risk. The Air Rules do not limit DEQ's analyses that follow EPA methodology and scientific principles for exposure duration adjustment in risk assessment for permits issued under the Air Rules.
E. Idaho's AACCs are not annual average air concentration limits or standards.

As described in the *Final Order*, the primary TAP of concern from the SGP is Arsenic. Arsenic comes in several forms, occurs naturally in soil and minerals, and volcanic eruptions are a source of arsenic. Arsenic can enter the atmosphere from wind-blown dust. Arsenic concentrations in soil are variable, as some areas having higher arsenic levels than others. When soil is disturbed arsenic can become airborne and carried with dust particles. Since arsenic is naturally in the environment, everyone is exposed to some arsenic by eating food, drinking water, or breathing air. People normally ingest small amounts of arsenic from breathing air, drinking water, and eating food. "Of these, food is usually the largest source of arsenic. The predominant dietary source of arsenic is seafood, followed by rice/rice cereal, mushrooms, and poultry." (ATSDR 2007)

Impacts of arsenic exposure are also well-studied. Arsenic presents risks of both noncarcinogenic (acute) and carcinogenic (long-term) health effects. Long-term, or carcinogenic, health effects are evaluated through animal or worker studies. EPA states that risk assessment is a scientific process that depends on 3 factors: (2024 - About Risk Assessment | US EPA)

1. **How much of a stressor is present** in an environmental medium (e.g., soil, water, air) over what geographic area,
2. **How much contact (exposure)** a person has with that environmental medium, and
3. **How it affects** the health of humans (e.g., **toxicity)**

EPA published toxicity values for both carcinogenic and noncarcinogenic health effects of arsenic (EPA 1984). These toxicity values are the result of many years of research and evaluation. The

carcinogenic toxicity values for arsenic via inhalation were developed by EPA using a linear extrapolation method that assumes that any level of exposure carries a risk. EPA stated: "It is assumed, unless evidence exists to the contrary, that if a carcinogenic response occurs at the dose levels used in a study, then responses at all lower doses will occur with an incidence that can be determined by an appropriate extrapolation model." (EPA 1984). The linear model used by EPA incorporated 4 different studies and resulted in the calculation of an IUR of 4.3Ex 10^{-3} per $\mu g/m^3$ for arsenic. According to EPA, the mode provides a plausible estimate of the upper limit of risk; the true risk could be considerably lower. The figure below is one of several created by EPA; a combined figure for all studies from which the IUR was calculated is not available. (EPA 1984).

Figure 1

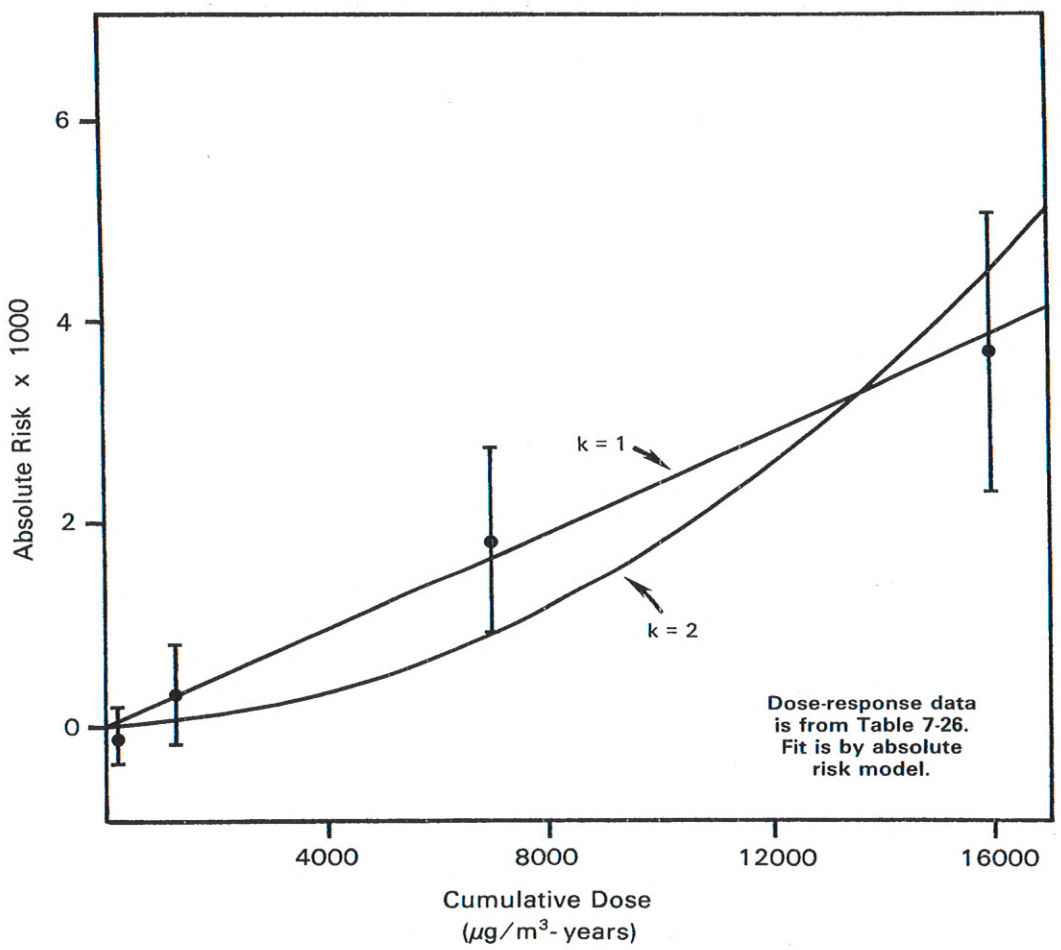

Figure 7-5. Absolute risks and 90% confidence limits for data of Higgins (1982).

The figure highlights EPA's scientific bases for risk assessment using the IUR for arsenic. The dose is cumulative. The exposure is assumed to occur over years. The IUR provides a measure of risk per unit exposure over a lifetime, assumed to be 70 years.

All IURs are based on an incremental lifetime risk of 1 in one million from exposure to 1 µg/m^3 of a substance continuously, every day over a lifetime of exposure (assumed to be 70 years). Importantly, this is an incremental risk considering unrelated risks present over a lifetime.[1]

VI. SUPPORT FOR OPINIONS INCLUDED IN DECLARATION

A. DEQ interpreted and applied the Air Rules to the SGP consistent with EPA's risk assessment methodology including accepted scientific principles governing toxicity values, exposure evaluations, and cancer risk.

DEQ adopted the EPA's values for assessment of risk in the TAPs rules. Correspondingly, DEQ adopted EPA's risk assessment methodology and underlying scientific principles governing those adopted values and risks. To interpret the Air Rules any other way would be to defy the science, toxicology, and application of these values established by EPA.

IDAPA 586 explicitly includes both a Unit Risk Factor (URF) and an Acceptable Ambient Concentration for Carcinogens (AACC) for each listed compound, including arsenic. Neither the URF (4.3E-03/µg/m^3) nor the AACC (2.3E-04 µg/m^3) for arsenic were developed by DEQ. EPA developed these values and published them in the IRIS (EPA 2024b), which is a database maintained by EPA (and only EPA). DEQ adopted these values into the TAPs Rules in 1993-1994. (Idaho DEQ 1992, Appendix 6; Idaho DEQ 1993)

DEQ adopted the URF directly from EPA's IUR, and the URF reflects the *cancer risk* based on continuous exposure to a concentration of 1 µg/m^3 of a particular compound over a lifetime. (Idaho DEQ 1992, Appendix 6; Idaho DEQ 1993). Separately, the AACC reflects that *ambient concentration* that would result in a 1 in 1 million risk of developing cancer assuming a constant exposure to that ambient concentration over a 70-year lifetime.

As noted above, the IUR represents the incremental increased cancer risk from a lifetime (70 years) inhalation exposure to a constant (24 hours/ day and 365 days/ year) dose concentration of 1 µg/m^3. In other words, the exposure duration is assumed within the IUR and the cancer risk assumes constant, lifetime (70 years) exposure. Because the IUR estimates cancer risk based on continuous

[1] The National Institute of Health (Cancer Statistics - NCI) states that approximately 40.5% of men and women in the US will be diagnosed with cancer at some point during their lifetimes (based on 2017–2019 data); that is roughly a risk of 4 persons in every 10 persons developing cancer over a lifetime. Risks of 1 in one million or one in 1 hundred thousand are very low. To put that risk in perspective, the National Oceanic and Atmospheric Association estimates that the chances of getting struck by lightning is much higher—1 in 15,300 in a lifetime (How Dangerous is Lightning? (weather.gov)

exposure to 1 µg/m^3 of a chemical over a lifetime (70 years), the IUR does not represent the lifetime risk of developing cancer after a single exposure.[2]

The URF in IDAPA 586 and the EPA IUR for arsenic are presented in Figure 1. EPA considers a lifetime to be 70 years. EPA recognizes that exposure duration is not always this long.

The AACC for each chemical is based on and derived from the EPA URF and a lifetime (70 years) exposure duration. The AACC is the identified risk divided by the URF. The AACC reflects the ambient concentration of arsenic to which a person could be exposed 24 hours a day, 365 days a year, for a 70-year lifetime before the identified cancer risk level is exceeded. The AACC value appears in EPA's IRIS database. EPA calls this value the "Air Concentration at Specific Risk Levels," and these levels assume a lifetime of 70 years and a constant exposure for 70 years.

Figure 1 illustrates: (A) risk level: (B) how the AACC is derived, (C) the AACC concentration, and (D) the ambient air concentration of arsenic that an individual would need to be exposed to for a full year to equal a full lifetime (70-year) exposure at a cancer risk expressed in the AACC (1 in 1,000,000).

Figure 2:
Inhalation Unit Risk — 4.3E-3 per (µg/m^3)
Extrapolation Method —absolute-risk linear model

A	B	C	D
Risk Level	**How AACC is derived *(risk level /URF)***	**AACC Concentration *(risk level/URF)***	**Annual Air Concentration equating to a 70-year constant exposure**
E-4 (1 in 10,000)	0.0001 / 4.3E-3	2.3E-2 µg/m^3	1.6 µg/m^3 (0.023 x 70 years)
E-5 (1 in 100,000)	0.00001 / 4.3E-3	2.3E-3 µg/m^3	0.16 µg/m^3 (0.0023 x 70 years)
E-6 (1 in 1,000,000)	0.000001 /4.3E-3	2.3E-4 µg/m^3	0.016 µg/m^3 (0.00023 x 70 years)

Source: Arsenic IUR from EPA [*Integrated Risk Information System (*Arsenic, inorganic (CASRN 7440-38-2) | IRIS | US EPA*), modified by adding Column B to illustrate how the AACC is derived and Column D showing the Annual Air Concentration equating to a 70-year constant exposure.]*

As illustrated, the risk in Column A may manifest when the annual air concentration shown in Column D is emitted 24 hours per day, 7 days per week, for 365 days in one year. One year of constant exposure at the levels in Column D is to equal the constant exposure of the AACC concentration in Column C, over 70 years.

DEQ applied the TAPs rules to the SGP consistent with EPA's risk assessment methodology including accepted scientific principles governing toxicity values, exposure evaluations, and cancer risk. The

[2] EPA IRIS defines Inhalation Unit Risk (called URF in the IDAPA 586 table) as: Inhalation unit risk (IUR) is an estimate of the increased cancer risk from inhalation exposure to a concentration of 1 µg/m^3 for a lifetime. The IUR can be multiplied by an estimate of lifetime exposure (in µg/m^3) to estimate the lifetime cancer risk.

worst case SGP annual air concentration is 0.00414 µg/m^3 (page 305 of 506 in the SOB dated 6/17/2022) and is significantly lower than the annual air concentrations in Column D. This means that if arsenic were emitted from SGP at the worst-case level (0.00414 µg/m^3) constantly for a single year, the dose would not equal the dose of the AACC level (Column C) over 70 years. The Board's concern that SGP could emit the equivalent of 70-year emissions in one year is not possible. I confirmed this conclusion applying EPA methods and common toxicology analyses.

DEQ also applied the TAPs rules to the SGP consistent with the agency's principles reflected in Idaho DEQ 1992 that explained the bases for the Board's adoption of the TAPs rules. The statements explain that EPA risk assessment methodology formed the foundation of the TAPs rules.[3] Specifically, the document directs use of refined modeling, consistent with guidance documents from EPA at the time, updated guidance on the use of URFs, and adjustments for exposure duration in the assessment of risk.

The statements explain the basis of the Board's adoption of the TAPS rules are consistent with DEQ's calculation of an exposure concentration, indicate that the AACCs are screening levels, allow for refined modeling as needed, and reference EPA as the source of URFs (and the AACCs) with the indication that their use should be consistent with EPA risk assessment guidance. The 1992 Meeting Packet refers to the AACCs (as well as all other TAPs values) as "screening levels." Specifically:

> The DEQ list of regulated air toxics is quite large in scope. However, this was not done to burden industry. Quite the contrary. It was done in order, to the maximum extent possible, provide industry with a ready reference to acceptable screening levels of these various compounds. This enables new sources to review their processes and see if controls, may be needed early on in the planning process, there by maximizing start up budget planning. In addition, it allows existing sources to review their emissions and see how they compare to the screening levels that DEQ considers reasonably protective of human health and the environment.

Appendix 6 describes that the exposure must be 24 hours/day for 70 years to interpret the risk associated with a URF or AACC properly. The appendix describes that the URFs in IDAPA 586 are the same as EPA's IURs, noting that the URF is the probability of developing excess cancers over a 70-year lifetime exposure to 1 µg/m^3 of a carcinogen expressed in terms of a screening emission level or an acceptable ambient concentration for a carcinogenic TAP. (Idaho DEQ 1992, Appendix 6).

Appendix 7 describes that URFs are applied to determine the risk to off-site receptors and that refined modeling is used to evaluate the risks. According to DEQ's statements in Appendix 7, refined modeling can include adjusting model parameters such as emission, topography, meteorology, or receptors. (Idaho DEQ 1992, Appendix 7).

---

[3] This packet was first introduced in this proceeding when the Idaho Conservation League (ICL) submitted a declaration that included reference to a 1992 document titled "Meeting Packet: Idaho Department of Environmental Quality, Monday July 13, 1992" (Idaho DEQ 1992).

These adjustments are made in compliance with IDAPA 210.02 as described in a relevant rulemaking document (Idaho DEQ 1993, Comment 108, page 30).

DEQ's approach to implementing the TAP rules is rooted in rulemaking documents that express its intentions and authority to follow well established risk assessment methodologies adopted by EPA.

B. Based on methods consistent with EPA and DEQ policies and methodologies, DEQ appropriately adjusted the exposure duration to 16 years (16/70) consistent with conditions in the PTC limiting project life because this adjustment was necessary for a scientifically defensible "apples to apples" comparison with the AACC.

The values set forth in IDAPA 586 and applied by DEQ are based on EPA toxicological determinations and derived from EPA's IRIS database. DEQ's application of the AACCs to comply with the Air Rules conforms to EPA guidance for evaluating risk, including accounting for the appropriate exposure duration. As detailed in this section, DEQ appropriately conducted its analysis following EPA methodology by comparing modeled concentrations from the SGP to the arsenic AACC.

One of the critical considerations in evaluating risk is exposure duration. EPA's definition for IUR reads (emphasis added):

> Inhalation unit risk (IUR) is an estimate of the increased cancer risk from inhalation exposure to a concentration of 1 µg/m^3 for a lifetime. The IUR can be multiplied by an estimate of lifetime exposure (in µg/m^3) to estimate the lifetime cancer risk.[4]

The AACCs set forth in IDAPA 586 assume an estimate of lifetime cancer risk based on 70 years of constant exposure and a 70-year lifetime. The assumed exposure is 24 hours /day and 365 days /year for 70 years. In other words, at a specific risk level, say 1 in 1,000,000, a person can be exposed to the AACC level (0.00023 µg/m^3) of arsenic every day, 24 hours/day, for 70 years and will have a 1 in 1,000,000 risk of developing cancer. A project that is permitted to operate for 70 years or more would properly assume a 70-year lifetime exposure when comparing modeled concentrations against the AACC.

If 70 years is not the exposure duration, then adjustments to the exposure duration are necessary to appropriately evaluate the cancer risk, as directed by EPA and as intended by the Air Rules (Idaho DEQ 1993, Comment 108, p.30)[5]. For a project like SGP with a 16-year project life, the analysis is adjusted to reflect the actual exposure duration for an "apples to apples" comparison with the AACC.

In this case, the AACC (0.00023 µg/m^3) is based on an assumed 70-year exposure. The SGP exposure duration is shorter (16 years), so the cancer risk cannot be determined accurately by comparing the modeled exposure concentration (0.00414 µg/m^3) to the AACC. Comparing those emissions to the AACC would result in an over-estimation of cancer risk because the dose will not continue for the 70-year lifetime exposure assumed in the development of the AACC. For an "apples to apples" comparison, evaluation of SGP emissions must take into account the shorter exposure duration.

[4] https://www.epa.gov/iris/basic-information-about-integrated-risk-information-system

[5] IDHW believes that the revised [IDAPA] Section 210. 02 Quantification of Emissions Rates and Ambient Concentrations, which allows site specific data gives adequate flexibility in compliance with toxic standards.

EPA guidance provides methodologies to assess risk, taking into consideration the exposure to an air concentration based on a formula for "air concentration adjusted for exposure." EPA guidance reflects this approach through a calculation methodology called the "adjusted air concentration" ($\mathbf{C}_{air\text{-}adj}$), which considers "the timeframe over which inhalation exposure occurs." (EPA 2009, EPA 2024a) (Exposure Assessment Tools by Routes - Inhalation | US EPA).

According to EPA, and as undertaken by DEQ, the exposure concentration must be adjusted for exposure duration to accurately reflect the exposure, associated dose, and resultant risk of cancer response. This adjustment allows for a correct ("apples to apples") comparison of exposure concentration to the AACC. This adjustment allows DEQ to evaluate whether the risk from actual exposure over the life of the project is acceptable under EPA methods and the AACCs.

DEQ followed this EPA methodology to assess the risk of arsenic emissions from the SGP.[6] The approach taken by DEQ for the SGP is set forth below (shaded notes are presented by author clarification):

$$\mathbf{Cair\text{-}adj = Cair \times ET \times 1day/24\ hours \times EF \times ED/AT}$$

Where:

$\mathbf{C}_{air\text{-}adj}$ = Air Concentration adjusted for exposure
$\mathbf{C}_{air}$ = Concentration of contaminant in air (mg/m^3) (this is the modeled or measured annual air concentration)
ET = Exposure time (hours/day) (this is assumed to be 24 hours/day)
EF = Exposure frequency (days/year) (this is assumed to be 365 days/year)
ED = Exposure duration (years) (this is 16 years – the life of operations)
AT = Averaging time (days) (this is lifetime – 70 years x 365 days/year; it never changes for any carcinogen)

EPA specifies that the first variable, concentration in air ($\mathbf{C}_{air}$) is either a measured or modeled value based on an annual average concentration. *For the SGP, DEQ used the highest modelled concentration after considering 14 different scenarios (0.00414 $\mu g/m^3$)*[7]

The temporal parameters in the equation include the following:

- Exposure time (**ET**) and exposure frequency (**EF**), which refer to the frequency with which the exposure occurs and might be provided in hours per day and days per year, respectively. *For the SGP DEQ used 24 hours/day for ET and 365 days/year for EF for the SGP review.*

[6] EPA established three calculations to assess risk properly. For completeness the additional EPA calculation methods for are presented in Attachment B.
[7] See Kevin Lewis Declaration

- Exposure duration (**ED**) is the amount of time that an individual or population is exposed to the contaminant being evaluated and is typically given in years. *For the SGP, DEQ used the 16-year life of mine ED reflected in enforceable PTC conditions.*
- Averaging time (**AT**) is the amount of time over which exposure is averaged and is equal to ED for assessing non-cancer risks. For chronic assessments (e.g., cancer), potential lifetime average daily dose (LADD) is calculated in which lifetime (LT, in days) is substituted for AT. *For the SGP, DEQ used 70 years, the default value, for the SGP review.*

Inclusion of a project-specific exposure duration in the calculation of the exposure concentration is essential for an accurate assessment of potential risks and for an appropriate comparison to the AACC to determine compliance with the Air Rules.

Using the highest modelled annual average arsenic concentration from the project of 0.00414 µg/m^3 (page 305 of 506 in the SOB dated 6/17/2022)[8] the calculation of the air concentration adjusted for exposure from the SGP is as follows:

$C_{air\text{-}adj}$ (Air Concentration adjusted for exposure) =

$$[\ C_{air}\ x\ ET\ x\ {}^{1}/_{24}\ x\ EF\ x\ ED\ ]\ /\ [\ AT\ ]\ =\ C_{air-adj}$$

$$\left[0.00414\,\frac{\mu g}{m3}\,x\,24\,\frac{hours}{day}\,x\,\frac{1\ day}{24\ hours}\,x\,365\,\frac{days}{year}\,x\,16\ years\right]\ /\ \left[365\,\frac{days}{year}\,x\,70\ years\right]\ =\ 0.00095\,\frac{\mu g}{m3}$$

In this analysis, the numerator (ET x EF x ED = 24 hours/day x 1 day/24 hours x 365 days/year x 16 years) reflects the exposure duration and the denominator of the equation (AT = 365 days/year x 70 years) reflects the 70-year averaging time for carcinogens. The resulting arsenic air concentration from the SGP adjusted for exposure risk review is 0.00095 µg/ m^3.

This approach follows the underlying rulemaking documents, including the authority noted in IDAPA 210.02. (Idaho DEQ 1993, Comment 108, p.30). DEQ appropriately adjusted the SGP evaluation to use 16 years (the actual exposure duration) because there can be no exposure to emissions beyond the life of mine. DEQ evaluated the highest annual air concentration modelled to determine the risk of a maximum 16-year exposure over a 70-year lifetime (modelled concentration x Exposure Duration (16 years)/70-year lifetime x URF. DEQ's approach followed EPA scientific principles, accepted risk assessment method, and foundational DEQ rulemaking documents.

C. The highest air concentration projections modelled for arsenic emissions from SGP are below the acceptable lifetime risk established by the T-RACT AACC listed in IDAPA 210.12 and 586, and therefore the risk from the SGP as permitted is protective of human health and the environment.

The calculated air concentration adjusted for exposure is 0.00095 µg/ m^3 -- this is the proper project-specific arsenic concentration to compare to the T-RACT AACC of 0.0023 µg/ m^3 for a cancer risk of 1:100,000 (see page 305 of 506 of the 6/17/2022 SOB).

This method is reflected in the permitting reviews to determine that the arsenic emissions risk was acceptable. Comparison to the T-RACT AACC is as follows:

[8] See Kevin Lewis declaration

$$\frac{1}{100{,}000} T\text{–}RACT\ Risk\ x\ 0.00095 \frac{\mu g}{m3} C_{air-adj} \ /\ 0.0023 \frac{\mu g}{m3}\ T\text{–}RACT\ AACC =$$

$$= 4.1E\text{–}6\ or\ \frac{1}{240{,}000} Actual\ Risk$$

This acceptable method provides an "apples to apples" comparison of SGP arsenic air concentrations to the AACC adjusted for T-RACT. This is the mathematical equivalent of 16-year emission rate of arsenic, plus 54 years of zero arsenic emissions, divided by 70 years to produce an annual exposure concentration that can be compared to the AACC.

DEQ's use of EPA toxicity values and risk assessment methodology in evaluating emissions from the SGP is consistent with IDAPA 586 because the same EPA toxicity values and risk assessment methodology formed the basis of the AACCs.

D. IDAPA 210.15 allows for a 10-times adjustment to the AACC when a project will operate for 5 years or less and is an example of DEQ's use of EPA's methods to achieve "apples to apples" analyses to compare with the AACC values.

IDAPA 210.15 provides that "[f]or short term sources, the applicant may utilize a short-term adjustment factor of ten (10). For a carcinogen, multiply either the applicable acceptable ambient concentration (AACC) or the screening emission rate, but not both, by ten (10), to demonstrate preconsturction compliance."

The *Final Order* held that the Air Rules do not explicitly authorize an adjustment for sources that will operate for more than 5, but less than 70 years. *Final Order* at 21. The Air Rules and IDAPA 210.15 should not be read to impede adjustment for exposure duration when a project will operate for less than 70 years. (Idaho DEQ 1993, Comment 108, p.30). An exposure duration is necessary and proper from a scientific and toxicological standpoint to apply the AACCs accurately. Omitting this adjustment is contrary to common scientific practice and the intent of the Air Rules as reflect DEQ documents (Idaho DEQ 1992 and Idaho DEQ 1993). Specifically the refernce from Petitioners reads:

> For short term sources (usually less than five years in duration), such as remediation projects, a probability of greater than one in a million risk (over 70 years) will generally be acceptable to account for the decreased term of exposure. It is not acceptable however, for exposed individuals to receive a full 70 year exposure during the life of a short term project. (Idaho DEQ 1992).

Unpacking this content may be helpful. First, the accepted scientific approach to determine risk is to calculate a lifetime average daily dose that includes the air concentration for the duration of exposure. In other words, to compare "apples to apples" an evaluator must adjust the default exposure duration (70 years) to the actual of exposure duration (16 years for SGP) then divide by 70 years to account for a lifetime-based URF. This is the proper method to determine "a probability of greater than one in a million risk (over 70 years)" as described.

Next, to expose individuals to "a full 70-year exposure" means that the AACC value is multiplied by 70 to derive the full exposure. See Figure 1 above. For arsenic emissions, the calculations follow:

- At a risk of 1E-6, using the AACC of 0.00023 µg/m^3 arsenic air concentration
  - 0.00023 µg/m^3 x 70 years = 0.016 µg/m^3
  - Exposure to 0.016 µg/m^3 air concentration every day for one year would expose an individual to the full 70-year exposure in one year.
- At a risk of 1E-5, using the T-RACT AACC of 0.0023 µg/m^3 air concentration
  - 0.0023 µg/m^3 x 70 years = 0.16 µg/m^3
  - Exposure to 0.16 µg/m^3 air concentration every day for one year would expose an individual to the full 70- year exposure in one year.

The AACC is not a one-year exposure limit and such an interpretation ignores both the definition of the URF and the definition of the AACC.

E. Idaho's AACCs are not annual average air concentration limits or standards.

The AACCs are distinct from annual average air concentrations and are not limits or standards. (Idaho DEQ 1993, Comment 31, page 10; Comment 111, page 32). One is an apple, the other an orange. The reference to an annual average concentration represents the longest period for which air concentrations are projected by air emission models, specifically AERMOD. Models only project concentration estimates over certain time periods of prediction (hourly, daily, monthly) within one year or over an annual duration. Models do not address exposure duration.[9]

The AACCs (derived from EPA's URFs) reflect exposure duration (i.e., 70-year lifetime) and present an acceptable constant dose of a contaminant over a known averaging time (70 years is the default averaging time for carcinogens). The AACC is the concentration that a person may be exposed to for a lifetime continuously, with an incremental risk of cancer of 1 in 1,000,000. The T-RACT AACC is the concentration that a person may be exposed to for a lifetime continuously, with an incremental increased risk of cancer of 1 in 100,000. The AACCs are not one-year limits. Compliance with IDAPA 586 is not based on comparing annual air concentrations from the model to an AACC. (Idaho DEQ 1993, Comment 111, page 32).[10]

Comparing an annual average concentration from a model to the AACC is not a risk evaluation and does not demonstrate acceptable risk. Nor is the annual average concentration predicted from modeling the same as an exposure concentration.[11]

DEQ understood and applied these distinct parameters properly in the PTC reviews for the SGP. For the SGP PTC, DEQ reviewed maximum daily emissions under 14 modeling scenarios that were each modeled for 365 days/year to produce an annual average arsenic concentration for each of the 14 scenarios. DEQ then used the highest annual average concentration—0.00414 µg/m^3—to conduct its risk evaluation calculations following EPA and DEQ guidance referred to above to compare to the AACC. This conservative approach assumed that the highest annual concentration modelled is

---

[9] See Kevin Lewis Declaration

[10] In the design of this rule, the AAC relates to a stack emission rate. In the most prescribed sense, the AAC would be assured by a permit ted emission limit. This emission limit then might be guaranteed by some ample control technology design or perhaps an operational limit prescribed in the permit.

[11] See Kevin Lewis Declaration

emitted for all the years of operation at SGP. To demonstrate compliance with the arsenic AACC, DEQ adjusted the exposure duration as directed by EPA (methodology explained above) and the DEQ guidance referred to above. Based on the modeling and scientific risk evaluation methods, DEQ concluded that the maximum arsenic emissions from SGP would cause an increased cancer risk of less than 1 in 100,000. This use of the annual average concentration in DEQ's AACC risk evaluation followed appropriate scientific methods.

Treating the AACC as an annual emission limitation or annual limit on ambient exposure concentration would result in significantly lower acceptable risk from TAPS emissions than envisioned by the Air Rules. If the T-RACT AACC of 0.0023 $\mu g/m^3$ were based on a one-year exposure, then the risk represented by that value would be about 1 in 7,000,000. Using the EPA guidance for URFs, and assuming continuous exposure to the T-RACT AACC concentration for an exposure duration of 1 year, the $CA_{air\text{-}adj}$ is:

0.0023 $\mu g/m^3$ x 24 hrs/day x 365 days/yr x 1 yr / (70 yrs x 365 days/yr x 24 hrs/day) = 0.000033 $\mu g/m^3$

And the associated risk of developing cancer over a 70-year lifetime is:

0.0043 ($\mu g/m^3$) x 0.000033 $\mu g/m^3$ = 1.4 E-7 (about 1 in 7,000,000)

The AACC (and the URF it is based on) represent the upper-bound excess lifetime cancer risk estimated to result from continuous exposure to a contaminant over a lifetime at an air concentration of 1 $\mu g/m^3$. In other words, the AACC and T-RACT AACC represent the risk to an individual if exposed all day, every day for a lifetime to a concentration of 1 $\mu g/m^3$. The AACC and T-RACT AACC do not represent the risk of a cancer response following a single exposure. The latter interpretation defies fundamental toxicological science used by the EPA in the development of IURs (URFs).

F. The 5-year rolling average production limit will ensure that the ambient arsenic concentration caused by the SGP does not cause unacceptable cancer risk.

The *Final Order* expresses concern that the use of a 5-year rolling average production limit will allow for smoothing out of peak ambient concentrations of ambient arsenic and may not be equally protective of ambient air as the AACC limits set forth in IDAPA 586.

First, the AACC is not a limit based on my reading of the relevant documents cited in this memorandum, in particular Idaho DEQ 1992 and Idaho DEQ 1993. Second, in my opinion, for purposes of evaluating cancer risk, use of a 5-year rolling average production limit is as protective as an annual production limit.

As described earlier in the report, risk assessment evaluates the probable response to a particular dose of a carcinogen over time. Risks increase from cumulative long-term exposure, not short-term annual emissions. Risks are assessed based on total cumulative dose, as demonstrated in Figure 1, column D. As shown in Figure 1, a total cumulative dose of 0.16 $\mu g/m^3$ of arsenic would cause an increased cancer risk of 1 in 100,000. However, whether this dose occurs in 1 year, 5 years, 16 years, or 70 years, the risk would not change.

The 5-year average production limit ensures that if production is above the limit in one year, then future production must be reduced below the limit. This ensures that the cumulative ambient arsenic concentration does not exceed the acceptable ambient concentration level for the defined risk. The 5-year average production limit in the PTC ensures that the ambient arsenic concentration from the SGP over the project life (exposure duration of 16 years) results in an acceptable cancer risk under the Air Rules.

VII. CONCLUSIONS

Based on my review of the modeled emissions from the SGP, the Air Rules, and EPA risk assessment methodology, and relevant explanatory documents, arsenic emissions from the SGP will result in an increased cancer risk of less than 1 in 100,000. DEQ appropriately applied a project specific adjustment factor to account for exposure duration, consistent with established EPA risk assessment methodology. The permit issued to SGP, including the five-year rolling average production limit, represents acceptable risk confirmed by methods that follow EPA's approaches for using URF, IUR values in risk assessments.

ATTACHMENT B

For completeness the additional EPA calculation methods for are presented here.

Method 2: Calculate the risk associated with the air concentration

The second option for correct use of the URF in the evaluation of project risk is to forward-calculate a risk from the modelled concentrations and using the IUR (URF) as shown in the "Equation 6" from EPA 2009 (below).

The EPA screening levels, associated risk calculator and several guidance documents published by EPA rely on the unit risk factor (again, called IUR by EPA and called URF in the Air Rules). For arsenic, the IUR is 0.0043/(µg/m^3)(from EPA 2024b and shown in IDAPA 58.01.01.586 as the URF). Exposure for inhalation is determined by the following equation for carcinogenic chemicals (EPA 2009), which necessarily relies upon an exposure time, frequency and duration to estimate dose. Exposure concentration (EC) is the parameter that is to be evaluated by use of the URF; Concentration in Air (CA) is the estimated contaminant concentration that is predicted by the model. The exposure concentration is the equivalent to the adjusted air concentration described in Method 1.

From EPA 2009, Risk Assessment Guidance for Superfund, Part F. Page 14

EC = (CA x ET x EF x ED)/AT **(Equation 6)**

Where:
EC (µg/m^3) = exposure concentration;
CA (µg/m^3) = contaminant concentration in air;
ET (hours/day) = exposure time;
EF (days/year) = exposure frequency; ED
(years) = exposure duration; and
AT (lifetime in years x 365 days/year x 24 hours/day) = averaging time

The EC is then multiplied by the URF to calculate incremental lifetime risk.

Using the SGP highest modeled air concentration for arsenic of 0.00414 µg/m^3:

Exposure Concentration (µg/ m^3) =

[CA x ET x EF x ED] / [AT] = EC

$$\left[0.00414\,\frac{\mu g}{m3}\,x\,24\,\frac{hours}{day}\,x\,365\,\frac{days}{year}\,x\,16\,years\right] / \left[70\,years\,x\,365\,\frac{days}{year}\,x\,24\,\frac{hours}{day}\right] = 0.0095\,\frac{\mu g}{m3}$$

Then, the Exposure Concentration (EC) x IUR (or URF) estimates the risk:

$$0.00095\,\frac{\mu g}{m3}\,EC\;x\;0.0043\left(\frac{\mu g}{m3}\right)^{-1}\,IUR = 4.1E{-}6\;or\;\frac{1}{240{,}000}\,Risk$$

Method 3: Adjust the AACC to reflect the Project Duration

The same calculation can be re-arranged to estimate a screening concentration in air, as shown in Table 4 from EPA 2009 (below).

TABLE 4

RECOMMENDED PROCEDURE FOR CALCULATING RISK-BASED SCREENING CONCENTRATIONS FOR CONTAMINANTS IN AIR

	Cancer Risk-Based	Hazard-Based[1]
Step 1: Select Target Levels	Select target cancer risk (e.g., 1 x 10^{-6}).	Select target HQ (e.g., 1).
Step 2: Identify Toxicity Value[2]	Identify inhalation cancer potency value (e.g., IUR). If none exists, proceed with hazard-based screening level calculation.	Identify inhalation reference value (e.g., RfC) to match exposure scenario (acute, subchronic, or chronic). If none exist, proceed with cancer screening level calculation.
Step 3: Calculate CA	Using target cancer risk from Step 1 along with the receptor- and scenario-specific exposure parameter values, calculate CA; the following equation is recommended: CA = (AT x Target Risk)/(IUR x ET x EF x ED)	Using target HQ from Step 1 along with the receptor- and scenario-specific exposure parameter values, calculate CA; the following equation is recommended: CA = (AT x Target HQ x RfC x 1000 µg/mg)/(ET x EF x ED)
Step 4: Select Screening Concentration	Select minimum of predicted cancer risk- and hazard-based values as screening concentrations.[3] Repeat for each receptor/scenario combination of interest.	

[1] Hazard-based screening concentrations are typically derived from reference values such as RfCs. These values may be available for non-cancer effects but may include cancer, if a nonlinear MOA is thought to operate for a chemical. [2] If no inhalation toxicity value is available for a chemical, contact STSC for further direction on how to proceed.

[3] Screening levels estimated from the equations presented in Step 3 could yield concentrations that exceed the maximum possible vapor concentration for a chemical. In such cases, it may be useful to calculate the maximum possible vapor concentration of the pure contaminant at the temperature of interest, using the following formula: C_{max} = S x H x 10^3 L/m^3, where S = solubility at 25° C (or temperature of interest) and H (unitless) = Henry's Law Constant at 25° C (or temperature of interest). This equation is based on an established relationship (see, for example, Schwartzenbach et al. 1993), that allows the Henry's Law Constant to be estimated as the ratio of a compound's vapor pressure and aqueous solubility for compounds that are slightly to moderately soluble in water. When the dimensionless Henry's Law constant, H, is used, the relationship described above can be used to calculate the vapor concentration of a saturated solution of a given compound, assuming equilibrium between the vapor and aqueous phases.

Note: MOA = Mode of Action, which refers to the way in which a chemical exerts a health effect.

In Step 3 of this table AT is averaging time as described in "Equation 6" from EPA 2009 or 70 years x 365 days for carcinogens (note - for noncarcinogens only, AT is equal to the Exposure Duration) (source: EPA RSLs 2024c, EPA Risk Assessment Guidance for Superfund 2009).

As shown in Step 3 the third option for assessing risk is to adjust the screening value (here, the AACC) to reflect the project-specific exposure duration. The default exposure duration assumed in the AACC is 70 years. The AACC values represent a concentration in air (CA) for a 24 hour/day, 365 day/year, and for 70-years of exposure (using both a lifetime exposure duration and lifetime for averaging time). At a T-RACT risk of 1:100,000 the calculation of the T-RACT AACC is as follows, using the equation in Step 3 of EPA guidance (2009):

$$[\ AT\ x\ \text{Target Risk}] / \left[\ \text{IUR}\ x\ \text{ET}\ \left(\frac{\text{hours}}{\text{day}}\right) x\ {}^{1\ day}/_{24\ hours}\ x\ \text{EF}\ x\ \text{ED}\ \right] = CA$$

$$specifically$$

$$\left[70\ years\ x\ 365\ \frac{days}{year}\ x\ {}^{1}/_{100{,}000}\right] / \left[4.3E{-}3/\frac{\mu g}{m3}\ x\ 24\ \frac{hours}{day}\ x\ \frac{1\ day}{24\ hours}\ x\ 365\ \frac{days}{year}\ x\ 70\ years\right] =$$

$$= 0.0023\ \frac{\mu g}{m3}\ Screening\ concentration, CA_{70-year\ ED}$$

The adjustment used by DEQ for the exposure duration reflects the 16-year life of the mine (i.e., there can be no operations related exposure after operations cease). Accordingly, the appropriate AACC for this project is:

$$[\ AT\ x\ \text{Target Risk}] / \left[\ \text{IUR}\ x\ \text{ET}\ x\ {}^{1\ day}/_{24\ hours}\ x\ \text{EF}\ x\ \text{ED}\ \right] = CA$$

specifically,

$$\left[70\ years\ x\ 365\ \frac{days}{year}\ x\ {}^{1}/_{100{,}000}\right] / \left[4.3E{-}3/\frac{\mu g}{m3}\ x\ 24\ \frac{hours}{day}\ x\ \frac{1\ day}{24\ hours}\ x\ 365\ \frac{days}{year}\ x\ 16\ years\right] =$$

$$= 0.0102\ \frac{\mu g}{m3}\ Screening\ concentration, CA_{16-year\ ED}$$

The adjusted AACC of 0.0102 µg/m^3 is used to compare the highest annual average concentration from the modeling without further adjustment to determine the risk. In this case it would be:

$$\frac{1}{100{,}000}\ Target\ Risk\ x\ 0.00414\ \frac{\mu g}{m3}\ C_{air}\ /\ 0.0102\ \frac{\mu g}{m3}\ CA_{16-year\ ED} =$$

$$= 4.1E{-}6\ or\ \frac{1}{240{,}000}\ Actual\ Risk$$

Using Method 1 (presented in the memorandum) or Method 2 or 3 presented here, the same estimate of lifetime risk is obtained, which for this project is 4.1E-6.

ATTACHMENT C

TETRA TECH

Theresa K. Lopez, MSPH
Principal Toxicologist

EXPERIENCE SUMMARY

Ms. Lopez has worked extensively in public health, epidemiology, human health risk assessment, toxicology, and occupational health and safety, representing both the public and private sector for over 30 years. She has been a task manager for a variety of human health risk assessment projects, including developing a disease burden reduction model for the optimized placement of infrastructure. She has led investigation and assessment of chemical releases and environmentally compromised sites such as former nuclear weapons plants, active and closing naval bases, and mining, commercial, and school sites. Ms. Lopez has worked extensively for federal, State, Provincial, and private clients. Her work includes assisting in remediation of former mining sites in the United States (US) and Canada with heavy metal, pesticides, TPH and other chemicals of concern; and risk assessments for proposed mines, hazardous waste release sites, and TPH remediation in the US and Canada. She has prepared human exposure assessments for schools and recreational settings, and assessed clean-up goals and remediation strategies for closed industrial, mining, redevelopment, and other sites. These sites often include the consideration of native and indigenous peoples.

In addition, she has provided exposure and dose reconstruction for Oak Ridge Associated Universities to quantify radiation doses to former nuclear weapons workers. She provided the exposure assessment information and mathematical evaluation for the development of a computer-based mouthing exposure tool for Health Canada which involved comparative evaluation of equations selected from a variety of countries and multi-national interest groups (including Japan, European Chemicals Agency, US, and UK). Currently, Ms. Lopez is performing the human health risk assessments involving both radionuclide and chemical impacts, modeling of indirect exposure pathways, TPH evaluations, and exposure assessments for private clients and US and international regulatory agencies, as well as providing scientific peer reviews and authoring reports for Health Canada related to the Existing Substances Risk Assessment Bureau mandates.

EMPLOYMENT HISTORY

Tetra Tech, Inc., Senior Toxicologist, 1997–present

PRC Environmental Management (NKA Tetra Tech EMI), Senior Toxicologist/Toxicology Group Leader, 1992–1997

University of Colorado Health Science Center, Student/Professional research Assistant, 1989-1992.

EDUCATION

MS, Public Health, University of Colorado, 1991

BS, Nutritional Science (Zoology minor), University of Florida, 1989

AREAS OF EXPERTISE

- Human Health Risk Assessment
- Chemical Risk Assessment
- Radiological Risk Assessment
- Regulatory toxicology
- Risk-based Remediation
- Public Health
- Epidemiology
- Guidance Development
- Exposure Assessments

TRAINING/CERTIFICATIONS

- Qualified Person, Site Assessment Chapter and Corrective Action Plan Chapter, Saskatchewan
- FEMA Emergency Response Training IS-00005.a, 230.d, and00029

PROFESSIONAL AFFILIATIONS

Society for Risk Analysis

Society for Environmental Toxicology and Chemistry

RELEVANT EXPERIENCE

Peer Review of Chemical Assessments, Consumer Product Safety Commission (2022-present). Program manager and lead toxicologist for peer review of chemical and nanomaterial risk assessments developed for and by the Consumer Product Safety Commission. Current project is the review of class-based assessment for organic flame retardants. The peer review will include response to charge questions as well as commentary on the approach and case study to evaluate scientifically defensibility, thoroughness, and accuracy.

Navajo EPA Ambient Water Quality Standards. **(8/2018 – present)**. Provided a review of existing ambient water standards and calculated health-based standards for the Navajo Nation based on human exposures, livestock exposures, plants, and food ingestion pathways. The report will be the basis of Navajo EPA water standards for surface water bodies and specifically the San Juan River within the Navajo Nation boundaries.

Technical Support Services, Agency for Toxic Substances and Disease Registry (ATSDR) (US-Nationwide). (12/2016-present). Managing a contract with ATSDR to provide ad-hoc scientific advice on a variety of public health assessment issues, including chemical toxicity, public health, environmental risk assessment and education and

outreach activities as needed. Projects to date have involved being a subject matter expert in public health assessments methodology, review of minimal risk levels and toxicity data used by ATSDR, and reviewing EPA databases (including the TRI) for potential uses in public health evaluation and outreach as well as providing technical support for ATSDR's soilSHOP outreach (a lead poisoning prevention program). The most current project involves measuring uptake of metals and PFAS from soil to common food plants.

Arizona Department of Environmental Quality. Phoenix AZ. (11/2019 – present). Providing toxicology and risk assessment review of reports submitted to ADEQ for approval under the Voluntary Cleanup Program, as well as conducting site-specific risk assessments for historic mining sites to facilitate remediation. Reviewing a variety of submitted reports for former industrial facilities and release sites throughout Arizona.

Toxicological Literature Reviews and Summaries, Health Canada. Ottawa, Ontario. (1/2015-present) Provided literature search and summary for various chemicals and exposures. A specific example include a literature review and data summary for 36 organic flame retardants and 45 salicylates. A literature search was conducted for each chemical in these two efforts, and summaries of material ranged from a few pages to over 120 pages per chemical depending on the amount of literature identified. Both carcinogenic and noncarcinogenic endpoints were included in the search, and endpoints included acute toxicity (single exposure), short-term toxicity (2 to 89 days), subchronic toxicity (90 days to 1 year), chronic toxicity (more than 90 days), carcinogenicity, reproductive and development toxicity, genotoxicity, endocrine effects, immune system, sensitization, and irritation. In addition, a data extraction project for ultrafine particles was also undertaken, reviewing health outcomes for human exposure to ultrafine particles in over 130 epidemiological papers.

Peer Review of Screening Assessment Reports (SARs), Health Canada. Ottawa Ontario. (1/2015 – present) Providing peer review of screening assessment reports for a variety of chemicals in consumer products for the Existing Substances Risk Assessment Bureau under the Chemicals Management Plan. Reviews include a literature search, review of identified literature, qualitative and quantitative exposure assessments, toxicity assessment, calculation of margins of exposure for each exposure pathway, and recommendations on the methodology used to assess the chemicals. Over 50 reviews have been conducted to date.

Peer Review of New Assessment Methodologies, State of the Science Reports, and Occupational Exposure Guidelines, Health Canada, Ottawa, Ontario (4/2017-present). Providing peer review of new assessment methodology reports (including *in silico* learning and transcriptomics), State of the Science (including PFAS compounds and Vitamin A) , and Occupational Exposure Guidelines (STOT RE for carbon black) for Health Canada under the Chemicals Management Plan and Hazardous Products Regulations.

Review of Proposed Drinking Water Guidelines, Health Canada, Ottawa, Ontario (8/2021- 12/ 2023). Providing peer review of six drinking water guidelines, focused on health-based standards and toxicological concerns, for several inorganic and organic chemicals under the Chemical Management Plan for the Water and Air Quality Bureau (WAQB). The reviews included verification of toxicological information, calculation of a guideline, and other technical issues relevant to water guideline development.

Exposure Assessment Studies, Health Canada, Ottawa, Ontario 4/2017-present). Provided peer review of exposure assessment reports, including internal backgrounders on body weight, drinking water intake rates, inhalation rates, and soil/dust intake rates, dermal surface area, and breast milk and formula intake. Collected literature and provided detailed reports for Health Canada on vapor recovery systems and air quality, chemical exposure in nail salon settings. Created and implemented consumer product surveys for hand sanitizer, automobile products, certain arts and crafts products, paint remover and essential oils. The hand sanitizer project was published while the paint remover and essential oil surveys are currently in progress. The automobile products and arts and craft product surveys remained internal to Health Canada but follow-up work may be planned.

UNICEF WASH Program, Pacific Island Countries. (4/2024-present). Assessed current disease burden rates for Solomon Islands including diarrheal disease and other water-related illness to determine economic benefits from placement of water and sanitation infrastructure improvements. The public health evaluation identified areas with potentially the highest rates of diarrheal disease and the reduction in disease burden that can be achieved by providing chlorinated water supplies and sanitation systems. The model that was created also can estimate disease reduction through reduced flooding and drainage improvements. A mathematical model was developed for this effort that included weighting factors to account for poverty and age, and different percentages for infrastructure improvements, to estimate disease and mortality reduction from the provision of disinfected water and sanitation infrastructure.

Relative Risk Ranking Model for Sanitary System Overflow Diversions, Metro Vancouver. (3/2024 – present). A model was developed for the relative risk to humans and ecological receptors from 5 options for based on options developed for consideration. This evaluation considered several inputs to evaluate potential risks to receptors from the overflow to conveyances, surface water, and eventually the bays surrounding Metro Vancouver. This is was not a quantitative risk assessment but rather a relative ranking of the risks associated with each option. Inputs to the model included overflow volume, distance to conveyance from overflow, distance to receiving body, dilution, chemical/bacterial measurements, and percent paved area surrounding conveyance. Special status ecological receptors in the areas of interest were identified, as well as human uses of the land and communities of special consideration. A ranked score was created for each option, under the broad categories of logistical, ecological risk, human health, and chemical inputs.

Public Health Assessment and Disease Burden Reduction, Millennial Challenge Corporation, Timor-Leste. (1/2020 - 9/2022). Assessed current disease burden rates for Dili, Timor Leste, including diarrheal disease and other water-related illness to determine areas that will achieve greatest disease burden reduction from proposed infrastructure improvements. The public health evaluation identified areas with potentially the highest rates of diarrheal disease and the reduction in disease burden that can be achieved by providing chlorinated water supplies, sanitation systems, and drainage improvements to reduce flooding. These improvements may be implemented individually or together, depending on the area. A mathematical model was developed for this effort that included weighting factors to account for poverty, age, and gender differences in the population.

Development of Biomonitoring Equivalents for Glyphosate and Ethylene Thiourea (1/2021-12/2023). In partnership with Summit Toxicology, gathered biomonitoring data, regulatory information, and adsorption, distribution, metabolism and excretion (ADME) data for these two pesticides. Data were used to develop biomonitoring equivalents and manuscripts have been developed documenting the results (one has been published and the other has been submitted).

City of Campbell River, British Columbia, Canada. (1/2023-present). Performing human health and ecological risk assessment for soil and groundwater with PFOS and PFOA impacts from firefighting training at an airport. Exposure pathways include drinking water, soil contact, and impacts to off-site freshwater bodies.

Human Health and Ecological Risk Assessment, Duck Lake, British Columbia. (4/2018-11/2018). Conducted a human health and ecological risk assessment of a former railway right-of-way using. The intent of the risk assessment was to document any potential risks associated with legacy polycyclic aromatic hydrocarbon residue from Site use as a railway, and the community plans to redevelop the right-of-way into a multi-use recreational trail. Site was submitted for closure and redevelopment in November 2018 based on the risk assessment findings.

Human Health and Ecological Risk Assessment, Aitchelitz, BC. (7/2021-7/2023). Conducting a human health and ecological risk assessment of a former industrial operations area. The intent of the risk assessment was to document any potential risks associated with current and legacy buried wastes and petroleum releases from the area, including any discharge of groundwater to the Aitchelitz Creek and use of groundwater as a drinking water source. As well, ecological effects in the Aitchelitz Creek were evaluated, particularly for endangered species.

Human Health and Ecological Risk Assessment, Kitsumkalum, BC. (3/2018 – 3/2019). Conducted a human health and ecological risk assessment of a former industrial and woodmill operations area. The intent of the risk assessment was to document any potential risks associated with legacy buried wood waste and petroleum releases from the area, including any discharge of groundwater to the Kitsumkalum River and use of groundwater as a drinking water source. The community planned to redevelop a portion of the Site for industrial re-use, while a portion was being considered for residential redevelopment. The Site was submitted for closure and redevelopment in March 2019 based on the risk assessment findings.

Human Health and Ecological Risk Assessment, Wei Wai Kum First Nation (WWK), Myra Fall Mine (MFM) and Indigenous Services Canada (ISC), Campbell River BC. (2021-2022). Providing human health and ecological risk assessment for Wei Wai Kum First Nations for this former port area located on Vancouver Island. Chemicals of potential concern include metals and PAHs, with a particular concern regarding marine life in the area and food chain exposures.

Evaluation of Human Toxicity Data for PFAS and PCBs to Determine Applicability to Marine Mammals, British Columbia Ministry of Environment and Climate Change (BMOECC). (9/2020-3/2021). Vancouver, British Columbia. Provided BCMOECC and federal agencies with a methodology and example of how data developed for the assessment of human toxicity could be extrapolated for use in protecting the endangered

Southern Resident Killer Whale population, as well as other marine mammals. Specific chemicals of interest were PCBs and PFAS.

San Juan River Risk Assessment, Utah Department of Environmental Quality. (2/2017 – 3/2018). Task leader for the human health and agricultural risk assessments of the San Juan River. Evaluating impacts of heavy metals (including arsenic) from the Gold King Mine release to residents, ranchers, farmers, and other users of the San Juan River water. Providing data evaluation including comparisons to background values, assessment of data from tributaries to the San Juan River, as well calculating exposure point concentrations. Providing assessment of current and future risks, including consideration of regulatory levels as well as site- and receptor-specific exposure parameters to fully evaluate potential long-term impacts of the release on receptors and the eventual deposition of impacted sediment in Lake Powell.

Exposure Assessment for Nanoform Cerium Oxide Silver, Titanium Dioxide and Zinc Oxide, National Industrial Chemicals Notification and Assessment Scheme, Australian Government Department of Health and Ageing. (11/2012 – 6/2013). Provided an exposure assessment of the public to nanoform cerium oxide, silver, titanium dioxide, and zinc oxide present in consumer products. Assessed both qualitative and quantitative measures of exposure, based on a range of nanomaterial content and use of consumer products. For each nanomaterial, provided current information on commercial uses, sources, synthesis methods, characterization, potential exposure routes, toxicokinetics, and environmental fate and transport, as well as addressing data gaps where information was not found. Developed exposure scenarios for each of the four nanomaterials, including exposure to workers, the public (consumers), and the environment, and provided estimates of exposure to the extent possible. Identified data gaps that introduced uncertainty into the estimates or prevented a quantitative estimate of exposure, including that the toxicity of nanomaterials may be related to the number of particles rather than mass of particles present, and that measures of exposure based on mass of material may therefore underestimate potential toxic effects.

Use of Biomonitoring Data and Biomonitoring Equivalents in Risk Assessment, Health Canada, Ottawa, Ontario. (1/2015-7/2015). Prepared a report for Health Canada regarding the current use and application of biomonitoring data and biomonitoring equivalents (BE) in regulatory settings as well as considerations for varying types of pharmacokinetic data used to interpret biomonitoring data for various matrices. Authored chapters defining BEs as the translation of screening exposure guidelines or criteria to chemical- and biological media-specific concentrations that can be used interpret biomonitoring results for specific chemicals in a health risk context. Provided an overview of its application in regulatory risk assessment as well as considerations for varying pharmacokinetic data in both animals and humans, and described international efforts in biomonitoring of several chemicals, including perfluorinated compounds, mercury, lead, 2,4-D, and phthalates. In addition, the report contains a discussion of how pharmacokinetic data can be used to interpret biomonitoring data for regulatory risk assessment of industrial chemicals under the Chemicals Management Plan.

Peer Review of Personal Care Products (PCP) Module III, Assessment of Exposures to Chemicals in Personal Care Products for the Hair. Health Canada, Ottawa, Ontario. (12/2014-4/2015). Provided a peer review for the Existing Substances Risk Assessment Bureau (ESRAB) - Healthy Environments and Consumer Safety Branch (HECSB) of the proposed Health Canada methodology for assessing consumer exposure to chemicals in hair care products, including an evaluation of recommended default exposure parameters for all receptors and a literature review to determine if additional applicable data were available for use in the effort.

Peer Review of OECD Documents, Health Canada Risk Assessment Bureau, Ottawa, Ontario. (8/12-8/13). Performed peer reviews of regulatory and advisory health summary documents for Health Canada for the Organization for Economic Co-Operation and Development (OECD) Cooperative Chemicals Assessment Meeting No. 4 (CoCAM 4). Peer review included verification of health effects data reported in IUCLID Dossier, Screening Information Data Set (SIDS) Initial Assessment Reports, and SIDS Initial Assessment Profiles documents.

Mouthing Exposure in Young Children: In Silico Tool. Health Canada, Ottawa, Ontario. (11/2013-7/2014). Designed exposure assessment and mathematical models for 26 separate equations to assess chemical exposure to children through mouthing of various consumer products. Provided a variety of algorithms that may be used with default or user-specified parameters to assess mouthing exposures in children from birth to 8 years of age. Identified mathematical approaches and modeling tools from a targeted search of the scientific literature, as well as various government sources, using on-line search engines and established medical information search tools and included a discussion of the circumstances and modulating factors surrounding an attempt at assessing object-to-mouth exposures in children as well as limitations to assessing such exposure. Also authored the user's guide to accompany the computer-based model that included description of mathematical similarities and differences in assessing exposure to non-food substances through direct mouthing, hand-to-mouth behavior, and swallowing as

well as compiling exposure data to provide users with a range of parameter values to assess chemical intake.

Human Health and Ecological Risk Assessment, Cantung Mine site, Northwest Territories, Canada. (3/2017-present). Lead human health and ecological risk assessor for this closed tungsten mine. Providing a detailed quantitative assessment of potential human exposure to metals, petroleum hydrocarbons, and other chemicals of concern at this site, including exposures through hunting, fishing, and gathering of plants as traditional food sources given the remote location and First Nations traditional land uses. Provided assessment of direct exposures including soil ingestion, particulate inhalation, dermal contact with impacted soil and tailings; and ingestion and incidental contact with surface water. Provided a detailed background comparison for metals in soils that will be used to guide soil remediation.

Risk Assessment, Public Works and Government Services Canada, Tulita NWT and Fort Reliance, NWT, and Yellowknife, NWT. (9/2017-3/2018). Currently performing human health and ecological risk assessment for petroleum hydrocarbon releases at three sites in Canada related to previous spills and releases at Royal Mounted Canadian Police detachments and Crown-owned residences. Provided methodology and risk calculations to evaluate indoor air exposure, soil exposure, groundwater impacts, and ecological receptor exposure.

Confidential Maryland Redevelopment Site, Baltimore Maryland. (3/2022 – 7/2022). Conducted a multimedia, Site-Specific Risk Assessment for redevelopment of a former electrical manufacturing facility located in Baltimore, Maryland. Using soil, groundwater and soil vapor data, evaluated the potential risk to future residential, commercial, and recreational receptors for Chemicals of Potential Concern (COPCs) included PCBs, chlorinated compounds, petroleum compounds, metals (including lead), and PAHs. Working collaboratively with the Maryland Department of the Environment, the risk assessment was completed in accordance with voluntary cleanup guidance and provided a health-protective path forward to redevelopment.

Risk Assessment, Beazer, L.A. Paint Site, Vernon, California. (5/2014 – present). Performing a human health risk assessment for vapor intrusion to indoor air from soil gas and groundwater data at historical release site, including paint manufacturing process solvents and petroleum products. Providing risk calculations and correlation of soil, soil gas, and groundwater data to provide multiple lines of evidence to assess potential risks from site reuse and redevelopment. Working cooperatively with both State and local regulators involved in this risk assessment process to address concerns and obtain site closure.

Indoor Air Risk Assessment, Lockheed Martin Corporation, Palo Alto, California. (9/2016-10/2021). Risk assessor for ongoing monitoring and assessment of soil vapor plume for solvent release site for Lockheed Martin Corporation (LMC) in Palo Alto, California. Provide updates of indoor air modeling and risk assessment every 6 months using soil gas data collected from 3 impacted areas.

Risk and Dose Assessment, American Jewish University, Simi Valley, California. (2/2016-5/2018). Performed a review of historic data and risk assessments conducted for the site. Evaluated the potential for the AJU campus, which is downgradient of the Santa Susana Field Laboratory (SSFL), to receive storm water discharge, groundwater, and air-dispersed particulates from former operations at the SSFL. Reviewed AJU and SSFL data related to release of metals, dioxins, perchlorate, polycyclic aromatic hydrocarbons, and TCE, as well as radionuclides. Evaluated historic data and recently collected data to determine if any risks currently exist to patrons of the AJU campus. Conducted site evaluation involving tracing potential migration pathways of contaminants from origin to the campus, and review of soil, sediment, surface water, groundwater, and food data, as well as gamma survey results. Evaluation of impacts to the campus relied upon establishing background and ambient conditions that could influence sampling results, including the effects of forest fires and releases from other facilities in the surrounding urban areas. Exposure evaluation included delineating areas of specific use on the campus, as well as the types of activities, exposure durations, and populations that have access to the areas. Currently providing technical and scientific support as needed.

Human Health Criteria Development using 2000 Human Health Criteria Methodology for U.S. EPA. (Nationwide). (2/2015-5/2018) Supported EPA in updating the human health ambient water quality criteria for 94 chemicals published in late 2014 and researched bioaccumulation factors (BAFs) using EPA's 2000 *Methodology for Deriving Ambient Water Quality Criteria for the Protection of Human Health* and its 2003 *Technical Support Document Volume 2: Development of National Bioaccumulation Factors*. Conducted a systematic review of peer-reviewed available literature and peer-reviewed public toxicology databases to obtain data to update the BAFs, as well as conducting research of peer reviewed sources to update the relative source contribution (RSC) values used in the 2014 criteria. Also helped provide exposure information to support relative source contribution values using the decision tree in EPA's 2000 Methodology and is currently assisting in producing BAFs and AWQC for 24 metals (including arsenic) and persistent organic pollutants.

Policy Briefings and Update to Human Health Ambient Water Quality Criteria Methodology Document for U.S. EPA (Nationwide). (9/14-1/15). Assisted in reviewing toxicological information, exposure factors, relative source contributions, and bioaccumulation potential of the contaminants included in this project. Provided technical input to the methodology recommendations that included recommendations for using human surveillance data as an input in the development of human health criteria, identification of exposure factors, and determination of exposure factors to appropriately assess minority and low-income populations engaged in subsistence fishing practices. Reviewed the use of NHANES data for determining fish consumption rates for this project and provided technical review of several issue papers and briefings discussing options for calculating different exposure factors, use of probabilistic methods for deriving criteria, and developing technically defensible approaches for filling critical data gaps.

Computer Program to Evaluate Risks from Residential Indoor Water Use, Agency for Toxic Substances and Disease Registry (ATSDR). (6/15-8/17). Assisted in providing exposure and risk assessment support in the development of a desk top computer application to assess potential risks associated with volatile organics and other compounds from the use of contaminated groundwater for showering, bathing, and other household residential uses. Provided input to the assessment of inhalation and dermal exposures, as well as consideration of background exposure concentrations in ambient air. Performed detailed QA/QC of the model through numerous test runs of each exposure scenario for various chemicals and concentrations. Reviewed EPA databases, including the TRI, to determine if a component could be added to this program to incorporate anthropogenic sources to address background concentrations.

Human Health and Ecological Risk Assessment, Treasury Metals, Goliath Mine, Ontario. (6/2014-6/2016). Provided oversight of the Screening Level Risk Assessment (SLRA) for a Proposed Mine Site in Ontario in support of the Environmental Impact Statement, which included a preliminary human health risk assessment and assessment of ecological health risks associated with potential exposures to dust, tailings, waste rock, and mine effluent in the operational and post-closure phases of the proposed mine. Performed the human health risk assessment using guidance from Health Canada, and relied upon site assessment and chemical of concern selection performed using guidance from Environment Canada's Federal Contaminated Sites Action Plan (FCSAP) and Canadian Council of Ministers of the Environment (CCME) as well as Ontario's Provincial Water Quality Objectives (PWQO) and CCME's Water Quality Guidelines. Performed a country foods risk assessment to determine risks from exposures through food items harvested from the proposed mining site during both the operational period and post-closure phases, focusing on mercury and lead. Also attended three public meetings on behalf of the mine proponent to discuss human health risk concerns with the community and First Nations members.

Human Health Risk and Dose Assessment Review, United States Forest Service, Sundance, Wyoming. (1/2014-6/2015). Provided a review of the radiological dose from rare earth mining at this proposed mine site. Performed radiological and nonradiological human health risk assessment for the proposed mine based on the Plan of Operations and baseline studies to date, including soil, ore, air, and water data. Provided calculations and predicted risks and hazards from the estimated heavy metal releases from mining operations combined with ore concentrations, rare earth recovery rates, transportation concerns, and radiological dose. Assigned estimated risks to both the operational and post-closure site conditions as determined in the Plan of Operations as part of this predictive risk assessment. The reports are under consideration as part of the Environmental Impact Statement (EIS) process and permitting processes related to mining and radiological material handling.

Human Health Risk Assessment of Metals and Radionuclides, United States Forest Service, Riley Pass, South Dakota.). (4/2015 – 1/2018). Reevaluated 2006 risk assessment and risk-based cleanup goals for arsenic, molybdenum, copper, radium-226, uranium, and thorium at a former uranium mine. The risk-based cleanup goals focus on site-specific receptors as determined by the U.S. Forest Service and land use patterns of Native Americans for the site. In addition, reevaluated food ingestion pathways related to hunting and ranching in developing updated risk-based goals. Currently, providing risk assessment input to the clean-up actions being performed at the Site.

Risk-based Remediation Goal Calculations, State of Montana, Grant Kohrs Remediation Site. (12/2014-2/2015). Calculated site-specific remediation concentrations for soil to remediate heavy metals, including arsenic, from former mining releases at a currently used recreational area. Evaluation and calculations involved identifying site-specific exposure parameters for different areas of the site based on usage patterns of different occupational and recreational receptors, and were used by the State to guide remediation of the site.

Human Health Risk Assessment, Ross Adams Uranium Mine, Newmont Mining, Prince of Wales Island, Alaska. (8/2009 – 6/2016). Responsible for human health screening evaluation of data from inactive mines, mine roads, shoreline area, and surrounding marine area. Environmental media of interest include soil, surface water,

stream sediment, and marine sediment. Determined the background dataset and selected chemicals of potential concern (COPCs) for different media and locations throughout the mine area; the selected COPCs (uranium, thorium, arsenic, and lead) formed the basis of both the human health and ecological risk evaluations. Included food ingestion pathways related to hunting and gathering activities in the risk assessment for both terrestrial and marine foods. Evaluated historical data to provide recommendations for future sampling and analysis, as well as to define the conceptual site model to be used to assess human health risks.

Human Health Risk Assessment of Lead Exposures, Confidential Client, Former Mining Site, Colorado. (2011). Conducted a risk assessment for school-aged children exposed to lead in soils from historical mining activity. Results of the risk assessment determined the acceptability of continuing to use the site for a school, as well as the need for any alteration in plans to renovate and expand the existing school grounds.

Human Health Risk assessment in Support of Permitting, Sheep Mountain Uranium Mine, Titan Uranium, Jeffrey City, Wyoming. (2011). Responsible for input regarding impacts to human health in application for NRC license, including portions of the Environmental Report regarding public and occupational health impacts from the preferred alternative. Assisted health physicists in incorporating information from their evaluations into appropriate sections of the Technical Report and Environmental Report that were submitted to the NRC.

Environmental Sampling QAPP, Cameco, Wyoming. (2011). Prepared a draft Quality Assurance Project Plan (QAPP) for the Smith Ranch-Highland Uranium Project (SR-HUP) facility that included environmental sample collection and laboratory procedures for environmental samples. Report included data quality assurance procedures, quality control specifications, and other technical activities that assure that the data collected at SR-HUP meet appropriate data objectives and protocol per NRC guidance.

Screening Level Evaluation of an Off-site Relocation of the Large Tailings Pile, Homestake Mining Company, Grants Site. (2012). Compiled and evaluated of costs and risks associated with moving a large tailings pile from the Site to an off-site location. The purpose of the report was to explore costs, efforts, and regulatory requirements to be met under the alternatives of continuing with the current remediation and reclamation strategy or a hypothetical move of the tailings pile to a location outside of the San Andres Aquifer basin and the Village of Milan. For costing purposes, a distance of 30 miles for relocation was chosen in this evaluation. Costs, impacts, and potential risks of the off-site removal were evaluated to assist in long-term remediation decisions.

TENORM Dose Assessment, Waste Management of Colorado. (9/2017-5/2018). Provide radiation dose assessment for 2 landfills and one solidification plant in Colorado. Used site-specific inputs to provide dose assessment for current workers and future hypothetical resident farmers at the Sites, and to support alternative disposal limits for technologically enhanced naturally occurring radioactive material (TENORM).

Human Health Risk Assessment, American Bumper and Plating, Missoula, Montana. (2/2015-2/2016). Responsible for calculating risks and hazard indices associated with residual metal impacts in soils for potential current and future receptors. Evaluation included site-specific exposure pathways of soil ingestion, dermal contact, and inhalation of particulates by adult and child receptors, as well as an evaluation of the acceptability of lead concentration in soil for each of the four areas of the Site that were sampled and, in some cases, remediated.

Review of Subsurface Vapor Intrusion Model and Risk Assessment, Lockheed Martin Corporation, Torrance, California. (2011). On behalf of LMC, conducted an internal review of a human health risk assessment for the site related to subsurface vapor intrusion from a large, heterogeneous groundwater plume in several hydrogeologic formations. Identified potential issues surrounding the vapor intrusion modeling used, as well recommending a revision of the selection of chemicals of concern. Identified potential issues for LMC from calculating risks associated with non-detected chemicals and recommended a different approach to assessing non-detect data.

Human Health Risk Assessment, Department of Toxic Substances Control, Los Angeles, California. (2/2010 – 5/2010). Assisted in conducting a human health risk assessment for Chatsworth Park South, a park owned by the City of Los Angeles that had residual contamination from former skeet shooting activities. Assessment included metals related to dissolved lead pellets and PAHs from clay pigeons in shallow soil. The risk assessment will be used to guide remediation activities to re-open the facility.

Human Health Risk Assessments, Los Angeles Unified School District, Los Angeles, California. (2005-2010). Task leader for conducting risk assessments for proposed school sites in the greater Los Angeles Area. Environmental contamination assessed varied by site, but included petroleum products, pesticides, and heavy metals. In general, soil was the medium of interest and both direct and indirect exposure pathways were of concern. Provided risk assessments that focused on school-based and residential receptors to conform to California

guidance. In some cases, investigations were required at existing schools; in these cases, provided an evaluation of indoor exposure to impacted air or dust to current receptors. Data from these projects was shared with Department of Toxic Substances Control to establish a regional background concentration of arsenic in soil, which is still in regulatory use in the greater Los Angeles area.

Radiation Dose Reconstruction, Oak Ridge Associated Universities, Various Sites. (2003-2009). Reviewed historical documents and estimated potential occupational medical radiation exposures at former nuclear weapons facilities as part of the U.S. Department of Labor's Energy Employees Occupational Illness Compensation Program Act (EEOICPA). Duties included site research of former nuclear facilities and reconstruction of occupational medical practices at each facility that would contribute to worker radiation exposures. Dose reconstruction project at former nuclear weapon facilities was conducted as part of CDC's National Institute for Occupational Safety and Health program to facilitate their response to concerns of DOE workers and contractors requesting compensation for radiation-related cancers resulting from work-related exposure.

Human Health Risk Assessments, Naval Air Station Moffett, Naval Air Station Alameda, Naval Air Station Lemoore, Naval Air Weapons Station China Lake, Naval Auxiliary Landing Field Crows Landing, Naval Fuel Depot Point Molate, and Naval Station Treasure Island, California. (1996-2000). Task Leader for Risk Assessment of propellants, explosives, jet fuel, diesel, and gasoline releases to soil and groundwater and the potential to migrate to surface waters. Integrated ASTM Risk based Corrective Action (RBCA) processes and the California RWQCB's guidance documents, developed methods for screening potentially hazardous components. Method proved to be cost effective by allowing use of all data collected and decreasing the cost of confirmation sampling. Successfully negotiated site specific approach to evaluating volatilization into buildings, resulting in lower site specific air concentrations and cost savings by avoiding expensive air sampling. Site specific environmental conditions were used to demonstrate an increased rate of degradation of the components.

Human Health Risk Assessments, Naval Air Station Lemoore, Naval Air Station Alameda, Naval Air Weapons Station China Lake, Naval Air Station Moffett and Naval Auxiliary Landing Field Crow's Landing, California. (1996-2000). Task Manager for oversight of human health risk assessments and statistical programs, including evaluation of exposure scenarios and pathways; validation of toxicity values and calculated risks; negotiation of appropriate exposure areas based on current and future land use plans for the base and surrounding communities; statistical evaluation of several data acts; selection of chemicals of concern from combined data sets; and estimation of risks using several data aggregation methods. Evaluated exposure concerns including migration of contaminants from soil to groundwater and surface water. Chemicals of concern included chlorinated pesticides, herbicides, volatile organic chemicals, semi-volatile organic chemicals, metals (including arsenic), TPH, dioxins, furans, and perfluorinated compounds. Provided risk analyses of many different environmentally contaminated areas, including landfills, pesticide/herbicide storage, mixing, and application areas, industrial complexes, artillery ranges, and areas impacted by runoff or groundwater infiltration from these sites. Developed confirmation sampling plans for several sites based on grid sampling patterns and statistical methodology, as well as deriving risk-based concentrations for remediation and compliance studies involving PCBs, pesticides, and explosives.

Technical Support for Human Health Risk Assessments, U.S. Environmental Protection Agency. (1992-1996). Provided technical support on epidemiology, public health, and statistical issues to EPA's RCRA/CERCLA program as part of a technical enforcement support (TES) contract. Conducted technical reviews of human health risk assessment documents submitted to EPA to evaluate compliance with CERCLA guidelines. Also reviewed work plans, technical memoranda, and risk assessments submitted to EPA regarding RFETS. Provided oversight for RFETS, and assisted EPA in the development of Monte Carlo simulations for the site. Acted as EPA's representative in negotiating all phases of risk assessments for Rocky Flats, including sampling procedures, data evaluation, exposure scenarios and pathways, chemical intake assumptions and risk characterization. RFETS risk assessments included radionuclides and nonradioactive chemicals such as heavy metals, polycyclic aromatic hydrocarbons, and solvents. Also provided technical oversight in EPA Region VIII include F.E. Warren Air Force Base in Wyoming; Tooele Army Depot in Utah; and Hill Air Force Base in Utah. Project Manager and provided technical oversight for human health and ecological risk assessments at Amoco Mandan Refinery, a RCRA site in EPA Region VIII.

IDAHO DIVISION of

ENVIRONMENTAL QUALITY

MONDAY, JULY 13, 1992

Our Goal for Air Toxics Policy/Rule Making:

To protect the public health and the environment from the harmful effects of toxic air pollutants (TAP) per our responsibilities set forth in IDAPA 16.01.1011,01 and 1601.1952,02. and provide regulated industries with a reasonable, flexible, minimally burdensome framework with which to work.

Our Goal for this meeting:

To successfully negotiate air quality rules revisions that will satisfy the regulated industries need to have reasonable, flexible regulations that do not place an unwarranted impediment to their ability to do business in Idaho, while at the same time providing adequate protection to the public from the harmful effects of TAP. We hope that these revisions will provide industry with an awareness of what DEQ considers harmful and provide the basis for a straight forward and efficient permitting process.

Brief History of the DEQ TAP List

The DEQ TAP list (hereafter referred to as the list), was conceived as part of the New Source Review Policy, which was a response to the need to control the emissions of airborne toxic chemicals in the absence of effective EPA regulations. NESHAP (National Emmision Standards for Hazardous Air Pollutants, §122 of the 1970 Clean Air Act) had proven to be an ineffective means of of controling TAP as only seven pollutants were ever regulated after 17 years of the NESHAPS program.

It was the position of the DEQ that given the resources that we had available to us, that we would only attempt to hold the line on air quality and try to insure that new sources of air pollution did not "injure or unreasonably affect human or animal life or vegetation." One of the principal ways that we chose to do this was the development of a comprehensive list of TAP and, where possible, health based emissions limits and or acceptable ambient concentrations.

Our list was developed from a combination of sources. We surveyed what other states were doing and found that New Mexico had the most logical, straight approach to air toxics. The New Mexico list was chosen as the basis for our own TAP list. In addition, we looked at the Occupational Health and Safty Administration (OSHA), American Conference of Government and Industrial Hygenests (ACGIH) and National Institute for Occupational Safty and Health (NIOSH) occupational exposure limits (OEL) and threshold limit values (TLV) for non-carcinogens. For carcinogens we looked at the

data from the International Agency for Research on Cancer (IARC) and the Carcinogen Assesment Group of the EPA (CAG). In addition, we reviewed data from the Agency for Toxic Substances and Disease Registry of the Public Health Service. As many who have received periodic updates know, we have tried to continuously refine the list to reflect new data and to correct inaccuracies.

The DEQ list of regulated air toxics is quite large in scope. However, this was not done to burden industry. Quite the contrary. It was done in order, to the maximum extent possible, to provide industry with a ready reference to acceptable screening levels of these various compounds. This enables new sources to review their processes and see if controls, may be needed early on in the planning process, there by maximixing start up budget planning. In addition, it allows existing sources to review their emissions and see how they compare to the screening levels that the DEQ considers reasonably protective of human health and the environment. Please see appendix 6 for the derivation of emissions limits (EL) and acceptable ambient concentrations (AALC).

DEQ Position on the EPA "198" List

The EPA list of 189 compounds to be regulated represents a political process by the congress, rather than being put together by any environmental agency. This list is inadequate in and of it self to protect the air quality of Idaho or other specific location in the nation. This opinion is based on the following:

* The EPA 189 list is not an attempt to protect people or the environment of any specific area but a compromise list to address some of the major nation-wide sources of air pollution. The original proposed list contained 224 compounds, including ammonia and hydrogen sulfide which were later removed. We do not believe that this nation-wide effort can be effectively applied to Idaho and be adequate to address the unique Idaho situation. All along, EPA admitted that their agenda was not to protect all communities completely, rather their intent and design has been to address only pollutants and source catagories that are national in scope.

* The EPA 189 list does not include all the well documented carcinogens that have been assigned unit risk factors[1], let alone most possible and suspected carcinogens as listed in DEQ Appendix A2 of the New Source Review Policy. State and local agencies need to have the flexibility to protect public health by regulating the emission into the air of these very dangerous compounds should they be present locally.

* From only a partial inventory, we have found that there are currently being emitted into the ambient air of Idaho three known or suspected carcinogens which are not addressed by the EPA 189 list. In addition there are about 35 non-carcinogens of varying toxicity levels currently being emitted or being reviewed for new source permits.

* While it is not possible to predict the future, in a fast growing state like Idaho it is very reasonable to assume that new industries will be moving to Idaho as our work force expands with new residents. In addition, as environmental regulations in California and other states become more restrictive, Idaho will look more attractive to many of these regulated industries. This is already occurring in Nevada. While we certainly want the jobs and incomes that these industries may represent, just as certainly, we do not want to become a "toxic magnet" for polluting industries that other states don't want.

---

[1] Unit Risk Factors for a known or suspected carcinogen describes the possibility of developing excess cancers over a 70 year lifetime of exposure to 1 microgram per cubic meter of that substance.

* Title III of the Clean Air Act Amendments of 1990 (CAAA) requires EPA to publish a list of source categories and then promulgate maximum achievable control technology (MACT) for the first 40 categories. MACT standards are then required for the rest of the categories on a phased in schedule. Even if this time schedule was adhered to, the first MACT standards would not be available before November of 1992. Without its own TAP policy or rules and regulations, Idaho is thus without any appropriate air toxics regulation until EPA is finished. EPA is already late in publishing the first source category list.

* If a particular source in Idaho is not addressed in the first 40 source categories, the DEQ could be unable to address toxic emissions from that source no mater how toxic the emissions might be or in what quantity the emissions may be emitted until EPA finally promulgates MACT standards. Given the past history of EPA deadlines, this is a very real concern. Even if EPA adhered to all deadlines, some sources would conceivably still be able to emit unregulated toxics until the year 2000, if that source was in the last group to have standards promulgated. It should also be noted that not all sources are covered by these MACT standards. As a consequence, sources not covered by this MACT standard would be essentially unregulated in Idaho. Further, the majority of covered sources are associated with surface coating and manufacturing of the regulated chemicals, while fore most sources of TAP in Idaho, the TAP in question is used in or produced as a by-product of their processes.

* Finally, Congress itself apparently felt that this list was not final. Congress required the EPA to periodically review the list and add pollutants "...which present or may present ...a threat of adverse human health effects (including but not limited to, substances which are known to be, or may be reasonably be anticipated to be, carcinogenic, mutagenic, teratogenic, neurotoxic, which cause reproductive dysfunction, or which are acuity or chronically toxic) or adverse environmental effects..." The EPA 189 list should be considered to be a starting point for toxics regulations.

* It is not the intent of DEQ to require sources to do an emissions inventory of every compound on the DEQ list. It is quite reasonable to assume that any source, including the small sources, be familiar with their own processes. There are common, readily available sources of information, such as Material Safty Data Sheets (MSDS)[2] that will assist a source

---

[2] MSDS provides data concerning the nature and concentrations of hazardous or toxic components of substances used by a source. These sheets are available from the manufacturers of all compounds with hazardous or toxic components.

to ascertain what compounds can be reasonably assumed to be present in their process. They then need only inventory those compounds that can reasonably assumed to be emitted. In addition, the DEQ will be happy to assist sources in identifying potential TAP.

Some Options for Discussion

Option 1: Maintain current situation.
Pros: Would, of course, make DEQ happy; require no further legislation; all ready in place and functional.
Cons: Could make several in industry unhappy; may be seen as burdensome by industry; a policy is not as clear as a standard.

Option 2: Go with Maximum Achievable Control Technology (MACT) as per the 1990 CAAA or Best Available Control Technology (BACT) or Lowest Achievable Emissions Reduction (LAER) or Adaqualtly Demonstrated Control Technology (ADCT) or some other control technology based standard.
Pros: No EL or AALC; single consistent standard.
Cons: MACT/BACT etc. difficult to define: must be industry and chemical specific; lack flexibility esp. for relatively "clean" industries; no provision for new pollutants; may not adequately protect human health and the environment, esp. in the case where MACT/BACT has not been defined for various toxic chemicals.

Option 3: Regulate EPA "189 List" only
Pros: Would reduce the list in size; could possibly speed up permitting process
Cons: Not protective enough of human health and the environment; lacks flexibility; would not address many pollutants that are commonly emitted by modern industry; no provision for new pollutants; somewhat pointless as the EPA is already doing it; could complicate and slow the permitting process by increasing public comment over pollutants not covered.

Option 4: Regulate EPA "189 list" plus currently known TAP
Pros: list would be somewhat shorter and simpler;
Cons: no provision for adding new pollutants; could require more extensive and costly emissions inventories.

Option 5: Regulate EPA "189 List" plus any thing that has been identified elsewhere as toxic, hazardous or a carcinogen
Pros: Would be comprehensive; would regulate only pollutants that have been demonstrated to be of concern; would be similar to current policy, require little or no new legislation;
Cons: Could be a large list; May be seen as burdensome by some in industry; no provision for adding pollutants.

Option 6: Develop a series of "source specific" TAP lists
Pros: Would be easier for specific industries to know what to report on; A number of useful references available See Appendix 9.
Cons: Could require emissions inventories of some regulated industries; no provision for variation among industries of the same type; MSDS will not reflect bi-product compounds.

Option 7: Options 1 and 3 through 6 with the addtion of a method out side of DEQ to add TAP to lists. (Pros and Cons would, of course depend on the method for adding to the list, but in general, a board or review panel of some sort seems to be a common notion.)
Pros: Would provide DEQ with industry input on additions to lists; would provide DEQ with industry input on standards; would provide DEQ and industry with input by public interest groups;
Cons: Could slow down the process of adding new toxics and there for probably slow down the permitting process because of the public particapation process; could cause a political battle over the structure of the addition process; could convert the health based process for additions to list into a political one; depending on the make up of the committee/board, could be less protective of the public health.

Appendix 1

The following are known or possible carcinogens that have a URF but are not listed by EPA on the list of 189 toxics but are listed on Appendix A2 (carcinogens)

Aldrin* insecticide
Bis(2-chloroethyel)ether solvent
chloromethane methyl chloride
DDT insecticide, most uses banned; used for Tussock moth
1,2-dibromoethane solvent chemical industry
1,1-dichloroethane solvent
1,2-dichloroethane degreaser, ore flotation, solvent, paint, finish removers
1.1-dichloroethylene solvent
Dieldrin* insecticide
diethylstilbestrol synthetic estrogen
dimethylnitrosamine solvent
heptachlor epoxide insecticide
hexachlorodibenzo-p-dioxin (1:2 mixture) Possible. herbicide, a contaminant, poison
hydrazine sulfate mineral analysis, determination of arsenic in metals, fungicide, fumigant
3-methylcholanthrene biochemical research
N-nitroso-n-butylamine**
N-nitrosopyrrolidine**
pronamide herbicide
reserpine antihypertensive [lowers blood pressure], tranquilizer
thiourea photography, analytical reagent chemical intermediate

* part of current permit analysis at INEL Chem. Lab.
** no reference located
Benzo(a)pyrene, dibenz(a,h)anthracene, chrysene and other polynuclear aromatic hydrocarbons can be regulated under polycyclic organic mater (POM) which, as a category, is listed on the EPA list of 189.

Only two of these chemicals are currently under review. However, many of these chemicals are solvents which would seem to have the potential for use in industries common to Idaho (light manufacturing, electronics and so forth).

Appendix 2

The following are carcinogenic substances that are or have been reviewed in conjunction with permit applications in Idaho. These substances are not on the EPA 189 list but are on Appendix A2 (carcinogens):

Aldrin and **Dieldrin** as noted above
dimethyl sulfide from craft pulping black liquor

Appendix 3

The following are non-carcinogenic substances that are or have been reviewed in conjunction with permit applications in Idaho. These substances are not on the EPA 189 list but are on Appendix A1 (non-carcinogens): Note: many of these compounds are on the EPA Extremely Hazardous substances list, and the Community Right to Know list.

hydrogen sulfide: rotten eggs smell, human poison by inhalation, severe irritant, violent reaction with various metals & chemicals
methyl mercaptan: poison by inhalation,
turpentine: toxic by inhalation, irritant, experimental tumorigen
methanol: toxic by inhalation, experimental teratogen, reproductive effects, human mutagenic data.
fluorine: toxic by inhalation, irritant, mutagenic data
aluminum: possible cause of pulmonary fibrosis by inhalation
copper: tumorigen, teratogen, experimental reproductive effects
iron: potentially toxic by inhalation (arc welders lung)
magnesium: toxic by inhalation
zinc: relatively nontoxic
terphenyl: little toxicological data available
nitric acid: poison, corrosive, experimental teratogen and reproductive effects
isophorone diiysocyanate: poison by inhalation,
methyl ethyl ketone peroxide: moderately toxic by inhalation, experimental tumorigen
cyclohexanone: moderately toxic by inhalation, irritant
acetone: moderately toxic by various routes, irritant
hydrogen peroxide, 90%: moderately toxic by inhalation, skin contact, corrosive irritant, experimental tumorigen, suspected carcinogen
dimethyl disulfide: poison by inhalation
dimethyl sulfide: volitile liquid, gas odorant, solvent

Appendix 4

The following are non-carcinogenic substances that are or have been listed on the Toxic Release Inventory (TRI)[3] for Idaho. These substances are not on the EPA 189 list but are on Appendix A1 (non-carcinogens). Note: many of these compounds are on the EPA Extremely Hazardous substances list, and the Community Right to Know list.

sodium hydroxide: corrosive irritant, mutagenic data
methanol: toxic by inhalation, experimental teratogen, reproductive effects, human mutagenic data.
nitric acid: poison, corrosive, experimental teratogen and reproductive effects
hydrofluoric acid: human poison by inhalation, corrosive irritant, experimental teratogenic, reproductive effects, mutagenic data
chlorine: Moderately toxic by inhalation, irritant, human mutagenic data
ammonia: experimental poison by inhalation, irritant, mutagenic data
phosphoric acid: human poison, corrosive irritant
copper: tumorigen, teratogen, experimental reproductive effects
Methylene diphenyl diisocyanate (MDI): poison by inhalation, irritant, mutagenic data
Freon 113: most uses will be fazed out by 1995
ammonium sulfate: moderately toxic by several routes
ammonium nitrate: powerful allergen
zinc compounds: relatively nontoxic
barium compounds: low toxicity
hydrochloric acid: poison by unspecified route, mildly toxic by inhalation, corrosive irritant
manganese compounds: toxic by inhalation

The following substances are non-carcinogenic substances that are being reviewed in conjunction with permit applications or field inspections. These substances are not on the EPA 189 or currently on the DEQ list. ***This points out the need to be able to respond to changing circumstances.***

Acenaphthylene: irritant, mutagenic data
Amino functional Siloxane: organosilicon oxide polymer, mild to severe irritant
Busan 1127D (2-(thiocyanomethylthio)benzothiazole): mist is considered moderatly to highly toxic.
Carbitol Acetate (2-(2-Ethyoxyethoxy) Ethyl Acetate): solvent and placticizer
dimethyl disulfide: poison by inhalation

---

[3] The TRI is a report of all emissions of compounds required to be disclosed under SARA Title III.

Appendix 5

The following are examples of sources now existing in Idaho that have air releases of substances not on the EPA 189 list:

American Micro systems Inc.
Basic American Foods
Blount Industries
Borden Inc. Dairy
Del Monte Foods USA #130
Deming Industries
Fiberglass Systems Inc.
FMC Corp.
Gustafson
Hewlett Packard
IBP Inc.
INEL
J.R. Simplot
J.R. Simplot Food Di.
John E. Quinn
Kerr McGee Vanadium Facility
Kraft Inc.
MIcron Technology
Monsanto
N.A Degerstrom Inc.
Nu-West Industries Inc
Ore-Ida Foods
Peabody Spunstrand
Penford Products Co.
Pondarosa Paint Mfg. Inc.
Post Falls Particalboard
Potlatch
Spears Manufacturing Inc.
Unitech Composites Inc.
Zilog

Appendix 6

In developing emissions limits for new permitted facilities, the Idaho DEQ uses the terms Unit Risk Factors and Threshold Limit Values. The following is an explanation of these terms and how they are used.

UNIT RISK FACTOR

A unit risk factor (URF) is used to describe the possibility of developing excess cancers over an average 70 year lifetime. This is based on being exposed to concentration of one microgram of a carcinogenic (cancer causing) substance in one cubic meter ($1\ ug/m^3$) of air over 70 years. The term excess cancers means cases of cancers in excess of what would be normal for a given population. For example, if there was normally 5 cases of a given type of cancer in Anytown USA before a given exposure to some substance and 7 after the exposure, there would be 2 excess cancers.

Inhalation URFs are developed for carcinogenic substances by the EPA. Each URF represents months of research and often years of policy process. Teams of toxicologists gather toxicological data for each known or suspected carcinogen. The available data are then rated or point factored per the quality of the research involved. A URF is then a probability statement derived from this process. Each URF proposed by EPA is extensively reviewed and debated in public by scientists, health officials and industry representatives. Every URF represents a consensus of the best science and health opinion of the potency of a given carcinogen.

URFs are usually expressed as a number times 10 to some negative power. For example, benzene, an organic hydrocarbon found in various petroleum products and cigarette smoke has a unit risk factor of 8.3×10^{-6}. This means that are 8.3 chances in one million of getting cancer if a person is exposed to $1\ \mu g/m^3$ 24 hours a day for 70 years.

Another example would be asbestos. Asbestos has a URF of 2.3×10^{-1}. That means that if exposed to $1\ ug/m^3$ concentration for 70 years, the chances of getting cancer would be .23 in 10.

Within IAQB New Source Review (NSR) policy, URFs are used to calculate acceptable ambient levels for a given carcinogen. IAQB generally establishes that an ambient concentration which causes no more excess cancers than one in a million (1×10^{-6}) is acceptable. Once an acceptable ambient level is established, IAQB can then back calculate via engineering equations to an acceptable emission rate (in pounds per hour) for a given stack.

THRESHOLD LIMIT VALUE

Threshold Limit Value (TLV) is a time weighted exposure limit developed by the Occupation and Safety Administration or the American Council of Government Industrial Hygienists. This value is used to limit the exposure of informed workers to a given toxic substance in the work place. The value is based on exposure of adult males working an eight hour shift. The DEQ uses TLV information to screen proposed new source emissions levels. The DEQ divides the TLV first by a value of 10 due to the fact that an ambient air exposure of a carcinogen means people are usually living under that exposure longer than eight hours out of 24. This value is then again divided by 10 to compensate for the fact that not everyone who is potentially exposed is an adult male. Other people may be more sensitive. The TLV thus is divided by a total of 100 for use in setting an acceptable ambient level.

For example, the TLV for cyanide is 5 milligrams per cubic meter (mg/m^3). An acceptable ambient level under DEQ policy would be 5 divided by 100 or 0.05 mg/m^3. For another example, the TLV for Lindane (an insecticide) would be 0.5 mg/m^3 concentration. The acceptable ambient level would be 0.5 divided by 100 or 0.005 mg/m^3. As with carcinogens, the TLV derived acceptable ambient levels are used by the DEQ engineers to back calculate an acceptable stack emission rate for any proposed new source.

EL and AAL(C) as listed in the TAP list are *screening levels*, not standards. If a proposed source, at any level of review is shown to be under the screening level for the TAP in question then the source goes forward in the permitting process. If, on the other hand, the source is shown to likely exceed the screening level, then there is a number of options such as further analysis or enhanced controls that can be pursued. See: Idaho DEQ Procedures for Modeling Impacts of Toxic Air Emissions and Assessing Associated Risk Appendix 7, and the General Summary of DEQ's New Source Review Policy for Toxic Air Pollutants, Appendix 8 for a more complete discussion of this topic.

APPENDIX 7

DRAFT

Idaho DEQ Procedures for Modeling Impacts of Toxic Air Emissions and Assessing Associated Risk

Procedures for modeling the dispersion of air emissions are consistent for criteria pollutants and toxics.

Emissions are calculated for the specific operation, with EPA's AP-42 as the standard guidance document. Impacts for any toxic air pollutant (TAP) emitted in potentially significant amounts are estimated through a three tiered evaluation approach, using the Division of Environmental Quality (DEQ) TAP list and models approved by EPA for regulatory use.

The emissions screening levels as listed on the DEQ TAP list are a quick way to determine if modeling is needed. If a toxic air pollutant has the maximum potential to be emitted at levels below the screening emission level, the proposed emission is typically approved by the DEQ.

If the maximum potential emissions are above the screening levels, then modeling is performed. The models most commonly used for the first modeling run are TSCREEN and SCREEN for single emission points, or ISC with worst case meteorological data for multiple emission points. In "screening modeling", quantified emissions and stack (or fugitive) data are required, as well as distance to property boundary or, with DEQ approval, an off site receptor. Estimates of off site concentrations of the pollutant(s) are output by the model, which assumes a variety of worst case dispersion conditions. Model output is typically in one hour averages. Persistence factors are usually used to estimate worst case impacts for other averaging periods. Unit risk factors are then applied to translate the predicted off site concentrations to determine risk to those exposed.

If, after "screening modeling", unacceptable risks still are shown to be possible, refined modeling may be done. Refined modeling replaces many worst case assumptions in screening modeling with actual conditions. In refined modeling, a more realistic three dimensional simulation of emissions, topography, meteorology, and receptors is supplied. Actual on site meteorological data typically helps the applicant, since the alternative is a worst case meteorological data file like that used in screening modeling. The most commonly used models are ISC, COMPLEX1, and FDM. Refined modeling provides the most detailed and accurate assessment of potential air quality impacts.

After ambient concentrations are determined, these ambient levels are, in the case of known or suspected carcinogens (TAP list Appendix A2), converted to annual concentrations using persistence factors as mentioned above. They are then multiplied by the EPA

unit risk factor (URF) to obtain a risk level. A risk level of one in a million is generally considered acceptable for a long term or permanent emissions source. The acceptable ambient levels for a carcinogen (AALC) listed in the TAP list Appendix A2 reflect this one in a million risk level for carcinogens with established URFs.

For short term sources (usually less than five years in duration), such as remediation projects, a probability of greater than one in a million risk (over a 70 years) will generally be acceptable to account for the decreased term of exposure. It is not acceptable however, for exposed individuals to receive a full 70 year exposure during the life of a short term project. In addition, first impacts at receptor sites farther from the source than property boundaries may be considered for short duration projects.

For non-carcinogens (TAP list Appendix A1) the risk assessment procedures are similar. Ambient concentrations are compared with 1/100 of the published American Council of Government and Industrial Hygienists (ACGIH) Occupational Exposure Limits (OEL) or other ambient standard adopted by the DEQ in the absence of a published ACGIH OEL.

The 1/100 factor was derived to accommodate two levels of extrapolation of potential risk to the general public:

1. ACGIH factors assume an eight hour exposure; source exposures are generally continuous (24 hrs.).

2. ACGIH factors are derived from historical data that comes essentially from a work force of healthy adult males.

Thus we have used an uncertainty factor of 100 (10X for each of the above conditions) to accommodate the more sensitive populations.

In the absence of any published URF or OEL. the acceptable ambient concentration will be considered the detection limit unless it can be demonstrated to the satisfaction of the DEQ that an ambient level higher than the detection limit will not have an adverse effect on human health or the environment. In such cases we have allowed the toxicological profiles of like chemicals or compounds to be substituted for the unknowns.

General Summary of Idaho Air Quality Bureau's New Source Review Policy for Toxic Air Pollutants

Regulation Summary

January 1991

Toxic substances within ambient air are regulated in Idaho by IDAPA 16.01.1011,01. Toxic Substances, which states:

> *Any contaminant which is by its nature toxic to human or animal life or vegetation, but is not specifically controlled elsewhere in Idaho Department of Health and Welfare Rules and Regulations, Title 1, Chapter 1, "Rules and Regulations for the Control of Air Pollution in Idaho," shall not be emitted in such quantities or concentrations as to alone, or in combination with other contaminants, injure or unreasonably affect human or animal life or vegetation. As information becomes available, limits will be specified for concentration of toxic materials in the ambient air and emission limits will be set accordingly.*
>
> *(1-24-69)*

Any new source of air pollutants (including toxic pollutants) not specifically covered by the thirteen (13) specific New Source Performance Standards is regulated by IDAPA 16.01.1952,02 Sources Not Specifically Regulated which states:

> *Sources not specifically regulated under Idaho Department of Health and Welfare Rules and Regulations Sections 01.1955 through 01.1999 shall achieve the greatest degree of emission reduction that has been adequately demonstrated.*
>
> *(1-1-75)*

Idaho Air Quality Bureau (IAQB) has developed a method for permitting new sources of toxic air pollutants consistent with our responsibilities and authority under the Rules and Regulations for the Control of Air Pollution in Idaho. For that method, IAQB compiled a list of toxic air pollutants (TAP) and screening level emission limits for those substances.

Permit Decisions

If the Bureau finds that an eight-hour average ambient concentration of a toxic air pollutant will likely not exceed one hundredth (.01) of the OEL for non carcinogens, or is below detection levels for a compound without an OEL or URF, the Bureau shall grant the permit.

Similarly, if the Bureau can substantiate that ambient concentrations due to emissions of known or suspected carcinogens are not likely to cause excess cancers of more than one in a million (10^{-6}) then the bureau shall grant a permit.

If potential new source emissions are shown to likely cause ambient concentrations:

1. in excess of 1/100 of the OEL or

2. which could cause cancers in excess of one in one hundred thousand (10^{-5}) or

3. which exceed minimum detection levels for TAP without an OEL or URF,

the Bureau may grant the permit if the applicant implements the best available control technology (BACT) for that source or pollutant and after considering other factors.

If the TAP screening level is shown to likely be exceeded the Bureau will make a final decision considering the following factors:

(a) the health and environmental assessment prepared by the applicant (if one is required by the Bureau);

(b) the nature of the toxic air pollutant and the susceptibility and proximity of the human population;

(c) other health and environmental impacts associated with the anticipated level of exposure.

The Bureau may grant a permit for a new source to emit carcinogens which are likely to cause excess cancers between 1/100,000 and 1/1,000,000 (between 10^{-5} and 10^{-6}) after the applicant proves that additional controls would be a severe hardship.

Appendix 9

Samples of Industry Specific TAP Emissions Data for an Example Industry; the Asphalt Paving Mixtures and Block Industry, SIC Code 2951

4.5 CUTBACK ASPHALT, EMULSIFIED ASPHALT AND ASPHALT CEMENT

4.5.1 General[1-3]

Asphalt surfaces and pavements are composed of compacted aggregate and an asphalt binder. Aggregate materials are produced from rock quarries as manufactured stone or are obtained from natural gravel or soil deposits. Metal ore refining processes produce artificial aggregates as a byproduct. In asphalt, the aggregate performs three functions. It transmits the load from the surface to the base course, takes the abrasive wear of traffic, and provides a nonskid surface. The asphalt binder holds the aggregate together, preventing displacement and loss of aggregate and providing a waterproof cover for the base.

Asphalt binders take the form of asphalt cement (the residue of the distillation of crude oils) and liquified asphalts. To be used for pavement, asphalt cement, which is semisolid, must be heated prior to mixing with aggregate. The resulting hot mix asphalt concrete is generally applied in thicknesses of from two to six inches. Liquified asphalts are (1) asphalt cutbacks (asphalt cement thinned or "cutback" with volatile petroleum distillates such as naptha, kerosene, etc.) and (2) asphalt emulsions (nonflammable liquids produced by combining asphalt and water with an emulsifying agent, such as soap). Liquified asphalts are used in tack and seal operations, in priming roadbeds for hot mix application, and for paving operations up to several inches thick.

Cutback asphalts fall into three broad categories: rapid cure (RC), medium cure (MC), and slow cure (SC) road oils. SC, MC and RC cutbacks are prepared by blending asphalt cement with heavy residual oils, kerosene-type solvents, or naptha and gasoline solvents, respectively. Depending on the viscosity desired, the proportions of solvent added generally range from 25 to 45 percent by volume.

Emulsified asphalts are of two basic types. One type relies on water evaporation to cure. The other type (cationic emulsions) relies on ionic bonding of the emulsion and the aggregate surface. Emulsified asphalt can substitute for cutback in almost any application. Emulsified asphalts are gaining in popularity, because of the energy and environmental problems associated with the use of cutback asphalts.

4.5.2 Emissions[1,2]

The primary pollutants of concern from asphalts and asphalt paving operations are volatile organic compounds (VOC). Of the three types of asphalts, the major source of VOC is cutback. Only minor amounts of VOC are emitted from emulsified asphalts and asphalt cement.

VOC emissions from cutback asphalts result from the evaporation of the petroleum distillate solvent, or diluent, used to liquify the asphalt cement. Emissions occur at both the job site and the mixing plant. At the job site, VOCs are emitted from the equipment used to apply the asphaltic product and from the road surface. At the mixing plant, VOCs are released during mixing and stockpiling. The largest source of emissions, however, is the road surface itself.

For any given amount of cutback asphalt, total emissions are believed to be the same, regardless of stockpiling, mixing and application times. The two major variables affecting both the quantity of VOC emitted and the time over which emissions occur are the type and the quantity of petroleum distillate used as a diluent. As an approximation, long term emissions from cutback asphalts can be estimated by assuming that 95 percent of the diluent evaporates from rapid cure (RC) cutback asphalts, 70 percent from medium cure (MC) cutbacks, and about 25 percent from slow cure (SC) asphalts, by weight percent. Some of the diluent appears to be retained permanently in the road surface after application. Limited test data suggest that, from rapid cure (RC) asphalt, 75 percent of the total diluent loss occurs on the first day after

application, 90 percent occurs within the first month, and 95 percent in three to four months. Evaporation takes place more slowly from medium cure (MC) asphalts, with roughly 20 percent of the diluent being emitted during the first day, 50 percent during the first week, and 70 percent after three to four months. No measured data are available for slow cure (SC) asphalts, although the quantity emitted is believed to be considerably less than with either rapid or medium cure asphalts, and the time during which emissions take place is expected to be considerably longer (Figure 4.5-1). An example calculation for determining VOC emissions from cutback asphalts is given below:

Example: Local records indicate that 10,000 kg of RC cutback asphalt (containing 45 percent diluent, by volume) was applied in a given area during the year. Calculate the mass of VOC emitted during the year from this application.

To determine VOC emissions, the volume of diluent present in the cutback asphalt must first be determined. Because of density of naptha (0.7 kg/l) differs from that of asphalt cement (1.1 kg/l), the following equations should be solved to determine the volume of diluent (x) and the volume of asphalt cement (y) in the cutback asphalt:

$$10{,}000 \text{ kg cutback asphalt} = (\text{x liter, diluent}) \cdot \left(\frac{0.7 \text{ kg}}{\text{liter}}\right) + (\text{y liter, asphalt cement}) \cdot \left(\frac{1.1 \text{ kg}}{\text{liter}}\right)$$

and

$$\text{x liter, diluent} = 0.45\ (\text{x liter, diluent} + \text{y liter, asphalt cement})$$

From these equations, the volume of diluent present in the cutback asphalt is determined to be about 4900 liters, or about 3400 kg. Assuming that 95 percent of this is evaporative VOC, emissions are then: 3400 kg x 0.95 = 3200 kg (i.e., 32% by weight, of the cutback asphalt eventually evaporates).

These equations can be used for medium cure and slow cure asphalts by assuming typical diluent densities of 0.8 and 0.9 kg/liter, respectively. Of course, if actual density values are known from local records, they should be used in the above equations rather than typical values. Also, if different diluent contents are used, they should also be reflected in the above calculations. If actual diluent contents are not known, a typical value of 35 percent may be assumed for inventory purposes.

In lieu of solving the equations in the above example, Table 4.5-1 may be used to estimate long term emissions from cutback asphalts. Table 4.5-1 directly yields long term emissions as a function of the volume of diluent added to the cutback and of the density of the diluents and asphalt cement used in the cutback asphalt. If short term emissions are to be estimated, Figure 4.5-1 should be used in conjunction with Table 4.5-1.

No control devices are employed to reduce evaporative emissions from cutback asphalts. Asphalt emulsions are typically used in place of cutback asphalts to eliminate VOC emissions.

REC 4347

TR 1032

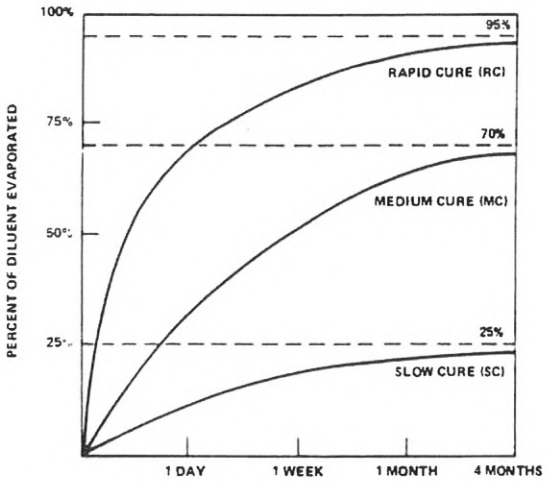

Figure 4.5-1. Percent of diluent evaporated from cutback asphalt over time.

TABLE 4.5-1. EVAPORATIVE VOC EMISSIONS FROM CUTBACK ASPHALTS AS A FUNCTION OF DILUENT CONTENT AND CUTBACK ASPHALT TYPE[a]

EMISSION FACTOR RATING: C

Type of Cutback[b]	Percent, by Volume, of Diluent in Cutback[c]		
	25%	35%	45%
Rapid cure	17	24	32
Medium cure	14	20	26
Slow cure	5	8	10

[a]These numbers represent the percent, by weight, of cutback asphalt evaporated. Factors are based on References 1 and 2.

[b]Typical densities assumed for diluents used in RC, MC and SC cutbacks are 0.7, 0.8 and 0.9 kg/liter, respectively.

[c]Diluent contents typically range between 25-45%, by volume. Emissions may be linearly interpolated for any given type of cutback between these values.

FIRE AND EXPLOSIVE DATA

Flash Point - N/A
Autoignition Temperature NFPA - N/A
Extinguishing Media - CO2, Class "B" extinguisher, foam and water fog.
Special Fire Fighting Procedures - Avoid breathing vapors, wear self-contained breathing apparatus.
Unusual Fire Explosion Hazards - DO NOT heat material above 212f to avoid generating excessive steam pressure.

REACTIVITY DATA

Stable: X Unstable:

Conditions to Avoid	-	DO NOT HEAT ABOVE 212f, Ignition sources.
Incompatible Materials	-	Avoid strong oxidizing agents
Hazardous Decomposition Products	-	Combustion may form CO2, CO, and sulfur oxide.
Hazardous Polymerization	-	Will not occur.

HEALTH HAZARD DATA

Route of Exposure	Primary Route	Signs and Symptoms
Inhalation	[X]	Use with good ventilation. May cause respiratory tract irritation
Skin Absorption	[ ]	No significant symptoms indicative of skin absorption expected.
Skin Irritation	[X]	Will cause burns when product is hot. May cause dermatitis and acne like lesions on prolonged exposure.
Ingestion	[ ]	May cause nausea and diarrhea.
Eye Contact	[X]	Will burn and irritate.

Listed as Carcinogen? Not listed by NTP, IARC, or OSHA.

EMERGENCY FIRST AID

Inhalation:	Remove to fresh air. Give oxygen or artificial respiration as needed Obtain medical attention promptly.
Eye Contact:	Flush eyes with low pressure water for at least 15 minutes and obtain medical attention immediately.
Skin Contact:	If product is hot, cool with cold water. Otherwise wash thoroughly with soap and water.
Ingestion:	Call physician. Do not induce vomiting.

PROTECTIVE EQUIPMENT / CONTROL MEASURES

Respiratory Protection:	Avoid breathing vapors in confined spaces. NIOSH approved respirators may be required if TLV's are exceeded.
Eye Protection:	Use safety glasses, goggles or face shields.
Skin Protection:	Use rubber gloves, coveralls and impervious footwear.
Engineering controls:	Local exhaust ventilation may be required to meet exposure standards in confined areas.
Handling Precautions:	Avoid heating over 212f.

SPILL AND DISPOSAL

Spill or Release:	Stop release, prevent flow from entering sewers or public waters. Allow to cool. Recover large spill. Let product cure or soak up with sand on smaller spills.
Waste Disposal Method:	Handle in accordance with federal, state and local regulations.

REVISION #1

LABEL INFORMATION

Chemical name: Asphalt Cements
Common name: Penetration Graded Asphalt AASHTO M-20;
Viscosity Graded Asphalt AASHTO M-226.

DANGER! VAPOR HARMFUL
DO NOT INTRODUCE WATER

Keep away from flames and other sources of ignition
Stable unless moisture is introduced
Extinguishing media - CO_2 or Class 'B' extinguisher
DO NOT APPLY WATER
Avoid breathing vapors. May contain low concentrations of hydrogen sulfide. Wear self-contained breathing apparatus when fire fighting. May cause dermatitis and acne lesions on prolonged and repeated exposure. Can cause severe burns when hot material contacts unprotected skin. Wear chemical resistant gloves, goggles or face shield, long sleeve shirt and pants. Use NIOSH approved respirator if TVL's are exceeded.

FIRST AID

Inhalation - Remove victim to fresh air. Start artificial resuscitation if necessary. Call a physician.

Eyes - Flush eyes with water for at least 15 minutes. Call a physician.

Skin- If hot material contacts skin, place affected part in cold water. Have a physician remove material or for small amounts use mineral oil for removal.

Ingestion - If ingested call a physician.

For further information refer to data sheet for Asphalt Cements.

P.O. Box 909, Laurel, Montana 59044

Asphalt Cements
Quick Identifier

MATERIAL SAFETY DATA SHEET

The information contained herein is based on data considered accurate, however, no warranty is expressed or implied regarding the accuracy of these data or the results to be obtained from the use thereof. Vendor assumes no responsibility for injury to vendee or third person proximately caused by the material if reasonable safety procedures are not adhered to as stipulated in the data sheet. Additionally, vendor assumes no responsibility for injury to vendee or third persons proximately caused by abnormal use of the material even if reasonable safety procedures are followed. Furthermore, vendee assumes the risk in his use of the material.

SECTION 1 GENERAL

Manufacturer's Name: Farmers Union Central Exchange, Inc. (CENEX)

Emergency Telephone No. 406/628-4518 | Information Telephone No. 406/628-4311

Chemical Name: Asphalt Cements | Date Prepared: 9/20/85

Chemical Family: Petroleum Asphalt Cements

Common Name(s): Penetration graded asphalt AASHTO M-20; Viscosity graded asphalt AASHTO M-22(

SECTION 2 HAZARDOUS INGREDIENTS/IDENTITY

This product, when heated above the softening point, may contain low concentrations of hydrogen sulfide. This gas, at low concentrations, may be irritating to eyes, skin and respiratory tract.

OSHA PEL: Petroleum Asphalt Cement Not Available

ACGIH TLV'S: Asphalt Cements - 5mg/m^3 Fumes; STEL - 10mg/m^3

SECTION 3 PHYSICAL/CHEMICAL CHARACTERISTICS

Boiling Point	Above 1050°F	Specific Gravity	1.02-1.06
Vapor Pressure	<1	Melting Point	Unknown
Vapor Density	>1	Evaporation Rate	Unknown

Solubility in Water: No

Appearance and Odor: Black semi-solid thermoplastic material; odor of hydrocarbon.

Becomes liquid above 90-130°F

SECTION 4 FIRE AND EXPLOSION HAZARD DATA

Flash Point in Degrees F (Method Used)	Above 325°F COC (D-92)	Flammable Limits in air % by volume	LEL Unknown	UEL Unknown

Extinguishing Media: CO_2 and Class 'B' extinguisher

Special Fire Fighting Procedures: Avoid breathing vapors, wear self-contained breathing apparatus. DO NOT APPLY WATER.

Unusual Fire and Explosion Hazards: Flammable at temperatures above 500°F.

DO NOT MIX WITH WATER.

SECTION 5 REACTIVITY DATA

Stability	Unstable		Conditions to Avoid	Stable unless moisture is introduced
	Stable	X		Flames and other sources of ignition

Incompatability (Materials to Avoid): Water, hydrocarbon solvents, strong oxidizing agents

Hazardous Decomposition Products: Fumes, smoke, carbon monoxide in the case of incomplete combustion

Hazardous Polymerization	May Occur	REC 4365	Conditions to Avoid	
	Will Not Occur	X		

TR 1050

SECTION 6 HEALTH HAZARDS

Acute Will cause severe burns if hot material contacts unprotected skin.

Chronic Respiratory tract irritation

Signs & Symptoms of Exposure May cause dermatitis and acne like lesions on prolonged and repeated exposure to dust or vapors.

Medical Conditions Generally Aggravated by Exposure Respiratory disease and infection; cardiovascular diseases

Chemical Listed as Carcinogen or Potential Carcinogen	National Toxicology Program	Yes		IARC	Yes		OSHA	Yes	
		No	X		No	X		No	X

ROUTES OF ENTRY WITH EMERGENCY & FIRST AID PROCEDURES

1. Inhalation Remove victim to fresh air. Start artificial resuscitation if necessary. Call a physician.
2. Eyes Flush eyes with water for at least 15 minutes. Call a physician.
3. Skin If hot material contacts skin, place affected part in cold water. Have a physician remove material or for small amounts use mineral oil for removal.
4. Ingestion If ingested call a physician.

SECTION 7 SPECIAL PRECAUTIONS

Precautions to be Taken in Handling and Storing Never introduce water when hot. Avoid skin exposure to hot material. Avoid breathing vapors in confined spaces. Avoid sources of ignition.

Shipping Information DOT ID #NA1999 - No Placard Required

Steps to be Taken in Case Material is Spilled or Released In case of spillage allow to cool and pick up when solid or semi-solid. Have proper extinguishing media present.

Waste Disposal Methods Handle in accordance with federal, state and local regulations.

SECTION 8 CONTROL MEASURES

Ventilation 1. Local Exhaust 2. Mechanical — If possibility of vapor or fume accumulation exists, utiliz explosion proof ventilating equipment, to avoid toxic or explosive concentrations.

Protective Gloves Chemical Resistant

Eye Protection Goggles or Face Shield

Respiratory Protection (Specify Type) Use appropriate NIOSH approved respirator if TLV's are exceeded.

Other Protective Clothing or Equipment Long sleeve shirt and pants to minimize skin contact.

Work & Hygienic Wash exposed skin with soap and water after work periods and before

Idaho Division of Environmental Quality

Air Permitting Screening Policy for Air Strippers used in the Cleanup of Petroleum Contaminated Groundwater

DRAFT

DRAFT

This policy is designed to quickly identify air stripper cleanups of petroleum contaminated ground water which pose limited risk to the public through the air pathway, and to expedite the approval for such air emissions. This policy is designed to work together with DEQ's Screening Model and Risk Assessment Procedures For Air Quality Permitting of Vapor Extraction Systems and Air Stripping Used for Leaking Underground Storage Tank Cleanup. Version 1.0 of that document is being updated to include this screening policy for air stripping.

The policy is implemented through a simple question and answer form (a copy of which follows), which conservatively estimates the significance of the emissions given the distance to the nearest property boundary or receptor. Sources with relatively insignificant emissions, as determined by answering the questions on the form and documented as required on the form, are offered DEQ review and final action within two weeks of the date of receipt. This significantly accelerates DEQ turnaround time to expedite the cleanup, since the timeline on processing air permit applications is typically 90 days or more.

For the purposes of this policy, a sensitive receptor is defined as any building or location occupied or frequented by persons who, due to age, infirmity or other health based criteria as defined by the Division of Environmental Quality, may be more susceptible to the deleterious effects of a toxic air pollutant(s) than the general population. Examples of sensitive receptors include but are not limited to: elementary and secondary schools, licensed day care centers, playgrounds and parks, hospitals, clinics and nursing homes.

The existence of a sensitive receptor within 500 feet of the proposed action will not necessarily result in a permit denial, but will trigger tighter DEQ scrutiny of risks to the surrounding population.

This screening policy does not supersede any other DEQ policies or requirements, but instead complements existing DEQ policies by identifying low risk sources, removing them from the standard air permit workload, and accelerating their review. Sources not approvable through this screening policy still may be approvable through the DEQ air quality permitting program. In those cases, a more thorough risk assessment will be required and DEQ review will remain on traditional timelines.

DRAFT

AIR PERMIT SCREENING TEST FOR AIR STRIPPING PETROLEUM CONTAMINATED WATER

Company/facility name _____
Facility address _____

A. PRESENCE OF SENSITIVE RECEPTORS

Is the proposed air stripping site located within 500 feet of a sensitive recepto: defined in the attached Air Permitting Screening Policy for Air Strippers used i Cleanup of Petroleum Contaminated Ground water?

YES _____ NO _____

B. CALCULATE UNCONTROLLED BENZENE LEVELS IN AIR EMISSIONS

1. Flow rate of water into Air Stripper in gallons per minute. The proposed flow must have DEQ approval. The proposed flow rate must be sufficient to adequ control, contain, and remove the petroleum contamination. Please a documentation verifying DEQ approval of the proposed flow rate.

_____ gal./min

2. Convert flow rate to liters per minute.
Multiply line 1 by 3.785. _____ l/min.

3. Determine Benzene concentration in ground water.

Is free product present in any ground water well associated with this petroleum release site? YES _____ NO _____

a. If you marked YES, you must conduct a pilot test to determine expected be concentrations. See the attached "Directions for Conducting a Pilo Determine Benzene Concentrations in Ground Water" for more informatio the benzene concentration here.

Benzene concentration from pilot test = _____ ppb (ug,

b. If you marked NO and free product is <u>not</u> present in any well, determine benzene concentration in the ground water by one of the following two met

i. Enter the Benzene concentration from a ground water well with the hi benzene concentration. Use only the most recent analysis.

Benzene concentration from single well = _____ ppb (ug,

ii. Conduct a pilot test to determine benzene concentrations following directions of the attached "Directions for Conducting Pilot a Tes Determine Benzene Concentrations in Ground Water."

Benzene concentration from pilot test = _____ ppb (ug,

4. Calculate benzene flow rate to air stripper.
Multiply line 2 by line 3a or 3b, whichever is appropriate. _____ ug/min.

5. Convert uncontrolled benzene air emission rate from ug/min to lbs/day. Multiply line 4 by 3.18E-6. _____ lbs./day

B. CALCULATION OF MAXIMUM ALLOWABLE BENZENE EMISSION RATE

6. a. Distance to nearest property line. _____ ft
b. Distance to nearest offsite structure serving as a workplace or residence _____ ft

DRAFT

7. **Allowable Benzene emission level.**

a. Divide Line 6a by 100. _____
b. Divide line 6b by 200. _____
c. Enter the larger of line 7a or Line 7b _____
d. Enter the value 1.5 or the result from 7c, whichever is smaller. _____ lbs./day

The result in line 7d is the maximum allowable benzene emission rate for the proposed stripping operation at this site. Is the uncontrolled emission rate for benzene in li less than the maximum allowable benzene emission level in line 7d?

Yes ____ Control of benzene air emissions shall not be required. You ay skip Sec C. of this form and proceed directly to Section D. Document all data ent and enclose complete set of most recent water sampling results, a site map c to scale showing monitoring wells, and your monitoring plan. Send them with form to Division of Environmental Quality, Permits and Enforcement Program, N. Hilton, Boise, ID 83706.

No ____ Control of benzene air emissions shall be required. Call (208) 334-5898 review air quality permit requirements or proceed to the following page complete questions on emissions controls.

C. **CALCULATE CONTROLLED BENZENE LEVELS IN AIR EMISSIONS**
(please complete lines 1 to 7 before proceeding with this section)

8. Describe the type of emissions control you propose to use.
_____
_____
_____

9. Control Efficiency (0 < eff. < 1) 0.

10. 1.0 - Control Efficiency 0.

11. Enter uncontrolled benzene air emission rate from line 7 on reverse side. _____ lbs/day

12. Controlled benzene emissions Multiply lines 10 and 11. _____ lbs/day

Is the controlled emission rate for Benzene in line 12 less than the maximum allow Benzene emission rate calculated in line 7d?

Yes ____ Document all data entries and enclose complete set of most recent water samp results, a site map drawn to scale showing monitoring wells, your monitc plan, and documentation on the control equipment (manufacturer's specificatic its application at the proposed site, and its efficiency if credit is take emission controls through this process. Send them with this form to Div: of Environmental Quality, Permits and Enforcement Program, 1410 N. Hilton, Bc ID 83706.

No ____ Call (208) 334-5898, to review air quality permit requirements with DEQ staff

D. **SIGNATURE AND CONTACT INFORMATION**

Applications approved through this process will be required to document emissions rat DEQ during the initial two months of operation. Emissions rates exceeding those calcu above may result in further emissions limitations. DEQ may, in its sole discretion, rec modification to any project plans in order to protect public health.

Directions for Conducting a Pilot Test to Determine Benzene Concentrations in Ground Water (Air Stripping)

Benzene emission rates in air associated with air stripping operations are estimated using a benzene concentration in ground water. These data are then used to determine whether air emissions from the air stripping equipment require controls. The Division of Environmental Quality (DEQ) has determined that a short-term, full-scale pumping test with ground water sampling is an appropriate method for determining the benzene concentration in ground water in some cases. This procedure is required for determining benzene concentrations in ground water when free product is present in monitoring or recovery wells. It is also an acceptable, but not required, method of determining benzene concentrations when free product is not present.

For purposes of this guidance, the term "pilot test" shall mean the process of pumping ground water from the contaminated subsurface in the area targeted for remediation. Water samples shall be collected for laboratory analysis to determine benzene concentrations prior to treatment by the air stripping equipment. The criteria contained herein are designed specifically as a means of determining the concentration of benzene in pumped ground water. It may be possible to modify an aquifer test (designed to determine subsurface hydraulic parameters) conducted during site investigation work to obtain the same data. Alternatively, it may be appropriate to design or modify the pilot test so that subsurface hydraulic parameters are determined along with the expected benzene concentration.

Note that DEQ does not require air stripping equipment to be installed prior to conducting the pilot test. The pilot test may be conducted at any time within the site investigation as long as the benzene concentration is not likely to increase appreciably over time and site conditions are expected to be comparable between the time of sampling and cleanup. The criteria to be followed in performance of an acceptable pilot test are:

- Pumping shall take place from recovery well(s) expected to be used in the full-scale cleanup.

- The pumping rate shall be the same rate used in the full-scale cleanup. Usually, the pumping rate is approved by DEQ

REC 4372

TR 1057

through submission of a written cleanup plan. The pumping system shall operate continuously at the desired rate for a minimum of two (2) hours and a maximum of twelve (12) hours. Upon completion of pumping, one (1) grab sample shall be collected and analyzed for benzene, toluene, ethylbenzene, and xylenes (BTEX).

- One (1) duplicate sample shall be collected and analyzed for BTEX. Duplicate sample analyses must result in a relative percent difference (RPD) of 25% or less.

- Samples shall be collected from the pumping system at a location representative of inflow to the air stripper but after any preliminary treatment equipment (i.e., oil/water separators, etc.).

- The laboratory analysis method must be an EPA-approved method and must have a lower detection limit of no greater than one (1) ug/l (ppb). Sampling must be conducted in accordance with the RCRA Ground Water Monitoring Technical Enforcement Guidance Document (National Water Well Association, 1986) or equivalent.

- Contaminated water generated during the pilot test must be treated or disposed of in a safe and acceptable manner. On-site storage prior to treatment system completion is acceptable as long as all applicable regulations and ordinances are followed. The treatment and disposal of all generated wastes are the sole responsibility of the person(s) conducting the pilot test.

C. List appropriate soil sample analytical results from excavated contaminated soil. Samples collected shall be representative of the respective stockpiled PCS. If the petroleum is not gasoline or fuel oil, attach separate table.

col.1 Stockpile volume (yd^3)	col.2 Sample I.D.	col.3 Sample type TPH-Gas TPH-Diesel	col.4 Grab or composite sample?	col.5 Sample TPH (ppm)	col.6 Average TPH per stockpile	col.7 Multiply average TPH (col. 6) by stockp volume (col. 1)

sum of col. 1 _____ sum of col. 7 = _____

Note: Copies of lab results and chain of custody forms must be included.

IV. **Screening test for air emissions.**

A. Calculate average TPH for all PCS to be treated.

1. Enter TOTAL TPH x VOL. (sum of col. 7) here. _____
2. Enter TOTAL VOLUME (sum of col. 1) here. _____
3. Calculate AVERAGE TPH. Divide line 1 (TOTAL TPH x VOL.) by line 2 (TOTAL VOLUME) and enter quotient here. _____

B. Refer to table 2 to determine setback requirement based upon the TOTAL VOLUME and AVERAGE TPH values calculated above. Enter the setback requirement here. _____

Note: If the setback requirement is greater than the distance to the nearest building or residential property line appearing in line II.D, then the land-treatment proposal will not be approved under this expedited format and further review of the land-treatment proposal will be required.

V. **Include the following figures:**

A. Copy of county soil survey map (if the county has been mapped) with copies of the interpretation tables or sheets. CLEARLY MARK location of site on the soil map.

B. Map with exact land treatment site location marked.

REC 4376

TR 1061

Idaho Department of Health and Welfare

Responses to Comments and Questions Submitted
During a Public Comment Period and Public Hearings
on the Proposed Repeal and Reissuance of
Rules for the Control of Air Pollution in Idaho

INTRODUCTION

The Notice of Proposed Rules for the Idaho Department of Health and Welfare's proposed repeal and reissuance of the Rules for the Control of Air Pollution was published in the Administrative Bulletin on September 3, 1993. The public comment period for the proposed rules was held from September 3, 1993 through October 8, 1993. Hearings were held in Coeur d'Alene, Pocatello and Boise, Idaho on September 30, October 5 and October 7, 1993, respectively. In addition, the portions of the proposed rules addressing toxic air pollutants were released for public comment in accordance with the old Administrative Procedures Act from March 12, 1993 through April 21, 1993. Hearings were held in Idaho Falls, Coeur d'Alene, Pocatello, Lewiston, Twin Falls and Boise, Idaho on April 6, March 23, March 24, March 24, March 25 and March 29, respectively.

IDHW is proposing a repeal and reissuance of the chapter due primarily to the extensive renumbering, restructuring and reformatting requirements of the Administrative Rules Coordinator. Most sections of the rules are not substantively affected by this rulemaking, and thus, comments regarding such sections are not considered to be substantive.

Substantive public comments which concern the proposed rulemaking have been summarized below. Each comment is followed by the Department's response. Some comments have been combined and paraphrased in order to eliminate duplication and provide a clearer summary. Each response to a comment discusses only the facts necessary to address the comment.

GENERAL COMMENTS

Comment #1: The State's proposed permitting rule is extremely restrictive; and we believe the State permit program should deviate as little as possible from the federal permitting program, in order to avoid inconsistent liabilities and to protect Idaho from possible loss of primacy.

IDHW Response: Many sections of 40 CFR Part 70 are left to the discretion of the implementing state. The Department has incorporated the basic frame work from 40 CFR Part 70 into these rules while designing an operating permit program that meshes with existing Idaho programs. The Department has incorporated the legislated directive to take advantage of the flexibility authorized in the Clean Air Act into these rules.

Comment #2: The proposed permitting regulations also lack implementing detail. The implementation of these regulations provides the "teeth" to the permitting process.

- **How are PTC/PSDs to be "rolled" into the operating permits?**
- **What is the schedule for submittal of permit applications?**
- **What is the schedule for approval of permit applications?**
- **What is the schedule for reissuing permits after initial approval?**
- **What is the recommended format for permit application?**
- **When will permit application forms be provided?**

IDHW Response: The Department has reworked the Tier I rules in response to this and other similar comments. The final rules have been rearranged to improve the logical organization and to clarify the procedures and requirements of the Tier I operating permit program.

Comment #3: The portions of the rules addressing toxic air pollutants are too complex and confusing.

IDHW Response: The rules have been changed in response to this comment. The rules have been revised and reorganized for the sake of clarity.

Comment #4 : The lists are too broad.

IDHW Response: The rules have not been changed in response to this comment. IDHW has attempted to regulate common industrial chemicals for which there is adequate data and for which there may be a reasonable anticipation of exposure to the public. There are currently millions of industrial chemicals in use. There is health data on about 70,000. IDHW is currently proposing to regulate less than 600 non-carcinogenic chemicals and less than 100 carcinogenic chemicals. Lacking a comprehensive emissions inventory, it is impossible to develop a list of regulated substances that take into account only those substances actually emitted at this time in Idaho. Processes change, and new business start so this sort of a "snapshot in time" list of chemicals becomes problematic if not impossible. Finally, if we do not have a reasonable program to control TAP in Idaho, both present and future, we run the risk of becoming a "toxic magnet" for businesses desiring to move to a more unregulated area.

After receiving similar comments after the withdrawn toxics rulemaking we reviewed the proposed list with such comments in mind and removed a number of compounds that we agreed did not materially add to the protection of the public health or the environment. It is IDHW's position that the TAP lists as currently compiled are a reasonable compromise between the need of industry to do business and the need to protect human health and the environment.

Comment #5 : The regulatory levels are too stringent.

IDHW Response: The rules have not been changed in response to this comment. IDHW has attempted to strike a balance between the needs of industry to do business and the need to protect human health and the environment. We believe that IDHW formula for figuring ambient and emissions levels for both carcinogen and non-carcinogens alike is reasonable and strikes the above noted balance. Finally, when compared to the ambient levels of other states, the ambient levels developed and adopted by IDHW are within regulatory norms.

Comment #6: The proposed regulations require too much IDHW involvement in the permitting process. Deminimis levels should be provided and department approved language should be eliminated.

IDHW Response: The rules have not been changed in response to this comment. The proposed rules and the rules as proposed for adoption already provide "deminimis levels" for permits to construct. If the source is not otherwise required to obtain a permit to construct, emissions of toxic air pollutants that are below the screening emissions levels are exempted without further action by the owner or operator of the source and emissions of toxic air pollutants that are above the screening emissions levels but below the acceptable ambient concentrations are exempted upon sending notice of the emissions to IDHW. If the source is otherwise required to obtain a permit to construct, emissions of toxic air pollutants that are below the screening emissions level are analyzed quickly. Emissions that are above the screening emissions level may be analyzed using several methods.

Deletion of the language requiring approval by IDHW would eliminate IDHW's oversight responsibility and allow the owners and operators of sources to decide for themselves whether they should receive a permit.

Comment #7: IDHW should adopt rules requiring an applicant to demonstrate compliance with the National Environmental Policy Act (NEPA) and DOE Orders in order to receive an air quality permit. Also recommend procedures for ensuring compliance with NEPA and DOE Orders.

IDHW Response: The rules have not been changed in response to this comment. IDHW believes that the Board of Health and Welfare may not be authorized by the air quality provisions of the Environmental Protection and Health Act to adopt rules requiring an applicant to demonstrate compliance with NEPA and DOE Orders in order to receive an air quality permit.

Comment #8: **Include a table of contents.**

IDHW Response: The form of the rules is dictated by the Office of the Administrative Rules Coordinator (ARC). The ARC does not publish a table of contents in the Administrative Bulletin, however, a table of contents for the final rules will be available in other publications and services.

Comment #9: **By restructuring and streamlining the federal regulation as a state rule, the requirements of 40 CFR 70.1(b), 70.7(b), and 70.7(c)(iii) that a source have and comply with a Title V permit has been omitted. In order for the Idaho operating permit program to be approvable, it must clearly require that all the affected sources must have an operating permit and must operate in compliance with that permit.**

IDHW Response: The Department has modified the rules in response to this comment. A prohibition has been added in Section 301.

Comment #10: **The existing Idaho rules regarding confidentiality of business information are too broad and may provide prohibit the public release of information on emissions or other materials in a permit application. In order for the Idaho operating permit program to receive full approval, these confidentiality rules must be revised to be consistent with the requirements of §114(c) of the Clean Air Act and 40 CFR 70.4(b)(3)(vii).**

IDHW Response: The Department has modified the rules in response to this comment. Section 126 has been modified to match a change in Idaho statute effective January 1, 1994. The change requires a person to certify that the information designated as confidential qualifies in accordance with Idaho Code 39-111.

Comment #11: **Although it is acceptable for Idaho to forego adopting phase II acid rain permitting requirements at this time (provided the Governor commits to timely adoption and submittal of rules for phase II permits), Idaho must adopt at this time all of the Title V permit provisions which relate to Title IV (acid rain) sources. The Title V provisions are necessary to address the potential need to permit some Title IV affected sources (e.g., new units, opt-in units) under Title V prior to the effective date of Phase II permits.**

IDHW Response: The Department believes the modifications to Sections 300 through 399 have addressed this comment. Responses to specific comments on Acid Rain provisions can be found in later sections of this document.

Comment #12: The rules do not address interstate contributions to air pollution.

IDHW Response: The rules have not been changed in response to this comment. This is beyond the scope of this rulemaking.

Comment #13: Some concern was expressed over the cost to regulate the substances on our appendices.

IDHW Response: The rules have not been changed in response to this comment. Under the current rule addressing toxic substances, IDHW has been regulating a broader list of chemicals than is regulated by the toxic air pollutants carcinogenic and noncarcinogenic increments. IDHW expects the costs per source to decrease as a result of this rulemaking.

Comment #14: It is unfair that these rules apply only to new sources.

IDHW Response: The rules have not been changed in response to this comment. The new portions of the rules addressing toxic air pollutants apply only to the net emissions increases from new and modifying sources of toxic air pollutants. It is common for new rules to "grandfather" existing sources and exempt them from compliance with the new rule. The existing portions of the rules regulating toxic substances will be applicable to all sources of toxic substances, including existing sources. The toxic substances rule will be implemented through the Tier II operating permit program on a case-by-case basis.

Comment #15: It will be nearly impossible for sources, especially small ones to identify what may come out of their stack.

IDHW Response: The rules have been changed in response to this comment. New section 210.01 has been added to provide information regarding how to identify toxic air pollutants emitted by the source.

Comment #16: IDHW has inadequate resources to enforce the requirements of the permit to construct program in general, and the new rules addressing toxic air pollutants in particular.

IDHW Response: The rules have not been changed in response to this comment. Under the current rule addressing toxic substances, IDHW has been effectively regulating a broader list of chemicals than is regulated by the toxic air pollutants carcinogenic and noncarcinogenic increments. IDHW expects to receive adequate

resources to implement and enforce the proposed rules addressing toxic air pollutants.

Comment #17: **Any rules more stringent than the federal regulations must be approved by the legislature which may cause Idaho to have only the EPA minimums.**

IDHW Response: The rules have not been changed in response to this comment. Idaho Code § 39-118B states in part "...that where EPA adopts or has adopted a specific standard, emission limitation or control technology requirement under the clean air act a more stringent standard, emission limitation or control technology requirement promulgated by the board shall not become effected until specifically approved by statute." The terms "specific standard," "specific emission limitation" and "specific control technology requirement" limit the scope of the section, and thus, the section is not applicable to "any state rule" as suggested by the commenter. In addition, the rules addressing toxic air pollutants are not more stringent than any such federal provision and will not need statutory approval to become effective.

Comment #18: **Does EPA have to approve state air toxics rules?**

IDHW Response: The rules have not been changed in response to this comment. With few exceptions, Idaho's air quality programs are adopted and implemented under state authorities. Federal approval of state air quality programs is only necessary to avoid federal sanctions and obtain federal benefits. The toxic air pollutant program is not mandated by the federal Clean Air Act and IDHW does not expect to submit them to EPA for federal approval.

Comment #19: **The IDHW makes its permitting decisions based only on the data that the source provides.**

IDHW Response: The rules have not been changed in response to this comment. IDHW conducts a thorough engineering review of all data submitted by the applicant. This data is checked for completeness and accuracy. A permit is issued only after IDHW engineers, meteorologists and other professionals are satisfied that the data submitted are complete and accurate. Furthermore follow up source testing and other appropriate methods for demonstrating actual and continuing compliance are required in permits.

Comment #20: **It was suggested that IDHW determine T-Ract for source categories. Additionally, the question was asked, how will IDHW know what control technology is available for each regulated chemical.**

IDHW Response: The rules have not been changed in response to this comment. Industries in Idaho are dissimilar enough in process to make this very difficult.

Any given control technology will control more than one specific substance. There is substantial literature available on what technologies control what categories of substances. IDHW will work with the applicants on a case by case basis to identify T-RACT.

Comment #21: A few commenters suggested that the IDHW restrict its new source review policy to the list of 189 substances listed in Section 112 of Title Three of the 1990 Clean Air Act Amendments (CAAA).

IDHW Response: The rules have not been changed in response to this comment. It is the position of the IDHW that this is not in the best interests of the people of Idaho for a number of reasons.

First, the EPA 189 list is not an attempt to protect people or the environment of any specific area but a compromise list to address some of the major nation-wide air pollution source types of air pollution. The EPA and congress have both reiterated that they do not wish negatively impact current state air toxics programs. The original proposed list contained 224 compounds, including ammonia and hydrogen sulfide which were later removed as the result of the political process. We do not believe that this nation-wide effort can be effectively applied to Idaho and be adequate to address the unique Idaho situation.

The EPA 189 list does not include all the well documented carcinogens that have been assigned unit risk factors. State and local agencies need to have the flexibility to protect public health by regulating the emission of TAP into the air.

While it is not possible to predict the future, in a fast growing state like Idaho it is very reasonable to assume that new industries will be moving to Idaho as our work force expands with new residents. In addition, as environmental regulations in California and other states become more restrictive, Idaho will look more attractive to many of these regulated industries. While we certainly want the jobs and incomes that these industries may represent, just as certainly, we do not want to become a "toxic magnet" for polluting industries that other states don't want.

Title III of the Clean Air Act Amendments of 1990 (CAAA) requires EPA to publish a list of source categories and then promulgate maximum achievable control technology (MACT) for the first 40 categories. MACT standards are then required for the rest of the categories on a phased in schedule. If a particular source in Idaho is not addressed in the first 40 source categories, the IDHW without TAP rules, could be unable to address toxic emissions from that source no mater how toxic the emissions might be or in what quantity the emissions may be emitted until EPA finally promulgates MACT standards. Given the past history of EPA deadlines, this is a very real concern. Even if EPA adhered to all

deadlines, some sources would conceivably still be able to emit unregulated toxics until the year 2000, if that source was in the last group to have standards promulgated. It should also be noted that not all sources are covered by these MACT standards. As a consequence, sources not covered by this MACT standard would be unregulated for air toxics in Idaho.

Finally, Congress itself apparently felt that this list was not final. Congress required the EPA to periodically review the list and add pollutants "...which present or may present ...a threat of adverse human health effects (including but not limited to, substances which are known to be, or may be reasonably be anticipated to be, carcinogenic, mutagenic, teratogenic, neurotoxic, which cause reproductive dysfunction, or which are acuity or chronically toxic) or adverse environmental effects..."

COMMENTS ON SPECIFIC SECTIONS OF THE PROPOSED RULES

SECTION 100

Comment #22: **There should be a general exemption from all air quality rules for agriculture and agriculture-related industries. This suggestion was made in the context of several definitions.**

IDHW Response: The rules have not been changed in response to this comment. Most agricultural activities and services are exempted from permit to construct requirements, including those addressing toxic air pollutants. Federal statutes and regulations mandate which sources of total suspended particulates and other air pollutants will be required to obtain Tier I operating permits. Except as prohibited by statute, it is appropriate to retain the ability to review all agricultural practices through the Tier II operating permit program. In addition, many of the definitions identified by the commenter have not been substantively changed by this rulemaking. IDHW does not consider it appropriate to respond to comments concerning aspects of the rules that were not substantively addressed in this rule making, but only renumbered, reformatted and restructured as required by The Administrative Rules Coordinator for this rule making.

Comment #23: **Section 100. DEFINITIONS. Definitions of the term "emissions allowable under the permit," must be added to comply with the requirements of Title V of the Act and 40 CFR Part 70.**

IDHW Response: The Department has incorporated a definition of this term into Section 103 of the final rules.

Comment #24: **Section 100.03. Definitions of Actual Emissions. The phrase added in subpart "6" appears to unnecessarily limit when**

permitted emission rates may be considered actual emissions and should be deleted.

IDHW Response: The Department has not modified the rules in response to this comment. This phrase was added to clarify under what circumstances the Department could consider permitted emission rates to be equivalent to actual emissions.

Comment #25: Section 100.03. Actual Emissions. The phrase "January of the current year or the date on which an application for a permit was filed" must be changed to "a particular date". There are many provisions in the permit rules where the actual emissions of a stationary source or emissions unit will need to be determined for some date in the past and this provision would not allow or provide for that determination.

IDHW Response: The Department has made the suggested modification.

Comment #26: Section 100.06 Agricultural Activities and 100.07 Agricultural Field. As drafted, the definition applies only to the agricultural activities "at the point of cultivation," which immediately exempts all animal husbandry activities. The definition should include all agricultural activities. Revised language was suggested. For Agricultural Field, the phrase for commercial sale should be deleted.

IDHW Response: The rules have been changed in response to this comment. IDHW agrees that these definitions need revision but had concerns with the specific language suggested. The rules now define the term "agricultural activities and services". The Definition of "agricultural field" has been deleted.

Comment #27: Section 100.08. Affected States. This definition should be revised to refer to the State of Idaho and not to any "State in which a Tier I permit...".

IDHW Response: The Department has modified this section of the rules in response to this comment.

Comment #28: Section 100.08. Air Pollutant. The use of the term "air pollutant' is likely to cause some confusion with the term "air contaminant," as used in the Idaho Code Section 39-103.04. Revised language was suggested.

IDHW Response: The rules have not been changed in response to this comment. The definition of "air pollutant/air contaminant" in the rules is consistent with the language and intent of the Environmental Protection and Health Act, Idaho Code §§ 39-101 et

seq., and the federal Clean Air Act, 42 U.S.C. §§ 7401 et seq., so that Idaho may obtain and retain federal delegation of several air quality programs.

Comment #29: **Section 100.11. Air Pollutant. This definition must be revised to cover every pollutant regulated under the federal Clean Air Act, not just those covered by the Idaho Act and these rules.**

IDHW Response: The Department has modified this section of the rules in response to this comment.

Comment #30: **Section 100.12. Air Pollution. This definition should use the term "air pollutant," not "contaminant" since only "air pollutant" is defined herein.**

IDHW Response: The Department has incorporated the suggested modification into the rules.

Comment #31: **Section 100.15 Definition of Ambient Air quality Standards and Violations. There is no definition of the term "ambient air quality standard." The definition of "ambient air quality violation" suggests that any locality may set standards which would them be enforced by IDHW. There may be some confusion with the Air Toxic Increments being assumed to be "air quality standards."**

IDHW Response: The rules have not been changed in response to this comment. Local entities may be able to adopt emission standards or ambient air quality standards depending upon the powers and duties that they have been granted by the Idaho Constitution and Idaho Code. If a local entity adopts such standards, IDHW is required to determine whether a proposed source complies with the standard before issuing a permit to construct. This type of determination is usually accomplished by asking the local entity to certify that the proposed source complies with the local standard. IDHW would probably include terms or conditions in the permit to construct that are relevant to the local standard, and thus, a violation of the local standard would probably also be a violation of the permit to construct. Although IDHW could enforce the permit to construct term directly, in most cases the local entity would take the lead in the matter and initiate an enforcement action.

The Toxic Air Pollutant Carcinogenic and Noncarcinogenic Increments are expressed in terms of an ambient air concentration, but they are not ambient air quality standards.

Comment #32: Section 100.16. Allowance. Note that this definition uses the term "affected unit" which either needs to be defined or replaced with the term "Phase II unit."

IDHW Response: The Department has incorporated the suggested modification into the rules.

Comment #33: In Section 100.16 "Unit" is not defined. Replace "unit" with "emissions unit."

See response to comment #32(the comment above).

Comment #34: Section 100.19. Applicable Requirement. This definition must be revised in a number of ways in order to meet the requirements of Title V:

(1) The parenthetical phrase in the opening sentence must be revised to indicate that applicable requirements are only those that have been promulgated or approved by EPA. Rules promulgated by Idaho that have not been approved by EPA are not applicable requirements for purposes of Title V of the Act.

IDHW Response: The Department has modified this section in response to this comment.

Comment #35: Section 100.19. (2) Subsection (a) must be revised to include any standard or requirement promulgated by EPA under Title I of the Clean Air Act.

IDHW Response: The Department has modified this section in response to this comment.

Comment #36: Section 100.19. (3) Subsection (b) must be revised to include terms and conditions in preconstruction permits issued by EPA under Title I (there are permits issued by EPA before Idaho's preconstruction review program was approved by EPA). Furthermore, the clause beginning with "solely excluding..." must be deleted since this definition by its own terms, only applies to Tier I sources.

IDHW Response: The Department has modified this section in response to this comment. The Department has maintained the clarification that terms and conditions relevant only to toxic air pollutants are not applicable requirements.

Comment #37: Section 100.19. (4) Subsection (c) should be revised to refer to all provisions under section 111 of the Act, such as 40 CFR Part 62.

IDHW Response: The Department has modified this section in response to this comment.

Comment #38: Section 100.19. (5) Subsection (d) should be revised to refer to all provisions under section 112 of the Act, such as 40 CFR Part 63.

IDHW Response: The Department has modified this section in response to this comment.

Comment #39: Section 100.19. (6) Subsection (f) must be revised to reference any monitoring requirements promulgated under Section 504(b) of the Act.

IDHW Response: The Department has modified this section in response to this comment.

Comment #40: Section 100.19. (7) Subsection (h) must be revised to avoid any possible confusion in combing the references to 42 U.S.C. §§ 7511b(e) and (f). We suggest the phrase "and tank vessels" be added after the words "consumer and commercial products."

IDHW Response: The Department has incorporated the suggested modification in the rules.

Comment #41: Section 100.19. (8) Subsection (i) must be revised to include reference to Title VI of the Act since future Title VI requirements could be promulgated under provisions other than 40 CFR. Part 82.

IDHW Response: The Department has modified this section in response to this comment.

Comment #42: Section 100.19. (9) An additional subsection must be added, consistent with the EPA regulations, to include any national ambient air quality standard or increment or visibility requirement under part C of Title I of the CAA as applied to temporary sources.

IDHW Response: The Department has added a section to the rules in response to this comment.

Comment #43: Section 100.25. Best Available Control Technology (BACT). This definition must be revised to include reference to 40 CFR Part 63, since all National Emission Standards for Hazardous Air Pollutants are not included in 40 CFR Part 61.

IDHW Response: The Department has modified this section in response to this comment.

Comment #44: Section 100.26. Collection Efficiency. The term "contaminant" should be changed to "air pollutant."

IDHW Response: The Department did not modify the rules in response to this comment. However, the definition of air pollutant has been modified.

Comment #45: Section 100.39. Designated Representative. This definition must be revised to use the term "affected unit", not just "unit". Also it must be consistent with the definition in EPA's Acid Rain regulations. "Unit" is not defined. Replace "unit" with "emissions unit.

IDHW Response: The Department has modified this section to clarify that a "unit" is a "phase II unit".

Comment #46: Section 100.39. Effective Dose Equivalent. While this definition is taken directly from the Code of Federal Regulations, it could be written more clearly. Different language was suggested.

IDHW Response: The rules have not been changed in response to this comment. Changing the definition would adversely affect the regulatory scheme for radionuclides from sources regulated under 40 CFR Part 61 or 40 CFR Part 63 since the emission standards for such air pollutants are based on "effective dose equivalent" as defined in the federal regulations.

Comment #47: 100.51. Excess Emissions. The definition is not tagged to stationary sources nor are time limits given. Suggest that the language be clarified and appropriate exemptions included in the rule.

IDHW Response: The rules have not been changed in response to this comment. The definition does not need to reference "stationary sources" or "time limits." The term is only used in the context of provisions regulating stationary sources and there is no time limit associated with the term.

Comment #48: Section 100.45. Emission Standard. This definition must be revised to include any requirement established by the EPA, not just the Department. Again, this definition must also reference 40 CFR Part 63 to cover all of the National Emission Standards for Hazardous air pollutants.

IDHW Response: The Department has modified this section in partial response to this comment. The Department will incorporate future federal requirements into these rules in accordance with state rule-making procedures.

Comment #49: Section 100.46. Definition of Environmental Remediation Source. Sources, which are not remediating oil or hazardous wastes, but which generate Air toxics should be included in the definition.

IDHW Response: IDHW has looked at this definition and has revised it by taking out the reference to hazardous materials. This was done because of potential conflicts with RCRA regulations. However Section 210.12 Specialized Method E: Department Approved methods can be used to allow review of a non-petroleum remediation project that may generate emissions of a toxic air pollutant. IDHW believes that this will remove potential RCRA conflicts while allowing flexibility in permitting non-petroleum remediation sources.

Comment #50: Section 100.47. Emission Unit. This definition must be expanded to indicate that it does not alter or affect the definition of the term "unit" for purposes of title IV of the Clean Air Act.

IDHW Response: The Department has incorporated the suggested modification in the rules.

Comment #51: Sections 100.47., 100.137. and 100.142. The definitions of Emissions unit, Source and Stationary Source all seem to be talking about the same thing. Choose one and use it throughout the rules.

IDHW Response: The rules have not been changed in response to this comment. This comment will, however, be considered when IDHW drafts future rulemakings regarding air quality.

Comment #52: Section 100.63. Hazardous Air Pollutant. This definition must be revised to include the pollutants listed in or pursuant to section 112(b) of the Clean Air Act. These pollutants are "hazardous air pollutants" even though they may not yet be subject to a standard under section 112.

IDHW Response: The Department has modified this section in response to this comment.

Comment #53: Section 100.68. Insignificant Activities. This definition is not used in the text of the rules and needs to be referenced therein to implement the concept. This approach is important to maintain a manageable program that is well understood by both the agency and public. New definition language was suggested.

IDHW Response: The Department has not modified this section in response to this comment. However, a subsection has been added to Section 314 that does incorporate the term "insignificant activities". This term was added to the rules solely for use in the Tier I operating permit program.

Comment #54: Section 100.71. Insignificant Activities. The item for space heating must include a size cutoff so that large central heating systems are not inappropriately exempted from permit requirements.

IDHW Response: The Department has modified this section in response to this comment.

Comment #55: Section 100.75, 100.76 Major Facility and Modifications. One commenter questioned the import of the changes to these definitions in the proposed rules. Another commenter stated that Section 100.75.b.ii and Section 100.76.c are not consistent.

IDHW Response: The Department modified the rules in response to this comment and the following comment. The Department has returned the existing definition of Major Facility. This definition is consistent with the definition of Major Modification.

A second definition of Major Facility has been placed in the new Section 103 "Definitions for the Purposes of Sections 300 through 399".

Comment #56: Section 100.75. Major Facility. This definition must be revised in a number of ways:

(1) Either the term "facility" must be used instead of "stationary source" or the definition must be substantially revised to conform with the EPA definition of "major stationary source".

(2) In subsection (a) the term "hazardous regulated air pollutant" must be changed to simply "hazardous air pollutant" and the provisions allowing EPA to establish lesser quantities for some pollutants and alternatives for radionuclides must be added.

(3) In subsection (b), the term "stationary source" must be changed to "facility," and paragraph (ii) must be revised to cover all regulated pollutants, not just those covered by the standards to comply with 50 CFR 51.166, and reference to 40 CFR Part 63 must be included. Note that this provision is now inconsistent with the

definition of "major modification" in that this definition exempts all "fugitive emissions" whereas the definition of "major modification" only exempts "fugitive dust."

IDHW Response: The Department has modified this section in response to this comment.

Comment #57: Section 100.76. Major Modification. Subsection c. must be revised to include reference to 40 CFR Part 63 in order to cover all sources regulated under section 112 of the Clean Air Act.

IDHW Response: The Department has incorporated the suggested modification into the rules.

Comment #58: Section 100.79. Member of the Public. The definition of "member of the public" as it applies to the regulation of radionuclide emissions should be amended to mean "any human being who is in any public access area, who receives the maximum potential dose exposure."

IDHW Response: The rules have not been changed in response to this comment. Changing the definition would adversely affect the regulatory scheme for radionuclides from sources regulated under 40 CFR Part 61 or 40 CFR Part 63 since the emission standards for such air pollutants are based on the effective dose equivalent for a "member of the public" as defined in the federal regulations.

Comment #59: Section 100.94. Nonattainment Area. The proposed change in this definition makes the basis for the designation less clear, and the parenthetical appears to extend the traditional reach of a non-attainment area.

This definition must be revised to include reference to Section 107(d) of the Clean Air Act. Although the state can add additional areas, it must consider as nonattainment all areas designated by EPA under section 107(d).

IDHW Response: The Department has modified this section in response to these comments.

Comment #60: Section 100.102. Process or Process Equipment. Delete the word "whatever" from the definition.

IDHW Response: The Department did not modify the rules in response to this comment.

Comment #61: The change in definition of PM-10 Emissions might be interpreted to also imply a change in reference method. We do not

support such a change, particularly in this manner. We would appreciate the opportunity to discuss the intended import of this change or the deletion of the proposed language.

IDHW Response: The Department did not change the rules in response to this comment. This definition was updated to match the federal definition of PM-10.

Comment #62: Section 100.105. Phase II Source and 100.106. Phase II Unit. These definitions must either be made consistent with the definitions of the EPA terms "affected source" and "affected unit" or replaced with those terms and their definitions.

IDHW Response: The Department has modified this section in response to this comment.

Comment #63: Section 100.110. Potential to Emit/Potential Emissions. This definition must be revised to include "facilities" as well as stationary sources since it is used primarily to determine if a facility is major. Second, the provision ensuring that this term will not alter or affect the term "capacity factor" used in title IV of the Clean Air Act must be added.

IDHW Response: The Department has modified this section in response to this comment.

Comment #64: Section 100.112. PPM (parts per million). The term "contaminant" should be changed to "air pollutant."

IDHW Response: The Department did not modify this section in response to this comment. See the definition of Air Pollutant.

Comment #65: Section 100.118.a.xx. One commenter made three related suggestions regarding the definition of "significant" as it applies to radionuclide emissions from sources regulated under 40 CFR Part 61 or 40 CFR Part 63. The commenter suggested that there should be a clearer determination of how the Department determines PSD so that a source knows whether to submit a PSD application; the designation of any radionuclide emission as significant, if total facility-wide emissions exceed an EDE of 3 mrem/yr, is overly conservative, and not based on any known scientific reasoning or regulatory precedence; and the definition should include only those radionuclide emissions that result in an EDE of at least 0.1 mrem/yr (NESHAP below-regulatory-concern level) if total facility-wide emissions are maintained below the NESHAP standard of 10 mrem/yr. Another commenter suggested that the existing definition of "significant" should not be amended, and thus, "any" amount of radionuclides would remain a "significant" emission.

IDHW Response: The rules have not been changed in response to these comments. The rules delineate application and permit to construct requirements based upon whether a proposed source is "major" and whether the proposed source is, or is located at, a facility with a potential to emit 250 tons or more of any air pollutant. If the proposed source is located at an existing major facility, it is a "modification" and the definition of "major modification" is based upon whether the proposed source has a net "significant" increase in emissions. The definition of "significant" is based on specified amounts of listed air pollutants. Therefor, an applicant should refer to the definition of "significant" and to whether the facility has the potential to emit 250 tons of air pollutants to determine what application information is required and what type of permit review will be conducted.

The regulatory scheme for radionuclides included in the definition of "significant" reflects many aspects of the federal scheme, but is also designed to meet the needs of the State of Idaho. It reflects a balancing of diverse and complex public, governmental and industry interests.

Comment #66: Section 100.118.b. One commenter suggested that Section 100.118.b be deleted because of his understanding of the provisions. He states that prior to these proposed regulations, this provision had relatively little impact since it only applied to pollutants regulated by the Clean Air Act and that now that there is no distinction between an air contaminant and pollutant in Idaho's regulations, this provision defines emission of any pollutant regulated by either the Clean Air Act or Idaho's regulations as significant.

IDHW Response: The rules have been changed in response to this comment. Without confirming the commenter's reasoning, IDHW has amended the section so that toxic air pollutants will not be "significant" emissions.

Comment #67: Section 100.118.a. The phrase "or any radionuclide emission rate, if the Department determines that Section 205 shall apply" should be deleted.

IDHW Response: The rules have been changed in response to this comment. The phrase was deleted.

Comment #68: Section 100.118.b. Prior to these proposed regulations, this provision had relatively little impact since it only applied to pollutants regulated by the Clean Air Act. Now that there is no distinction between an air contaminant and pollutant in Idaho's regulations, this provision defines emission of any pollutant regulated by either the Clean Air Act or Idaho's

regulations as significant. It is recommended that Section 100.118.b. be deleted.

IDHW Response: The rules have been changed in response to this comment. Without confirming the commenter's reasoning, IDHW has amended the section so that toxic air pollutants will not be "significant" emissions.

Comment #69: Section 100.131. Significant. Subsection (b) must be revised to include the phrase "or facility" since potential to emit applies to facilities as well as sources.

IDHW Response: The Department has incorporated the suggested modification in the rules.

Comment #70: Section 100.131. A TIER II Source. If the Tier I Source and Tier II Source are going to define the two types of permits, there should be a definition of each and more descriptive names.

IDHW Response: The Department has modified the rules in partial response to this comment. Section 302 has been moved to the general definition section of the rules. The Department has not defined "Tier II Source" in these rules. However, Section 401 describes which facilities are affected by the Tier II operating permit rules.

Comment #71: SectionS 100.146-149. These four definitions are used in many general schema for environmental calculations. Many of the conclusions are directly applicable to normal practice of agriculture and should be exempted.

IDHW Response: Agricultural activities and services are specifically exempt for new source review for toxic air pollutants.

Comment #72: One commenter noted that the rules appear to be incorporating Clean Air Act Section 114 Letter Authority by rule in Section 122 of the proposed rules. The commenter does not support this action and suggests that it is not required for an approvable Title V Program. The commenter also questions IDHW's legislative authority for the action and suggests that Section 122 be totally deleted.

IDHW Response: The rules have not been changed in response to this comment. This rulemaking is not limited to rules required for approval of the Tier I operating permit program. The Environmental Protection and Health Act grants the Board of Health and Welfare adequate authority to adopt Section 122.

Section 122 is an important aspect of this rulemaking. It will provide IDHW with the ability to obtain certain types of information from specified persons as necessary to develop, implement and enforce Idaho's air quality programs. It will drastically increase the efficiency and effectiveness of several of Idaho's air quality programs, including enforcement and the development and implementation of the area plans for the nonattainment areas. The State of Idaho and the public face severe sanctions if the nonattainment areas are not brought into attainment by the federally mandated deadlines. In addition, the United States Environmental Protection Agency's (EPA) ability to request information is very similar to the ability provided by Section 122. Section 122 will allow IDHW to request information directly from industry and other members of the public, and thus, IDHW will be able to collect necessary information without contacting or involving EPA.

Comment #73: **Section 123. Certification of Documents. It appears that neither the federal regulations nor the Clean Air Act require notarization on all forms, documents, progress report, monitoring data, test data, and other information to be submitted. Requiring notarization in the proposed rules is overly burdensome and unnecessary.**

IDHW Response: The rules have been changed in response to this comment. The phrase requiring notarization has been deleted and a section requiring all documents to be truthful, accurate and complete has been added to accomplish the same goal as notarization.

Comment #74: **New Section 100. Permit Successions. It would be useful in administration of the air quality program to establish by regulation the relationship between permits to construct and operating permits (both Tier I and Tier II). Section 150, a new proposal, attempts to define this relationship.**

IDHW Response: The Department did not make the suggested modification to the rules. However, the Department has modified Section 209.06 (now 209.05) to clarify how the permit to construct program interacts with the Tier I operating permit program. Section 401 describes how a Tier II operating permit can be used to net out of the Tier I operating permit program.

Comment #75: **Section 100.161. Toxic Substances. Referring to the listed acceptable ambient impact levels as ambient air quality standards (those levels that cannot be exceeded, regardless of the source) is confusing and conflicts with what IDHW indicated the toxics regulations would apply to. The definition of these limits to the increase in ambient concentrations should be changed to more**

clearly indicate that they are ambient increments, similar to PSD increments.

IDHW Response: The rules have been changed in response to this comment. The Department has incorporated the suggested modification into the rules.

Comment #76: Section 100.161. Toxic Substances. Other sections of the regulations deal more specifically with emissions of toxics. This section is unnecessary since the other regulations are more specific and should be deleted.

IDHW Response: The rules have not been changed in response to this comment. This sections contains the definition of toxic substances on which the other sections are based. In addition this section allows the IDHW the option of addressing a situation that may present a threat to public health or the environment by imposing a Tier II operating permit. IDHW believes that this section is basic to the state's efforts to protect the environment and human health by controlling toxic air pollutants.

Comment #77: Section 161. TOXIC SUBSTANCES. The structure of this provision is confusing. Paragraphs .02 and .03 should be subparagraphs under the provision in paragraph .01 (i.e. delete the number .01, and renumber .02 and .03 to .01 and .02, respectively).

IDHW Response: The rules have been changed in response to this comment. This Section has been rewritten to be clearer.

Comment #78: Section 121.01. This paragraph should be clarified to specify that the schedule prepared by the source is a "proposed" compliance schedule.

IDHW Response: The rules have been changed in response to this comment. The Department has incorporated the suggested modification into the rules.

Comment #79: Section 130. UPSET CONDITIONS, BREAKDOWN. This provision is not approvable as a part of the Idaho SIP as it fails to comply with the requirements of the Clean Air Act for violations of applicable SIP emission limits.

IDHW Response: The Department did not modify the rules in response to this comment.

Comment #80: Sections 140 through 149. VARIANCES et seq. These sections are not approvable as revisions to the Idaho SIP. First,

EPA does not approve "variances" to Idaho rules. EPA can approve revisions to the Idaho SIP which have been adopted by the Department and submitted to EPA, including variances that the Director has granted pursuant to this provision. As such, this section must be revised significantly. Furthermore, the variance provisions must either be inapplicable to Title V sources, or the rules must clarify that a variance must be accomplished through a revision to the source's Title V permit.

IDHW Response: The Department has replaced "EPA" with "Department" to correct this section. Sections 300 through 399 have been revised to clarify the requirements that apply to facilities affected by the Tier I operating permit program.

Comment #81: Section 141.02. Petitions. It is unclear what the term "petitioner and other..." refers to. Modified language is suggested.

IDHW Response: The Department has modified this section in response to this comment.

Comment #82: Section 145.03 Authorization of Hearing. Suggested that this section could be more clearly worded.

IDHW Response: The Department has modified this section to clarify that the Department, not EPA, may authorize a hearing. The suggested modification has been incorporated into the rules.

SECTION 200

Comment #83: Section 200 Procedures & Requirements for Permits to Construct. The proposed rules do not contain guidelines as to how the State of Idaho will develop MACT standards, if the EPA misses its deadline to develop MACT standards (Section 112 (j) of the Clean Air Act). As a result, we recommend that the Department issue guidance on how they will determine MACT standards, if and when the EPA does not meet its deadline, these Procedures should be developed through rulemaking.

This incrementalism approach will end up costing industry more to comply because they will go ahead with an addition, approved under a new source review permit but then have to make major modifications to that new source as part of the operating permit later on.

IDHW Response: The rules have not been changed in response to this comment. As EPA finalizes its various implementations procedures for §112(g) and 112(j) IDHW will respond appropriately. Until these federal rules and guidance are done, IDHW considers it inappropriate to attempt to develop rules by trying to guess what

EPA might do. When IDHW develops its responses to federal requirements IDHW will comply with all state and federal guidelines for public participation.

IDHW has built in a high degree of flexibility onto these rules in order to assist industry in complying with required controls. However, given the unsettled nature of new source MACT, IDHW has chosen to defer this issue until EPA finalizes and promulgates regulations in this area.

Comment #84: Section 201. Put the original effective date (January 24, 1969) into the regulation to eliminate any confusion as to what date it is.

IDHW Response: The rules have been changed in response to this comment. The phrase "after the original effective date of Sections 200 et seq." was deleted.

Comment #85: Section 201. Permit to Construct Applicability. As stated in previous comments to the Department on an earlier draft of these proposed revisions, the changes to the permit to construct rules which are being made to incorporate the hazardous air pollutant sources will adversely impact the currently-approved SIP provisions for criteria pollutant sources. If adopted as currently proposed, EPA would be required to disapprove these rules and the Idaho permit to construct program.

As discussed in my letter of June 29, 1993 (copy attached), the proposed revisions to the permit to construct applicability provision will not be approvable as revisions to the Idaho SIP for a number of reasons.

(1) The new exemptions for Category I, II, III, and IV sources inappropriately relaxes the currently approved SIP, and fails to comply with the requirements of section 110(a)(2)(C) of the Clean Air Act and 40 CFR Part 51, Subpart I of EPA regulations. Specifically, the four categories are not mutually exclusive and therefore would allow a source to be exempted under one provision where another provision would require a permit.

IDHW Response: The Department has not modified the rules in response to this comment. Categories I through III specifically require that the source not cause or significantly contribute to a violation of an ambient air quality standard. Category IV sources are either already exempted from obtaining permits to construct in the currently effective rules or are activities that the Department has historically not regulated.

The exemptions were not designed to be mutually exclusive. If a source qualifies under any of the categories, it is exempt from obtaining a permit to construct. The Department carefully examined sources and activities that have been exempted from obtaining a permit to construct in the past. This information was used to develop the categories in these rules.

Comment #86: (2) Broad discretionary exemptions such as 201.01.g., 202.02.d.i., etc. are not approvable.

IDHW Response: The Department has modified the rules in partial response to this comment. However, the Department has exercised discretion to exempt sources from obtaining a permit to construct under existing rules (16.01.01012,02.h). The Department is not aware of any concern expressed by EPA in its use of the discretion allowed by this rule.

Comment #87: (3) Section 201.02.a. exempts all major sources by using the term "Not."

IDHW Response: The Department has modified this section in response to this comment.

Comment #88: (4) The reference in 201.03. to "Section 200 et seq." should be changed to 201.03 since the source need not verify compliance with all of Sections 200 to 299, only the provisions of 201.03.a. through d.

IDHW Response: The Department has modified this section in response to this comment.

Comment #89: (5) In subparagraph (vi), the phrase "agricultural activities and services" is used, whereas the definition section defines only "agricultural activities." Also, the clarification of what are not agricultural activities (i.e. manufacturing, bulk storage and handling for resale or formulating any listed chemical) should be moved to the definition section unless this exempted activity is intended to be narrower than all "agricultural activities"

IDHW Response: The Department has modified the definition of Agricultural Activities.

Comment #90: (6) The permit to construct applicability provisions must ensure that all new, modified, or reconstructed stationary sources subject to any standard under sections 111 or 112 of the Clean Air Act are required to obtain a permit to construct. Idaho's Title V operating permit program cannot be approved unless it demonstrates that it can implement and enforce all of the requirements of sections 111 and 112 for subject sources, including the requirements for preconstruction review and initial source compliance determinations.

1010

REC 4400

TR 1085

IDHW Response: The Department has not modified the rules in response to this comment. The Department is committed to updating the rules in accordance with future federal rule-making.

Comment #91: Sections 201.01.f, 201.02.d.i, 201.03.d.ii: Category I, II, and III Sources. The State requirements should be consistent with the Federal NESHAP requirements in 40 CFR 61.96 Applications to Construct or Modify.

IDHW Response: The rules have not been changed in response to this comment. The regulatory scheme for radionuclides reflects many aspects of the federal scheme, but is also designed to meet the needs of the State of Idaho. It reflects a balancing of diverse and complex public, governmental and industry interests.

Comment #92: Section 201.02.iii-iv. Each of these sections represent the use of equipment essential to some phases of agriculture. These engines are potentially used in remote or populated locations. As such, an agricultural exempted may be appropriate.

IDHW Response: An agricultural activities and services exemption is provided for in Section 220 Category IV exemption

Comment #93: Section 201.03.d. Pilot Plants. Pilot plants pose a serious potential risk of radiation exposure. and should not have any exclusions from PTC requirements.

IDHW Response: The rules have not been changed in response to this comment. To qualify for an exemption, pilot plants may have no emissions of a radionuclide for which a National Emission Standard for Hazardous Air Pollutant (NESHAP) exists. The IDHW considers this adequately protective.

Comment #94: Section 201.04. Each of the above sections would be more clearly defined and interpreted if an agricultural exemption consistent with Idaho Environmental Protection and Health Act, Idaho Code Sections 39-101 et seq. (1993), which is clearly incorporated into this rule making.

IDHW Response: An agricultural activities and services exemption is provided for in Section 220 Category IV exemption

Comment #95: Section 201.04.c Permits to Construct, Category IV Exemptions. Section viii. needs to be expanded to allow the Director to exempt sources other than "equipment." This will allow the concept of "insignificant activities" which was earlier defined

but never used in the text of the rule, to be compiled into a publicly available list. This would allow the list to be compiled over time in a less expensive fashion than listing all insignificant sources in the rule. The additions list should be published annually in the Idaho Administrative Bulletin.

IDHW Response: The Department has modified this section in partial response to this comment. It should be noted that Insignificant Activities have been defined solely for the purposes of the Tier I operating permit program.

Comment #96: Section 201.04.c. Grain storage and handling facilities do not always fit cleanly under the agricultural exemption for a number of reasons.A new section should be added to exempt Country Grain Elevators under the 1 million bushel PSD size in PM-10 attainment areas.

IDHW Response: The Department has not modified the rules in response to this comment. Because there are no enforceable limits on the potential to emit from these facilities, the Department cannot exempt them from the requirement to obtain a permit to construct.

Comment #97: Section 202. APPLICATION PROCEDURES. The phrase "by the owner or operator" should be replaced with "in accordance with Section 123" now that section 123 sets out who must be the certifying official for permits to construct. Furthermore, Section 202.01.c. should be expanded to include a reference to 205.07

IDHW Response: The Department has incorporated the suggested modification into the rules.

Comment #98: Section 203. The old Section 203 stated that IDHW shall conduct a T-Ract evaluation for specific sources within 180 days, while Section 209 requires that a proposed permit be issued or denied within 60 days after the permit is declared complete. Recommended that the time frame in Section 209 take precedence.

IDHW Response: The rules have been changed in response to this comment. New Section 210.07 provides the applicant with two alternative procedures and timelines. Under Section 210.07.a, the applicant will submit the information regarding T-RACT in her initial application and IDHW will issue a permit action in accordance with the timelines in Section 209. Under Section 210.07.b, the applicant may supplement her application and the timelines in Section 209 will be reinitiated when a complete supplemental application is received.

Comment #99: Section 202.b.viii. Application Procedures. The list of Ambient concentrations is hard to read.

IDHW Response: The rules have not been changed in response to this comment. The form of the rules is dictated by the Office of the Administrative Rules Coordinator.

Comment #100: Section 203.03.c and d Adjustment Factors. Incorporate language to allow use of the adjustment factors for applicability determinations.

IDHW Response: The rules have not been changed in response to this comment. This concept is inherent in the language of the existing section.

Comment #101: Section 203.03 through 05. Recognize that these provisions for new and modified air toxics sources do not meet the requirements of section 112(g) of the Clean Air Act. When EPA's regulations to implement section 112(g) are promulgated, Idaho will have to substantially revise and tighten these requirements.

IDHW Response: The rules have not been changed in response to this comment. The IDHW rules concerning toxic air pollutants are for the control of toxic air pollution from new and modified sources and were not drafted with the intent of mirroring potential federal regulations. Additionally, the EPA has not finalized its guidance on §112(g) yet so IDHW believes that this comment is premature. As EPA promulgates further 112(g) guidance, IDHW will propose legislation to respond to these future federal requirements. IDHW acknowledges that this may entail extensive revisions of these rules.

Comment #102: Section 203.04. T-RACT. Best Available Control Technology (BACT) should not be changed to Reasonably Available Control Technology for Toxics (T-RACT). Some thought that T-RACT should not be available in non-attainment areas. (There were multiple comments expressing this sentiment)

IDHW Response: The rules have not been changed in response to this comment. The change from BACT in the old TAP policy to RACT in the proposed rules will allow a greater degree of flexibility, both economic and technological, in complying with the various emissions and ambient levels of the toxic air pollution (TAP) regulations. BACT is a term applied to prevention of significant deterioration (PSD) in classified airsheds and as such is not directly relatable to toxics. This change in control technology will address a small segment of carcinogenic emissions falling between the one in a million and one in a hundred thousand risk levels. It will have no effect on non-carcinogens. Emissions of carcinogens of greater

risk than one in a hundred thousand will not be allowed regardless of the control technology used. In real application, T-RACT as defined and implemented will closely approximate BACT

The assumptions that the IDHW uses when figuring these risk levels are conservative, that is, likely to err on the side of caution. These assumptions protect the maximally exposed individual as opposed to the average exposed individual. It is the position of the IDHW that given the combination of these very conservative assumptions and the limited segment of potential emissions that this change will cover, these changes represent a feasible compromise between the needs of industry and protection of public health.

Nonattainment for air quality pertains to a number of criteria pollutants (oxides of nitrogen and sulfur, particulates, etc.) and does not pertain to TAP. Therefor this concern is not directly relevant to the proposed TAP rules.

Comment #103: **Section 203.04 T-RACT Determination. A few commenters suggested that the economic feasibility aspects of the T-RACT determination are an unreasonable burden on industry and could be used arbitrarily. They asserted that old Section 203.04.e requires the applicant to determine the economic feasibility of every control technology approved by the Department and that this could be quite expensive and time consuming. If there are only one or two options worth considering, an economic analysis should only be done for them. Provisions to allow the applicant and the Department to agree on what control technology scenario will be evaluated should be included.**

IDHW Response: The rules have been changed in response to this comment. Without confirming the reasoning of the commenters, IDHW deleted old Section 203.04.e. The proposed rules and the rules that are submitted for adoption both provide that the applicant is to submit proposals that are technologically and economically feasible; not proposals that are technologically or economically feasible.

Comment #104: **Section 203.05.a. Emissions Screening. Since this requirement is only meant to address new sources, the language needs to be modified to reflect that.**

IDHW Response: The rules have been changed in response to this comment. This section has been rewritten to be more clear.

Comment #105: **Some commenters expressed concerns that the toxics provisions should apply only to new sources and that "the limiting factor is the additional quantity of a specific toxic in the atmosphere that results from operation of the proposed new source."**

Existing background should be taken into account when permitting new sources. Are the incremental increases to become part of background to be ignored if another addition was made in the future ad infinitum.

IDHW Response: The rules have been changed in response to this comment. On the issue of clarifying that the toxics policy applies to new sources and modifications, IDHW has rewritten and an reorganized sections to make this more clear. That the current toxics policy and the proposed rules deal with new sources and modifications only has been the IDHW position since the inception on the toxics policy in 1989.

The concern that the incremental increase will become part of the background is addressed the definition of Net Emissions Increase, §102.07 of the revised rules. This definition excludes this possibility and has been applied to Section 209.

IDHW acknowledges the tensions between the ability of industry to operate effectively and efficiently and the public's right to a safe and clean environment. It is IDHW's position that the rules changes noted above strikes a middle ground between these needs.

Comment #106: Air toxic impacts, both non-carcinogenic and carcinogenic, should only be evaluated at or beyond the facilities property boundary, even if the public has access to the property. The words "or the closest point of public access" should be deleted.

IDHW Response: The rules have been not changed in response to this comment. Section 209.b. (which replaces 203.05.c.) allows the use of the point of greatest impact located at or beyond the facility property boundary nearest the source or closest point of public access. Generally, people going to a source on business are not considered part of the "public" while on the property. Therefor, parking lots and the like will not generally be considered the closest point of public access.

Comment #107: Section 203.05.f. This section is redundant as the concept is already addressed in 203.05.h. and should be deleted.

IDHW Response: The rules have been changed in response to this comment. Section 203 has been reorganized to make it clearer and in so doing, subsection 203.05.f has been deleted.

Comment #108: Section 203.05.g. Unit Risk Factors are based on a 70-year exposure. This is not appropriate for an industrial park situation that will never be a residential application. The refined analysis should be liberalized to include a different model, actual meteorological data, more appropriate risk factors, actual hours of operation, more accurate emissions factors obtained

through source testing, more accurate annual potential to emit scenarios and any other justifiable refinements. New wording for this section has been suggested to reflect this.

IDHW Response: The rules have been changed in response to this comment. IDHW agrees that for industrial areas that will never be used for residential purposes, a 70 year risk base may be conservative. However, it is hard to predict future land use patterns. Examples of unforeseen new land uses with significant environmental and human health concerns have become quite common.

IDHW has based its emission numbers on the best available data. IDHW has strived to take a balanced approach taking into account the needs of industry to operate and the need to protect human health and the environment. Since it is not possible to account for such real life factors as lifetime exposures, additive or multiplicative effects of exposures to the large variety of industrial chemicals in use in Idaho, it is necessary to make our emissions standards generally applicable and reasonably conservative.

It is not possible for IDHW to carve out special exemptions or emissions factors for potential or hypothetical new or modified industrial sources or exposure scenarios. Our rules must take a balanced approach that is generally applicable and consistently applied. IDHW can not develop special emissions factors specifically for industry dominated areas. IDHW believes that the revised Section 210.02 Quantification of Emissions Rates and Ambient Concentrations, which allows site specific data gives adequate flexibility in compliance with toxic standards.

Comment #109: Section 203.05.j Screening Emissions Tables. Commenter recommends that ammonia be eliminated from the list of toxic pollutants or, alternatively, that emission levels for ammonia applicable to the danger caused by high concentrations and which also recognize the harmless effect of low concentrations be established. This request is based on a number of issues. First, ammonia was deleted from the EPA "189 list". Second, ammonia is generally considered relatively non or mildly toxic in very low concentrations. Third, ammonia is regulated under SARA Tile III for accidental release. Fourth, substantial releases of ammonia come from animal wastes and other organic materials. Fifth, the control of ammonia at the levels specified in the proposed rules would be severely burdensome for industry, particularly the fertilizer and sugar beet industries.

IDHW Response: The rules have not been changed in response to this comment. IDHW disagrees that Ammonia should be unregulated in Idaho. IDHW also declines to modify its screening emissions levels (EL) and acceptable ambient (AAC) concentration for ammonia.

In general, IDHW basis its non-carcinogenic standards on the work and occupational exposure limits developed by the American Conference of Government Industrial Hygienists. These standards

are set relative to the toxicity of the compound in question so the relatively low toxicity of ammonia is already reflected in the numbers.

In addition, IDHW has identified a specific procedure for developing ELs and AACs that is consistent for all sources and compounds. IDHW believes that deviating from this procedure would be unfair to other applicants and the public and introduce too much subjectivity into the process.

IDHW will address the specific areas of concern cited in the request to remove ammonia from the rules:

First, ammonia was deleted from the EPA "189 list". IDHW has reiterated its position on the "189 list" on numerous occasions. However, in brief the IDHW does not consider this to be a valid point because the "189 list" is a result of a political process on the national level. The "189 list" represents a list of pollutants that have significant national concern. The "189 list" was never meant to necessarily protect environments on a local level. Congress has made it clear the "189 list" and the Title III/ NESHAP program was not meant to replace state air toxics programs. Consequently, IDHW disagrees that the presences or absences of a compound on the EPA "189 list" is necessarily relevant to the Idaho TAP program.

Second, ammonia is generally considered relatively non or mildly toxic in very low concentrations. IDHW agrees that this is a valid point. However as mentioned above, the EL and AAC for this compound has taken the level of toxicity into account. In addition, 22 state and local air pollution control agencies have set standards for ammonia in air, some less stringent and some more stringent than Idaho. In addition, the Division of Health has been consulted and has recommended that ammonia continue to be regulated on the basis of its significant irritant effects.

Third, ammonia is regulated under SARA Title III for accidental release. SARA Title III is concerned with the catastrophic release of large quantities of dangerous chemicals and the communities right to know that these chemicals are being used and stored nearby. SARA Title III does not regulate these chemicals but only requires reporting of their presence. IDHW does not consider this to be excessive "double regulation". The intent of the IDHW TAP program and SARA Title III are very different so IDHW disagrees that this sort of "double regulation" is either unwarranted or unreasonable.

Fourth, substantial releases of ammonia come from animal wastes and other organic materials. While IDHW agrees that this is true, IDHW disagrees that this point is germane. The intent of the rules concerning toxic air pollutants is to control the emissions of toxics air pollutants from new and modified sources. Agricultural activities and services are generally exempted from the toxics rules.

Fifth, the control of ammonia at the levels specified in the proposed rules would be severely burdensome for industry, particularly the fertilizer and sugar beet industries. IDHW is very sensitive to the potential economic impacts of these proposed rules and economic impacts are always considered. However, these regulations apply to new and modified sources only. IDHW does not agree that economic effect on the regulated community will be so severe so as to out weigh their environmental benefit. Further, IDHW does not believe that it is appropriate carve out regulatory exemptions for the economic benefit of a particular industry or industries.

Comment #110: Section 203.05(j). Remove Phosphorous pentoxide from the Table in Section 203 .05(j).

IDHW Response: The rules have not been changed in response to this comment. The IDHW believes that our regulation of this chemical is both reasonable and responsible. Phosphorus pentoxide is an irritant and is being regulated on that basis.

Phosphorous pentoxide is listed on the EPA extremely hazardous substance list; It is listed in the Toxic Substances Control Act (TSCA) Substances Inventory; It is listed by the Department of Transportation (DOT) as a corrosive material; Sax's Dangerous Properties of Dangerous Materials. Vol. III. Eighth Ed. Richard J. Lewis, Sr. New York: Van Norstrand Reinhold 1992. 2795. notes that it is a "Poison by inhalation. A corrosive irritant to the eyes, skin and mucous membranes"; The Hazardous Substances Data Base (HSDB) produced by Micromedix, Inc. Vol. 16 notes that "Particles of solid Phosphorous pentoxide in contact with eye react vigorously, & even small amounts may cause burns of lids, conjunctivae, & corneas, producing blue-white opacities, which may be permanent."

Since phosphorous pentoxide in quite hydrophilic and rapidly forms phosphoric acid, the ACGIH Threshold Limit Value (TLV) of 1mg/m3 for phosphoric acid was used. In addition the HSDB reports that Patty's Industrial Hygiene and Toxicology: Volume 2A, 2B, 2C: Toxicology. 3rd Ed New York: John Wiley Sons, 1981-1982. recommends a Hygienic Std. of 1mg/m3.

Comment #111: Section 203.05.j. and 203.05.k. There should be short term ambient standards for non-carcinogens (8 and or 24 hr. standards). A formula for the development of such standards was submitted.

IDHW Response: The rules have been changed in response to this comment. An annual averaging period will be used for both screening and refined models for all toxic air pollutants. The issue is complex and important enough to deserve clarification.

The acceptable ambient concentrations (AAC) are not ambient air quality standards. Rather they are acceptable increments of

toxic air pollutants that are responsibly protective of human health and reasonably permissive of industrial expansion. Because the AAC are not ambient standards the air quality management techniques of averaging collective emissions to some total ambient build up do not apply.

In the design of this rule, the AAC relates to a stack emission rate. In the most prescribed sense, the AAC would be assured by a permitted emission limit. This emission limit then might be guaranteed by some ample control technology design or perhaps an operational limit prescribed in the permit.

Comment #112: Section 203.05.j. and 203.05.k. There is inadequate health based data for the ambient levels set. OSHA standards "were struck down in court" as a result of "OSHA's unlawful rule making" because OSHA's standards were not based the "significant risk" and "feasibility" requirements of the OSHA statutes" our ambient standards were on "...very shaky legal ground..."

IDHW Response: The rules have not been changed in response to this comment. The IDHW bases its non-carcinogenic levels on work done by the American Conference of Government Industrial Hygienists (ACGIH), not OSHA. The ACGIH is a respected health effects research body and the IDHW has every confidence in ACGIH data. For carcinogens, the IDHW used published unit risk factors from EPA and supporting data from the National Institutes of Health and the International Agency for Research on Cancer (IARC). It does not seem reasonable for IDHW to attempt to "reinvent the wheel" in the face of so much available data. To do so would be an astronomical undertaking, far beyond the capabilities of most if not all state governments.

Comment #113: Section 203.05.j. and 203.05.k. Standards derived from those of other states should be removed.

IDHW Response: The rules have not been changed in response to this comment. IDHW has included substances on our lists that we feel have valid health concerns. Some of these substances do not have Occupational Exposure Levels (OEL) published by an agency such as the ACGIH. However they do have substantial health data. On occasion, some states have looked at some of these chemicals and developed emissions and or ambient standards. We have no reason to believe that states such as Washington or New York are frivolous or capricious in their risk assessment actives. Quite the contrary, we consider other states to be responsible agencies subject to oversight by their respective legislatures, industry groups and the public, much like Idaho.

The IDHW then looks at these standards to see if we consider them reasonable, based on the available literature and other criteria. If we find that to be the case we may then adopt these standards or modify them as the data warrant. If, in the future,

the ACGIH develops standards differing from the standards we have adopted, we will seek to modify our rules accordingly.

Comment #114: **Section 203.05.j. and 203.05.k. Are some of the compounds on Appendix 1 are suspected carcinogens?**

IDHW Response: The rules have been changed in response to this comment. It is the policy the IDHW to regard any substance that is considered a B2 ranking by EPA (or equivalent ranking by IARC) a carcinogen for purposes of regulation. A B2 carcinogen is one that has sufficient animal evidence. C (or equivalent ranking by IARC) ranked compounds have limited animal evidence and inadequate or less human evidence. The IDHW does not believe that C ranked carcinogens have sufficient data available to support the regulatory scheme required by carcinogens. Therefore some compounds on Appendix 1 may be suspected carcinogens in other references. In addition, some carcinogens were mistakenly listed on both appendices. These errors have been corrected.

Comment #115: **Section 203.05.j. and 203.05.k. The range of allowable emissions of carcinogens is too narrow and the accuracy of the models used to calculate potential risks is inadequate.**

IDHW Response: The rules have not been changed in response to this comment. The narrow range of allowable carcinogenic risk reflects a upper limit of one in a hundred thousand, above which the IDHW considers risk to be unacceptable. The IDHW considers this to be reasonable and in line with risk acceptability of other states and the EPA.

The IDHW acknowledges that models used to calculate potential risk are not exact and that there are variations in the appropriateness of the models vis a vis specific applications. The IDHW has tried to allow maximum flexibility in model selection by requiring only that the model must be EPA approved and must be reviewed for appropriate application by the IDHW. The IDHW considers that EPA approval and IDHW review of all models used is a reasonable requirement.

Comment #116: **Section 203.05.j and 203.05.k Screening Emissions Tables. The publication in the rules of OEL and URF values that are based on continually changing OSHA, and EPA exposure criteria will contribute to confusion and errors in use of the most current (and appropriate) criteria.**

For modeling analyses, URFs should be taken from the EPA IRIS database, which is updated on a monthly basis. OELs should be taken from their source documents - either OSHA PELs, ACGIH TLVs, or NIOSH RELs, which are updated on an annual basis. The regulations should either reference these sources or include a statement to the effect that the OEL, URF, AAC, and AACC values may

change (based on the latest revision to the source) without requiring change to these regulations.

IDHW Response: The rules have not been changed in response to this comment. IDHW believes that annual updates through rulemaking and emergency rulemaking, if necessary, will provide an adequate and reasonable method to keep the appendices updated. Providing the appendices as part of the rules insures consistency. In addition, the Administrative Procedures Act of Idaho prohibits language that automatically incorporates by reference the latest edition of a reference. A specific document must be incorporated. IDHW would also note that this aspect of the rules was partially in response to industry's strongly stated desire to have the various references made part of the rules so that there would be regulatory consistency.

Comment #117: Section 205.06 - The cited Section 205.01.b. should be Section 205.01.b.ii.

IDHW Response: The Department did not modify this section in response to this comment. The cites are correct.

Comment #118: Section 209. PROCEDURE FOR ISSUING PERMITS. This section should perhaps be moved to after Section 400, et seq, since it applies to both permits to construct and tier II permits. In addition, the second reference to "major modification" in 209.01.c. must be changed to "modification." Finally, the last sentence in 209.05 must be deleted since permits to construct do not expire and are not "renewed" like operating permits.

IDHW Response: The Department has modified the rules in response to this comment. The sections in 209 that also apply to Tier II permits have been incorporated into Section 404.

Comment #119: Section 209 provides no time frame for conduction public comment periods or hearings after a proposed permit to construct is issued for major facilities or modifications. Language is suggested.

IDHW Response: The Department has not changed the rules in response to this comment. The Department makes every effort to conduct public comment periods and hearings in a timely manner.

Comment #120: Emissions Screening levels should take into account such realistic assumptions as reactivity of gaseous air toxics and deposition rates of dusts. It was suggested that the values be recalculated using these realistic assumptions.

IDHW Response: While IDHW agrees that gas reactivity and deposition rates of dusts are real world occurrences, it is impossible to use these assumptions in figuring emissions screening levels because of their site specific nature. Reactivity of gases varies considerably with different circumstances. For instance, the concentration of hydroxyl radicals in the atmosphere, the amount of sunlight present and various aspects of reaction kinetics are items that have a significant effect on atmospheric gas reactivity. Deposition rates of dusts and other particles can vary greatly with circumstances such as wind velocity and precipitation rates.

Comment #121: Section 209.01. This section should provide for language to a permit to be automatically deemed complete if the Department does not notify the applicant of incompleteness within 60 days, similar to Section 342.03

IDHW Response: The Department has not modified the rules in response to this comment. The rules provide for a completeness determination within 30 days. The Department has not had a permitting backlog for four years. Therefore, the Department believes that the suggested modification is unwarranted.

SECTION 300

Comment #122: Section 302.05. This provision must be expanded to include source categories designated by EPA.

IDHW Response: The Department has not modified this section (although it has been moved to section 101) in response to this comment. The Department is committed to updating the rules in accordance with future federal rule-making.

Comment #123: Section 313. Timely Application. We recommend that Section 342.02.a. be reworded to require one-third of Tier I facilities to submit their application before the end of the 12-month period, to enable the first third to be processed by the end of the 12-month period.

IDHW Response: The Department has modified the rules in response to this comment. Sections 313 and 367 have been modified to clarify how the Department will act on applications during the transition period.

Comment #124: Section 313.02. Preconstruction Permits. The Federal Program allows states to provide for concurrent processing of pre-construction permits and operating permits, provided that the procedural requirements of both programs are met. We recommend that applicants in Idaho be given this option.

IDHW Response: The Department has modified Section 209 in response to this comment. Subsection 209.05 describes the permit to construct procedures for Tier I sources.

Comment #125: Section 313.04. Renewal Applications. For purposes of permit renewal, redefine timely renewal application, a timely application is one that is submitted at least six months prior to the date of expiration, unless the applicant requests and the operating permit specifies a longer period (not to exceed 18 months).

IDHW Response: The Department has modified the rules in response to this comment. Sections 313 and 367 have been modified to clarify how the Department will act on applications during the transition period.

Comment #126: Section 313.04. In accordance with 40 CFR 70.5(a)(a)(iii), the State must require that applications for permit renewals be submitted between 6 and 18 months before expiration of the permit. Requiring renewal applications to be submitted more than 18 months before expiration is not approvable. This provision needs to be reworded to ensure that the application is submitted no earlier than 18 months prior to expiration and no later than (some time between 6 and 18) months prior to expiration.

The rules defining a timely application will be hard on commenter because of the need for very rapid turn around time needed in the semiconductor business.

IDHW Response: The Department has modified the rules in response to these comments. See Section 313.03.

Comment #127: Section 314.02. Standard Application Form and Required Information. Please clarify what type of description is required by this section. The Department should include in a Checklist or detailed Instructions on the level of detail and what criteria the Department will use to determine whether any response to this requirement is "complete."

The description of the source's products and processes must include information about the applicable SIC codes.

IDHW Response: The Department has modified the rules in response to these comments. Subsection 314.02.b clarifies that the description must include narrative and applicable SIC codes.

The Department has developed a completeness checklist and a draft Tier I operating permit guidance manual. These documents are available on request to the Department. The guidance manual will not be finalized until after the rules are final.

Comment #128: Section 314.04.a. Emissions Information. The application must also include information on all air pollutants, that are not also regulated air pollutants, for which the source is major. The Department must also have authority to require additional information to determine the applicability of applicable requirements for all air pollutants, not just regulated air pollutants and as necessary to collect any permit fees. In addition, the reference to exempted units must be more specific than simply "Section 314, et seq."

IDHW Response: The Department has modified this section in response to this comment.

Comment #129: 314.04.a. Emissions Information. This section requires specification of emissions of regulated air pollutants emitted from any non-exempt emissions unit. this requirement should be limited to information about "relevant emissions units," meaning only those emissions units that are subject to applicable requirements.

IDHW Response: The Department has not modified the rules in response to this comment. The Department must receive information as described in the preceding comment. Section 314 has been revised to clarify what information must be submitted in the Tier I operating permit application.

Comment #130: 314.04.a. Emissions Information. The second sentence of Section 314.04 states that the Department shall require additional information related to the emissions of regulated air pollutants sufficient to verify which requirements are applicable. This should be written in the form of a requirement for the applicant, rather than an instruction to the Department, to avoid having the Department requesting additional information after the application has been submitted. Suggested language is submitted.

IDHW Response: The Department has deleted this sentence.

Comment #131: Section 314.04.b. and 314.05.b. Emission Information. This section refers to requirements of the "Act." This should be a reference to the "Clean Air Act," since Title V permits are required to implement the applicable requirements of the Clean Air Act (which includes requirements under an approved SIP or preconstruction program). Requirements that applicable to the source pursuant to the (State) Act or these Rules only, are to be segregated from those requirements that are federally enforceable "applicable requirements" under the Federal Clean Air Act.

IDHW Response: The Department's modifications to the rules address this comment. See sections 314.04 and 322.17.j.

Comment #132: Section 314.04.c. Emission Information. We recommend using "applicable standard reference test method, if any" instead of "applicable test method."

IDHW Response: The Department has not modified this section in response to this comment. If there is no applicable test method, then the applicant will not have to identify terms necessary to establish compliance with the applicable test method.

Comment #133: Section 314.04.f. Emission Information. Since Title V operating permits address "regulated air pollutants," this requirement should be so limited.

IDHW Response: The Department has not modified the rules in response to this comment. The applicant is required to submit information regarding all air pollutants that are regulated by the Clean Air Act. In addition, any applicant that has a permit to construct that addresses Toxic Air Pollutants will be required to submit information regarding those emission.

Comment #134: Section 314.08. Additional Information. This section should include, in addition to "alternate operating scenarios," other provisions, such as emissions trading and emissions caps, allowed by the Clean Air Act. These alternate provisions, if incorporated into the permit, may be implemented without a permit revision.

Alternative Operating Scenarios. This section should clearly provide intent of alternative operating scenarios and include permit allowances for emissions trading, emissions caps, or other optional requirements pertinent to maintaining operational flexibility.

The last phrase needs to be revised to clarify that the additional information relates to permit terms and conditions allowing for emissions trading and cross reference the appropriate Idaho bubble rules.

IDHW Response: The Department has modified Section 314 to include a section relating to alternative operating scenarios (314.09) and a section relating to trading scenarios (314.12).

Comment #135: Section 314.09. Pursuant to 40 CFR 70.5(c)(8)(iv), the compliance plan must also include a schedule for submission of certified progress reports no less frequently than every 6 months for every source required to have a compliance schedule to remedy a violation.

Section 314.11.c. Certification of Compliance. Compliance certifications will require an enormous commitment of resources because of the certifications as to accuracy and completeness required of a senior official. Requiring certification more frequently than annually will be costly and will serve little purpose. We recommend that the Idaho Program be consistent with the Federal Program, except where the applicant and the Department have agreed to a more frequent certification in a compliance schedule.

Section 314.11.d. This paragraph must be revised to require a statement indicating "whether" the source is in compliance, not "that the source is in compliance."

IDHW Response: The Department has rewritten the sections covering Compliance Certifications and Compliance Plans (now Sections 314.10 and 314.11). These sections were rewritten to improve the organization and to clarify what information is required. The modifications to these sections address these comments.

Comment #136: **Section 314.13. The phrase "activities which are exempted from permitting requirements of Sections 200 et seq." must be changed to "insignificant activities." The requirements of Title V (operating permits) of the Clean Air Act are completely different from the requirements of Title I (new source review) and the exemptions for construction permits are not approvable as exemptions from operating permits. Also, in the case of insignificant activities, the source must also submit such information as is necessary to demonstrate that the exemption applies.**

IDHW Response: The Department has deleted this section. New Section 314.04.b has been added to clarify that Insignificant Activities need only be listed in the Tier I operating permit application. The Department believes that the list of Insignificant Activities is specific enough that sources do not need to demonstrate that the definition applies.

Comment #137: **Section 315. Duty to Supplement or Correct Application. One commenter notes that Section 315 provides that the Department may request additional information deemed to be necessary to evaluate or take final action on the application and recommends adding language to allow the applicant to file a contested case, if the applicant believes the information is not authorized by law or the rules, or is not reasonably necessary to evaluate or take final action on the application.**

IDHW Response: The rules have not been changed in response to this comment. Completeness determinations are based on a limited review of the application so IDHW often needs to request additional information from applicants in order to conduct the full review of

the application and issue a permit action. The request is not a final action, and thus, it is not appealable as a contested case. Applicants may respond to the request from IDHW by explaining why the applicant believes the information has already been provided or why the information is unnecessary. If IDHW agrees with the applicants explanation, IDHW continues with the review. If IDHW disagrees, it notifies the applicant and the applicant may provide the information or IDHW will deny the permit application. A denial of the permit application is an appealable action.

Comment #138: Section 317. Permit Continuance. For additional clarity, this paragraph should cross reference the provision which gives sources the ability to operate without a permit if the source submitted a timely application.

IDHW Response: The Department has deleted this section and has modified Section 301 (see 301.02.a) to clarify that sources may continue to operate if the source is in compliance with Sections 311 through 315.

Comment #139: Section 322. Standard Permit Requirements. The permit must also require the reporting of deviations from permit requirements and must define promptness in relation to the degree and type of deviation likely to occur and the applicable requirements in accordance with 40 CFR 70.6(a)(3)(iii)(B).

IDHW Response: The Department has not modified this section in response to this comment. Section 326 covers deviations from permit requirements and provides time frames for reporting for each type of excess emission event.

Comment #140: Section 322.01. Standard Permit Requirements. The permit must include emission limitations that assure compliance with all applicable requirements even if such requirements are identified after submission of the application.

IDHW Response: The Department has not modified this section in response to this comment. However, Section 315 requires the applicant to promptly provide information regarding requirements that become applicable after the date a complete application was file by prior to the release of a proposed action.

Comment #141: Section 322.03. Standard Permit Requirements. This provision needs to be revised to clarify that there must be at least one permit term for each requirement.

IDHW Response: The Department has incorporated the suggested modification into the rules.

Comment #142: **Section 322.04. Alternative Operating Scenarios. Commenter commends IDHW for incorporating the alternative operating scenario provisions, and is recommending that two phrases be added to clarify that the source must outline reasonably foreseeable operating scenarios in its permit application for IDHW to approve them as a part of the operating permit.**

IDHW Response: The Department has not modified the rules in response to this comment. The Department does not want to be put in the position of deciding whether or not an applicant could reasonably foresee operating under a proposed operating scenario. Maximum flexibility requires that the Department to base approval of alternative operating scenarios based on their compliance with underlying requirements not on whether or not a facility would ever operate under the requested scenario.

Comment #143: **Section 322.04. Alternative Operating Scenarios. The reference to operating scenarios approved in accordance with Section 314.08 is confusing because Section 314.08 does not address the approval of such scenarios, only the information to include in an application. The permit must also include provisions that assure compliance with all applicable requirements for each such scenario.**

IDHW Response: The Department has modified this section in response to this comment.

Comment #144: **Section 322.10.e. Compliance Certifications. The state is the only regulatory agency, so the reference for sending certifications to EPA could be deleted.**

IDHW Response: The Department has not modified the rules in response to this comment. This section is required by 40 CFR 70.6(c)(5)iv.

Comment #145: **Section 322.13. Tier II Applicable Requirements. This provision must be deleted since no Tier II requirements can be applicable to Tier I sources. A source is either subject to Title V of the Clean Air Act or it is not.**

IDHW Response: The Department has deleted this section.

Comment #146: **Section 322.14. Provisions Stating the Following. This section lists provisions that are included in the permit. A subsection needs to be added that allows PTC/PSD permits to be automatically included into the operating permit. Without this, a PTC/PSD permit could be obtained but the modification could not take place until the operating permit was also changed. Rather**

than have the delay and duplication of two separate permitting activities there should be one activity.

IDHW Response: The Department did not modify the rules in response to this comment. Sections 209.05 and 385 cover the relationship between these two programs.

Comment #147: Section 322.14(f). Provisions Stating the Following. It is unclear whether requiring all information requested under Section 122 is as broad as 40 CFR 70.6(a)(6)(v). This could perhaps be clarified by the Attorney General opinion.

IDHW Response: The Department has not modified the rules in response to this comment. The Attorney General opinion on the final rules will cover this issue.

Comment #148: Section 322.14(h). Provisions Stating the Following. This provision is contrary to 40 CFR 70.6(f) and Section 325 of the Idaho regulations in that it doesn't provide that the permit is a shield only as to applicable requirements listed in the application and expressly determined in writing by the permitting authority not to be applicable.

IDHW Response: The Department has deleted this section. The Department has rewritten Section 325 to clarify the shield provisions and to replace instructional language with actual language.

Comment #149: Section 322.15. Provisions Prohibiting. The last clause should be revised to clarify that it refers to a "modification under any provision of 42 U.S.C. Section 7401 to 7515."

IDHW Response: The Department has modified this section to prohibit facility alterations without complying with Sections 380 through 387.

Comment #150: Section 322.17. TIER I Limits. This section seems to render everything federally enforceable. This section should be modified to differentiate between State enforceable regulations and Federally enforceable regulations. Suggested language is included.

IDHW Response: The Department has modified this section (now 322.17.j) in response to this comment.

Comment #151: Section 322.20. Provisions Requiring Registration Fees. As discussed below, Idaho must demonstrate that all Tier I sources are subject to Sections 525 through 538. For example, it

is not clear that Tier I sources which are major only for hazardous air pollutants would be subject to registration fees.

IDHW Response: The Department has not modified this section in response to this comment.

Comment #152: **Section 322.22. Permit Duration. The phrasing is awkward and could possibly be revised to state: "...a permit term of five years; except...." Also, the provision allowing for permits of shorter duration during the first four years after EPA approval cannot be applicable to acid rain sources.**

IDHW Response: The Department has modified this section (now 322.15) in response to this comment.

Comment #153: **Section 326. Excess Emissions. One commenter has suggested substantial additions, deletions and modifications to Section 326.**

Section 326.01. This provision is not approvable and will preclude EPA from approving Idaho's Title V operating permit program. An upset must still be considered a violation. A state may, however, provide reasonable procedures for the exercise of enforcement discretion for upsets. Also, exercise of enforcement discretion for scheduled maintenance, start up and shut down is strictly limited. Idaho's provision is far too broad.

Section 326.03(a). By linking reporting to detection, the rule is much more permissive than Idaho's existing upset rule, which links reporting to occurrence. By linking reporting to detection, they can always say they didn't know about the upset. This provision must be revised to be consistent with the current requirements.

Section 326.03.d. This section allows the Division to shut down an entire facility if one emissions unit is the cause of excess emissions. The conditions under which an entire facility will be shut down should be well defined. Prior to the last sentence before i., add: "The decision regarding whether to shut down a facility will be based on the amount the rest of the facility contributes to excess emissions. Under no circumstances will an entire facility be shut down, if the shut down of the emissions unit resolves the problem."

IDHW Response: The Department has modified Section 326 in response to these comments. Most of the suggested modifications have been incorporated into this section. For suggested changes to sections 329.03 e-g, the Department has responded by editing these sections and deleting the "avoidable" and "absolve" clauses. The Department has retained the ability to revoke or modify the procedures because the approval will be issued with 48 hours to allow continued operations so there will be very limited review. The ability to revoke or modify will allow the Department to more liberally grant approvals initially because the Department can revoke or modify the

approval if new information becomes available, the permittee abuses the approval, or if the public objects.

Comment #154: Section 326.04. Excess Emissions. Allowing sources to send written notice within 15 days is more liberal than their current upset provision, which requires written notice by the end of business on the next working day. This provision must be revised to be consistent with the current requirement.

IDHW Response: The Department has not modified this section in response to this comment. For startup, shutdown and scheduled maintenance, the permittee is required to notify the Department no later than 2 hours prior to the start of the excess emissions event. For upset and breakdown, the permittee must notify the Department of the event no later than 24 hours after occurrence. The permittee is then required to submit a written report for each excess emissions event no later than 15 days after the beginning of the event.

Comment #155: Section 326. Excess Emissions. The section on permit content must include a provision meeting 40 CFR 70.6(b) regarding designation of state only requirements in the Tier I permit.

IDHW Response: The Department has modified the rules in response to this comment. See Section 322.17.k.

Comment #156: Section 342.03. Action on Applications. Section 342.03 provides that the Department shall promptly provide notice to the applicant of whether the application is complete and that, unless it is within the one year after EPA approves Idaho's Tier I Operating Permit Program or the Department requests additional information, or otherwise notifies the applicant of incompleteness within 60 days of receipt of an application, the application shall be deemed complete. Commenter recommends that the completeness determination be made with 60 days of submission of the application, regardless of when the application is submitted and that the permit shield be extended, and an application check list be provided.

This provision is contrary to 40 CFR 70.7(a)(4) in that it suspends the 60 day automatic completeness for applications submitted within one year after EPA approval of the program.

IDHW Response: The Department has modified the rules in response to this comment. See Section 361.

Comment #157: Section 342.01. Action on Applications. Clauses (b) and (c) appear to apply to the same actions, but use different

language. Making them consistent would avoid any possible ambiguity.

IDHW Response: The Department has modified these sections in response to this comment.

Comment #158: Section 342.01(f). Action on Applications. This provision does not appear to relate to any other subparagraphs in Section 342.01. It seems awkwardly placed. In addition, it is unclear whether this provision also includes increases in emissions of acid rain authorized by allowances, which, pursuant to 40 CFR 70.6(a)(4), must also be allowed without permit revision.

IDHW Response: The Department has deleted this section.

Comment #159: Section 342.02(a). Action on Applications. This provision also appears awkwardly placed, since it does not relate to the lead in provision of 342.02. Perhaps 342.02(a) should be renumbered 324.02, and the rest of what is now Section 342.02 should be renumbered 342.03.

IDHW Response: The Department has modified the rules in response to this comment.

Comment #160: Section 342.02.c and 342.06. Action on Applications. The definition of complete application allows open time limit if the Department determines application is not complete within 60 days. This section should require the Department to take final action on any complete Tier I operating permit application within six months of the permit application submittal.

IDHW Response: The Department has not modified the rules in response to this comment. Assuming that a complete application has been submitted, the Department must make a completeness determination within 60 days. Once the completeness determination has been made the Department must produce a draft Tier I operating permit within 60 days. The Department must provide a 30 day public comment period. The Department must then respond to comment and prepare a proposed permit within 30 days. The proposed permit will be sent to EPA for review period not to exceed 45 days. Therefore the expected time from submittal of a complete application to issuance of a final permit is seven and a half months barring any appeals.

The Department will reexamine the time required to take final action on a permit in the third year of the transition period. If warranted, the Department will shorten the 18 month deadline for final action on complete applications.

Comment #161: Section 342.02(d). Action on Applications. For clarification, this sentence should be revised: "Submittal of Tier I operating applications for and the permitting of...."

IDHW Response: The Department has modified this section in response to this comment.

Comment #162: Section 342.04. Action on Applications. This provision should be revised to clarify that the memorandum must set forth the "legal and factual basis" for the proposed permit.

IDHW Response: The Department has modified the rules in response to this comment. See Section 362.

Comment #163: Section 342.05. Action on Applications. For further clarity, this provision should be revised to make clear it refers to a complete Tier I application.

IDHW Response: The Department has modified the rules in response to this comment. See Section 361.03.

Comment #164: Section 342.06. This provision does not include the requirement that a responsible official must certify the submitted information.

IDHW Response: The Department has modified the rules in response to this comment. See Section 314.01.

Comment #165: Section 343.03.a. Permit Renewal & Expiration. While 343.03.a includes Tier II operating permits, 343.03.b. does not. Suggested language is included.

Section 343.03. and (b). This provision must be revised to clarify that the application must be both timely and complete. Furthermore, the references to "permit to construct" and "Tier II operating permit" must be deleted as Sections 300 et seq. do not apply to those permits.

IDHW Response: The Department has modified this section (now 368) in response to this comment.

Comment #166: Section 344. Off Permit Changes. The Department has included provisions incorporating this requirement in its draft regulations. Commenter is asking that additional language be added to specifically authorize trading of emission increases and decreases, and to otherwise accommodate SIP-authorized emissions trading. Additional language is included.

IDHW Response: The Department has modified the rules in response to this comment. See Sections 314.12 and 322.05.

Comment #167: Section 344. Off Permit Changes. Entitling this provision "off permit" changes is confusing, because Part 70 refers to changes of the type referred to in Section 322.16 as "off permit" changes. Changes of the type referred to in this paragraph are authorized under 40 CFR 70.4(b)(12). It may help to clarify Idaho's Title V program if all provisions allowing for operational changes outside the permit revision process were in the same place, such as off-permit changes, 502(b)(10) changes, and other operational flexibility provisions. Currently, some such provisions are here and some are either also or only in the permit content provision. This paragraph must also be revised to expressly exclude acid rain sources from making changes of the type permitted under this Section 344. In addition, this paragraph uses the term "emissions allowable under the permit," but that terms is not defined in Idaho's regulations. The term "emergencies" should also be defined.

IDHW Response: The Department has made modifications to the rules that address this comment. The Department has created a new section entitled "Alterations". The purpose of this section is to clarify what changes are allowed, the procedures that must be followed for each alteration, and the permit shield applicability of each type of alteration.

The Department has added or expanded the definitions mentioned in the comment. See Section 103.

Comment #168: Section 345. Administrative Permit Amendments. This provision can not apply for the acid rain portion of the permit. Instead, such amendments shall be governed by acid rain regulations.

IDHW Response: The Department has modified the rules in response to this comment. See Section 384.01.b.

Comment #169: Section 346. Minor Permit Modification Procedures. This provision can not apply for the acid rain portion of the permit. Instead, such modification shall be governed by acid rain regulations.

IDHW Response: The Department has modified this section (now 385) in response to this comment.

Comment #170: Section 346. Minor Permit Modification Procedures. IDHW has adopted minor permit modifications procedures. Commenter concurs with this approach, and has suggested some additional

language to make the purpose of the minor permit modification procedures more apparent. Commenter has also suggested a provision to allow group processing of minor modifications.

IDHW Response: The Department has modified this section (now 385) in response to this comment. The Department has added provisions allowing group processing of minor modifications (Section 385.07).

Comment #171: Section 346.01(d)(i). Minor Permit Modification Procedures. This provision must be clarified to provide that the emissions cap must be federally enforceable. Also, is the reference to "act" to Idaho law or to the Clean Air Act. The reference should include Title I modifications.

IDHW Response: The Department has not modified the rules in response to this comment.

Comment #172: Section 346.03. Minor Permit Modification Procedures. This provision must also require the State promptly to send any notice required under 40 CFR 70.8(b)(2).

IDHW Response: The Department has added this provision to the rules. See Section 385.04.

Comment #173: Section 346.04. Minor Permit Modification Procedures. This provision must be revised to provide: "Within 90 days of the Department's receipt of a complete application under the minor permit modification procedures or within 15 days after the end of EPA's 45 day review period, which ever is later,..."

IDHW Response: The Department has modified the rules in response to this comment. See Section 385.04.

Comment #174: Section 346.05. Minor Permit Modification Procedures. Based on the idea that the source also needs to comply with both the applicable requirements governing the change and the proposed permit terms and conditions until the Department takes action on 364.04.d. Commenter submitted new language.

IDHW Response: The Department has modified this section in response to this comment and to use terms consistent with the new Section 380.

Comment #175: Section 346.06. Minor Permit Modification Procedures. The permit shield does not apply to minor permit modifications at any time per 40 CFR 70.7(2)(vi).

IDHW Response: The Department has modified this section (now 385.06) in response to this comment.

Comment #176: Section 346. Minor Permit Modification Procedures. This section does not contain the requirements set forth in 40 CFR 70.7(e)(2)(iv) on the prohibition on issuance until after EPA review.

IDHW Response: The Department has modified the rules in response to this comment. See Section 385.04.

Comment #177: Section 348.01. Reopening For Cause. Subparagraphs (c) and (g) appear redundant. Also, the program must allow for reopenings for new requirements for acid rain sources in accordance with 40 CFR 70.7(f)(ii).

IDHW Response: The Department has modified this section (now 387) in response to this comment.

Comment #178: Section 348.02. Reopening For Cause. This provision must provide that reopenings shall be as expeditiously as possible. In the alternative, this assurance could be made elsewhere in the program submittal.

IDHW Response: The Department has modified this section (now 387.03) in response to this comment.

Comment #179: Section 349.03. Reopening For Cause by EPA. This provision should be revised to provide that the 90 days runs from receipt of an EPA objection.

IDHW Response: The Department has modified this section (now 387.05) in response to this comment.

Comment #180: Section 350.05. Public Participation. The language "...unless the director deems that additional time is required..." should be changed to provide for a 90 day maximum.

IDHW Response: The Department has not modified the rules in response to this comment. The Department makes every effort to respond to public comment expeditiously.

SECTION 400

Comment #181: Section 401. TIER II OPERATING PERMIT. Section 401.01. must be revised so that it applies to sources that are

subject to Section 300 et seq. not just Section 525. Tier II operating permits must be available to all sources which are not subject to Tier I operating permits and the applicability provisions of Section 525 are not the same as for Tier I operating permits. Furthermore, the parenthetical phrase must be revised because a source doesn't "net out" of applicability but rather limits its potential to emit to levels below the applicability provisions.

IDHW Response: The Department has modified this section in partial response to this comment. The Department has not changed the "net out" language.

Comment #182: Section 401.02. TIER II Operating Permit. Section 02. requires "that anyone with a permit to construct which establishes any emission standard different from those in these rules" to acquire a Tier II permit. If the Permit to Construct is valid for the life of the source then the emissions limitations included in the permit are also enforceable for the life of the source and nothing is really gained by the process of applying for additional permits. Section 03. is sufficiently broad to cover nearly any other circumstances. Delete section 02. and renumber the subsequent sections.

IDHW Response: The Department has not modified this section. This requirement is in the currently effective rules. Permits to construct do not have expiration dates but are superseded by operating permits issued after the permit to construct was issued.

Comment #183: Section 408.03. Conditions for TIER II Operating Permits. This section requires that all tier II operating permits be reissued every 5 years. The director, under section 401.03, has a great deal of discretion to modify or revise a Tier II permit. A permit to construct is issued for the life of the source. Delete Section 03. and renumber section 04.

IDHW Response: The Department has not modified this section. This requirement is in the currently effective rules.

Comment #184: Section 402. APPLICATION PROCEDURES. The phrase "by the owner or operator" should be replaced with "in accordance with Section 123" now that section 123 sets out who must be the certifying official for permits to operate. Furthermore, the reference to Section 300 must be replaced with Section 400.

IDHW Response: The Department has modified this section in response to this comment.

Comment #185: Section 402. APPLICATION PROCEDURES. The structure of this provision is confusing. Since all of section 402 applies to Tier II permits, the lead in to Section 402.01 should perhaps be revised to state: "An application for a Tier II permit must contain the following:" Also, the reference to Section 200 in 402.03 should be changed to Section 400 et seq.

IDHW Response: The Department has modified Section 402 to incorporate all applicable requirements from Sections 200 through 299.

Comment #186: Section 403. REQUIREMENTS FOR ALTERNATIVE EMISSION LIMITS (BUBBLES), Section 404. REQUIREMENT FOR BANKING EMISSION REDUCTION CREDITS (ERC'S), Section 405. REQUIREMENTS FOR EMISSION REDUCTION CREDIT and Section 406. DEMONSTRATION OF AMBIENT EQUIVALENCE. The structure of this part of the state's regulation is strained since Sections 400 et seq. apply to Tier II operating permits yet these Sections cover both Tier I and Tier II operating permits. These Sections should be relocated after Sections 400 - 499, since they apply to all sources, not just sources subject to Tier I operating permits.

IDHW Response: The Department has relocated these sections in response to this comment. See Sections 440, 441, 460 and 461.

Comment #187: Section 403.04. REQUIREMENTS FOR ALTERNATIVE EMISSION LIMITS (BUBBLES). This section needs to refer to all of the National Emission Standards for Hazardous Air Pollutants, not just those in 40 CFR Part 61 but those in Part 63 as well.

IDHW Response: The Department has modified this section in response to this comment.

Comment #188: Section 407.03. Procedures for Issuing Permits. Idaho may wish to consider using the term "permit revision" rather than "permit modification"

IDHW Response: The Department has modified this section in response to this comment.

Comment #189: Section 408.02. Conditions for Tier II Operating Permits. To ensure enforceability, this provision should specify a time period within which the source must provide the Department with a copy of the test results.

IDHW Response: The Department has not modified the rules in response to this comment. The Department can specify time periods for submission of test results in the Tier II operating permit.

Comment #190: Section 997. CONFIDENTIALITY OF RECORDS. One commenter noted that the Idaho rules which are incorporated by reference into these rules in Section 997 do not meet the requirements of 40 CFR Part 70 and Section 114 of the Clean Air Act. The rules must be revised in order for Idaho's Tier I operating permit program to receive full federal approval. In addition, another commenter noted that under Section 316 Tier I operating permit applicants may claim confidentiality for application information.

IDHW Response: The rules have been changed in response to this comment and to more accurately reflect the language and intent of current Idaho statutes. Old Sections 316 and 997 have been deleted and replaced with new Section 126. Section 126 provides procedures for a person to request IDHW to treat information as confidential information, requires Tier I operating permit applicants and permittees to submit copies of confidential information directly to EPA and clarifies that all information is subject to disclosure in accordance with Idaho Code §§ 39-111 and 9-301 et seq.

1 Introduction

1.1 Overview

This guideline is intended to assist air permit applicants, air quality specialists, and others who are reasonably proficient at performing atmospheric dispersion modeling analyses, in understanding the Idaho Department of Environmental Quality's (DEQ's) expectations for performing ambient air quality impact analyses associated with air quality permitting. This guideline does not have the force and effect of a rule and is not intended to supersede statutory or regulatory requirements or recommendations of the state of Idaho or the Environmental Protection Agency (EPA). It is provided as general guidance and does not alter the discretionary authority of DEQ to protect public health.

A working-level knowledge of air pollutant dispersion and air quality assessment is needed to understand and use this guideline. Applicants not proficient in atmospheric dispersion modeling are encouraged to use environmental consultants specializing in air quality modeling or other sufficiently experienced professionals having such modeling capabilities. DEQ does not have available resources to educate applicants or consultants in the fundamentals of performing atmospheric pollutant dispersion modeling analyses.

DEQ staff will not recommend a specific consultant; however, DEQ may provide a list of consultants used by applicants for recent permit applications for which dispersion modeling was required. Recent permit applications, DEQ-issued permits, and the Statement of Basis for issued permits are available on DEQ's website, and consultants used by specific applicants are often identified in application materials and the DEQ modeling memorandum (the modeling review memorandum is typically included as an appendix to the Statement of Basis). DEQ may perform the atmospheric dispersion modeling analyses for applicants in some circumstances. Section 1.2 of this guideline describes cases in which DEQ may perform the analyses.

Table 1 provides a basic step-by-step description of an air quality impact analysis, with specific sections of this guideline referenced for each step.

The purpose of an air quality impact analysis, performed in support of an air quality permit application, is to demonstrate that all applicable ambient air quality standards will be met if a proposed project is implemented or to demonstrate an existing facility's compliance with the standards.

Demonstration of compliance with the National Ambient Air Quality Standards (NAAQS), toxic air pollutant (TAP) increments, and prevention of significant deterioration (PSD) increments is required by the state of Idaho for permit issuance and certain exemptions. DEQ has determined this demonstration generally requires the applicant to perform air quality impact analyses using an atmospheric dispersion model, referred to as modeling analyses in this guideline.

The extent of the required modeling analyses will vary from one project to another depending on the type and magnitude of emissions and applicability of specific permitting requirements. For simple facilities (e.g., few sources and buildings), compliance may be shown by using screening- level techniques, including a screening-level model. No further analyses will be required if compliance can be adequately demonstrated with the use of an appropriate screening technique. Projects for which compliance cannot be demonstrated using screening techniques must use more refined methods. Complex multi-point emitting sources or sources with unusual pollutant dispersion environments, for

which screening techniques are not appropriate, are also required to use more refined modeling techniques. Facilities submitting applications for which the PSD requirements are applicable are required to perform more extensive analyses than when submitting a minor source application. This guideline focuses on the requirements for non-PSD applications. Facilities submitting a PSD application should refer to the New Source Review Workshop Manual (EPA 1990) and other available materials from EPA for additional guidance and should consult with DEQ before performing the required analyses.

This guideline follows the Rules for the Control of Air Pollution in Idaho (IDAPA 58.01.01 {Idaho Air Rules}), EPA guidance in the New Source Review Workshop Manual (EPA 1990), and the Guideline on Air Quality Models (EPA 2005). The 2005 version of the Guideline on Air Quality Models was used to develop this version of the guideline. However, the most current version of the Guideline on Air Quality Models should always be used when evaluating appropriate methods and data for a specific project.

The Guideline on Air Quality Models specifies:

"...air quality modeling techniques that should be applied to State Implementation Plan (SIP) revisions for existing sources and to new source reviews (NSR), including prevention of significant deterioration (PSD). Applicable only to criteria pollutants, it is intended for use by EPA Regional Offices, in judging the adequacy of modeling analyses performed by EPA, State and local agencies and by industry. The guidance is appropriate for use by other Federal agencies and by State agencies with air quality and land management responsibilities."

DEQ highly recommends that a modeling protocol be developed and submitted to DEQ for approval before performing any modeling analyses. A DEQ-approved protocol will help assure that methods and data used in the modeling analyses are appropriate and will be acceptable to DEQ reviewers. Guidance on the contents of a protocol is provided in Section 6.1.

Table 1. Sections of the Guideline Used in Performing an Air Impact Analysis

Step in Air Impact Analysis	Section
1) Determine whether professional assistance is needed for performance of the air impact analyses?	1.1, 1.2, 2.0
2) Review general modeling requirements and develop a methodology.	5.0, 6.0
3) Calculate the emissions increase for modeling applicability purposes.	3.3, 6.3
4) Determine whether dispersion modeling is required – compare applicability inventory to modeling thresholds.	3.1, 3.2
5) Select the appropriate model.	6.2, 5.0
6) Set up the modeling analysis, including facility layout, buildings, ambient air boundary, receptors, and elevation data.	6.4.3, 6.4.4, 6.4.5, 6.5, 6.6, 6.7, 6.9
7) Select meteorological data.	6.8
8) Determine background concentrations.	6.10
9) Prepare and submit protocol, and obtain DEQ approval.	6.1
10) Calculate emissions for significant impact analyses and TAPs analyses.	5.1.1, 6.3, 6.3.1, 6.3.2, 6.3.3, 6.4.1
11) Calculate/obtain emissions release parameters and document.	6.4.2
12) Evaluate model results for significant impact analyses and TAPs analyses.	4.1, 4.2, 4.3, 6.11
13) Calculate emissions for cumulative NAAQS analyses and document.	5.1.2, 6.3.1, 6.3.2, 6.3.3, 6.4.1
14) Evaluate model results for cumulative NAAQS analyses.	4.1, 6.11.1
15) Perform comprehensive quality assurance/control of the analyses and evaluation of results.	2.0, 6.11.2
16) Prepare permit application and modeling report.	6.12, 7.0

1.2 Responsibility for Modeling Analyses

The accuracy and representativeness of methods and data used in the modeling analyses is the responsibility of the applicant. DEQ may provide applicants with appropriate meteorological data (not always preprocessed and ready for model input) and default background pollutant concentration values, as described later in this guideline.

DEQ modeling staff may assist applicants or may perform the required modeling analyses in some instances. The following are cases in which DEQ may perform the modeling analyses for permit applicants:

- Renewal of a Tier II operating permit. If a facility has not been modified since issuance of a previous Tier II operating permit, DEQ may use the previously performed modeling results to demonstrate compliance with NAAQS. Previously conducted modeling analyses will not be acceptable if DEQ identifies errors in methods or data used, or if the model used is substantially outdated, such that compliance with NAAQS may be questionable. Changes in applicable standards would also trigger the need to remodel the facility.
- DEQ has current modeling files for the facility. In instances where DEQ has a current model for the facility, slight changes to account for a new source or modification can sometimes be easily made by DEQ modeling staff. The applicant will be responsible for providing, justifying, and

documenting all input parameters needed to adequately address the proposed changes. Modeling analyses performed by DEQ staff will be done outside of the regulatory time limit for permit application review and will be dependent on DEQ staff workload. The applicant must include justification and documentation of all parameters, even those provided in previously submitted analyses. DEQ's permitting process requires that each application be a complete package in itself and not merely reference previously submitted applications.
If compliance with standards cannot be easily demonstrated by DEQ's analyses it will be the applicant's responsibility to conduct more refined analyses.

- Simplistic modeling analyses for small businesses. DEQ may conduct the modeling analyses for small business in situations where there are a small number of sources and a simple facility layout. These decisions will be made on a case- by-case basis and will depend on current DEQ workload.

Modeling analyses performed by DEQ for permit applicants will typically be done outside of the regulatory review process and any review timelines. Data and results will typically be forwarded to the applicant for their review when the analyses are completed by DEQ staff. The applicant will then combine those analyses with other components of the application and submit the complete application to DEQ to initiate the agency review process.

Permit applicants will be responsible for submitting the following information/data to enable DEQ to perform modeling analyses:

- Detailed description of operations and equipment used.
- Requested allowable emissions rates for all criteria pollutants and TAPs for all applicable averaging periods.
- Maximum operational and material processing rates.
- Site description and scaled site plot plan, including a detailed description of any structures. Universal Transverse Mercator (UTM) coordinates, with the applicable datum listed, must be provided for all building corners, and heights of all building tiers must be provided.
- Emissions point information (stack location in UTM coordinates with the applicable datum listed, stack height, stack diameter, stack gas temperature, and flow rate) with thorough justification and documentation of such information.

If DEQ's analyses do not initially demonstrate compliance with applicable standards, it will be the applicant's responsibility to refine the analyses to achieve an adequate compliance demonstration.

DEQ has developed, or is in the process of developing, specific modeling approaches for several industrial types. For example, DEQ has conducted non-site-specific modeling for truck-mix concrete batch plants and portable hot-mix asphalt plants; and no source- specific modeling is require for these plants if they meet the production rate limits, minimum stack parameter specifications, and setback distances from specific receptors. DEQ air dispersion modeling staff should be consulted regarding availability and details of industry-specific modeling approaches.

2 Use of the Modeling Guideline

2.1 This Guideline Most Useful in Common Instances

This modeling guideline is presented as suggestions and instructions for performing a modeling analysis in the most common instances. The methods and data presented are not appropriate for all sources,

locations, and/or situations, and use of a method presented in the guideline does not necessarily assure DEQ approval of the method. DEQ may approve or require methods and/or data differing from those presented in this guideline, depending on the characteristics of the specific situation.

2.2 Level of Knowledge Required to Use This Guideline

This guideline is not intended to educate permit applicants or consultants in the basic principles of atmospheric dispersion or in the operation of various dispersion models, as stated in Section 1.1. A wide variety of commercially available courses are available for applicants to develop the level of knowledge needed to correctly perform pollutant dispersion modeling analyses.

If your specialist (your staff) or consultant and cannot easily answer the following questions, they may not be adequately skilled to properly perform an air impact analysis involving dispersion modeling for air permitting purposes:

1. Have you performed an atmospheric dispersion modeling analysis within the last five years?
2. Do you understand why a stack with a horizontal or rain-capped release is sometimes modeled using a stack flow velocity of 0.001 meters per second?
3. Do you know what a significant impact is, and its implications for modeled impacts?
4. Do you know when background concentrations are used in a modeling analysis and when they are not?
5. Do you understand the difference between a significant impact analysis and a cumulative NAAQS impact analysis?
6. Do you know what surface roughness, Bowen ratio, and surface albedo are and how they are used in the model programs and preprocessor programs?
7. Do you understand the difference in how point sources, area sources, and volume sources are treated in AERMOD, SCREEN3, and/or AERSCREEN?
8. Do you know whether AERMOD uses daily or hourly meteorological data?

Permitting regulations require the applicant to demonstrate that emissions will not cause or significantly contribute to a violation of a standard. The regulations do not require that the analyses estimate actual impacts to the greatest degree possible. Therefore, it is advised that applicants use reasonably conservative data and methods to demonstrate compliance – data and methods that both DEQ and the applicant agree will generate impacts greater than those that would be reasonably expected. However, overly conservative estimates of input parameters, especially emission quantities, may substantially overstate impacts. This could result in the inappropriate applicability of certain requirements and/or the imposition of unnecessary permit provisions and restrictions.

Use of unrealistic release parameters, such as stack flow rates or stack gas temperatures, could shift the location of maximum impacts. In situations where the modeling analyses involve numerous sources, this could result in either under-estimation or over-estimation of combined impacts. Therefore, it is recommended that reasonably accurate release parameters be used when modeling multiple sources, rather than overly conservative parameters. In some instances, where reasonably expected parameters are highly variable, it may be more appropriate to use multiple operational scenarios to evaluate the effects of varying parameters.

3 Requirements to Perform Air Impact Analyses

This section outlines the permitting requirement to demonstrate compliance with NAAQS and TAP increments, and it describes when project-specific air impact modeling analyses are needed for issuance of a PTC or Tier II Operating Permit. It discusses pollutant-specific regulatory applicability, regulatory requirements for permit issuance, and calculation of emission increases for project modeling applicability.

3.1 Air Impact Analysis Regulatory Requirements for Permit Issuance

3.1.1 NAAQS and TAP Compliance Demonstration Requirements

Idaho Air Rules Section 203.02 states that "no permit to construct shall be granted for a new or modified stationary source or modified stationary source unless the applicant shows to the satisfaction of the Department" that the source or modification "would not cause or significantly contribute to a violation of any ambient air quality standard." Section 203.03 similarly requires that no permit be issued unless it is demonstrated through the use of methods in Section 210 that the source or modification would not "injure or unreasonably affect human or animal life or vegetation as required by Section 161."

Air impact analyses are also required for the issuance of Tier II Operating Permits, with requirements of Idaho Air Rules Section 403.02 mirroring Section 203.02 for PTCs. There are no TAP impact analysis requirements for Tier II Operating Permits.

3.1.2 Below Regulatory Concern Exemption from Demonstration Requirement

Certain projects may be exempt from the requirement to demonstrate compliance with NAAQS or TAP increments. If a project would qualify for a Below Regulatory Concern (BRC) permit exemption as per Idaho Air Rules Section 221 if it were not for potential annual emissions of one or more pollutants exceeding the BRC threshold of 10 percent of emissions defined by Idaho Air Rules as "significant," then a NAAQS compliance demonstration may not be required for those pollutants with emissions below BRC levels. DEQ's regulatory interpretation policy of exemption provisions of Idaho Air Rules Section 221.01 is that: "A DEQ NAAQS compliance assertion will not be made by the DEQ modeling group for specific criteria pollutants having a project emissions increase below BRC levels, provided the proposed project would have qualified for a Category I Exemption for BRC emissions quantities except for the emissions of another criteria pollutant.[1]" The interpretation policy also states that the exemption criteria of uncontrolled potential to emit (PTE) not to exceed 100 ton/year (Idaho Air Rules Section 220.01.a.i) is not applicable when evaluating whether a NAAQS impact analysis is required. A permit will be issued limiting PTE below 100 ton/year, thereby negating the need to maintain calculated uncontrolled PTE under 100 ton/year.

The BRC exemption cannot generally be used to exempt a project from a pollutant-specific NAAQS compliance demonstration where a PTC is required for the action regardless of emission quantities, such as the modification of an existing emission or throughput limit.

However, in this instance, if post-project facility-wide annual emissions of the criteria pollutant are also below BRC thresholds, then a NAAQS compliance demonstration is not required.

3.1.3 Regulatory Requirements of the Air Impact Analyses

Once a permit is required for a proposed project, an air impact analysis is required for permit issuance unless the pollutant can be exempt from the requirement to demonstrate compliance with NAAQS and TAP increments, as described above in Section 3.1.2. Idaho Air Rules Section 203 for PTCs and Section 403 for Tier II Operating Permits require that air impact analyses demonstrate compliance with NAAQS and TAP increments "to the satisfaction of the Department." A key consideration is what constitutes DEQ satisfaction of compliance.

Use of unquestionably-conservative methods and data for all components of the analyses will generate predicted impacts that demonstrate compliance at near complete certainty. As analyses move back from methods and data that are highly conservative, then the certainty of NAAQS and TAP increment compliance decreases. Determining the point at which analyses no longer satisfactorily demonstrate compliance then becomes an important concern. This point is not defined in the regulations. DEQ asserts that a satisfactory compliance demonstration is an analysis where NAAQS and TAPs increment compliance is "highly confident," considering all variability and uncertainty in analytical methods and data.

The confidence level of compliance with air quality standards will be affected by the following:

- Magnitude and spatial extent of modeled impacts in comparison to applicable thresholds or standards.
- Potential for public exposure to impacts exceeding standards.
- Representativeness of meteorological data used, and the accuracy/conservatism of meteorological data processing methods used.
- Uncertainty and variability of estimated emissions. Emissions that will be verified by source testing will be considered as near certainty, while emissions based on low-ranked AP-42 factors (which usually represent an average across the industry) will be considered as low confidence.
- Method used to account for atmospheric chemistry (NO/NOx chemistry primarily).
- Representativeness and conservatism of background concentrations (note that using design value background levels with design value modeled results is more conservative for short-averaging periods than for annual averaging periods).
- Level of conservatism in modeling expected operational scenarios (handling variable load conditions, multiple intermittent sources, etc.).
- Representativeness/conservatism of methods used to handle complex emission points such as fugitive releases.
- Handling of building downwash.
- Handling of complex terrain.
- Methods use to hand co-contributing sources in a cumulative impact analysis.

3.2 Emission Thresholds Triggering Site-Specific Impact Analyses

Emission quantities from a source directly affect pollutant impacts to ambient air, and therefore affect the likelihood of a source to cause or contribute to a violation of an ambient air quality standard. Where emission rates are minimal, DEQ can be highly confident that the source will not cause or contribute to a standard violation without performing an impact analysis using pollutant dispersion modeling. Screening Emission Levels (ELs) are specified in the Idaho Air Rules as a de *minimis* TAP emission quantity, below which compliance with the TAP increment is assured. De *minimis* levels for criteria pollutants are not specified in Idaho Air Rules. However, this section presents criteria pollutant de *minimis* levels that DEQ

asserts will reasonably assure NAAQS compliance for various circumstances. These levels were established using the professional judgement of DEQ scientists and engineers, combined with results from computerized pollutant dispersion models for various generic configurations.

DEQ established emission de *minimis* levels as a function of the Significant Emission Rates (SERs) defined in Idaho Air Rules Section 005.108. The SERs are expressed as annual emission rates. To use SERs for NAAQS with short-term averaging periods, the SER is divided by 8,760 hours/year and compared to maximum hourly emissions for 1-hour standards or maximum daily emissions divided by 24 for 24-hour standards. DEQ also developed Significant Impact Level (SIL) thresholds for modification projects; emissions less than these rates are reasonably assured to have impacts less than the applicable SIL. SIL thresholds were developed by DEQ using dispersion modeling analyses of a generic facility with one point source.

Whether a specific emission quantity can cause or contribute to a violation greatly depends on whether those emissions occur from a new facility or are added to those of an existing facility, and whether the existing facility has recently demonstrated NAAQS compliance on a facility- wide basis through dispersion modeling. The confidence of NAAQS compliance is high where project emissions occur from a proposed new facility in an attainment area and predicted emission quantities are low. NAAQS compliance confidence is also high for projects at existing facilities where facility-wide air impact analyses were recently performed and emissions associated with the modification are minimal. Even if the increase in emissions at a previously modeled existing facility could cause impacts exceeding the SIL, it is unlikely that impacts could exceed the NAAQS when combined with co-contributing sources and background concentrations. This is because any high impacts from new sources are not likely to coincide in time and space with high impacts from the existing facility. In the unlikely event that such minimal emissions combine with a high background concentration and impacts from nearby sources to produce an impact exceeding the NAAQS, it is likely that such impacts would only occur in a small area, would only occur for limited periods, and would not affect areas where sensitive individuals could be present.

A modeling applicability threshold assuring project impacts less than the SIL is used for modification projects to facilities where facility-wide NAAQS compliance demonstrations have not been recently performed. This threshold assures with high confidence that the project will not significantly contribute to any potentially existing NAAQS violation. These threshold values were based on modeling of a generic DEQ-generated facility, using the AERMOD regulatory model with Idaho meteorological data. The analyses used the following parameters: stack height = 10 meters; stack diameter = 0.5 meters; velocity at stack exit = 10 meters/second; stack gas temperature at exit = 200 °F; ambient air is at a distance of 100 meters from the stack; the stack is centered on a 10 meter square building, 5 meters high. The SIL thresholds are emission rates that, when modeled using the generic DEQ-generated facility, result in impacts just below the applicable SIL.

Figures 1 and 2 show the project-specific air impact analysis applicability determination process for new facilities and modifications to existing facilities, respectively. This process should only be used for projects proposed in attainment or unclassifiable areas. DEQ should be consulted if a proposed project is located in a non-attainment area. Also, if DEQ observes project-specific conditions that suggest a threshold is not appropriate or protective of NAAQS, then DEQ may require project-specific air impact modeling even though emissions are below the listed threshold.

Table 2 lists the modeling applicability threshold values referenced in Figures 1 and 2.

Table 2. Modeling Applicability Thresholds (values in pounds/hour[(a)])

Pollutant and Averaging Period	SIL Threshold	BRC	1/8 SER	1/4 SER	SER
CO 1-hr	84	2.3[b,c]	2.9[b]	5.7[b]	100 ton/yr
CO 8-hr	26	2.3[b,c]	2.9[b]	5.7[b]	100 ton/yr
NO_2 1-hr	0.38	0.91[c]	1.14	2.3	40 ton/yr
NO_2 ann	0.43 (1.9 ton/yr)	4.0 ton/yr	5.0 ton/yr	10.0 ton/yr	40 ton/yr
SO_2 1-hr	0.40	0.91[c]	1.14	2.3	40 ton/yr
PM_{10} 24-hr	0.32	0.34[c]	0.43	0.86	15 ton/yr
$PM_{2.5}$ 24-hr	0.092	0.23[c]	0.29	0.57	10 ton/yr
$PM_{2.5}$ ann	0.085 (0.37ton/yr)	1.00 ton/yr	1.25 ton/yr	2.5 ton/yr	10 ton/yr
Pb 3-month	0.00102 (0.73 lb/mon)	9.9 lb/mon	12.3 lb/mon	24.7 lb/mon	0.6 ton/yr

a) Values in pounds/hour as averaged over the averaging period of the NAAQS, unless noted otherwise. Pound/hour values listed as a function of the SER were calculated by dividing the annual SER value by 8,760.

b) These values are more restrictive than the SIL Threshold. Therefore, the SIL Threshold may be used in place of these values.

c) BRC is based only on annual emissions. The pounds/hour values listed as BRC for short term standards are the annual BRC rate divided by 8,760 hours/year. Annual emissions from the project should be divided by 8,760 hours/year and then compared to the listed pounds/hour BRC threshold to evaluate whether the project can be exempt from NAAQS compliance demonstration requirements for the applicable pollutant.

d) These values are more restrictive than the SIL Threshold. Therefore, the SIL Threshold may be used in place of these values.

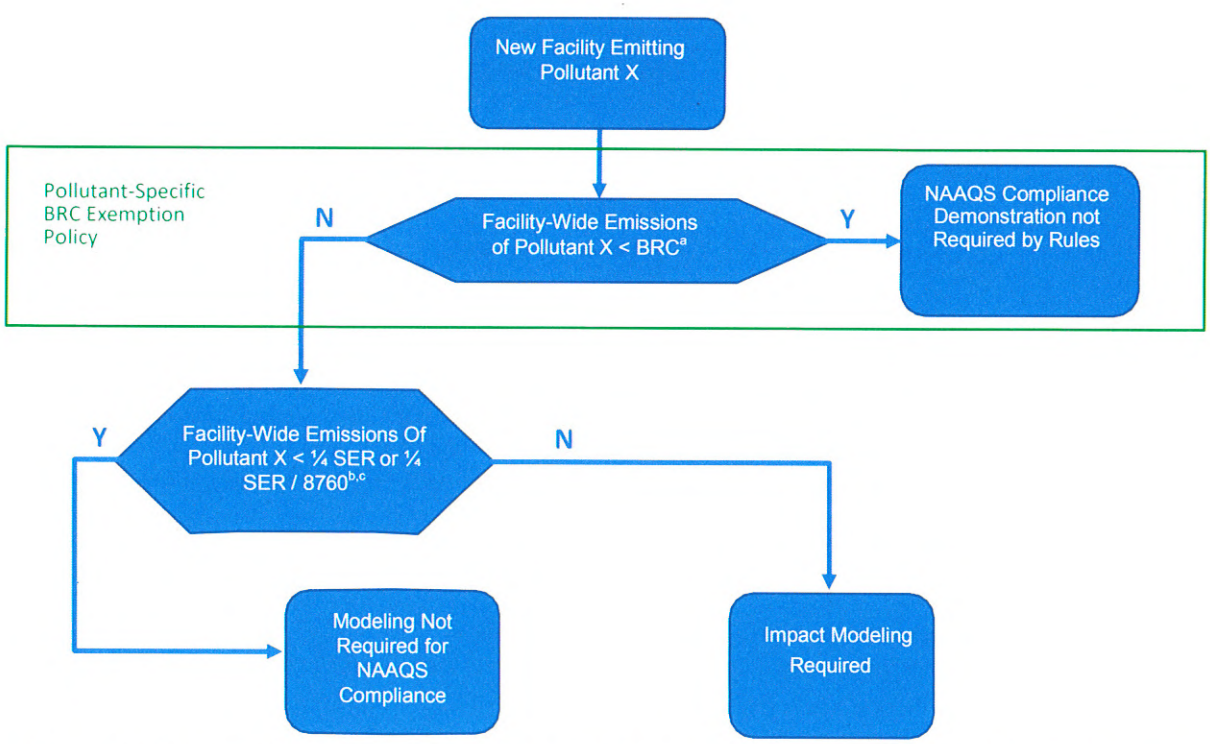

Figure 1. Pollutant-Specific Modeling Applicability Flow Chart for New Facilities in Attainment or Unclassifiable Areas

a) This evaluation is DEQ's regulatory interpretation of permit exemption rules, as described in: *Policy on NAAQS Compliance Demonstration Requirements*. Idaho Department of Environmental Quality Policy Memorandum. July 11, 2014. The evaluation is based only on annual emissions, and emissions qualifying as "fugitive" as defined by Idaho Air Rules for permit applicability are not included in the evaluation. Example: A company proposes to construct a widget maker facility. The project would qualify for a BRC permitting exemption under Idaho Air Rules Section 221.01, with emissions of Pollutant X below the BRC threshold, except that emissions of Pollutant Y exceed the BRC threshold and trigger the requirement to obtain a PTC. By DEQ regulatory interpretation, a NAAQS compliance demonstration for Pollutant X is not required by Idaho Air Rules for permit issuance.

b) Emissions calculated according to DEQ-specified methods. Fugitive emissions associated with the project are included in this evaluation. The threshold of 1/4 SER is applicable to NAAQS regulated on an annual average; and 1/4 SER/8760 is applicable to NAAQS on a short-term average, with the pound/hour threshold value compared to the maximum potential/allowable emission for the averaging period divided by the hours in the averaging period.

c) If DEQ observes project-specific conditions that suggest these thresholds are not appropriate or protective of NAAQS, then DEQ may require project-specific air impact modeling even though emissions are below listed thresholds.

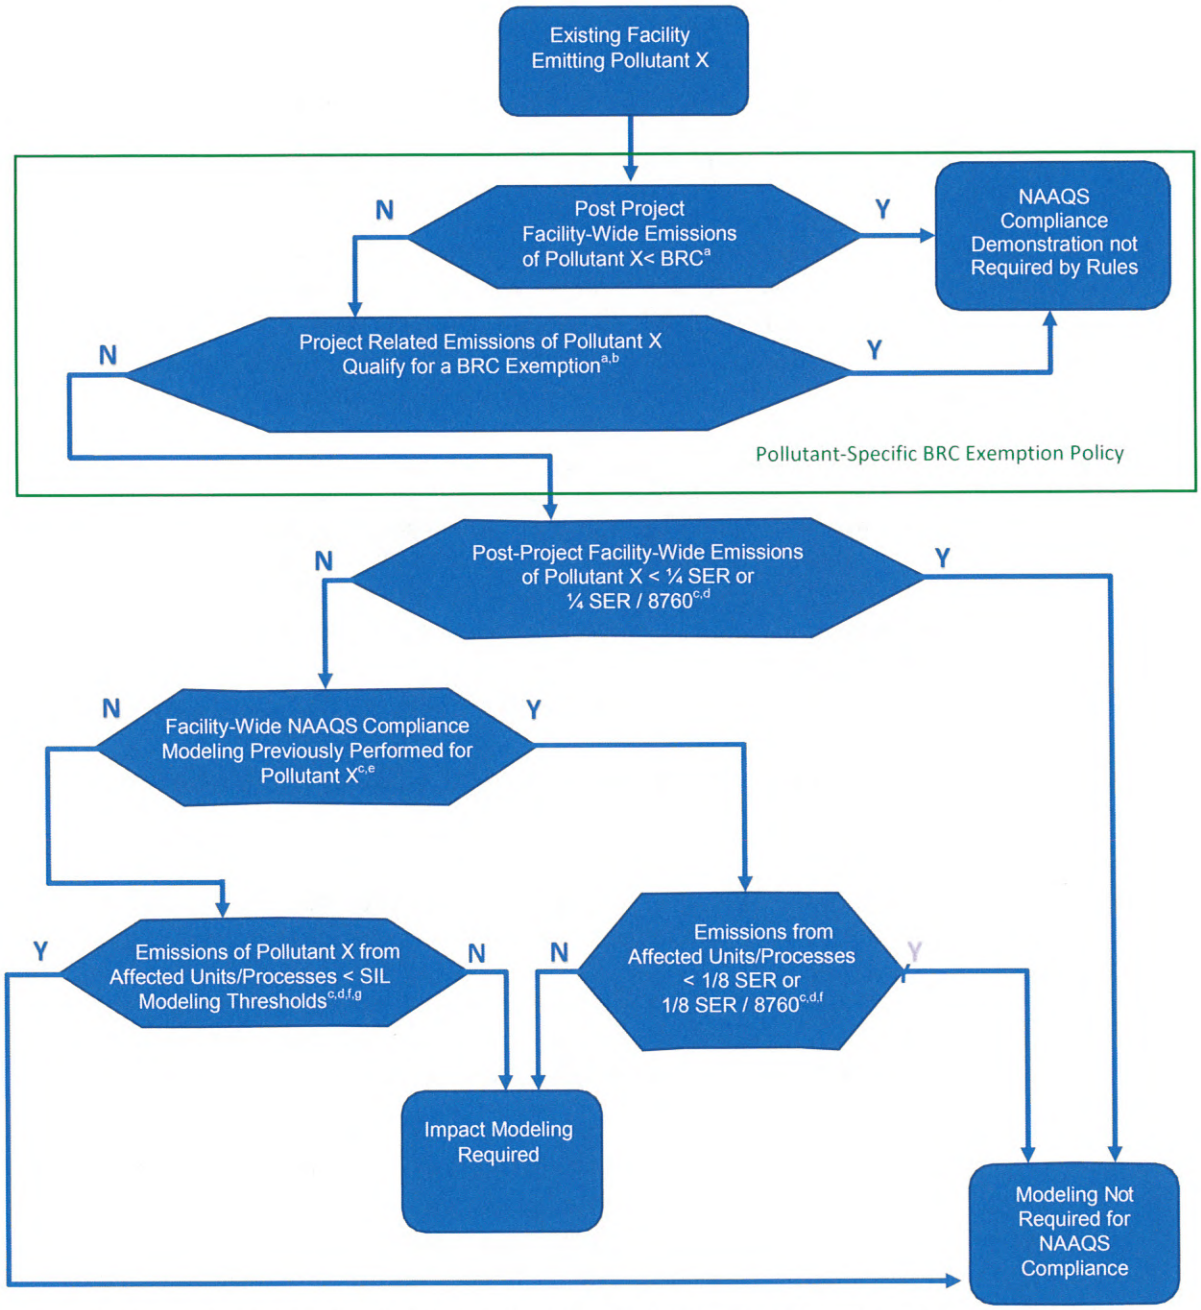

Figure 2 Pollutant-Specific Modeling Applicability Flow Chart for Modifications to Existing Facilities in Attainment or Unclassifiable Areas

a) This evaluation is DEQ's regulatory interpretation of permit exemption rules, as described in: Policy on NAAQS Compliance Demonstration Requirements. Idaho Department of Environmental Quality Policy Memorandum. July 11, 2014. The evaluation is based only on annual emissions, and emissions qualifying as "fugitive" as defined by Idaho Air Rules for permit applicability are not included in the evaluation.

b) Examples:

1. A company proposes to construct a widget maker at their existing facility. The project would qualify for a BRC permitting exemption under Idaho Air Rules Section 221.01, with emissions of Pollutant X below the BRC threshold, except emissions of Pollutant Y exceed the BRC threshold and trigger the

requirement to obtain a PTC. By DEQ regulatory interpretation, a NAAQS compliance demonstration for Pollutant X is not required by Idaho Air Rules for permit issuance.

2. A facility proposes to increase production at their existing, permitted widget maker. The existing permit limits widget production at 50 widgets per hour. The project proposes to increase production to 100 widgets per hour. The increase in emissions of Pollutant X is below the BRC threshold, but total emissions of Pollutant X from the unit are above the BRC threshold. A NAAQS compliance demonstration for Pollutant X is required because the project could not qualify for a permitting exemption, regardless of the emissions from other pollutants. The modification requires changing an existing permit condition, and therefore, could not qualify for a BRC exemption.

c) Fugitive emissions associated with the project are included in this evaluation.

d) If DEQ observes project-specific conditions that suggest these thresholds are not appropriate or protective of NAAQS, then DEQ may require project-specific air impact modeling even though emissions are below listed thresholds.

e) This applies if facility-wide modeling of the specific pollutant was performed for the averaging period of the NAAQS. Facility-wide modeling may be associated with a past permitting project or performed independently, and it may conservatively use allowable emissions or a more-refined reflection of actual emissions. Modeling must have been approved by DEQ, performed within the previous five years, be representative of the existing facility and operations, and include the pollutant of interest.

f) Emissions increase calculated according to DEQ-specified methods, including methods to handle projects involving relaxation of an emission-affecting permit limit.

g) SIL Modeling Threshold based on modeling of a generic hypothetical source.

3.3 Emission Increase Calculation for Project-Specific Modeling Applicability

Whether project-specific air impact modeling is required for a project depends on the increase in emissions resulting from implementation of the project. The emission increase for a new facility is simply the sum of potential or permit-allowable emissions from all emission sources associated with the project. The emission increase for a modification is defined in Idaho Air Rules as "the amount by which projected actual emissions exceed baseline actual emissions of an emissions unit." Section 3.3.2 provides more details on calculating the emission increase associated with modifications for modeling applicability.

The following types of emissions sources should be included in the modeling applicability calculation:

- All emissions sources that may be included in the permitting analyses or the issued permit, regardless of whether those sources may have (or will be issued) emissions or operating limits. Sources that are exempt from permitting as per Idaho Air Rules Section 220-223 must normally be included in the modeling applicability calculation. DEQ's modeling group should be consulted if there are questions regarding the inclusion or exclusion of emission sources in the modeling applicability determination.
- Process fugitive emissions from material handling, processing, etc. Fugitive emissions from vehicle traffic on facility roadways and wind erosion emissions from storage piles will not typically be considered for minor source permitting applicability unless DEQ determines such sources may have a substantial contribution to ambient concentrations. Mining facilities are typically in this category where such fugitive sources must be included.
- Intermittent sources such as batch processes, flaring, bin dumping, engine testing, etc. Emissions of NOx from intermittent testing of engines powering emergency generators and fire suppression water pumps can typically be excluded from the modeling applicability

determination for 1-hour NO2 NAAQS compliance demonstrations. Appendix A provides DEQ's final guidance on the modeling of NOx from intermittent testing and maintenance operations of engines powering emergency generators and fire suppression water pumps.

Sections 3.3.1 and 3.3.2 describe how emission quantities should be calculated for various scenarios to evaluate the need to conduct project-specific impact modeling. The modeling applicability emission inventory (used to determine whether modeling is needed) may be different than the modeling analysis emission inventory (used to conduct a significant impact analysis), as explained in Section 6.3.1.

3.3.1 Determining Whether Modeling is Needed for a New Source or Facility

Proposed allowable emissions, as specified in a permit application or calculated as potential to emit, of all new emissions sources will be used to evaluate the need for modeling a proposed new emissions source or new facility. No emission sources are typically exempt from the evaluation of whether modeling is needed. Also, any reductions in emissions at a different source cannot be considered at the modeling applicability stage.

3.3.2 Determining Whether Modeling is Needed for Modifications

Air impact modeling requirements for a modification hinge on the quantity of increased emissions that could occur as a result of the modification. For the purpose of project-specific applicability for performing an air impact analysis, any emission decreases are not typically considered. Creditable decreases may be considered in air impact modeling performed once the requirement to perform impact modeling has been established. If removal of an existing source or installation of control equipment on a source occurs concurrently with a modification, the emission reduction associated with such activities will not typically be considered in the evaluation of whether emissions exceed modeling applicability thresholds.

Emission increases for a modification must be carefully calculated to obtain an accurate or conservative assessment. From a regulatory standpoint, "Emissions Increase" is defined in Idaho Air Rules Section 007.04 as, "The amount by which projected actual emissions exceed baseline actual emissions of an emissions unit." Baseline actual emissions are a best-estimate of emissions that could realistically occur by operation of the source before modification. If the source is permitted, such emissions may be those allowed under the restrictions of the existing permit (using best available emission estimation methods and considering the permit limits that are the most restrictive to emission-causing operations). The following should be considered when calculating baseline actual emissions to evaluate the need for project-specific modeling:

- For a given process, the same emission calculation method and emission-affecting assumptions should be used for baseline actuals as is used for calculating future permit allowables, unless there are changes in the process that necessitate using different methods and assumptions. A change in emission factors or methods used to estimate emissions from a given process cannot be used to reduce the change in emissions associated with a proposed modification.
- Emissions considered as a conservative estimate for post-project allowable emissions (over-estimation of emissions), will result in an overestimate of baseline actual emissions for future projects. This may then result in an underestimation of the future project emission increase. DEQ approval of a conservatively high emission estimate of a source for initial permitting may not be appropriate for calculating baseline emissions for a future modification. However, the same emission factor or estimation method should be used for a given process, as noted in the previous bullet. For example, if a project involves increasing allowable throughput and the

emission generating mechanism does not change, the same emission factor should be used for both baseline actual emissions and post-project allowable emissions. Also, the applicant should use a factor they are confident does not underestimate post-project allowable emissions, even if it is suspected use of the factor overstates baseline actual emissions.

- Permit applicants should not simply use emission factors and other emission-affecting parameters from previous air impact analyses as a representation of baseline actual conditions. Many previous analyses were only required to demonstrate that the project will not cause a violation, and this was often accomplished by using simplistic estimates that substantially overestimate emissions. More accurate and updated emission rate data and release parameter information are frequently available for a source after initial permit issuance. This results from performance tests or from changes in emission factors. Baseline actual emissions should generally be calculated using the most accurate methods available. Overestimating baseline emissions will result in underestimation of the change in emissions resulting from a modification.
- Full operational levels (as allowed by the existing permit) can be considered in the calculation of baseline actual emissions, provided the facility/equipment could have accommodated such a level of operation. For example, a certain unit has a throughput limit of 1,000 units per day, and operational records indicate that only a maximum of 900 units per day has been processed. Baseline emissions can be calculated by assuming 1,000 units per day if it can be demonstrated that the facility could effectively attain those levels without a facility modification.
- Many permits contain both specific emission limits and limits on production. Baseline emissions must be based on the most restrictive limitation in the permit. As an example, consider a case where source testing has demonstrated that emissions per unit of production are lower than anticipated during initial permitting. As part of a proposed modification, the facility would like to raise the allowable production rate but not change the permitted emission rate. In this case, there will be an increase in allowable emissions because there is an increase in throughput. However, the applicant may calculate the increase in emissions using an updated emission factor that is based on recent source testing.

Future projected actual emissions will simply be permit-allowable emissions. Conservative emission estimates that overstate these emissions are acceptable and encouraged to facilitate expeditious DEQ approval of the modeling-applicability calculation.

Relaxation of Existing Permit Restrictions

Some modification projects involve the relaxation of an existing emission-affecting permit restriction, such as throughput limit, limit on hours of operation, material restriction on the type of material processed, or a direct emissions limit. In these cases, especially where the existing limit was needed to assure compliance with a NAAQS or a TAP increment, DEQ may require that the entirety of emissions from the unit be considered for modeling applicability rather than the increase alone. This approach is used because of the following:

- An increase in emissions at an existing emission point is more likely to cause or contribute to a NAAQS or TAP increment violation than if those emissions occurred at a new point. This is because emissions at two separate points must have overlapping plumes for their impacts to be additive.
- If a limit was needed on an emission point to assure NAAQS or TAP increment compliance, then increasing emissions at such a point would likely cause a violation.

This approach is intended to address potential "sham" permitting. A sham permit occurs when a facility originally intends to operate at a certain level, and equipment permitted is fully capable of operating at such levels, but NAAQS or TAP increment compliance cannot be demonstrated. As a result, the facility is issued a permit limit on the source(s) to assure compliance. Sometime after permit issuance, the facility then submits a permit application to relax the limit, addressing only the increase from the previous limit for impact analyses. This approach effectively circumvents the requirement to comply with NAAQS and/or TAP increments. To address this concern, the emission increase is calculated using a baseline associated with the facility prior to issuance of the permit establishing the limit that the facility now proposes to relax.

Generally, DEQ will use a 5-year period during which a project that involves relaxation of a limit (without a physical change at the facility) will be considered an adjustment/correction of previous permitting project rather than a new project. The emission increase will be calculated using the base emissions allowable prior to the previous permitting project (the project that established the limit to be relaxed) and the new proposed limit.

Replacement Projects

The need for modeling replacement projects that do not qualify as routine replacement is based on total allowable emissions from the proposed new source. The decrease in emissions associated with the removal of the old equipment is not generally considered for modeling applicability.

For example, if a sawmill proposes replacing an existing kiln with a new kiln (not routine replacement), modeling applicability would be based on the proposed allowable emissions of the new kiln without any consideration of the decrease in emissions associated with removal of the older kiln. The creditable emissions decrease associated with the kiln removed can be used in the air impact modeling to offset the emissions from the new kiln, modeled as negative values to evaluate the net impact of the project.

Modification of a Permitted Source

This scenario involves alteration of an existing and permitted emissions source. The need for modeling is normally based on the emission increase as determined by the difference between baseline actual emissions and future projected emissions (permit allowables). However, if the modification alters the release characteristics of the source (temperature, stack gas flow rate, stack height, etc.), then the entire allowable emissions from the modified source must be included for the purpose of modeling applicability. If the emission release characteristics do not change, then the applicable emissions will be considered as the increase resulting from the modification. An example of this is increased emissions-generating activities (that do not affect the temperature or volume of air exhausted) in a room where air is exhausted to the atmosphere through an existing stack. The emissions increase would be calculated as the difference between the current emissions rate and the new proposed allowable emissions rate. Determining the need for project-specific air impact modeling based on only the increase in emissions is approved by DEQ on a case-by-case basis, considering whether the point of release and release characteristics are very similar between the existing and modified emissions points.

A permit is not specifically required for instances where physical changes made at a facility affect dispersion but do not meet the definition of a "modification." Although such changes do not typically require a permit, they do effectively invalidate any dispersion modeling analyses performed prior to those changes and could alter the NAAQS compliance status of the facility. In some cases, DEQ may request facilities to perform air quality dispersion modeling analyses to affirm compliance with applicable standards.

4 Applicable Standards

This section discusses the applicable standards for assessing impacts on ambient air.

4.1 Criteria Pollutants

Table 3 lists the significant impact levels (SILs) used to determine whether or not the proposed project would have a significant impact on the air quality in the area. The proposed project has a significant impact on the ambient air quality if the resulting ambient concentrations exceed these levels due to an emissions increase.

Table 4 presents the NAAQS which are incorporated by reference (IBR) into Idaho Air Rules Section 107.03.b. Typically, there is about a year of lag time between when a new NAAQS is promulgated by EPA and the time when it is IBR into Idaho Air Rules. A NAAQS compliance demonstration involving modeling analyses for a specific standard is only required for permits issued after the date the standard is IBR into Idaho Air Rules. In cases where a NAAQS has been promulgated by EPA but not yet IBR to Idaho Air Rules, DEQ should be consulted for a determination on what specific analyses may be required for permit issuance.

Table 3. Significant Impact Levels (IDAPA 58.01.01.006)

Pollutant	Averaging Time	Significant Impact Levels ($\mu g/m^3$)[a]
CO	1-hour	2000
CO	8-hour	500
NO2	1-hour	4 ppb[b,c] (7.5 $\mu g/m^3$)[d]
NO2	Annual	1.0
SO2	1-hour	3 ppb[e] (7.9 $\mu g/m^3$)[d]
SO2	3-hour	25
SO2	24-hour	5
SO2	Annual	1.0
PM_{10}	24-hour	5.0
PM_{10}	Annual	1.0
$PM_{2.5}$	24-hour	1.2
$PM_{2.5}$	Annual	0.3[f]

a) Micrograms per cubic meter

b) ppb - parts per billion

c) Interim SIL (EPA 2010a)

d) µg/m3 value calculated for standard conditions

e) Interim SIL (EPA 2010b)

f) This value is the upper limit as listed in 40 CFR 51.165(b)(2). Without monitoring data supporting this value, DEQ will use the 0.2 $\mu g/m^3$ value recommended by EPA (EPA 2018)

Table 4. National Ambient Air Quality Standards

Pollutant	Averaging Time	Standard (µg/m^3)[a]
CO	1-hour	40,000[b]
CO	8-hour	10,000[b]
NO2	1-hour	100 ppb[c] (188 µg/m3)
NO2	Annual	100[d]
SO2	1-hour	75 ppb[e] (196 µg/m3)
SO2	3-hour	1,300[b]
SO2	24-hour	365[b]
SO2	Annual	80[c]
PM_{10}	24-hour	150[f]
PM_{10}	Annual	50[g]
$PM_{2.5}$	24-hour	35[h]
$PM_{2.5}$	Annual	12[i]
Pb	Quarterly	1.5[j]
Pb	3-month	0.15[k]

a) Micrograms per cubic meter.
b) Not to be exceeded more than once per year.
c) Three-year average of the 98th percentile of the annual distribution of 1-hour average daily maximum concentrations not to exceed standard.
d) Not to be exceeded in any calendar year.
e) Three-year average of the 99th percentile of the annual distribution of 1-hour average daily maximum concentrations not to exceed standard.
f) Never expected to be exceeded more than once in any calendar year.
g) Standard has been revoked.
h) Three-year average of the 98th percentile of the annual distribution of 24-hour average concentrations not to exceed standard,
i) Three-year average of the annual mean concentrations not to exceed standard.
j) Not to be exceeded in any quarter of any calendar year.
k) Not to be exceeded in any 3-month rolling average of any calendar year.

4.2 TAPs Increments

Applicable TAPs increments are listed in Idaho Air Rules Section 585 for non-carcinogens (AACs) and 586 for carcinogens (AACCs). The tables found in these sections of Idaho Air Rules list the ELs in pounds per hour (lb/hr) as well as the AACs for non-carcinogens and AACCs for carcinogens. Note that the concentrations for the non-carcinogens are in units of milligrams per cubic meter (mg/m3) and the concentrations for carcinogens are in units of micrograms per cubic meter (µg/m3).

4.3 Toxics

Idaho Air Rules Section 161 states, "Any contaminant which is by its nature toxic to human or animal life or vegetation shall not be emitted in such quantities or concentrations as to alone, or in combination with other contaminants, injure or unreasonably affect human or animal life or vegetation." DEQ may

require toxics analyses as a case-by-case basis in instances where DEQ suspects impacts of toxics may have an unacceptable impact.

5 Modeling Methodology

The required level of analysis will generally depend on the complexity of the proposed construction or modification, surrounding emissions sources and terrain features, current air quality levels, and classification (attainment vs non-attainment) in the impact area. Screening techniques may be adequate for simplistic or isolated sources. Screening techniques are not appropriate in complex situations such as a large number of buildings in the immediate area that create downwash for a point source or the presence of complex terrain within the modeling domain. More refined modeling will be necessary when screening modeling is inappropriate or cannot demonstrate compliance with applicable air quality impact limits.

5.1 Requirements for Permit Applications

As recommended by EPA (EPA 1990), dispersion modeling analysis generally involves two distinct phases. The first phase is the preliminary analysis, also known as the significant impact analysis; the second phase is the full impact analysis, also known as the cumulative NAAQS analysis. These analyses may be performed with either a simple "screening model" or with a more complex "refined model." A flowchart showing the general modeling methodology for permit modeling is presented in Figure 3.

5.1.1 Significant Impact Analysis

In the significant impact level (SIL) analysis, the highest estimated concentration in ambient air is compared to the SILs in Table 3. A five-year mean of the highest estimated concentration from each year can be used in the SIL analysis for pollutants with probabilistic standards. These pollutants include 24-hour PM2.5, annual PM2.5, 1-hour NO2, and 1-hour SO2. Only the changes in emissions associated with the proposed project are modeled in the significant impact analysis for new sources or modifications. Impacts from nearby and other background sources, including background concentrations, are not considered in the significant impact analysis. Section 6.3 provides guidance on sources and emissions to include in the significant impact analysis. No further analysis is generally required for the NAAQS or PSD increments if the estimated concentration is below applicable SILs. The source or modification is determined to have a significant impact on ambient air if the estimated impact exceeds the SILs. In this case, a cumulative NAAQS analysis will be necessary to demonstrate to the satisfaction of DEQ that the stationary source or modification would not cause or significantly contribute to a violation of any ambient air quality standard. Also, if DEQ has information that indicates existing facility emissions may not meet NAAQS, then DEQ may require the facility to demonstrate full NAAQS compliance at the time of the current permitting action or a later date.

The ambient concentration due to any proposed construction or modification cannot exceed the SILs listed in Table 3 for minor stationary sources in non-attainment areas (NAAs). Offsets are required even if the ambient impacts are below the SILs for major stationary sources or major modifications at major stationary sources in NAAs. The DEQ air modeling coordinator should be contacted for locations of NAAs in Idaho.

5.1.2 Cumulative NAAQS Analysis

In a cumulative NAAQS analysis, the scope of the analysis is expanded from the significant impact analysis to include impacts from all other sources at the facility and background concentrations. Assessing impacts from potential co-contributing sources may also be required in the cumulative NAAQS analyses. It is the applicant's responsibility to identify potential co- contributing sources. The factors to be reviewed include the type of source, distance between the facilities, location of potential impact, pollutants emitted, and emission rates of pollutants of interest. If impacts of neighboring sources, on receptors showing a significant impact from the sources subject to the permitting action, are not adequately accounted for by the background concentration used, then emissions from those sources must be modeled.

When conducting cumulative NAAQS modeling, the sources not explicitly included in the model (e.g., mobile sources; small, stationary sources; some fugitive sources; and large, distant sources) are accounted for by adding a background concentration representative of the air quality in the area. Background concentrations are based on ambient air monitoring data collected in the area or from similar areas determined to be reasonably representative. Section 6.10 provides a more detailed discussion of appropriate background concentrations. Background concentrations must account for all impacts not accounted for by sources specifically modeled. Current default background concentrations must be obtained from a DEQ air quality modeler.

Modeling assessments for major new source/modifications subject to the PSD program, and where project emissions cause an impact exceeding SILs, must include emissions from all point sources within the radius of significant impact and all sources outside the radius of significant impact that cause a significant impact within the radius of significant impact.

5.2 Additional Requirements for PSD Applications

Major facilities subject to PSD rules have many more responsibilities in the permitting process. DEQ engineers and analysts make the final determination of PSD applicability. If the proposed project is subject to PSD, the applicant should consult with DEQ during the early phases of the project development. If the proposed project is subject to PSD, the applicant should consult with DEQ during the early phases of the project development. This guideline only provides a brief summary of the PSD permitting program.

A PSD review is required if a proposed new facility is defined as a designated facility (Table 5) and emits or has projected actual emissions, after controls, of 100 tons per year (T/yr) or more of any regulated air pollutant. If the new facility is not one of the types listed in Table 5, then a PSD review is required if the facility emits or has projected actual emissions, after controls, of 250 T/yr or more of any regulated air pollutant. For PSD review, the potential to emit is defined as the maximum capacity of a stationary source to emit a pollutant under its physical and operational design (defined in Idaho Air Rules Section 006). A PSD review is also required if proposed emissions from a modification to an existing PSD major source are greater than the significant emissions rates listed in Table 6.

The location of the facility is important, as it determines the applicable increment of allowable air quality deterioration. Other factors, such as the topography and meteorology of the area and the proximity to a Class I area (specified areas of pristine air quality such as certain national parks, wilderness areas, etc.) or NAA, also determine the control requirements. The allowable increments, as of the publication of this document, for Class I, II, and III areas are listed in Table 7. Additional increment

limits can be promulgated by the EPA or DEQ, so it remains the applicant's responsibility to verify applicable PSD increment limits. The Class I areas in Idaho and surrounding states are shown in Appendix B. The remainder of the state is currently designated as Class II. There are no Class III areas in Idaho.

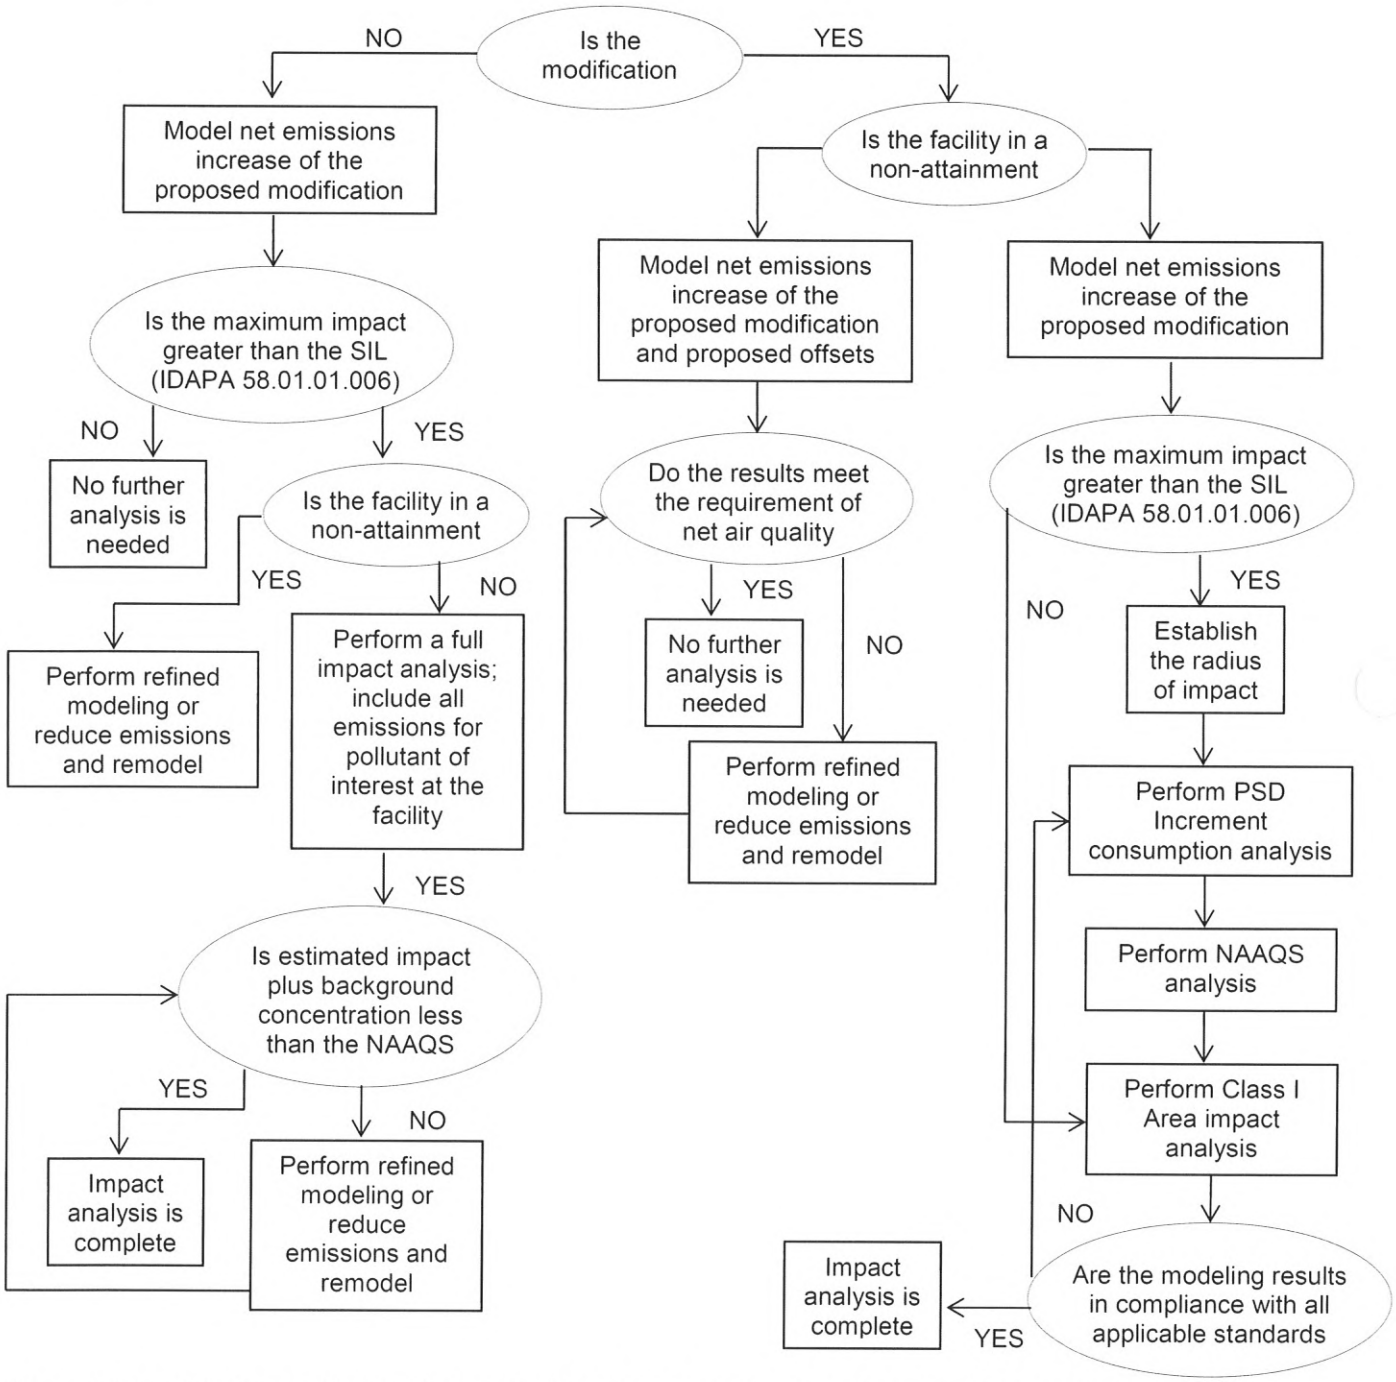

Figure 3. Flow Chart for Criteria Pollutant Ambient Impact Analysis for Permit to Construct Application

Pre-construction air quality is determined through ambient air monitoring. In some cases, there may already be enough data to establish the baseline. However, the applicant may be required to conduct up to one year of ambient monitoring at strategic locations if monitoring data are not available for the source area of the proposed construction site. Pre-construction monitoring will automatically be required if the model-predicted impact of the proposed source exceeds the levels in Table 8 and there are no current ambient air monitoring data available. DEQ may require pre-construction monitoring in other situations.

The following additional analyses are required in PSD applications:

- PSD increment consumption
- Class I area visibility and Air Quality Related Values (AQRVs) analysis
- Growth analysis
- Ambient air quality impact analysis (during construction)
- Soils and vegetation impacts
- Visibility impairment (in impact area, separate from the Class I area visibility analysis)

Refer to the *New Source Review Workshop Manual* (EPA 1990) for additional guidance.

Designated Facility Types as found in IDAPA.58.01.01.006:

1. Fossil fuel-fired, steam electric plants of more than 250 million British thermal units (Btu)per hour heat input
2. Coal cleaning plants (with thermal dryers)
3. Kraft pulp mills
4. Portland cement plants
5. Primary zinc smelters
6. Iron and steel mill plants
7. Primary aluminum ore reduction plants
8. Primary copper smelters
9. Municipal incinerators capable of charging more than 250 tons of refuse per day
10. Hydrofluoric acid plants
11. Sulfuric acid plants
12. Nitric acid plants
13. Petroleum refineries
14. Lime plants
15. Phosphate rock processing plants
16. Coke oven batteries
17. Sulfur recovery plants
18. Carbon black plants (furnace process)
19. Primary lead smelters
20. Fuel conversion plants
21. Sintering plants
22. Secondary metal production plants
23. Chemical process plants
24. Fossil fuel boilers (or combination thereof) totaling more than 250 million Btu/hour heat input
25. Petroleum storage and transfer units with a total storage capacity exceeding 300,000 barrels
26. Taconite ore processing plants
27. Glass fiber processing plants
28. Charcoal production plants

Table 5. Significant Emissions Rates (40 CFR 52.21 (b)(23); IDAPA 58.01.01.006)[a]

Pollutant	Emission Rate (T/yr)
CO	100
NOX	40
SO2	40
PM_{10}	15
$PM_{2.5}$	10 (40)[b]
Particulate matter	25
Ozone (VOC)	40 (of VOCs)
Pb	0.6
Asbestos	0.007
Beryllium	0.0004
Mercury	0.1
Vinyl chloride	1
Fluorides	3
Sulfuric Acid Mist	7
Hydrogen Sulfide (H_2S)	10
Total Reduced Sulfur (including H_2S)	10
Radionuclides from facilities regulated under40 CFR Par 61, Subpart H	0.1 mrem/yr
Reduced sulfur compounds (Including H_2S)	10
Any other pollutant regulated under the Clean Air Act including radionuclides	Any emission rate
Each regulated pollutant (from a major facility or major modification)	Emission rate that causes air quality impact of 1 µg/m3 or greater (24-hour basis) in any Class I area located within 10

a) A PSD review is required if the operation is modified and actual emissions of a pollutant will be greater than shown above

b) SO_2, NOx, and VOCs as precursors

Table 6. Prevention of Significant Deterioration Increment Limits

Pollutant	Averaging Period	Class I (µg/m^3)	Class II(µg/m^3)	Class III (µg/m^3)
NO_2	Annual[c]	2.5	25	50
SO_2	Annual[b]	2	20	40
SO_2	24-hour[c]	5	91	182
SO_2	3-hour[c]	25	512	700
PM_{10}	Annual[b]	4	17	34
PM_{10}	24-hour[c]	8	30	60
$PM_{2.5}$	Annual[b]	1	4	8
$PM_{2.5}$	24-hour[c]	2	9	18

a) The Class I, II, and III areas are defined and shown in Appendix A.

b) Never to be exceeded.
c) Not to be exceeded more than once a year.

Table 7. Modeled Impacts Above which Preconstruction Monitoring cannot be Exempted for PSD-Applicable Projects

Pollutant	Ambient Concentration ($\mu g/m^3$)	Averaging Period
CO	575	8-hour
NO2	14	Annual
SO2	13	24-hour
PM10	10	24-hour
PM2.5	4	24-hour
Ozone	100 T/yr increase of VOCs	N/A
Pb	0.1	Quarterly
Mercury	0.25	24-hour
Beryllium	0.0001	24-hour
Fluorides	0.25	24-hour
Vinyl chloride	15	24-hour
Hydrogen sulfide	0.2	1-hour

5.3 Facility Emission Cap (FEC) Permit Modeling

Contact DEQ for guidance on modeling requirements for FEC permits. In general, the modeling submitted must support all possible future emissions rates sources, and facility configuration.

6 Performing a Modeling Analysis

An application will be considered incomplete if it lacks sufficient information and/or a valid modeling analysis, supported by adequate documentation and justification of methods and data. Appendix C includes a copy of the DEQ modeling checklist, which is designed to help the applicant prepare the information necessary for a complete modeling package.

The procedures in this document, as well as the EPA documents *Guideline on Air Quality Models* (EPA 2005), *New Source Review Workshop Manual* (EPA 1990), and other more issue- specific guidance should typically be followed when conducting the modeling analysis. These documents provide guidance on appropriate model applications. DEQ will work with the applicant to determine acceptable impact assessment procedures where EPA or state policies are not clear cut or involve case-by-case review.

6.1 Modeling Protocol

Applicants are highly advised to contact the DEQ stationary source air quality modeling supervisor at (208) 373-0502 and submit a modeling protocol, as suggested in the modeling checklist (Appendix C), to ensure appropriate models, meteorological data, background concentrations, and procedures are applied. Use of a modeling protocol is a key component of DEQ's permit streamlining program, which

focuses on establishing mutually agreed upon methods and data prior to permit application submittal. This approach substantially reduces DEQ review time and the potential for the application to be determined incomplete or the permit denied because of problems with the modeling analyses.

The content of the modeling protocol is dependent on the type of permit application. A modeling protocol for a new, major source or a major modification at a major facility will be more detailed than one for a new, minor source or a minor modification. A modeling protocol checklist is presented in Appendix D. A description of the general methodology, as well as justification for assumptions and data used, should be included in the modeling protocol.

A modeling protocol, in written form and agreed upon by DEQ, provides the applicant the assurance that their approach and methodology as described will be accepted. However, the approval of a modeling protocol is not meant to imply approval of a completed modeling analysis. The facility should submit as much detailed information as possible in the modeling protocol to increase the likelihood of having the modeling analysis approved. The applicant should prepare the application with the understanding that DEQ will require a higher degree of documentation/justification of data and methods in cases where modeled concentrations are very near regulatory thresholds/standards.

A modeling protocol may be submitted in hard-copy format or may be emailed to the DEQ stationary source modeling coordinator. DEQ will typically provide comments on or approval of the protocol within two weeks from the date the protocol was received.

The following are key issues that should be addressed in the protocol:

- Ambient air boundary. It is the applicant's responsibility to accurately evaluate the ambient air boundary and identify any unique situations affecting the ambient air boundary that may exist at the facility. Such unique situations may include rivers bisecting the facility, easements or public roadways bisecting the facility, railways, lease agreements, and operating a business where the general public is allowed on site. See Section 6.5.
- Justification/documentation of stack parameters. The protocol should thoroughly describe how emissions release parameters (flow rates and stack temperatures) were measured or estimated, if such data are available at that time. A simple indication that parameters were checked will not be accepted as documentation and justification. Calculations of initial dispersion coefficients for volume sources should be provided such that DEQ reviewers can easily and quickly verify the values. See Section 6.4.2.
- Design concentrations. The protocol should clearly state what modeled concentrations will be used to evaluate compliance. For example, the maximum of 6th highest modeled concentrations at each receptor is typically used as the PM10 24-hour design value when modeling a five-year data set. See Section 6.11.1.
- Meteorological data. If meteorological data are not provided by DEQ, the applicant should thoroughly justify selection of the data, demonstrating how the data used are representative for the application site. The protocol should also describe the quality of the data, clearly demonstrating the data are adequate for use in an air impact analysis. See Section 6.8.
- Receptor grid. The receptor grid spacing proposed for the analyses should be thoroughly described. See Section 6.6.
- Background concentrations. Within the protocol, the applicant may either propose appropriate background concentrations or request that DEQ provide reasonably conservative background concentrations. See Section 6.10.
- Unique circumstances or scenarios used in the analyses. Any atypical conditions associated with the site or the project that could affect the results of the air impact analyses, or DEQ's approval

of the project, should be described in the protocol. Protocol approval only assures acceptability that those conditions or issues accurately described in the protocol are acceptable.

6.2 Choosing the Appropriate Models

Air quality models approved by the EPA for regulatory use are required (Idaho Air Rules Section 202.02 and 402.03). The DEQ modeling coordinator should be consulted to discuss or verify the model most appropriate for the release being simulated. Factors to consider when determining the appropriate model include, but are not limited to, type of release (e.g., elevated point or area), downwash, location of ambient air, meteorological conditions (e.g., stagnation), and availability of meteorological data. All modeling must use the current versions of models recommended in the EPA's *Guideline on Air Quality Models* (EPA 2005). Many of these models can be found on the EPA's Support Center for Regulatory Air Models (SCRAM) website (http://www.epa.gov/ttn/scram). Modeling performed with older versions may be rejected. Any modification or alteration of a guideline model must be approved by DEQ and, in most instances, the EPA. Approval of the use of other models is completely at the discretion of DEQ. When alternative models are used, DEQ may require the submittal of additional data (e.g., sensitivity analysis) for verification. The use of proprietary models (those models that are not available free of charge to the public) is generally not allowed for the demonstration of compliance with NAAQS, PSD increment, or TAPs increments. Proprietary graphical user interfaces (GUIs) that use unaltered publicly available regulatory models are not considered proprietary models. Results generated by such GUIs will be accepted provided input and output files are submitted and such files can be readily used as input for the publicly available model without the proprietary GUI.

6.2.1 Readily Available Models

The following is a summary of the most commonly used air quality models:

AERMOD – AERMIC (American Meteorological Society/Environmental Protection Agency Regulatory Model Improvement Committee) was formed to introduce state-of-the-art modeling concepts into EPA's air quality models. AERMIC's focus is on a new platform for regulatory steady-state plume modeling. This platform includes: 1) air turbulence structure, scaling, and concepts; 2) treatment of both surface and elevated sources; and 3) simple and complex terrain. The modeling system has three components: AERMOD - the air dispersion model; AERMET - the meteorological data preprocessor; and AERMAP - the terrain data preprocessor. AERMOD is the replacement model for ISCST3.

AERSCREEN – AERSCREEN is the screening-level model for applications where AERMOD would be appropriate.

SCREEN3 – SCREEN3 is a screening version of the ISCST3 model.

SCREEN3 is not considered an acceptable screening model for AERMOD, which is the model replacing ISCST3. *Analyses performed with SCREEN3 will no longer be accepted by DEQ for permitting purposes in most instances.*

CTSCREEN – (Complex Terrain Screening model) –A screening technique when complex terrain is important. CTSCREEN is a screening version of the CTDMPLUS model. CTSCREEN and CTDMPLUS are the same basic model. The primary difference is that CTSCREEN uses

an extensive array of predetermined meteorological conditions where site-specific meteorological data are not available.

AERMOD is considered a more refined model for complex terrain. AERSCREEN incorporates the same terrain algorithms as AERMOD, and may yield more favorable results than CTSCREEN.

ISCST3 – (Industrial Source Complex Model) – Historically, the most commonly used refined Gaussian plume model.

ISCST3 has been replaced as an EPA guideline model by AERMOD. *DEQ will generally no longer accept air quality analyses conducted with ISCST3 for permitting purposes.*

CTDMPLUS – (Complex Terrain Dispersion Model Plus Algorithms for Unstable Situations) – A refined air quality model for use in all atmospheric stabilities with sources located in or near complex topography. Since the model accounts for the three-dimensional nature of plume and terrain interaction, it requires detailed terrain and meteorological data that are representative of the modeling domain.

CALPUFF – A multi-layer, multi-species, non-steady-state, puff dispersion model that simulates the effects of time- and space-varying meteorological conditions on pollutant transport, transformation, and removal. CALPUFF is most commonly used to assess impacts on Class I areas and is applied at distances over 50 kilometers. It includes algorithms for subgrid scale effects (such as terrain impingement), as well as longer range effects (such as pollutant removal due to wet scavenging and dry deposition, chemical transformation, and visibility effects of particulate matter concentrations).

CALPUFF is not an EPA-approved model for near-field impact assessment (within 50 kilometers of a source). Any use of CALPUFF in the near-field must be thoroughly justified and approved specifically by DEQ and often by EPA.

VISCREEN – A screening model to assess visibility impacts on Class I areas. Calculates the potential impact of a plume of specified emissions for specific transport and dispersion conditions.

Screening models, such as SCREEN3 and AERSCREEN, are used to simulate the probable worst-case condition under normal, maximum operating conditions. They are generally simplistic representations, typically taking less computer time and yielding conservative impact predictions. A screening analysis must follow EPA guidance in *Screening Procedures for Estimating the Air Quality Impact of Stationary Sources, Revised* (EPA 1992) or any current EPA guidance for AERSCREEN. If a properly conducted screening analysis does not indicate an exceedance of the ambient standards from a proposed construction or modification, then a more refined analysis is not necessary to adequately demonstrate compliance.

6.2.2 Replacement of ISC by AERMOD

AERMOD was promulgated as the replacement model for ISC. During the one-year transitional period, between November 2005 and November 2006, applicants could use either ISCST3 or AERMOD to demonstrate compliance. After that, ISCST3 was no longer a guideline model and analyses conducted with ISCST3 were not typically accepted by DEQ.

There are several modeling scenarios that are problematic when using AERMOD:

1. Hot, buoyant plumes released horizontally or with a rain cap. With ISCST3 the typical approach is to set the exit velocity to 0.01 or 0.001 meters per second (m/sec) to effectively eliminate the plume vertical momentum flux, then increase the exit diameter to a point where the modeled volumetric flow is equal to that of the source. This approach cannot be used for AERMOD if plume downwash is considered because downwash behavior is a function of stack diameter in the PRIME downwash algorithm within AERMOD.

   Modeling with the actual stack diameter and a 0.001 m/sec exit velocity is recommended as a conservative measure. This method effectively eliminates vertical momentum of the plume; however, it also eliminates thermal buoyancy effects. In some instances, hand calculations of plume rise, using those equations in the AERMOD algorithms, may show that thermal buoyancy is overwhelmingly the dominant plume rise mechanism. In such cases, the source may be modeled as an uninterrupted vertical release. Use of this method or other methods should be discussed with DEQ prior to use.

   Methods to accurately model hot horizontal releases and capped vertical releases within AERMOD have been developed for Beta versions of AERMOD. Applicants should contact DEQ as to the availability of AERMOD versions to handle hot horizontal and capped releases.

2. Representative meteorological data are rather limited for many areas within Idaho. More site-specific meteorological and land surface characteristics are needed to run AERMOD than what is used for ISC. Therefore, using meteorological data from a distant station is more of a concern when using AERMOD.

   It is the applicant's responsibility to demonstrate the meteorological data used are representative of meteorological conditions at the application site. Applicants may be required to use specialized methods to demonstrate compliance in cases where available meteorological data are of questionable representativeness. Such methods could involve running additional modeling analyses using multiple meteorological data sets or otherwise providing a demonstration that use of on-site data could not reasonably be expected to give results that exceed applicable regulatory thresholds or standards.

6.3 Pollutants and Sources to be Included in the Impact Analyses

This section discusses what pollutants and sources should be included in modeling analyses submitted in support of applications for permits to construct (PTCs), Tier II operating permits, and FEC permits. Specific emissions sources that are exempt from permitting requirements are not necessarily exempt from a modeling analysis when a PTC or Tier II Operating Permit is required for other sources/reasons. DEQ modeling staff should be consulted before any emissions sources eliminated from the modeling analyses.

DEQ does have a list of activities that may be treated as "trivial" and are not required to be addressed in the permit application. In addition to the trivial activities listed below, Idaho Air Rules Section 317 list activities that are "presumptively insignificant emission units." DEQ has determined that these activities must generally be included in Tier II and PTC applications when facility-wide modeling is required. The list below was generated from an EPA white paper entitled Streamlined Development of Part 70 Permit Applications (EPA 1995).

Activities That May be Treated as "Trivial" (EPA 1995):

1. Combustion emissions from propulsion of mobile sources, except for vessel emissions from outer continental shelf sources.
2. Air-conditioning units used for human comfort that do not have applicable requirements under Title VI of the Clean Air Act.
3. Ventilating units used for human comfort that do not exhaust air pollutants into the ambient air from any manufacturing/industrial or commercial process.
4. Noncommercial food preparation.
5. Consumer use of office equipment and products, not including printers or businesses primarily involved in photographic reproduction.
6. Janitorial services and consumer use of janitorial products.
7. Internal combustion engines used for landscaping purposes.
8. Laundry activities, except for dry cleaning and steam boilers.
9. Bathroom/toilet vent emissions.
10. Emergency (backup) electrical generators at residential locations.
11. Tobacco smoking rooms and areas.
12. Blacksmith forges.
13. Plant maintenance and upkeep activities (e.g., grounds keeping, general repairs, cleaning, painting, welding, plumbing, re-tarring roofs, installing insulation, and paving parking lots) provided these activities are not conducted as part of a manufacturing process, are not related to the source's primary business activity, and do not otherwise trigger a permit modification.[(a)]
14. Repair or maintenance shop activities not related to the source's primary business activity, not including emissions from surface-coating or degreasing (solvent metal cleaning) activities, and not otherwise triggering a permit modification.
15. Portable electrical generators that can be moved by hand from one location to another.[(b)]
16. Hand-held equipment for buffing, polishing, cutting, drilling, sawing, grinding, turning or machining wood, metal or plastic.
17. Brazing, soldering and welding equipment, and cutting torches related to manufacturing and construction activities that do not result in emission of hazardous air pollutant metals.[(c)]
18. Air compressors and pneumatically operated equipment, including hand tools.
19. Batteries and battery charging stations, except at battery manufacturing plants.
20. Storage tanks, vessels, and containers holding or storing liquid substances that will not emit any volatile organic compound or hazardous air pollutant.[(d)]
21. Storage tanks, reservoirs, and pumping and handling equipment of any size containing soaps, vegetable oil, grease, animal fat, and nonvolatile aqueous salt solutions, provided appropriate lids and covers are utilized.
22. Equipment used to mix package soaps, vegetable oil, grease, animal fat, and nonvolatile aqueous salt solutions, provided appropriate lids and covers are utilized.
23. Drop hammers or hydraulic presses for forging or metalworking.
24. Equipment used exclusively to slaughter animals, but not including other equipment at slaughterhouses, such as rendering cookers, boilers, heating plants, incinerators, and electrical power generating equipment.
25. Vents from continuous emissions monitors and other analyzers.
26. Natural gas pressure-regulator vents, excluding venting at oil and gas production facilities.
27. Hand-held applicator equipment for hot-melt adhesives with no volatile organic compounds in the adhesive formulation.

28. Equipment used for surface coating, painting, dipping, or spraying operations, except those that will emit any volatile organic compound or hazardous air pollutant.
29. Carbon dioxide lasers, used only on metals and other materials that do not emit hazardous air pollutants in the process.
30. Consumer use of paper trimmers/binders.
31. Electric- or steam-heated drying ovens and autoclaves, but not the emissions from the articles or substances being processed in the ovens or autoclaves, or the boilers delivering the steam.
32. Salt baths using nonvolatile salts that do not result in emissions of any regulated air pollutant.
33. Laser trimmers using dust collection to prevent fugitive emissions.
34. Bench-scale, laboratory equipment used for physical or chemical analysis, but not for lab fume hoods or vents.[e]
35. Routine calibration and maintenance of laboratory equipment or other analytical instruments.
36. Equipment used for quality control/assurance or inspection purposes, including sampling equipment used to withdraw materials for analysis.
37. Hydraulic and hydrostatic testing equipment.
38. Environmental chambers not using hazardous air pollutant gasses.
39. Shock chambers.
40. Humidity chambers.
41. Solar simulators.
42. Fugitive emissions related to movement of passenger vehicles, provided the emissions are not counted for applicability purposes and any required fugitive-dust-control plan or its equivalent is submitted.
43. Process-water filtration systems and demineralizers.
44. Demineralized-water tanks and demineralizer vents.
45. Boiler-water treatment operations, not including cooling towers.
46. Oxygen scavenging (de-aeration) of water.
47. Ozone generators.
48. Fire suppression systems.
49. Emergency road flares.
50. Steam vents and safety relief valves.
51. Steam leaks.
52. Steam cleaning operations.
53. Steam sterilizers.

a) Cleaning and painting activities qualify as trivial they are not subject to volatile organic compound or hazardous air pollutant control requirements. Asphalt batch plant owners/operators must still get a permit if otherwise required.

b) "Moved by hand" means the generator can be moved without the assistance of any motorized or non-motorized vehicle, conveyance, or device.

c) Brazing, soldering and welding equipment, and cutting torches that emit hazardous air pollutant metals and are related to manufacturing and construction activities are more appropriate for treatment as insignificant activities instead of trivial activities based on size or production-level thresholds. Brazing, soldering, welding, and cutting torches that emit hazardous air pollutant metals and are directly related to plant maintenance, upkeep, and repair, or maintenance shop activities, are appropriately treated as trivial.

d) Consideration of storage tanks containing petroleum liquids or other volatile organic liquids as a trivial source should be based on size limits such as storage tank capacity and vapor pressure of liquids stored are not appropriate for this list.

e) Many lab fume hoods or vents might qualify for treatment as insignificant (depending on the applicable State Implementation Plan) or can be grouped together for purposes of description.

6.3.1 Permits to Construct

Criteria Pollutants

All increases in emissions of criteria pollutants are generally required to be accounted for in the significant impact analyses for PTC applications. However, the emissions sources and inventory used to evaluate the need for modeling, described in Section 3 of this guideline, may differ from the sources and inventory used for the significant impact analyses. All emissions changes associated with a proposed project are generally used in the significant impact analyses, including emissions reductions associated with sources removed from operation. Also, sources included in the significant impact analyses for minor source permitting may differ from sources included for PSD permitting. For minor source permitting, the significant impact analyses for criteria pollutants generally includes: all emissions increases and decreases associated with the proposed project. For PSD permitting, the net emissions increase, as defined in Idaho Air Rules Section 007, is modeled. The net emissions increase includes all increases and decreases that occurred within the previous five years or since the issuance of any PSD permit to the facility, whichever is a shorter period.

Cumulative impact analyses are required if impacts associated with the significant impact analyses exceed SILs, as described in Sections 5.1.1 and 5.1.2. A cumulative impact analysis involves modeling facility-wide emissions, modeling any co-contributing sources, and adding an appropriate background value to results.

DEQ highly suggests that applicants specify in a modeling protocol those sources to be included and/or excluded in the significant impact analyses with thorough justification and documentation. The following provides general guidance for the significant impact analyses performed for specific minor source scenarios:

- Modification to an existing emissions unit where the release parameters (flow rate, stack gas temperature, etc.) do not change. The emissions increase associated with the modification is modeled. If the existing source is currently permitted, the emissions increase will be calculated as the differences between the current permit limit (or whatever emissions rate was used in previous modeling analyses) and the future proposed limit. If the source is not currently regulated by a permit emissions limit, then current emissions should be based on actual emissions as defined by Idaho Air Rules.
- Modification to an existing emissions unit where the release parameters change as a result of the modification. Existing emissions for permitted and non-permitted sources should be calculated as described for scenario "a;" however, current emissions should be modeled as negative emissions (using the existing release parameters) and future allowable emissions modeled as positive emissions (using the new release parameters).
- Removal of, or emissions reductions from, an existing emissions unit. Emissions reductions from such units should be modeled as negative emissions to account for the net project impacts. Existing permit-allowable emissions rates may be used, or actual emissions (based on two years of operations within the previous ten years) for units not regulated by an existing emissions limit.

- Replacement or relocation of an existing emissions unit. Replaced units should be treated in the same manner as removed units, described in scenario "c."
- Addition or removal of units exempt from permitting. Units that are exempt from permitting should be included in the significant impact analyses in most instances, unless such units are considered as trivial per Table 9 in Section 6.3 of this guideline. Existing and future emissions should be based on maximum potential emissions unless otherwise directed or approved by DEQ.

TAPs

All TAPs, except those exempted under Idaho Air Rules Section 210.20, with project-total emissions increases above the DEQ TAP ELs (discussed in Section 4.0) must be included in the modeling analysis. The DEQ TAPs checklist, available on the DEQ website, should be used to demonstrate compliance with TAPs.

Fugitive Sources

Fugitive emissions are defined in Idaho Air Rules Section 006 as, "those emissions which could not reasonably pass through a stack, chimney, vent, or other functionally equivalent opening." This definition includes windblown dust from a stockpile. Generally, modeling is required for all fugitive emissions sources determined not to be unquantifiable. Fugitive emissions from vehicle traffic on roads and wind erosion from material storage piles are normally not included in the modeling analyses for minor source applications. However, DEQ may require modeling of these sources in instances where these emissions could substantially contribute to ambient concentrations and a potential exceedance of air quality standards. Process fugitive emissions such as those from material handling operations and equipment leaks should be included in the modeling analyses.

Intermittent Sources

Emissions sources that operate intermittently may be excluded from the SIL analysis and/or cumulative NAAQS analysis, approved by DEQ on a case-by-case basis, to the extent that it can be reasonably concluded that such sources could not measurably affect the compliance determination. If the intermittent sources are engines powering emergency generators or fire suppression water pumps, and operations are less than 100 hours/year for operational testing and maintenance, the sources can be excluded from compliance demonstrations for the 1-hour NO2 NAAQS, unless specifically required at the discretion of the DEQ Director. This guidance is explained in more detail in Appendix A.

Inconsequential Sources

The applicant may determine that some sources are "inconsequential" when estimating the design concentration (i.e., only contribute to a small percentage of the total, maximum, ambient impact for that project) and exclude them from the modeling analysis. If this is the case, the applicant must justify the exclusion of these sources. This justification, which is pollutant and averaging-period specific, must be based on emissions rates and a qualitative discussion of impacts. For example, if an emissions unit operates 24 hours per day but only 500 hours per year, the source may be "inconsequential" for the annual emissions, but not for the 24-hour emissions. The justification should include the following two phases:

1. Compare the emissions and operating conditions of each emissions source to the total emissions that would be modeled. If the uncontrolled emissions are "negligible" compared to the total emissions and are not expected to impact the maximum ambient concentration, the individual

emissions source may be deemed as "inconsequential" and may be excluded from the modeling analysis.

Unless there are a large number of negligible sources that will substantially slow the model run time, it may be easier to include such sources in the analyses rather than provide justification for their exclusion.

2. If more than one emissions source is excluded from the modeling analysis, the total emissions of those sources excluded and the total estimated ambient concentration must be compared to the total modeled emissions and qualitatively evaluated for impacts. This will ensure that all of the excluded sources are still "inconsequential" as a whole.

Non-Attainment Areas

Facilities located in an a non-attainment area for a specified pollutant may be required to model all the emissions for that specified pollutant, even those emissions that are deemed to be inconsequential. This process will be treated on a case-by-case basis. It is recommended that the applicant meet with DEQ staff prior to beginning the modeling analysis to discuss what sources will be included.

6.3.2 Facility-Wide Tier II Operating Permits

All emissions for the entire facility, excluding those listed in Table 9, are required to be included in a facility-wide Tier II application. All criteria pollutant emissions are generally required to be included in the modeling analysis submitted with the Tier II operating permit application. Facility-wide TAPs emissions are not typically required to be included in the modeling analysis for the Tier II application. DEQ reserves the right to request additional information or analysis, including the modeling of other pollutants, under Idaho Air Rules Section 402.04, if there is a concern relative to compliance with Idaho Air Rules Section 161. Modeling of all fugitive emissions may be required if DEQ determines it necessary to protect ambient air quality standards.

As with the PTC application, the applicant may determine that some criteria pollutant sources are "inconsequential" when estimating the design concentration (i.e., only contribute to a small percentage of the total, maximum, ambient impact for that project) and exclude them from the modeling analysis. The applicant should use the process presented above in Section 6.3.1. Facilities located in non-attainment areas for a specified pollutant must contact the DEQ modeling coordinator at (208) 373-0112 prior to submitting the Tier II application. DEQ modeling staff will review the current SIP for the area to determine the appropriate level of analysis. This process will be treated on a case-by-case basis. It is recommended that the applicant meet with DEQ staff prior to beginning the modeling analysis to discuss what sources will be included.

6.3.3 FEC Permits

Permit applications utilizing a facility emissions cap (FEC) must provide sufficient modeling scenarios to reasonably assess maximum impacts of potential source configurations. The modeling requirements for these permits are facility-specific and will vary greatly depending on the operational flexibility desired by the permit applicant.

6.4 Source Information Required

This section discusses the source information that is required for a modeling analysis.

6.4.1 Emission Rates

Tables 8.1 and 8.2 in the *Guideline on Air Quality Models* (EPA 2005) present the emissions information required for air dispersion modeling. The emissions rate used in the modeling analysis must be that associated with maximum design capacity or a federally enforceable permit condition (40 CFR 51, Appendix W, Table 9-2). For a major modification, the emissions rate to be modeled in the significant impact analysis for criteria pollutants is the net emission rate increase, as defined in Idaho Air Rules Section 007. To demonstrate compliance with applicable standards, potential emissions must be used in the modeling analyses rather than future projected actual emissions. For minor modifications, the emissions modeled are the emissions changes associated with the proposed project, as described in Section 6.3.1 of this guideline. Emissions decreases are modeled as negative values in the significant impact analyses. However, in instances where NAAQS compliance may be questionable, DEQ may require facility-wide modeling even though results of the significant impact analysis indicate impacts are below SILs. When a cumulative NAAQS analysis is required, the potential emissions for all sources and, if requested, any co-contributing sources are used in the modeling analyses.

For PTCs, the project-wide emissions rate increase of TAPs is compared to the EL in Idaho Air Rules Section 585 and 586. Any TAP that has a total project emissions increase that exceeds the EL must be modeled.

The maximum emissions rate for each averaging period must be identified. For example, PM2.5 has both a 24-hour and an annual standard. If a source will only operate 7,000 hours per year but can operate for 24 hours in a single 24-hour period, then different emissions rates would be modeled for the 24-hour standard and annual standard.

If any pounds per hour emissions rate used in a modeling analysis differs from that used in the emissions inventory, the application should clearly show how the modeled rate was calculated. For example, a source has a maximum hourly emissions rate of 2.0 pounds per hour and a maximum daily operations rate of 12 hours per day (not restricted to any specific daily schedule). The modeled emissions rate for demonstrating compliance with a 24-hour standard would be 1.0 pounds per hour ((2.0 lb/hr x 12 hr/day) / 24 hr = 1.0 lb/hr).

Modeling intermittent sources in a representative and worst-case manner can present a challenge to the modeler. These sources can be modeled in two ways:

1. The allowable emissions can be modeled for a time period equal to that of the actual source. The emissions event is then selected to reasonably represent worst-case impacts or a series of potential operational scenarios are modeled.
2. The allowable emissions for the event are evenly divided over the pollutant averaging period of interest.

As an example, a mill may have fugitive PM2.5 emissions from periodic loadout of a waste bin. The emissions may occur for one hour, three times per week. Modeling must demonstrate compliance with both the 24-hour and annual standards. It is determined that only one loadout can occur during any 24-hour period. Since there is no specific time when the loadout is likely to occur, 24-hour modeling was conducted by evenly dividing the emissions from one loadout throughout the entire 24-hour period. Annual impacts were modeled by calculating annual allowable emissions, and evenly dividing those emissions among each hour of the year.

If it is known that emissions are most likely to occur during a certain time of the day, it may be appropriate to distribute emissions only over those hours of the day. The applicant should consult with DEQ modeling staff to obtain approval of such methods prior to modeling intermittent sources.

DEQ may allow exclusion of some very infrequent periodic emissions from the modeling analyses. Monthly testing of an emergency generator for 35 minutes could be an example of an infrequent periodic emissions source. Approval of excluding such sources from the modeling analyses will be made by DEQ on a case-by-case basis considering:

- The pollutant of interest and the averaging period of the standard
- Quantity of emissions from the source
- Frequency of the emissions
- Averaging period of standards associated with pollutants emitted
- Number of sources to be excluded
- Distance from source to ambient air receptors
- Nearby sensitive receptors (hospitals, schools, residences)
- Modeled impact of other sources in relation to applicable standards

As indicated in Section 6.3.1. Intermittent Sources, DEQ allows the exclusion of NOx emissions from intermittent testing and maintenance of engines powering emergency generators and fire suppression water pumps for demonstrating compliance with the 1-hour NO2 NAAQS.

6.4.2 Source Parameters

Stack parameters for each point source that are required to be modeled are as follows:

- Stack base elevation (feet or meters)
- Stack height (feet or meters)
- Stack inside diameter (feet or meters) (If the stack is not circular, use equivalent dimensions determined by Area = d2/4, where d is the stack's inner diameter)
- Stack exit velocity (meters/second) or exit flow rate (actual cubic feet per minute (acfm))
- Stack exit temperature (F or K)

Source parameters for area sources include the following:

- Source height (meters)
- Easterly dimension (meters)
- Northerly dimension (meters)
- Initial vertical dimension (meters)
- Angle from North (degrees)

Source parameters for volume sources include the following:

- Source height (meters)
- Initial horizontal dimension (meters)
- Initial vertical dimension (meters)

The application must provide detailed documentation and justification of all source parameters used in the analyses, including calculations where appropriate. Applications not providing sufficient documentation/justification of source parameters will be declared incomplete or denied. Stating that parameters were provided by the manufacturer or design engineer is not considered as adequate documentation/justification.

Flow Rates and Stack Gas Temperatures

Maximum flow rates and maximum stack gas temperatures should not typically be used in the modeling analyses unless the source predominantly operates at such a rate. Although maximum emissions are typically associated with maximum flow rates and stack gas temperatures, maximum impacts are often associated with lower emissions rates and lower stack gas flow rates and temperatures. Applicants should either use multiple scenarios of emissions, flow rates, and temperatures, or conservatively use maximum emissions with more typical stack gas flow rates and temperatures.

Submitted modeling analyses should provide detailed documentation and justification of all release parameters used in the analyses. Stack gas temperatures and flow rates substantially affect dispersion, and the application should clearly show how these parameters were calculated or measured. If gas temperatures are based on measurements made at locations other than near the stack exit, the temperature used in the model should be adjusted to derive a temperature appropriate for the stack exit. Stack gas exit velocities exceeding 50 m/sec will generally be viewed as suspect by DEQ reviewers, and greater documentation of values used will be required.

Unrealistic stack parameters submitted in applications are most commonly associated with internal combustion engines, and typically involve overly high exit velocities and stack temperatures. Applicants often use temperature and flow data obtained for the exhaust manifold rather than for the point of release to the atmosphere. Actual flows and temperatures at the release point will be substantially lower after heat loss through the walls of an exhaust pipe and through an exhaust muffler.

Stack Orientation

DEQ also requires the following be included in the application and modeling analysis:

- Orientation of the stack (horizontal or vertical)
- Indication of the presence or absence of a rain cap or other obstruction in the released flow from a stack

Stack orientation information is important because it affects the dispersion characteristics of the pollutants. If either a horizontal stack or rain cap (or other obstruction) is present, it must be accounted for in the modeling analysis, since upward plume momentum is zero because of either the obstruction or the orientation of the stack.

The method recommended by DEQ for modeling horizontal or rain-capped sources, when using the model AERMOD where downwash is not considered, is based on a procedure recommended by EPA (July 9, 1993, memorandum from Joseph A. Tikvart, Source Receptor Analysis Branch, to Ken Eng, Chief, Air Compliance Branch, Region II). The method involves setting the stack velocity to 0.001 meters per second to effectively turn off momentum plume rise. The memo also recommends turning stack tip downwash off for horizontal releases.

The recommended method for modeling point sources of non-buoyant emissions with horizontal release or vertical release with the presence of a rain cap is as follows:

1. Define the emissions source as a point source, entering in the model the actual height of release, stack gas temperature, and the Universal Transverse Mercator (UTM) coordinates.
2. Plumes from horizontal emissions releases or vertical stacks with rain caps experience no momentum induced plume rise. Set the stack gas exit velocity to 0.001 meters per second to effectively prevent the model from accounting for momentum plume rise.

3. Stack tip downwash is not appropriate for horizontally released emissions. If the emissions vent in the horizontal direction, the stack diameter can be set to 0.001 meters to prevent stack tip downwash effects. This step should not be used for sources that vent vertically with a rain cap over the stack, since the rain cap will not prevent stack tip downwash effects. The actual inside stack diameter should be used for rain-capped stacks.
4. Run the model as otherwise required.

By setting the flow velocity and/or stack diameter to 0.001, plume rise from hot, buoyant plumes is inappropriately eliminated. Since the PRIME downwash algorithm within AERMOD is affected by stack diameter, it is not acceptable to artificially increase the diameter by a substantial degree to generate a more accurate mass of hot stack gas emitted.

Non-regulatory versions of AERMOD allow the modeler to identify sources as a horizontal release or rain-capped source, and the model will consider the thermal buoyancy flux in the plume rise calculation while not considering a vertical momentum flux. To use the non- regulatory version, the actual temperature, stack diameter, and flow rate are entered into the model, then the source is identified in the AERMOD input file as a capped or horizontal release. DEQ must approve the use of any non-regulatory options in AERMOD.

Alternate methods may be approved by DEQ on a case-by-case basis if there are unique circumstances. In such cases, DEQ strongly advises that the permit applicant or consultant contact DEQ prior to modeling to discuss the issue, prepare a modeling protocol, and obtain prior approval from DEQ to use the proposed method.

Initial Plume Dimensions for Volume Sources

Initial horizontal plume dimensions for volume sources should be calculated as follows:

- Single volume source:
  $\sigma y0$ = side length of source divided by 4.3
- Line source represented as a series of volume sources (separated or adjacent):
  $\sigma y0$ = side length of source divided by 2.15

Initial vertical plume dimensions for volume sources should be calculated as follows:

- Surface based source:
  $\sigma z0$ = height of source divided by 2.15
- Elevated source on or adjacent to a building:
  $\sigma z0$ = building height divided by 2.15
- Elevated source not on or adjacent to a building:
  $\sigma z0$ = building height divided by 4.3

6.4.3 Scaled Plot Plan

A scaled plot plan showing emissions release locations, nearby buildings, property lines, fence lines, and roads is required (Section 8.1.2(b), *Guideline on Air Quality Models* (EPA 2005). The dimensions of the buildings (height, width, and length) should be noted either on the plot plan or in a table in the report. If building dimensions are listed in a table format, then it should be easy to cross-reference between the plot plan, model input file, and table.

The use of site plot plans generated directly from the modeling files does not meet the scaled plot plan submittal requirement. The submittal should include those scaled plot plans used to generate the modeling files.

6.4.4 Building Downwash Parameters

According to Section 6.2.2 in the *Guideline on Air Quality Models* (EPA 2005), the air quality impacts associated with cavity and wake effects due to the nearby building structures should be determined for any stacks with stack heights less than good engineering practice (GEP). If AERSCREEN is used with the option of entering dimensions of a single building, the building with the greatest corresponding GEP stack height should be analyzed. This may not necessarily be the building closest to the stack. When the EPA's AERMOD model is used and stacks are less than GEP stack height, building profile information is required for use in the modeling. The recommended building profile software is the EPA's *Building Profile Input Program* (BPIP). This program can also be used to determine which building should be used in the screening analysis. BPIP is available on EPA's SCRAM website.

6.4.5 Source, Building, and Receptor Coordinates and Elevations

UTM coordinates are typically used to define locations of emissions points, building corners, and receptor locations. The datum (e.g., NAD27, NAD83, WGS84) must be specified for the coordinates used, and the same datum must be used for all locations specified in the modeling analysis to assure consistency. The same coordinate system should also be used to evaluate elevations for emissions points, buildings, and receptors.

6.5 Ambient Air Boundary

The ambient air boundary must be determined before an ambient air assessment can be completed. The definition of ambient air in Idaho Air Rules Section 006 is, "that portion of the atmosphere, external to buildings, to which the general public has access." The EPA has further stated that "the exemption from ambient air is available only for the atmosphere over land owned or controlled by the source and to which public access is precluded by a fence or other physical barriers" (Costle 1980). Based on these definitions, DEQ has developed the following guidance to be used when determining the ambient air boundary for a facility.

It shall be assumed that the air within the facility boundaries is ambient air unless the facility can demonstrate that public access is precluded. The facility-proposed ambient air boundary must include justification that demonstrates the facility has reasonable control of the area and effectively precludes public access on a routine basis. The following criteria must be satisfied when developing a facility-proposed, ambient-air boundary justification. A justification must accompany the answers.

For the purpose of defining ambient air, the "general public" is considered anyone not directly associated with the facility. In general, if someone present at the site would not be subject to OSHA or other worker exposure regulations, then they are considered as the general public.

1. Facility Control
    - Is general public access precluded by a physical barrier (e.g., fence with a gate)? If "yes," the facility is assumed to be controlled and public access effectively precluded, and the ambient air boundary can be set at the fence line. Proceed to No. 2. If "no," then proceed to No. 1b. Rugged terrain or a water body is not typically considered as a physical barrier.

- Is general public access discouraged by the type of area (e.g., industrial park site away from residential or recreational areas), size of the facility (e.g., the facility is surrounded by a buffer zone that is controlled by the facility), or a remote location away from the proximity of human habitation or activities? Is the facility controlled by reasonable posting of the property with "no trespassing" signs, or reasonable patrol of the property by a security person who routinely asks trespassers to leave? If "yes" to BOTH questions, the facility is assumed to be controlled, with public access effectively precluded, and the ambient air boundary is determined to be at the property boundary. Proceed to No. 2. If "no," to EITHER question, proceed to No. 1c.
- If the facility is not controlled by a physical barrier AND/OR general public access is not discouraged by the type of area, size of the facility, or the remoteness of the facility location, then the ambient air boundary is determined to be inside the property boundary. The actual point at which the ambient air boundary occurs is dependent on several factors, such as the type of operation at the facility (e.g., are employees outside on a regular basis?) and whether employees have a clear view, from the location where the employees normally work, of the entire property (e.g., are trees blocking the sight?). The ambient air boundary is determined to be at a point where employees are not regularly present and where they do not have a clear view of the property. To meet this criteria, a very detailed description of the facility and property must be provided. If a justification cannot be provided, the ambient air boundary is determined to be all air that is external to the buildings. Proceed to No. 2.

2. Facility Business
   Is the general public invited as part of the normal business conducted on the facility site (e.g., the facility includes a commercial establishment or service provider)? If "yes," then the area into which the public is invited is determined to be ambient air. Adjust the ambient air boundary determined in No. 1. If "no," the ambient air boundary determined in No. 1 is not changed. Proceed to No. 3.
3. Right-of-Way Access
   Is the general public allowed on site as a part of a right-of-way easement or a common service road? If "yes," then the right-of-way is determined to be ambient air. Adjust the ambient air boundary determined in No. 1. If "no," the ambient air boundary determined in No. 1 is not changed. Any streams or rivers transecting a facility will be considered as ambient air at all locations between high water levels unless the applicant adequately demonstrates and documents that public access can be legally precluded. Idaho Department of Lands and Fish and Game rules governing public access should be used for such a demonstration.
4. Leased Property
   Does the facility lease a portion of their site to another industry, business, or individual OR does the facility lease property from another entity? For example, if a facility leases part of its property to a farmer for growing crops, that portion leased may be considered as ambient air. These situations are frequently complicated, and DEQ should be consulted regarding any specific case involving leased property as it affects the ambient air boundary.

Any area outside the facility's (or facilities' if they are under common ownership) control will be considered ambient air. This includes other industrial facilities. The employees of other facilities are considered to be general public for the facility in question. Evaluation of the ambient air quality must include all sources within facility control if the source or source modification exceeds the SILs defined in IDAPA 58.01.01.006 (definition of significant contribution).

6.6 Receptor Network

A receptor network establishes locations where the air dispersion model calculates a pollutant concentration. Each location is called a receptor, to represent a receptor that might be exposed to that concentration at that location. Receptors are required to be placed in all areas considered to be ambient air.

Modeling must be conducted using a sufficiently dense receptor grid to reasonably resolve the maximum modeled concentration and confidently demonstrate compliance with standards.

DEQ may determine an application incomplete or may deny a permit if DEQ is not confident the receptor grid spacing used is adequate to confidently demonstrate NAAQS compliance. DEQ may also include additional receptors during verification modeling if it is questionable whether the maximum concentrations have been resolved, and approval will not be granted if results do not comply with applicable standards. Adequacy of the receptor grid can be evaluated by reviewing a plot of modeled design value concentrations and considering the following:

- Maximum modeled concentrations in relation to a trigger value (SILs, NAAQS, or AACs/AACCs)
- Concentrations at receptors immediately adjacent to the maximum modeled concentration
- Terrain features within the modeling domain and areas beyond the domain if maximum modeled concentrations are near the boundary of the domain

6.7 Elevation Data

Terrain elevations for sources and receptors should be used when appropriate (EPA 2005). Where AERMOD is the model used to demonstrate compliance, the applicant should generally use the latest established procedures and guidance provided by EPA (see the SCRAM website on EPA's TTNWeb-Technology Transfer Network (*http://www.epa.gov/ttn/scram*). Prior to 2009, elevations of receptors, sources, and buildings used in the modeling analyses were determined from U.S. Geological Survey (USGS) Digital Elevation Model (DEM) files. AERMAP now supports processing terrain elevations from the National Elevation Dataset (NED) developed by the USGS. Since the DEM files will no longer be updated, NED represents more up-to-date and accurate data, and these should be used in preference to DEM files. These data can be downloaded in a seamless data set in GeoTiff format for use in AERMAP.

A single, consistent source of terrain data should be used to establish elevations for receptors, emissions sources, and site structures. Using different datums within a single modeling analysis can result in critical problems such as sources located beneath ground-level, buildings suspended above ground-level, or facilities located on hillsides rather than valley floors.

6.8 Meteorological Data

The meteorological data used in the modeling analysis should be representative of the meteorological conditions at the particular site of the proposed construction or modification. Section 8.3 in the *Guideline on Air Quality Models* (EPA 2005) states that representativeness of the meteorological data is dependent on the following: (1) the distance from the meteorological monitoring site to the area under consideration; (2) the complexity of the terrain surrounding both the meteorological monitoring site and the area under consideration; (3) the exposure of the meteorological monitoring site; and (4) the period of time during which data are collected.

When using AERMOD, representativeness will also depend on the similarity between the monitoring site and the application site for: 1) surface roughness; 2) land type characteristics that influence parameters such as albedo and Bowen Ratio (vegetative cover and moisture content). Consult with the DEQ air quality modeling coordinator to determine if representative meteorological data are available for the area under consideration. If the only available meteorological data are of questionable representativeness, DEQ may require applicants to perform modeling analyses using multiple meteorological data sets. Alternatively, site-specific data could be acquired by the facility. Site-specific meteorological data are typically only required for PSD applications or when DEQ has concern regarding NAAQS compliance.

The collection of site-specific meteorological data should follow the recommendations provided in *Meteorological Monitoring Guidance for Regulatory Modeling Applications* (EPA 2000), as well as Section 8.3.3 in the *Guideline on Air Quality Models* (EPA 2005). Site-specific meteorological data must be approved prior to use in a modeling analysis. Generally, following EPA recommendations and procedures is determined to be adequate for DEQ approval. To receive approval, the facility must provide DEQ staff with standard operating procedures, the quality assurance plan for operating the meteorological tower, and quality control audit reports that cover the entire year of data. DEQ will review this information and respond with either an approval or denial letter. The facility should either reference or include a copy of the approval letter when meteorological data are used in a modeling analysis. This will help to expedite the review process of the permit application. If DEQ does not approve the data for air modeling purposes, the analyses will not be approved and alternate approaches must be developed.

There are several sources of meteorological data besides on-site collected data. The National Weather Service (NWS) collects data throughout the country. Much of these data are collected at airports. These and other data are available through the National Climatic Data Center (*http://www.ncdc.noaa.gov/oa/ncdc.html*), through EPA's SCRAM website, or possibly through DEQ's modeling coordinator.

As stated in Section 8.3.1.1 in the *Guideline on Air Quality Models* (EPA 2005), the model user should "acquire enough meteorological data to ensure that worst-case meteorological conditions are adequately represented in the model results." Section 8.3.1.2 recommends using five years of NWS data or at least one year of site-specific data. If more than one year of site-specific data are available, then all years, up to five years, should be used (see Section 8.3.1.2(b) in EPA 2005). Site-specific meteorological data must be subjected to DEQ-approved quality assurance procedures.

The following should be considered when generating meteorological data with AERMET:

- Surface characteristics specified for landuse types in AERMET are based on the meteorological measurement site, not the facility application site.
- The EPA program AERSURFACE should be used, following recommendations specified in the user's guide, to define season- and sector-specific surface parameters (albedo, Bowen Ratio, and surface roughness).
- A current aerial photograph of the meteorological measurement site, or a detailed land- use map, should be used to check the accuracy of land-use files used in AERSURFACE.
- Sector-specific values of surface characteristics should be calculated for each season.
- Documentation of the surface characteristics analyses should be submitted with the application. Sufficient detail must be provided such that DEQ staff can regenerate the AERMET output meteorological files.

6.9 Land-Use Classification

Determining if the area surrounding the facility is urban or rural is necessary before a dispersion modeling analysis can be conducted correctly. Two methods of classifying an area as urban or rural are described in Section 7.2.3.c in the *Guideline on Air Quality Models* (EPA 2005). The first is the land-use method. The area is classified according to the current land usage (according to the meteorological land-use typing scheme proposed by Auer [1978]) of its surroundings in a three-kilometer (approximately 1.8-mile) radius centered at the source. If 50 percent or more of the surrounding area is classified as I1, I2, C1, R2, or R3 (using classifications listed in Auer 1978), the source would be considered an urban source. Otherwise, the source would be considered rural. Appendix E provides a summary of the meteorological land-use typing scheme proposed by Auer (1978).

A second method relies on population density. If the population density within a three-kilometer (approximately 1.8-mile) radius, centered at the facility, is greater than 750 people per square kilometer, the urban modeling option for the area can be used. However, the population density method of source classification should not be applied to highly industrialized areas. This is because highly industrialized areas typically have low population densities, but the presence of buildings and areas of asphalt and concrete make the source more urban in nature. The *Guideline on Air Quality Models*, Section 7.2.3.e, states that, of the two methods, the land-use procedure is more definitive (EPA 2005).

6.10 Background Concentrations

Section 8.2 in the *Guideline on Air Quality Models* (EPA 2005) discusses the use of background concentrations in a cumulative NAAQS analysis. Background concentrations of regulated criteria pollutants must be included in cumulative NAAQS analyses for both PSD and non-PSD applications. The modeler is required to contact DEQ prior to performing the modeling analysis to obtain the appropriate, reasonably conservative background concentration(s) for the area and time intervals of concern. A different pollutant-specific concentration is needed for each applicable averaging period.

Background concentrations are developed based on air quality monitoring data collected from the area of the proposed project or from similar areas determined to be reasonably representative. DEQ has developed applicable background concentrations for specific areas and default concentrations for areas where monitoring data are not available. Facilities may propose alternate/refined background concentrations based on their own analyses. Use of an alternate background concentration should be proposed within a modeling protocol submitted to DEQ. An alternate background concentration proposal analysis should include the following:

- Description of monitoring data proposed as representative of the proposed project area. The description should include the statistics of the data set and the quality control/assurance measures conducted for the data if data were not provided by DEQ.
- Description of all emissions sources in the area of the proposed project and sources in the area(s) where claimed representative monitoring data were obtained. This should include both point sources and area/mobile sources, and should also address emissions source density. A discussion should be provided that compares the two areas and supports the use of the monitoring data for the project site.
- A detailed assessment of the meteorology of the project area and the area where monitoring data were obtained. Differences between the areas should be assessed for the effects they may have on pollutant dispersion and concentrations in ambient air.

Air monitoring data for Idaho can be obtained at the following EPA website address: *http://www.epa.gov/air/data/index.html*. In most instances, background concentrations calculated in the following manner will be accepted by DEQ:

- 24-hour PM2.5: The maximum 3-year mean of 98th percentile of 24-hour average concentrations over 1-year periods.
- Annual PM2.5: The maximum 3-year mean of annual averages, using 5 consecutive years of data.
- Short term standards of PM10, SO2, and CO: The maximum 2nd highest monitored value over each year of applicable data.
- 1-hour NO2: The maximum 3-year mean of the 98th percentile of the daily maximum 1-hour average concentrations over 1-year periods.
- 1-hour SO2: The maximum 3-year mean of the 99th percentile of the daily maximum 1-hour average concentrations over 1-year periods.
- Annual Standards of SO2 and NO2: The maximum annual average for the applicable data. The most recent 5-year data set should be used.

Existing emissions from a facility may have a measurable impact to monitored concentrations in some instances. It is the facility's responsibility to assess their contribution to the background concentration. Prior to this assessment, a protocol must be submitted to, and approved by, DEQ. The assessment must then be done in accordance with the DEQ-approved protocol. In such cases, the facility's impact may be subtracted from the monitored value to establish an appropriate background concentration value. The following should be considered in such analyses:

- To evaluate a facility's impact on background monitored values, modeling must be performed using meteorological data collected during the same period when monitoring data were collected.
- Site-specific meteorological data must be used. These data must be highly representative for both the facility site and the monitoring site.
- Actual emissions for the period modeled must be used in the analyses.
- Monitored and modeled values must be paired in time and space; i.e. modeled values subtracted from monitoring results must be those values modeled at the site of the monitor for the averaging period associated with the monitored value.
- One suggested approach would be to start with the highest monitored value and model the facility's impact on that value. If the result is lower than the next-highest monitored value, this process should be repeated for that monitored value. This process is repeated until the highest adjusted value is greater than the next unadjusted value. The highest adjusted value is used for the background concentration.

Use of other methods to calculate a background concentration will be evaluated on a case-by- case basis. Proposals for such methods should be thoroughly described in the protocol.

6.11 Evaluation of Compliance with Standards

6.11.1 Approval Criteria

The applicant must demonstrate compliance with all other applicable impact limits in addition to demonstrating compliance with NAAQS. For PSD applications, these include impact limits for Class I areas within 300 kilometers, non-attainment area impact limits (when in or potentially significantly impacting a non-attainment area), and TAPs increment standards in Idaho Air Rules Sections 585 and

586 (when emitting TAPs above DEQ ELs). Federal land managers have the responsibility to protect the natural and cultural resources of Class I areas from adverse impacts of air pollution. Refer to the Federal Land Managers Air Quality Related Values Workgroup (FLAG) Phase I Report- Revised (USFS et al 2010). In some cases, deposition of airborne pollutants (e.g., radionuclides or fluorides, for example) or human risk pathways associated with deposition of airborne emissions may be subject to regulatory impact limits.

The highest modeled ambient concentration must be used for comparison against the SILs for all applicable criteria pollutants. A multi-year average, consistent with the years of meteorological data modeled, of the maximum modeled concentration of each year modeled can be used for the probabilistic standards, including 24-hour PM2.5, annual PM2.5, 1-hour NO2, and 1-hour SO2.

The following design concentrations must be used when demonstrating compliance with the cumulative NAAQS:

- CO
  - 1-hour averaging period – maximum of second highest ambient concentrations at each receptor
  - 8-hour averaging period – maximum of second highest ambient concentrations at each receptor
- NO2
  - 1-hour averaging period – maximum of 5-year averages (at each modeled receptor) of the 98th percentile of the annual distribution (equal to the 8th high) of maximum daily 1-hour ambient concentrations
  - Annual averaging period – maximum of ambient concentrations at each receptor
- SO2
  - 1-hour averaging period – maximum of 5-year averages (at each modeled receptor) of the 99th percentile of the annual distribution (equal to the 4th high) of maximum daily 1-hour ambient concentrations
  - 3-hour averaging period – maximum of second highest ambient concentrations at each receptor
  - 24-hour averaging period – maximum of second highest ambient concentrations at each receptor
  - Annual averaging period – maximum of ambient concentrations at each receptor
- PM10
  - 24-hour averaging period – "the projected 24-hour average concentrations will not exceed the 24-hour NAAQS more than once per year on average" (EPA 2005). The design concentration is dependent on the number of meteorological data years used in the analysis. For example, if five years of NWS data were used, then the design concentration would be the sixth highest 24-hour ambient concentration that occurred at each receptor over that five-year period.
- PM2.5
  - 24-hour averaging period – maximum of multi-year average of annual maximum 24- hour ambient concentrations at each receptor. Using the multi-year average of the 98th percentile of the annual distribution (equal to the 8th high) of 24-hour concentrations for both the modeled design value and background is not adequately conservative because background concentrations are frequently the controlling factor for PM2.5.
  - Annual Averaging Period - maximum of multi-year average of annual ambient concentrations at each receptor.

- Pb
  - Quarterly averaging period – maximum of ambient concentrations at each receptor
  - 3-month rolling average – maximum of ambient concentrations at each receptor

If meteorological data used in the analyses are of questionable representativeness, DEQ may require a more stringent design value. DEQ may also require analyses using multiple meteorological data sets to compensate somewhat for increased uncertainty.

The following design concentrations must be used when demonstrating compliance with TAPs requirements:

- Noncarcinogens – 24-hour averaging period – maximum of ambient concentrations at each receptor
- Carcinogens – total averaging period (1-5 years depending on meteorological data availability) – maximum of ambient concentrations at each receptor

6.11.2 Adequacy of Analyses Results

The submitted analyses must demonstrate to the satisfaction of DEQ that applicable emissions do not cause or significantly contribute to a violation of any air quality standard, as per Idaho Air Rules Section 203 for PTCs and Idaho Air Rules Section 403 for Tier II operating permits. Approvability of the submitted analyses will depend on the results of the analyses as well as the representativeness and quality of input data and parameters used. DEQ recognizes the uncertainty in typical dispersion modeling analyses and the variability and uncertainty associated with input parameters such as background concentrations, emission quantities, operational characteristics, etc. These uncertainties will be considered in DEQ's evaluation and determination of acceptability.

DEQ will evaluate model inputs and parameters more carefully as modeling results more closely approach applicable standards. Modeled concentrations within about 90 percent of the standard will be more closely reviewed by DEQ. At these concentrations, approval will be based on a "weight of evidence" type approach, considering the model results, input data/parameters, potentially exposed public, any monitoring requirements specified in the proposed permit, and operational variability. DEQ will not approve any modeling results that do not show compliance with applicable standards. The following provides discussion on how DEQ will evaluate compliance in situations where modeled concentrations are very near applicable standards:

- Modeled Concentrations: Results within about 90 percent of the air quality standard will generally trigger DEQ to more carefully evaluate the analyses. In some instances, the analysis may not adequately demonstrate compliance even though modeled concentrations are below a standard.
- Emissions Estimates: Estimates of emissions can be a substantial source of uncertainty and/or variability. It is important to evaluate both uncertainty in the estimate and variability, and to distinguish between them. Where estimates of maximum emissions are highly uncertain and the estimate is not necessarily conservative, DEQ may consider modeling results slightly below the standard as not adequately demonstrating compliance. Alternatively, if emissions are highly variable and the allowable emission rate is set at the maximum, DEQ will consider the likelihood of high emissions occurring concurrently with conditions of poor dispersion.
- Representativeness of Meteorological Data: Using meteorological data from a distant location where the representativeness is questionable will add to the uncertainty of the modeling analyses. Applicants may be requested by DEQ to provide a more detailed assessment of the area's meteorology and qualitative comparisons to data used in the analyses. Such assessments

should be performed by meteorologists or those having considerable knowledge in surface meteorology. In some instances, DEQ may request an applicant to install and operate a meteorological station to resolve concerns with data representativeness. In cases where meteorological data used in the analyses are of questionable representativeness, DEQ may require the use of multiple meteorological data sets in the analyses.

- Background Concentrations: Background concentrations are often a very large source of uncertainty and variability, especially for 1-hour NO2, PM10, and PM2.5, where background concentrations can be a considerable fraction of the standard. When modeled 1-hour NO2, PM10 and PM2.5 concentrations are very near the standard, applicants should review and compare the meteorological conditions associated with the modeled result and the background concentration.
- Modeled Emissions Release Parameters: Parameters characterizing the release of emissions (stack temperature, flow rate, initial plume dimensions for volume sources, etc.) greatly impact the modeling results. The conservatism of these parameters will be considered by DEQ during the review.
- Permit Requirements: As modeled concentrations approach applicable standards, DEQ may require more extensive emissions monitoring, source testing, and possibly ambient air monitoring.
- Areas with High Concentration Impacts: DEQ will consider the land use of areas where models project high concentrations. DEQ will require a higher degree of certainty for areas where there is a high potential for exposures to the public, such as actual residences, businesses, parks, etc. However, it is important to consider that dispersion models are reasonably accurate at predicting the magnitude of maximum concentrations but often perform poorly at predicting the location or time of maximum concentrations.

6.12 Air Quality Modeling Report

The applicant must supply an air quality modeling report that presents the case as to how the modeling results demonstrate compliance with all applicable air quality standards. The level of detail of the report will depend on the complexity of the proposed facility and the permitting project.

Each submitted application must be a complete package in itself. Referencing previously submitted materials, such as those submitted in an earlier application, will not generally be considered as meeting the stated requirements to provide documentation/justification of air quality analyses and data used as inputs for those analyses.

Below is an example annotated outline of an air quality modeling report. The report should thoroughly describe all aspects of the air impact analyses performed. Specific sections of this guideline should be consulted to evaluate the details needed for the modeling report regarding certain aspects of the analyses.

I Purpose

- State the purpose of the air quality modeling analyses (i.e., demonstrating compliance for a permit to construct or a Tier II operating permit).
- Provide a detailed description of regulatory requirements as they relate to modeling, citing specific applicable regulations.

II Model Description/Justification

- Discuss what model was chosen and justify why it is the appropriate model for the situation. This discussion may be very brief if the applicant is proposing to use AERMOD for near-field impacts.

III Emissions and Source Data

- Present tables showing the current (either actual or permit allowable) emission rates, future allowable emissions rates (maximum for each applicable averaging period), and the requested emission increase (future allowable minus actual or current allowable).
- If cumulative NAAQS impact analyses are required, the applicant must thoroughly document all emissions used in the model, even when such sources are not affected by the particular proposed project. Emissions calculations, source test data, and/or other information justifying the value used should be provided for all sources unless those emissions are based on a specific emissions limit presented in an issued permit.
- Provide justification for those sources and/or pollutants determined to be "inconsequential" (if applicable).
- Provide stack parameters (emissions rates, stack height, stack elevation, stack diameter, stack gas exit velocity, and stack gas exit temperature) for each modeled emissions point. Values for stack parameters should be justified and well documented, indicating whether values are estimated or measured.
- Provide a facility plot plan to scale showing the fence line, ambient air boundary, emission sources at the facility, and buildings. Include the height, width, and base elevation of each building at the facility.
- Provide UTM coordinates of all emissions points, and list the datum used.

IV Ambient air boundary

- Thoroughly describe how the public are precluded from accessing all areas excluded from the receptor network, describing any complicating ambient air issues such as rivers bisecting the facility, leasing agreements, retail sales operations at the site, right of ways, etc.

V Receptor Network

- Describe the receptor network used. Include the distance between receptors for the fine and coarse grids. Justify any deviation from minimum recommendations in EPA or state guidelines, and provide a demonstration that the receptor grid allows for resolution of the maximum modeled concentration.

VI Elevation Data

- Describe any elevation data used and the source of the information, including the datum for the coordinates used. If necessary, include a USGS 7.5-minute map showing the location of the facility. A justification must be provided if elevation data are not used.

VII Meteorological Data

- Describe the source of the meteorological data and present a representative analysis according to Section 6.8. Electronic copies of the files must be included with the modeling report if meteorological data were not provided in model-ready format to the applicant from DEQ. If site-specific data are used, provide documentation that DEQ has reviewed and approved the data.
- If the applicant has generated AERMOD input meteorological files by running AERMET, rather than using AERMOD input files provided by DEQ, supporting AERMET documentation must be submitted with the application. A detailed report on the processing of meteorological data

should be submitted, including a report on running AERSURFACE to evaluate surface characteristics and a detailed report on data collection and quality for any on-site data processed. Copies of the raw meteorological data must also be submitted to DEQ.

VIII Land-Use Classification

- State the land-use classification for the area surrounding the source and provide the justification.

IX Background Concentrations

- State whether background concentrations were used and identify the source of the information.
- If DEQ default background concentrations were not used, the report must thoroughly describe and document how background concentrations were determined.

X Evaluation of Compliance with Standards

- Include tables summarizing the air quality model output (example tables are shown in Appendix F).

XI Electronic Copies of the Modeling Files

- Provide modeling input/output files (including BPIP and meteorological data, and intermediate files generated by AERMET, AERMAP, and AERMOD) on compact disk or other means.

7 DEQ Review of Modeling Analyses

DEQ dispersion modeling staff will review the submitted air quality analyses prior to approval and issuance of the permit. Review of the analyses will occur in two phases: 1) completeness review; 2) technical review of submitted analyses. The completeness review will focus on evaluating whether the required analyses were performed and the primary components of the air quality analyses were submitted with the application. The technical review will evaluate whether the data and methods used in the analyses are accurate and appropriate for the project.

Several methods and approaches can be used by the applicant to ensure the submitted modeling analyses are approved by DEQ or, if there are problems with the analyses, such problems are identified early in the completeness review and will minimize delays to the project:

1. Submit a modeling analyses protocol prior to conducting the analyses. The protocol, as described in Section 6.1, should provide details on the proposed methods and data to the greatest degree possible.
2. Provide a detailed and well-organized modeling analyses report, as described in Section 6.12. This will allow DEQ staff to quickly assess the appropriateness and technical accuracy of the analyses. If a modeling protocol was submitted to DEQ prior to the application, a copy of the protocol and DEQ's protocol approval notification should be included with the application.
3. Provide clear justification for methods and data used, and provide supporting documentation. Calculations should be provided such that the DEQ reviewer can easily verify the calculated values.
4. Ensure that emissions sources are named consistently between the emissions inventory used for the permit application forms and the modeling analyses.

Conduct quality assurance/control measures to minimize error in the submitted analyses. The following are some measures that will help minimize or identify errors in the analyses:

- Print or view a three-dimensional representation of the sources, building, receptors, and the ambient air boundary. This will identify any errors in UTM coordinates and elevations.
- Check that all sources included in the application are included in the modeling analyses. If some sources are not included, a detailed justification should be provided. If facility-wide modeling is needed for a cumulative impact analysis, the emissions inventory of other sources, not directly addressed by the current permitting action, should be thoroughly documented.
- Emissions rates used in the modeling analyses should be identical to those listed in the permit application forms and the emissions calculation section of the application. Any differences between emissions rates should be thoroughly documented and all calculation steps should be shown. This will allow DEQ reviewers to quickly evaluate how emissions rates were calculated.

8 Summary

This document provides guidance for performing an ambient air assessment, for permitting purposes, in the state of Idaho. This document should be used in conjunction with the EPA's *Guideline on Air Quality Models* (EPA 2005) and *New Source Review Workshop Manual* (EPA 1990), and other applicable guidance materials. Following the guidance in this document, as well as EPA guidance, will help expedite DEQ's review of the application.

Appendix A. Guidance for 1-Hour NO_2 Modeling of Intermittent Sources

DEQ Guidance for Minor New Source Review Modeling of 1-Hour NO_2 from Intermittent Testing of Emergency Engines

State of Idaho
Department of Environmental Quality

September 2013

TR 1172

Certain industrial facilities have internal combustion (IC) engines that are used only to power emergency generators or fire-suppression pumps. These engines only operate for periodic testing and during an actual emergency. As such, these sources with intermittent emissions are difficult to model in a way that accounts for impacts in a reasonably accurate but conservative manner. As a result, Tyler Fox, leader of Environmental Protection Agency's (EPA) Air Quality Modeling Group, developed a memorandum entitled "Additional Clarification Regarding Application of Appendix W Modeling Guideline for the 1-hour NO2 National Ambient Air Quality Standard, dated March 1, 2011. The memo provides states with the flexibility to exclude certain types of sources with intermittent emissions from Appendix W modeling.

Upon a review of other states' application of the Tyler Fox memo, comments from the public and Idaho industry, an internal review of Idaho sources, NO2 background levels, and various sample model runs; DEQ has determined that Nitrogen Oxides (NOx) emissions from the intermittent operational testing of engines powering emergency generators or fire-suppression water pumps may be excluded from the project-specific significant impact level (SIL) analysis and the cumulative NAAQS analysis for 1-hour NO2, providing the annual hours of operation from testing and maintenance are less than or equal to 100 hours per engine.

This determination is applicable to minor source air permitting projects and is not limited to any specific number of engines present at a facility. The Director may require deviation from this guidance if deemed appropriate to assure compliance with 1-hour NO2 NAAQS and IDAPA 58.01.01.203 or 01.403. DEQ will determine how emergency engines are included in permits for major sources, specifically those applicable to the Prevention of Significant Deterioration (PSD) program, on a case-by-case basis.

This guidance does not have the force and effect of a rule and is not intended to supersede statutory or regulatory requirements or recommendations of the state of Idaho or EPA. This guidance may be altered upon new or revised guidance from EPA, development of new methods to appropriately handle such emissions, or new information gained from technical analyses.

Contact the DEQ stationary source air modeling coordinator at (208) 373-0112 for any questions or additional information regarding data and methods for assessing air quality impacts from intermittently operated sources.

Appendix B. Class I Areas

Class I Areas

This appendix shows Class I areas in and near Idaho. The areas represent situations where air quality impact limits are stricter than the NAAQS. The information in this appendix is current as of the date of this document. Please check with DEQ to verify if it is still current.

Area Classifications

The Class I, II, and III areas are defined below (shown in Figure 1).

1. Class I - National park, recreation, and wilderness areas that were already established when the 1977 Clean Air Act was passed, and other designated parts of the country that now benefit from high quality air and where a high priority has been established for the maintenance of pristine conditions. Additional degradation of the air is severely restricted.
2. Class II - Areas that need reasonably or moderately good air quality protection. This is presently the class designation of most areas in the United States. Increments of deterioration have been stipulated that will generally accommodate most proposed development projects.
3. Class III - Areas that can, at the discretion of the states, be designated as allowing for larger increments of air quality degradation and therefore greater growth and development potential. No Class III areas have been designated in Idaho.

The Class I areas in Idaho include the following: Hells Canyon, Sawtooth, and Selway- Bitterroot wilderness areas, Craters of the Moon National Monument, and Yellowstone National Park.

Class I areas near Idaho's borders include the following: Spokane Indian Reservation, Washington; Hells Canyon and Eagle Cap Wilderness areas, Oregon; Cabinet Mountain and Anaconda-Pintler Wilderness areas, Red Rock Lakes, and Flathead Indian Reservation, Montana; Yellowstone National Park, Montana and Wyoming; Teton National Park, Wyoming; and Jarbidge Wilderness, Nevada.

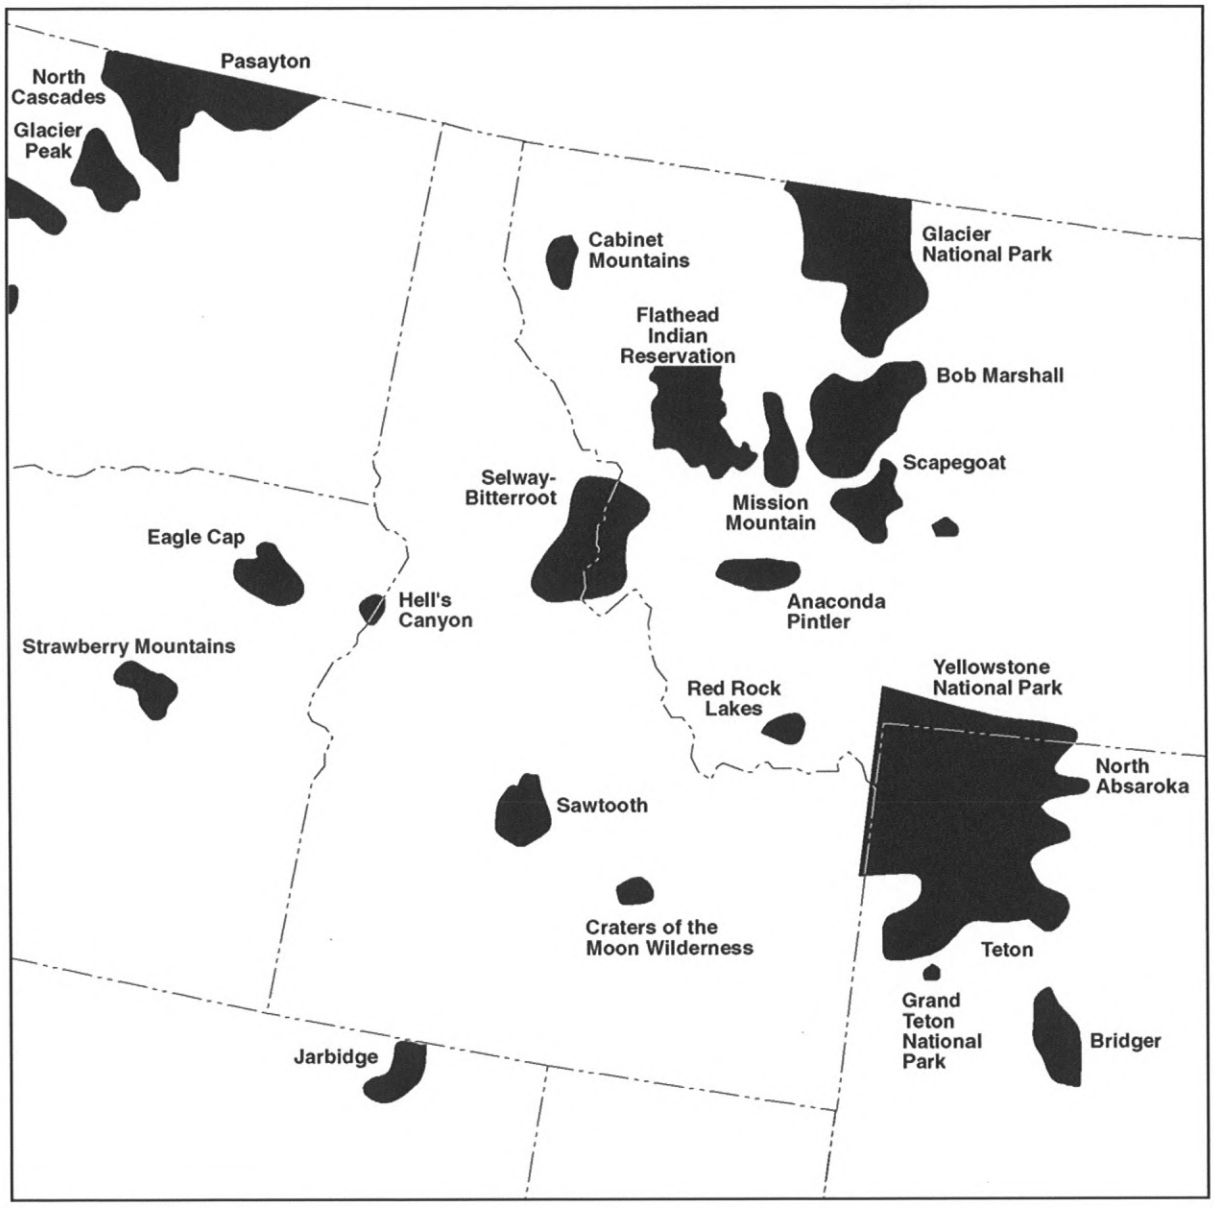

Figure A-1. Class I areas in and near Idaho.

Appendix C. Idaho DEQ Air Dispersion Modeling Checklist

Idaho DEQ Stationary Source Air Dispersion Modeling Checklist

- ☐ Reviewed the Idaho Air Quality Modeling Guideline and have determined the appropriate methods and data for use in this permitting action, contacting DEQ as needed to provide clarification.
- ☐ A modeling applicability analysis was performed for all criteria pollutants emitted by the new facility or modification, and modeling was performed for those pollutants having a total increase in emissions exceeding DEQ modeling thresholds.
- ☐ A TAPs modeling applicability analysis was performed for all TAPs emissions increases associated with the project, and TAPs modeling was performed for those TAPs having a project total emissions rate exceeding the emissions screening levels.
- ☐ Provided a description of the ambient air boundary and demonstrated how public access will be precluded from all areas excluded from ambient air.
- ☐ The receptor grid used meets minimal requirements specified by DEQ AND is adequate to reasonably resolve the maximum modeled concentration and confidently demonstrate compliance with applicable standards.
- ☐ The modeling domain used is sufficiently large to resolve the maximum impacts, accounting for impacts on distant elevated terrain.
- ☐ A scaled site plot plan was included in the application, showing emissions sources, buildings, and the ambient air boundary.
- ☐ Thoroughly documented all release parameters used in the model and provided justification for their use.
- ☐ Emissions rates provided in the emissions inventory section of the application are identical to those used in the modeling analyses or, if emissions rates are not identical, thorough justification of modeled rates has been provided.
- ☐ A cumulative NAAQS impact analysis was performed for all criteria pollutants for which modeled impacts from the significant impact analysis exceeded SILs. The cumulative NAAQS impact analysis included facility-wide emissions, emissions from any co-contributing sources, and a DEQ approved background concentration. Documentation of all emissions rates and release parameters used in the cumulative NAAQS impact analyses are provided in the application.
- ☐ Included all input and output modeling files for all pollutants and averaging periods.
- ☐ If a modeling protocol was prepared and submitted to DEQ prior to performing the air impact analyses, the protocol and DEQ's protocol approval notice is included with the application.

Appendix D. Modeling Protocol Checklists

Modeling Protocol Checklist for New Minor Sources or Minor Modifications

The following should be thoroughly addressed in a modeling protocol submitted to DEQ:
Introduction and Purpose

- General overview, facility description, description of area where facility is located.
- Project overview.
- Goals of the air quality impact analysis (i.e., demonstrate compliance for a PTC for a modification, PTC for a new facility, or a Tier II operating permit).
- Applicable regulations and requirements.
- Pollutants of concern.

Emissions and Source Data

- Description of facility processes and emissions controls affected by the permitting action.
- List of emissions points that will be included in the modeling analyses. Present a table showing current actual/allowable and future allowable emission rates (using pounds per hour rates for all applicable averaging periods) and the requested emissions increase (future allowable minus current actual or allowable).
- Good engineering practice (GEP) stack-height analysis for any stacks approaching GEP height.
- Graphic showing the facility layout: location of sources, buildings, emissions points, and fence lines.
- Description of methods used to calculate or otherwise determine source parameters (emissions rates, UTM coordinates, stack height, stack elevation, stack diameter, stack- gas exit velocity, and stack-gas exit temperature) for each source included in the modeling analyses.
- Methodology for including area and volume sources in the modeling analysis, including justification and calculations of initial dispersion coefficients and release heights.
- Methodology for including/excluding sources from the modeling analyses.

Air Quality Modeling Methodology

- Description of model selection and justification. This may be minimal in cases where the regulatory guideline model is used (AERMOD in most cases).
- Description of model setup and application
  - Model options (i.e., regulatory default). Describe and provide justification for any non-default settings.
  - Averaging periods used in the analyses and how emissions rates were calculated for specific averaging periods.
  - Land-use analysis in all cases where "urban" is used and in cases where land use is not obviously "rural."
  - Methods used to account for building downwash in the analyses.
  - Treatment of any chemical transformations (e.g., NO to NO2) accounted for in the analyses.
  - Any other unique methods or data used.Description of how elevations of sources, buildings, and receptors were determined.
- Receptor network
  - Description of receptor grids – include methodology for ensuring the maximum concentration will be estimated
  - Discussion/justification of ambient air boundary, including a description of how the general public will be excluded from areas not considered ambient air.

- Meteorological data
  - Selection of meteorological databases – justification of appropriateness of meteorological data to area of interest
  - Meteorological data processing
  - Meteorological data analysis (e.g., wind rose)
- Background concentrations

Applicable Regulatory Limits

- Methodology for evaluation of compliance with standards (i.e., determination of design concentration)
- Significant Impact analysis
  - Comparison to SILs
  - TAPs analysis
- Cumulative NAAQS impact analysis
  - NAAQS analysis
- Presentation of results – state how the results of the modeling analysis will be displayed (i.e., list what information will be included)

Appendix E. Land-Use Classification Procedure

Land-Use Classification Procedure

See Section 8.2.8.b of *Guideline on Air Quality Models* (EPA 2001) for additional information.

1. Determine a circular area centered on the source with a radius of three kilometers.
2. Classify the land use within this area using the meteorological land-use typing scheme presented in Table D-1.
3. If land-use types I1, I2, C1, R2, and R3 account for 50 percent or more of the area, use urban dispersion coefficients; otherwise, use rural dispersion coefficients.

Table D-1. Identification and Classification of Land-Use Types (Auer 1978)

Type	Use	Structures	Vegetation
I1	Heavy Industrial	Major chemical, steel, and fabrication industries; generally 3-5 story buildings, flat roofs	Grass and tree growth extremely rare; <5% vegetation
I2	Light-moderate Industrial	Rail yards, truck depots, warehouses, industrial parks, minor fabrications; generally 1-3 story buildings, flat roofs	Very limited grass, trees almost totally absent; <5% vegetation
C1	Commercial	Office and apartment buildings, hotels; >10 story heights, flat roofs	Limited grass and trees; <15% vegetation
R1	Common residential	Single family dwellings with normal easements; generally one story, pitched roof structures; frequent driveways	Abundant grass lawns and light-moderately wooded; >70% vegetation
R2	Compact residential	Single, some multiple, family dwellings with close spacing; generally <2 story, pitched roof structures; garages (via alley), no driveways	Limited lawn size and shade trees; <30% vegetation
R3	Compact residential	Old multi-family dwellings with close (<2m) lateral separation; generally 2 story, flat roof structures; garages (via alley) and ash pits, no driveways	Limited lawn size, old established shade trees; <35% vegetation
R4	Estate residential	Expansive family dwellings on multi-acre tracts	Abundant grass lawns and lightly wooded; >80% vegetation
A1	Metropolitan natural	Major municipal, state, or federal parks, golf courses, cemeteries, campuses; occasionally single story structures	Nearly total grass and lightly wooded; >95% vegetation
A2	Agricultural natural		Local crops (e.g., corn, soybeans); >95% vegetation
A3	Undeveloped	Uncultivated; wasteland	Mostly wild grasses and weeds, lightly wooded; >90% vegetation
A4	Undeveloped rural		Heavily wooded; >95% vegetation
A5	Water surfaces	Rivers, Lakes	Not applicable

Appendix F. Example Tables for Air Quality Modeling Report

Example Tables for Air Quality Modeling Reports

This appendix contains examples of tables that are useful in presenting information in modeling reports.

Table E-1. Example Stack Parameters Table

Parameter[a]	Generator Stack	Boiler Stack
Computer Model Identifier (Alias)		
Emissions Rate (lb/hr)		
Stack Height (ft)		
Stack Diameter (ft)		
Exit Temperature (°F)		
Exit Flow Rate (acfm)		

a) Provide thorough justification/documentation of values used in the model, including calculations used to generate values.

Table E-2. Example Significant Impacts Summary ($PM_{2.5}$)

Year	5-Year Mean of Highest Annual Concentration ($\mu g/m^3$)	Radius of Significant Annual Impact (m)	5-Year Mean of Highest 24-hour Concentration ($\mu g/m^3$)	Radius of Significant 24-hour Impact (m)
1987-1991				
Significant Impact Level	0.3	Not applicable	1.2	Not applicable

Table E-3. Example Maximum Impacts for Cumulative NAAQS Analysis (NO_2 impacts, 1-hour averaging period)

Years Modeled	Multi-Year Mean of 8th Highest Daily Maximum 1-Hour Concentration ($\mu g/m^3$)	Receptor Location		
		East (m)	North (m)	Elevation (m)

Table E-4. Example Maximum Impacts for Toxic Air Pollutants Analysis (Carcinogens)

TAPs	Period Average (5-year) Concentration ($\mu g/m^3$)	Receptor Location		
		East (m)	North (m)	Elevation (m)

Table E-5. Example Maximum Impacts for Toxic Air Pollutants Analysis (Noncarcinogens)

TAPs	Highest 24-hour Concentration ($\mu g/m^3$)	Receptor Location		
		East (m)	North (m)	Elevation (m)

Table E-6. Example NAAQS and Toxic Air Pollutants Impact Analysis Summary

Pollutant	Averaging Period	Total Ambient Impact (Baseline Plus Modification and Co-Contributing Sources) ($\mu g/m^3$)	Background Conc. ($\mu g/m^3$)	Total NAAQS Conc. ($\mu g/m^3$)	NAAQS ($\mu g/m^3$)
CO	1-hour				40,000
CO	8-hour				10,000
NO_2	1-hour				188
NO_2	Annual				100
SO_2	1-hour				196
SO_2	3-hour				1,300
SO_2	24-hour				365
SO_2	Annual				80
$PM_{2.5}$	24-hour				35
$PM_{2.5}$	Annual				12
PM_{10}	24-hour				150

USACE	United States Army Corps of Engineers
VOC	Volatile Organic Compound

Introduction

In April 2009, the Idaho Legislature approved the Department of Environmental Quality (DEQ) Rules IDAPA 58.01.24, Standards and Procedures for Application of Risk Based Corrective Action at Petroleum Release Sites (the Rule). This rule required that DEQ prepare a risk evaluation manual for petroleum releases which would be used as guidance for implementation of the Rule. This document represents that implementation guidance. The Rule may be obtained at: *http://adminrules.idaho.gov/rules/2012/58/0124.pdf*

Organization of This Document

The document begins with a general description of the steps in the risk evaluation (RE) process, which is then followed by detailed implementation information for each step. DEQ has developed software that complements the process described and is provided at no charge. Contact DEQ regarding its availability.

Information in the body of this manual is supported by 12 appendices. Appendices A–D address default exposure factors, fate and transport parameter values, physical and chemical properties, and toxicity values. Appendix E presents models and equations. Appendix F provides the methodology and calculations for remedial action target levels (RATLs). Appendix G discusses the vapor intrusion pathway, and Appendix H addresses the application of natural attenuation. Appendix I describes the estimation of exposure point concentrations. A sample table of contents from a risk evaluation report is provided in Appendix J. Appendix K addresses practical quantitation limits, and Appendix L contains a quality assurance project plan (QAPP) template.

Section 1. Overview of the Risk Evaluation Process

1.1 Steps in the Risk Evaluation Process

The overall evaluation process for a site where a petroleum release is discovered and reported to DEQ is illustrated in Figure 1. The process consists of multiple steps, each of which is briefly described in the pages following Figure 1. In some cases, when adequate data are available concerning a release, the owner or operator (as defined IDAPA 58.01.24.010) of the release site may skip the screening level evaluation and proceed directly to the site-specific RE, a more detailed level of evaluation, without formally completing the intermediate steps. DEQ should be notified in these instances. A comparison of the two RE options, with the types of values, models, and other factors used in each option, is presented in Table 1.

1.1.1 Site Discovery

The risk-based site management process begins with the discovery of a petroleum release site. A petroleum release site may be discovered and reported to DEQ under a variety of circumstances. These include, but are not limited to, citizen complaints, investigations conducted as a part of real estate transactions, environmental impacts observed in surface water bodies, and notification of accidents and spills. It is the owner/operator's responsibility to ensure that DEQ is notified.

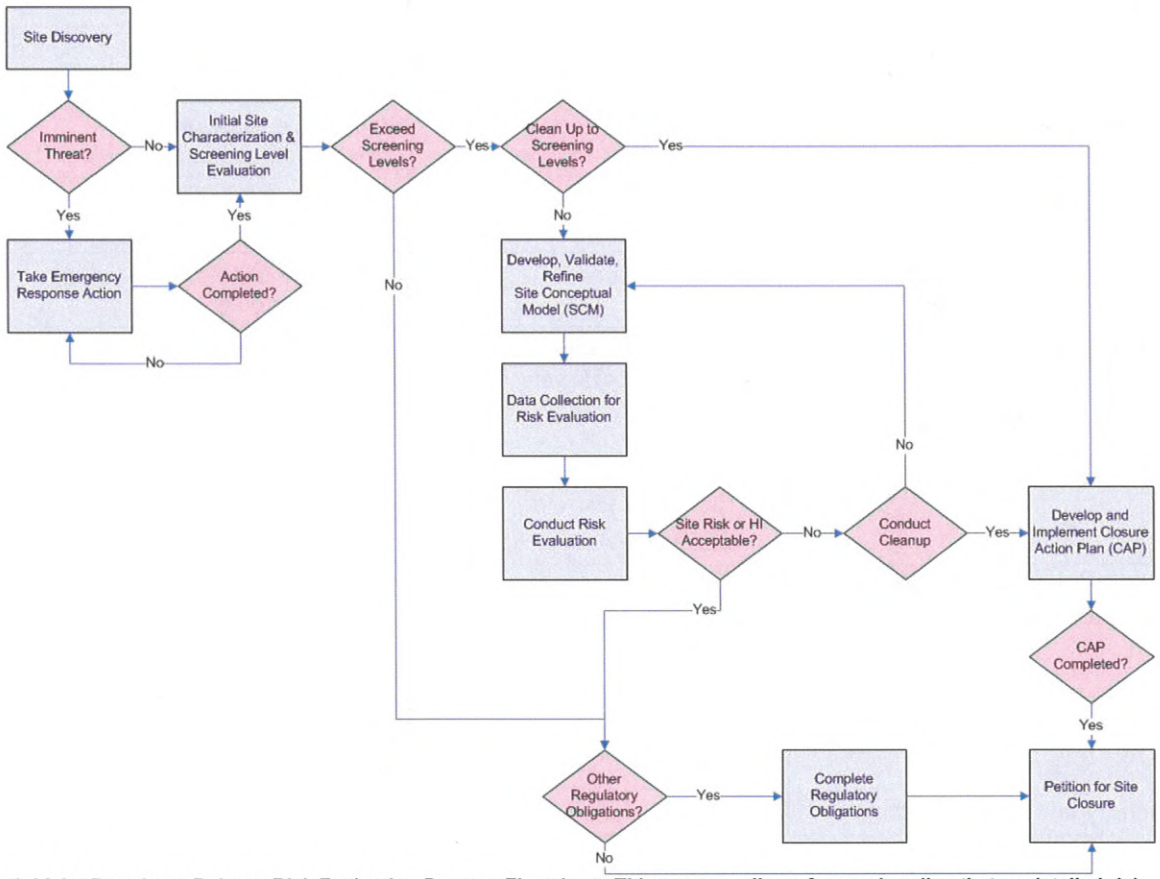

Figure 1. Idaho Petroleum Release Risk Evaluation Process Flowchart. This process allows for moving directly to a detailed risk evaluation without first completing a general screening level evaluation.

Table 1. Comparison of Risk Evaluation Options

Factors	Screening Level Evaluation	Site-Specific Risk Evaluation
Exposure Factors	Default	Site-specific/default
Toxicity Factors	Rule-specified values	Rule-specified values
Physical and Chemical Properties	Default	Default or DEQ accepted values
Fate and Transport Parameters	Default	Default/Site-specific
Unsaturated Zone Attenuation	None	None/Site-specific
Fate and Transport Models	Default	Default or other models acceptable to DEQ
Exposure Point Concentrations	Maximum	Statistical evaluation: Conservative Estimate of Mean:
Acceptable Target Risk	1×10^{-6}	Cumulative effects considered; target of 1×10^{-5}
Acceptable Target Hazard Quotient/Hazard Index	Hazard Quotient = 1	Cumulative effects considered; Hazard Index Target of 1
Groundwater Protection	Maximum contaminant level or risk based target levels	Maximum contaminant level or risk based target levels
Outcome of Evaluation	Either: • Petition for Site Closure, or • Risk Evaluation, or • Corrective Action Plan	• Petition for Site Closure, or • Refine RE, or • Corrective Action Plan
Soil Concentration Protective of Groundwater	Default model with point of exposure at source	Default model with point of exposure determined as per Section 4. Flexibility in model may be used subject to DEQ approval
Surface Water Classification	See Section 4	See Section 4
Point of Exposure	Source	See Section 4
Activity and Use Limitations	None	See Section 6

1.1.2 Determination of Imminent Threat

Upon site discovery, the owner/operator should carefully evaluate the available information to determine whether the site poses any imminent threat to human health or safety, or to the environment. Threats include, but are not limited to, impacts to water wells; vapors or odors in residential and commercial structures; concentrations approaching explosive levels; impacts to a surface waterbody; and impacts to human health and the environment. If any imminent threats are identified, the owner/operator should notify DEQ or State Communications Center (STATECOMM) immediately (see Section 2) and take immediate steps to abate the threat. Documentation of abatement activities and confirmation that imminent threats have been removed should be provided to DEQ. Further details of this step are provided in Section 2.

1.1.3 Initial Site Characterization and Evaluation

Upon completion of the emergency response action, if any, it is necessary to perform an initial site characterization and evaluation (ISCE). As a part of the ISCE, media-specific data (for soil, soil vapor, and groundwater media) should be collected to characterize the source. This step is intended to identify the maximum contaminant concentrations for the identified petroleum products in soil and groundwater. Since a site may be a candidate for closure after the completion of the screening level evaluation (see ☐), it is very important that the data collected at this time identify the maximum media-specific concentrations. Further details of this step are provided in Section 2.

1.1.4 Comparison with Screening Levels

This step involves the comparison of the maximum media-specific concentration of each contaminant, identified in the ISCE, with the screening levels developed by DEQ and presented in Table 2. There is a screening level for each contaminant in each media. The screening level is the lowest of the media-specific (soil, soil vapor, and groundwater) risk-based concentrations for the applicable exposure pathways. Screening levels are considered criteria that, if met (that is, maximum contaminant concentrations are below the screening levels), will allow unrestricted (residential) use of the property. Since exposure to these low concentrations (below the screening levels) of contaminants does not pose a threat to human health, if the owner/operator chooses to meet these criteria, they will not be required to evaluate site-specific exposure pathways and develop a site conceptual model (SCM), and no land use restrictions will be needed on the property.

When DEQ and the owner/operator agree that a petroleum release has been adequately characterized, DEQ will not require any further action of the owner/operator related to the release if the maximum contaminant concentrations in soil, surface water, and groundwater do not exceed the screening levels, subject to other applicable requirements, if any, as referenced in IDAPA 58.01.24.001.02. If any of the maximum soil, groundwater, or soil vapor concentrations exceed the screening levels, the owner/operator may either:

- adopt the screening levels as cleanup criteria and develop a corrective action plan (CAP) to achieve these levels, or
- perform a site-specific RE. Further details of this step are provided in Sections 3 and 4.

1.1.5 Development and Validation of a Site Conceptual Model

If the screening levels are exceeded, and the owner/operator chooses to conduct a more detailed (site-specific) RE, it is first necessary to develop and validate an SCM. An SCM provides the framework for the overall management of the site and should help guide data collection and risk management activities while the RE is being performed. The key elements of the SCM are:

- release scenario(s),
- source description,
- petroleum chemicals of interest (COI),
- an exposure model that incorporates the appropriate receptors,
- exposure pathways and routes of exposure (ROE),
- the site stratigraphy and hydrogeology, and
- the spatial and temporal distribution of the petroleum COI.

An important part of this step is to validate the SCM based on site-specific data. Further details of this step are provided in section 4.1.

1.1.6 Identify and Collect Data for Risk Evaluation

Depending on the site-specific conditions, the RE may require the collection of additional site-specific data. To prepare for conducting an RE, the owner/operator should review the SCM, identify requirements for filling data gaps, and collect additional data if necessary. This data will be used to calculate estimates of site-specific exposure point concentrations (see section 4.3.4 and Appendix I) and an estimate of the site-specific cumulative risk (see section 4.5) and, potentially, to develop RATL concentrations using the guidance provided in this document. Further details of this step are provided in section 4.2.

1.1.7 Site Specific Risk Evaluation

Conducting the RE requires developing site-specific estimates of exposure point concentrations for soil and groundwater, estimating site-specific cumulative risk, comparing these with acceptable target risk levels and, if necessary, developing media-specific RATL concentrations. RATLs are target concentrations developed by the owner/operator using a combination of conservative default and site-specific parameters. These concentrations depend on the receptor, media, pathway, and ROE and are developed for each petroleum COI and each media identified in the SCM. Using RATL concentrations instead of the defaults (the screening level criteria) may require that limitations be placed on activities and land uses that are allowed on the property. This step is discussed in section 4.6 and Appendix F.

1.1.8 Comparison with Acceptable Target Risk Levels and Decision Making

Once the site-specific cumulative risk has been estimated, it is compared to acceptable target risk levels, as specified in the Rule. If acceptable target risk levels are not exceeded, the site is eligible for closure, subject to other applicable requirements, if any, as referenced in IDAPA 58.01.24.001.02. If the site-specific cumulative risk exceeds the acceptable target risk levels, two options are available:

- Calculate and adopt media-specific RATL concentrations for each petroleum COI and develop and implement a CAP to achieve these concentrations.
- Refine the SCM and RE. It is possible that the site-specific cumulative risk is lower than initially estimated and may not pose an unacceptable risk, but this can only be determined with a more refined SCM and RE. This may involve the collection of additional data or the use of other models. Before collecting these additional data, it is optional to develop a work plan that outlines additional data needs and the overall approach for the refined evaluation. The plan may be submitted to DEQ for review and approval before proceeding with data collection and the evaluation. Although optional, the work plan and suggestions from DEQ may help with completing the required work more efficiently than might be the case without a DEQ-reviewed work plan. Details of this step, including the basic contents of a work plan, are included in section 4.7.

Upon completion of the RE, the owner/operator should provide recommendations to DEQ. In most cases, it is anticipated that DEQ and the owner/operator will work together to identify the best alternative. Note that it is not necessary to complete a screening level evaluation before conducting an RE, however, it is recommended that the owner/operator inform DEQ whether they will do a screening level evaluation or not. Often, DEQ can make suggestions to improve efficiency in the overall process.

1.1.9 Development and Implementation of a Corrective Action Plan

Based on the results of the RE process, the owner/operator proposes a set of remediation standards and prepares a CAP describing the measures that will be used to achieve the standards. The CAP is submitted to DEQ for approval. The CAP may include a combination of options for active remediation and passive remediation along with limitations on activities and land uses that were assumed in the RE step. Details of this step are included in Section 5.

1.1.10 Evaluation of Progress Toward Remedial Goals and Modification of the Corrective Action Plan if Necessary

The data collected during implementation of the CAP must be evaluated by the owner/operator and submitted to DEQ so that DEQ can determine whether the CAP is progressing as anticipated. Modifications to the CAP may be necessary in some circumstances. Circumstances that might require modifying the CAP include identification of significant deviations from the remedial strategy or unacceptable risk levels to receptors, by either DEQ or the owner/operator. Modification of the CAP also might be required if the data indicate that site cleanup is not progressing at the rate anticipated. In these cases, appropriate modifications to the CAP should be considered and an amended CAP should be submitted to DEQ for approval The specific modifications to the CAP that are needed will vary from site to site.

1.1.11 Site Closure with a Corrective Action Plan

The primary objective of the CAP at any site is to ensure the long-term protection of human health and the environment, taking into consideration the current conditions at the site and conditions that are reasonable to expect in the future. When the regulatory obligations specified in the DEQ-approved CAP have been achieved, the site is eligible for closure. Closure typically involves the owner/operator submitting documentation that all the work specified in the CAP has been completed and all remedial action goals have been achieved accompanied with a request for site closure.

1.1.12 Certification by a Registered Professional

If work is performed that the State of Idaho requires a professional geologist or professional engineer (Idaho Code, Title 54, Chapters 12 and 28) to perform, the owner/operator shall employ the use of, and obtain certification from, a professional geologist or professional engineer registered in Idaho for that work.

Section 2. Site Discovery and Initial Steps

2.1 Determining Imminent Threats

The first step, once an impacted site has been identified or a release is known to have happened, is to determine whether contamination poses any imminent threat to human health or the environment. If so, abatement measures must be completed before any other activities. Examples of abatement measures include taking action to prevent further release into the environment, providing an alternate water supply if drinking water supplies are impacted, evacuating residents/commercial workers if they are or could be exposed to vapors at high concentrations, installing booms on surface waterbodies that have a sheen, or ventilating utility facilities where vapors are present. If there is an imminent threat, or uncertainty regarding potential threats, associated with a release, call DEQ or STATECOMM at 1-800-632-8000 or (208) 846-7610. Releases that do not pose an imminent threat do not have to be reported to STATECOMM, but do have to be reported to DEQ. Owner/operators shall follow the Petroleum Release Reporting, Release Response and Initial Abatement Measures as provided in IDAPA 58.01.02.851 and 852.

2.2 Initial Site Characterization

2.2.1 Site Characterization Introduction

Within the RE process, initial site characterization is performed after any necessary emergency response actions are completed. The overall objective of the initial site characterization is, at a minimum, to identify the maximum chemical concentrations on the site in each of the affected media. These maximum concentrations are then compared with screening level criteria to determine the need for any further action.

A brief description of the initial site characterization process is presented below.

2.2.2 Site Description and Adjacent Land Use

The owner/operator should conduct a thorough site reconnaissance and a historical review of site operations to identify source(s) of contamination on site. Sources may be identified based on knowledge of a known or documented release; location of certain structures that typically represent a contamination source such as underground storage tanks (USTs), pipes, pumps, etc.; interviews with current and former site employees who may have knowledge of source areas.

In addition to identifying sources, the owner/operator should collect data related to historic, current, and future land use on and adjacent to the site. A chronology of relevant site activities is often useful in understanding the site.

Based on this information, the owner/operator should identify the type of petroleum that may have been released at the site. Data collected during initial site characterization should, at a minimum, satisfy the following requirements:

- Quality Assurance/Quality Control (QA/QC) measures recommended by the United States Environmental Protection Agency (EPA) have been met,
- Analyte quantitation limits (the minimum amount that can be detected by the laboratory), where feasible, do not exceed screening levels,

- Appropriate petroleum COI have been identified and included for analysis,
- Source areas have been adequately characterized to identify the maximum concentration, and
- Analytical methods used are appropriate for petroleum COI at the site.

2.2.3 Soil Source Characterization

The owner/operator should collect soil data representative of the release's maximum concentration of petroleum COI. The exact number of samples, the analytical methods used, and the specific technology used to collect data will vary among sites. It is recommended, but not required, that the owner/operator develop a work plan and have it reviewed and approved by DEQ before beginning the work. At a minimum, the owner/operator should verbally confer with DEQ before collecting any data.

The overall intent of initial site characterization is to identify maximum concentrations of petroleum COI. However, for sites that will likely require further characterization, it may be efficient and cost-effective to collect additional data at this stage of the evaluation. Additional data may be used to identify the nature and extent of contamination and potential for exposure. For example, if contamination is suspected to exist in both surficial and subsurface soil zones, samples representing maximum concentrations in both zones should be collected.

2.2.4 Groundwater Source Characterization

In the initial site characterization, if there is evidence of possible groundwater impact from the site release, the owner/operator should collect groundwater samples below or immediately adjacent to the source. For sites with a very localized source, it may be sufficient to collect only one groundwater sample using a temporary well. Sites with multiple sources may require multiple wells and samples. For sites that will require further characterization, it may be more efficient and cost-effective to install at least three monitoring wells so the magnitude and the direction of groundwater flow can also be established.

2.2.5 Documentation of Initial Site Characterization

The owner/operator should document the initial site characterization results in a brief report that is submitted to DEQ. The chemical data collected should initially be evaluated using the screening levels as discussed in Section 3, all of which should be described in this report. The report should discuss:

- Site history,
- Site description,
- Current site use,
- Sources and petroleum COI identified at the site,
- Methods used to collect and analyze soil samples,
- Locations of all samples (identified on a site map), including sample depths,
- Results from soil chemical data analyses,
- Methods used to collect and analyze groundwater samples,
- Location, construction, and lithology of all wells,
- Results of groundwater chemical data analyses,
- Other site hydrogeological test data results, and
- QA/QC information.

Section 3. Screening Level Evaluation

Data collected during the initial site characterization is typically initially evaluated using screening levels. This evaluation is intended to achieve the following objectives of the screening level evaluation:

- Demonstrate that the site or portions of the site do not pose a threat to human health and hence does not require any further evaluation, and
- Identify areas of the site that need further evaluation.

These objectives are achieved by comparing the maximum site concentrations with the screening level values.

3.1 Screening Levels

The screening levels for the petroleum COI in the Rule have been developed by DEQ and are included in Table 2. The screening levels are risk-based target concentrations developed with the following:

- the assumption that receptors will be residential,
- conservative input parameter values,
- an acceptable target risk of 10^{-6}, and
- a hazard quotient (HQ) of 1.

Specific exposure factors and models used to develop screening levels are presented in Appendices A and E. Screening levels are the lowest target concentrations for the following exposure pathways and ROE for soil, soil vapor, and groundwater.

Specifically, screening levels for soil are the lowest of the following concentrations:

- Surficial and subsurface soil concentrations protective of exposure via groundwater ingestion at maximum contaminant levels (MCLs) or risk-based concentrations at the downgradient edge of the source or
- Subsurface soil concentrations protective of exposure via indoor inhalation of vapors emanating from soil for a residential scenario, or
- Surficial soil concentrations protective of combined ingestion, dermal contact, and outdoor inhalation exposures for a residential scenario.

Screening levels for groundwater are the lowest of the following concentrations:

- MCLs for chemicals that have them or calculated values for ingestion of water in a residential scenario, or
- Groundwater concentrations protective of exposure via indoor inhalation of vapors emanating from groundwater for a residential scenario.

Screening levels for soil vapor are protective of exposure via indoor inhalation of vapors emitted from contaminated soil or groundwater. Screening levels in sub-slab and near-source soil gas are derived by applying attenuation factors of 0.03, to the EPA Regional Screening Levels (RSLs) for both residential and industrial ambient air.

Table 2 lists the screening levels for unrestricted use. For comparison, Table 2 provides the risk-based concentrations in soil and groundwater for all the pathways and ROE listed above. The screening level values incorporated in the Rule are indicated in bold.

Because of the methods and assumptions used in the development of the screening levels and the current limitations of laboratory analytical methods, the calculated screening levels may be lower than the practical quantitation limit reported by a laboratory for selected chemicals. In these situations, site-specific review by DEQ will be required based on the criteria provided in Section 500 of the Rule and Appendix K.

Table 2. Screening Level Concentrations for Soil, Groundwater, and Soil Vapor

	SOIL (mg/kg)			GROUNDWATER (mg/L)		TARGET SUB-SLAB AND NEAR-SOURCE SOIL GAS CONCENTRATIONS (ug/m3)	
						Unrestricted Use	Commercial/ Industrial
CHEMICAL	Vapor Intrusion	Direct Contact	Groundwater Protection	Vapor Intrusion	Ingestion	Vapor Intrusion	Vapor Intrusion
Benzene	0.08	8.3	**0.025**	0.044	**0.005**	**12**	53
Toluene	1300	7930	**6.6**	340	**1**	**170000**	733333
Ethylbenzene	**0.25**	39	7.4	**0.05**	0.700	**37**	163
Xylenes	**27**	6100	93	**8.7**	10	**3500**	14667
Naphthalene	**0.12**	44	21	**0.07**	0.73	**2.8**	12
MTBE	2.4	340	**0.08**	6.8	**0.04**	**360**	1567
1,2-Dichloroethane	0.02	3.7	**0.013**	0.03	**0.005**	**3.6**	16
Ethylene Dibromide	0.001	0.27	**0.00014**	0.004	**0.00005**	**0.16**	0.67
Acenaphthene	NA	4470	**200**	NA	**2.2**	NA	NA
Anthracene	NA	22300	**3200**	NA	**11**	NA	NA
Benzo(a)anthracene	106	1.4	**0.68**	0.60	**0.00022**	**0.56**	6.67
Benzo(a)pyrene	NA	**0.14**	2.1	NA	**0.0002**	NA	NA
Benzo(b)fluoranthene	NA	**1.4**	2.29	NA	**0.00022**	NA	NA
Benzo(k)fluoranthene	NA	**14**	22.5	NA	**0.0022**	NA	NA
Chrysene	NA	139	**69**	NA	**0.022**	NA	NA
Fluoranthene	NA	2970	**1400**	NA	**1.5**	NA	NA
Fluorene	NA	2970	**240**	NA	**1.5**	NA	NA
Pyrene	NA	2230	**1000**	NA	**1.1**	NA	NA

Values in bold are current screening level values. Screening level values for sub-slab and near-soil gas concentration are equivalent to EPA Regional Screening Levels (EPA, 2018) for residential and industrial ambient air divided by an attenuation factor of 0.03.

NA: not applicable because the chemical does not meet EPA volatility criteria or does not have a Regional Screening Level for ambient air.

3.2 Comparison of Site Concentrations with Screening Levels

Based on the initial site characterization (discussed in Section 2), the owner/operator should identify the maximum soil and ground water petroleum COI concentrations at the site. These maximum concentrations are then compared with screening levels, obtained from Table 2.

If the maximum site concentration does not exceed the screening level for any petroleum COI in any media, the site is eligible for closure subject to other regulatory obligations (IDAPA 58.01.24.200) The owner/operator may request DEQ approval for site closure. If the maximum site concentration for any petroleum COI exceeds the screening level, the owner/operator must select one of the following options:

- Option 1: Adopt screening levels as cleanup remediation standards and develop a CAP (see Section 1).
- Option 2: Perform a more detailed, site-specific RE.

The owner/operator should clearly indicate to DEQ which option has been chosen.

3.3 Screening Level Evaluation Report

The owner/operator must submit a screening level evaluation report to DEQ if they have chosen option 1 above. The report should include, at a minimum:

- Site maps indicating land use, structures on site, locations and depths of samples, and locations of contaminant sources,
- A description of site history and activities leading to the release,
- A description of current land use adjacent to the site,
- A summary of initial site characterization results for soil and, as appropriate, groundwater,
- A discussion of data quality,
- A comparison of maximum soil and, as appropriate, groundwater concentrations with screening levels,
- A list of recommendations, and
- Laboratory reporting sheets, including QA/QC data.

Section 4. Site-Specific Risk Evaluation

Site-specific RE is needed only if the owner/operator chooses not to conduct a screening level evaluation or to use the default screening levels as the remediation standards.

Conducting a site-specific RE requires the completion of several important steps. These include developing an SCM, identifying the chemicals present in environmental media, assessing exposure and exposure pathways, assessing the toxicity of the chemicals present, characterizing human risks, and characterizing the impacts on or risks to the environment. This section describes each of these steps and also provides the suggested format for some of the deliverables (most of which are reports) that assist in developing and documenting the evaluation.

4.1 Site Conceptual Model

An SCM provides an overall understanding of the site and an SCM report can be a convenient format for compiling all the relevant data associated with a release. The SCM provides a framework for the entire project and can help identify specific data needs (the correct quality and quantity of data that will be needed). An SCM is necessary in the development of any data collection work plan and is also an important communication tool for regulators, owner/operators, and stakeholders.

In addition to basic site information (discussed in section 4.1.1), there are three key elements that should be included in the SCM. Each element will require certain types of data in order to validate the SCM. The amount of data required is typically based on site-specific considerations. The SCM is a dynamic entity that should be revisited and potentially refined any time additional data is collected for a site. The resulting SCM refinements should be incorporated, if necessary, into the RE.

The three key elements are:

- **Sources**: Contaminant source areas (nature, magnitude, and extent of release) and COI (see section 4.1.2).
- **Pathways**: Release fate and transport mechanisms, exposure pathways, and ROE (see section 4.1.3).
- **Receptors**: Characteristics of land use and likely receptors (see section 4.1.4).

More detailed information on these elements is provided below and in the sections on data requirements (section 4.2) and exposure assessment (section 4.3).

4.1.1 Site Characteristics

The following basic site characteristics should be included in the RE; each is described in the following sections:

- Site history and map,
- Ground surface conditions,

- Location of utilities on and adjacent to the site, and
- Location and description of site structures.

4.1.1.1 Site History and Map

The SCM should include a comprehensive chronology of events including remediation projects, tank removal activity, reported releases, etc. The chronology of events must be clearly and accurately documented.

All maps should be made to scale, with a bar scale and a north arrow. As appropriate, multiple site maps should be prepared to show sample collection points and locations of various site structures. A detailed facility map showing the layout of USTs, above ground storage tanks (ASTs), pipes, loading and unloading areas, sumps, paved and unpaved areas, canopy buildings, etc. should be prepared. A second facility map should be prepared to show locations of all on-site monitoring wells, water use wells, soil borings, soil vapor extraction wells, and soil excavation areas. All on-site structures should be clearly identified.

4.1.1.2 Ground Surface Conditions

Before conducting an RE, DEQ highly recommends the owner/operator and any other parties that will be involved make a site visit and walk through. It is important to document areas of the site that are paved, unpaved, landscaped, or covered with buildings. It is also highly useful to note the type, extent, slope, and general condition of the ground surface, and current land uses.

4.1.1.3 Location of Utilities on and Adjacent to the Site

Due to potential for preferential flow of contaminated groundwater and vapors into underground utility lines and conduits, a thorough documentation of the location of and potential impacts to underground utilities should be performed. Utilities may include phone lines, water lines, sanitary sewers, storm sewers, and natural gas lines. A combination of site observations, knowledge of buried utilities, and discussions with utility representatives and the site owner should reveal the utility locations.

At a minimum the following activities should be performed:

- Locate all underground utility lines and conduits within the area of known or potential soil and groundwater impact, both on site and off site, where the release may have migrated, or may migrate in the future.
- Determine the direction of flow in the utilities (water, storm water, and sewage).
- Identify utility lines/conduits on a base map that illustrates the extent of soil and groundwater impacts.
- Determine depth of utility lines/conduits relative to the depth of groundwater. Seasonal fluctuations of groundwater levels should be carefully evaluated. As appropriate, a cross-sectional diagram should be provided illustrating the depth to groundwater and the locations and depths of the lines/conduits.
- Determine any past impacts to utilities and any pertinent complaints that may have been previously filed with DEQ.

4.1.1.4 Existing Structures

The location, condition, and construction characteristics of each structure on and adjacent to the site should be described.

4.1.2 Contaminant Source Areas

This element of the SCM should include a discussion of the nature, location, timing, and magnitude of petroleum products spilled at the site. The petroleum COI should be determined. Any actions performed as a part of emergency response should be delineated and their impact on the source evaluated. The residual size of the source after any emergency or interim actions should be determined.

Knowledge about the nature, magnitude, and extent of the release is necessary to identify the petroleum source in soil and/or the groundwater at the site as well as to identify the petroleum COIs. The following information regarding a release, if available, is critical:

- Release location,
- Release quantity,
- Petroleum product released, and
- Interim corrective action measures performed.

Release-related information can be obtained by reviewing inventory records, interviewing current and past employees, and checking any spill incident reports filed with DEQ. Information related to site activities can also help identify source location and petroleum COIs.

4.1.2.1 Location of Release

The location of the release defines the source of the petroleum that is in the soil and potentially the groundwater. Likely release locations include, but are not limited to, corroded or damaged tanks, pipe bends and joints, and loading and unloading areas.

The owner/operator should review operational history to determine the likely location of the source. The assessment should focus on the identified release area; however, the exact location and timing of the spill source area may not be known. In these cases, soil and groundwater sampling should be used to identify the extent (vertical and horizontal) of residual soil and/or groundwater source. The exact number and location of necessary samples shall be determined on a site-specific basis using professional judgment. It will be important to understand the location and timing of past spills and releases in making decisions regarding assessment needs related to current releases. It is recommended, but not required, that the owner/operator consult with DEQ before conducting sampling. DEQ may be able to provide information at this point that can help the owner/operator improve the overall efficiency of sample collection or the entire RE.

4.1.2.2 Quantity of Release

The RE process does not necessarily require knowledge of the exact release quantity. However, an estimate of the amount released may help evaluate the severity of the impact and extent of contamination, and may help in planning site characterization measures. Estimation of release quantities is typically based on inventory records.

4.1.2.3 Chemicals of Interest and Spatial and Temporal Trends

This section should include a discussion of chemicals detected in each media and their spatial and temporal distribution. As appropriate, contour maps indicating concentrations of individual petroleum COIs may be useful. Graphs of petroleum COI groundwater concentrations in individual wells and concentration along the flow line (concentration vs. distance plots) may be useful as well. Based on data collected over time, it should be determined whether the chemical concentrations are stable, declining, or expanding.

Identification of specific petroleum product(s) spilled or released is important to identify the petroleum COIs. Evaluation of non-petroleum chemicals in addition to those in Subsection 800.01 (Table 1) may be required by DEQ when there is a reasonable basis based on site-specific information. A reasonable basis shall be demonstrated by DEQ when it can show documentation of releases or suspected releases of other non-petroleum chemicals. The environmental behavior (mobility, persistence, bio-degradation, and inter-media transport) of the petroleum product and its adverse environmental and human health effects depend on chemical properties and their concentrations in the petroleum product.

If a release can be identified as a single petroleum product based on a documented release, free product analysis, or location of impact (e.g., tank bottom of a particular product tank), only the COIs for that petroleum product need to be analyzed. If the product released cannot be conclusively identified, it is recommended that monitoring samples be analyzed for all petroleum COIs associated with the products suspected to have been stored at the site. Additional assessment may be required to identify the source of the release.

If previously collected data did not include all suspected site petroleum COIs, additional sampling may be necessary for petroleum COIs before an RE can be performed.

4.1.3 Pathways and Transport Mechanisms

The objective for this portion of the SCM is to describe site characteristics and mechanisms which have influenced or will influence the release, fate, and transport of chemicals of interest and to determine which exposure pathways and ROE will be most likely to occur.

4.1.3.1 Site Stratigraphy and Hydrogeology

The owner/operator should conduct a review of published literature and any investigations conducted on adjacent sites to determine regional hydrogeology, soil types, and aquifer characteristics. This evaluation should be used to determine the type and depth of aquifers in the area and whether they are confined, semi-confined, or unconfined. Regional information will help the owner/operator in efficiently collecting site-specific soil and groundwater information. The SCM should include a detailed discussion of site-specific stratigraphy and hydrogeology. Site stratigraphy should be determined based on boring logs and an adequate number of geologic cross sections.

The hydrogeologic discussion should include estimates of horizontal and vertical hydraulic gradients, seasonal variations in groundwater elevations and flow direction, and hydraulic conductivity of relevant water-bearing zones. How these characteristics may influence the fate and transport of chemicals to potential receptors should be discussed.

The survey should also locate potentially impacted surface waterbodies located within one-half (1/2) mile of the site. If a surface water body is identified, information including the type (perennial or intermittent), water flow rate, flow direction, depth of water, width or surface area of the water body, and water use should be provided. The location of the water body must be indicated on an area map.

4.1.3.2 Complete Exposure Pathways and Routes of Exposure

A complete exposure pathway involves a source of petroleum products, release and transport mechanisms, ROE, and potential receptors. The definition of complete exposure pathways starts with knowledge of the release, petroleum COIs, and site physical conditions (described above), then combines these with assumptions about land use and likely receptors. Exposure pathways and ROE are described and discussed in more detail in section 4.3.3.

The SCM should identify each of these components in its descriptions of exposure pathways. One example of a common exposure pathway would be leaching of petroleum chemicals from a gasoline release in soils (release) to the groundwater with subsequent transport (fate and transport) to a residential well where water is extracted for drinking water and ingested by residents (land use and likely receptors). Another would be volatilization of petroleum chemical vapors from a soil source with subsequent transport through the soil and into the air in an occupied structure where they are inhaled.

Another part of defining the complete or potentially complete exposure pathways and ROE in an SCM is identifying the locations where exposure to petroleum chemicals can occur and the media of concern at those locations. These known or potential exposure locations are commonly called exposure units. The exposure unit for each complete pathway and receptor should be described. The exposure unit may consist of a specific location such as a well or it may be an area, such as a parcel, over which receptors move. For large sites, it may be useful or necessary to subdivide the site into multiple exposure units. This may also be true at sites where impacts of the release have moved offsite.

Exposure pathways defined in the SCM are subsequently used in the exposure assessment phase of the RE, which is described in detail in section 4.3.

4.1.3.3 Protection of Groundwater

During the development of the SCM, it should be assumed groundwater may be used for drinking water. Consequently, if groundwater is not remediated to levels suitable for ingestion, the CAP must also include provisions in the final remedy for implementing limitations on activities and land uses. Such limitations are achieved through environmental covenants (activity and use limitations [AULs]) to prevent exposure via groundwater ingestion throughout the horizontal and vertical extent of the plume that has concentrations exceeding the criteria for groundwater ingestion presented in Table 2.

The SCM, as it relates to the use of groundwater, should include characterization and evaluation of the following groundwater aspects.

- The current and historical use of the groundwater for drinking water or irrigation.

- The location and approved use of existing groundwater wells within a one-half (1/2) mile radius from the release point at the contaminated site.
- The potential for communication between the impacted groundwater and other groundwater-bearing zones or surface water.
- The location of delineated source water protection areas for public drinking water systems.

This information, along with other data collected for the evaluation, will be used to determine if groundwater ingestion is a complete exposure pathway in the SCM, and will guide the selection and use of appropriate remedial target concentrations, measures, timeframes, and compliance conditions.

A water well survey should be conducted to identify all water use wells within a one-half (1/2) mile radius. Information sources include the U.S. Geological Survey, the Idaho Department of Water Resources (IDWR), water system operators, and local residents. If available, well characteristics including depth, water use, and screened interval should be documented. It is necessary to identify any dewatering wells located within a 1,000-foot radius of the site (or greater if the groundwater plume is extensive).

Land use considerations include, but are not limited to:

- Current zoning and land use. Consultation with local planning and zoning officials regarding future land use planning direction and interpretation of planning and zoning policies.
- Land use development trends. Conversion of agricultural land to residential land uses requires development of drinking water sources. The proximity of these conversions to urban centers and available public drinking water supplies should be taken into account.
- Local ordinances that include agreements with IDWR governing well drilling or state-designated restrictions or specifications for constructing wells into groundwater in a locality for drinking water purposes.
- The existence of source water assessment delineations and source water protection plans and ordinances associated with public drinking water supplies.
- The availability of alternative water supplies.

4.1.4 Land Use and Receptors

This portion of the SCM describes the current and future assumptions about land use as they relate to identifying potential receptors. The identification of land uses includes both the site of the release as well as adjacent properties which may be impacted by the release.

4.1.4.1 Land Use

Evaluating current and reasonably likely future land uses at and adjacent to the release site is a critical component when determining potential exposure points, exposure pathways, receptors, and exposure factors during the RE process and when determining cleanup concentrations.

Residential land use generally requires lower target concentrations. Cleanup to residential standards will usually allow unrestricted land use. Whenever assumed land use is other than

residential and cleanup is not to residential standards, DEQ may require that an AUL be imposed on the property through the use of an environmental covenant.

Residential land uses include use by sensitive subpopulations. Examples of land uses with sensitive subpopulations include but are not limited to hospitals, nursing homes, schools, childcare centers, farms with houses, and any other areas/structures with sensitive human activity.

The owner/operator should submit to DEQ illustrated land use maps clearly identifying current land uses at the site and the adjacent properties. One map should clearly show the area within one-half (1/2) mile of the known or likely extent of contamination. At sites where there is likelihood that the extent of impacts may be greater, due to the magnitude of the spill or other site-specific conditions, a land use map covering the entire impacted and potentially impacted area is necessary. A walking land use survey should be conducted for the area within a 500-foot radius of the source, with an emphasis on the down-gradient direction and potential offsite impacts. The survey should clearly identify the following: schools, hospitals, residences (apartments, single-family homes, and others), day care centers, nursing homes, and types of businesses. In addition to this survey, efforts should be made to identify structures with basements (which may enhance the transport of contamination) in areas in closer proximity to the source and where site conditions warrant it, such as where shallow groundwater or non-aqueous phase liquid (NAPL) is present. The map should also identify surface water bodies, parks, recreational areas, wildlife sanctuaries, wetlands, and agricultural areas.

Current land use refers to land use as it exists today and that can be readily determined by a site visit. A site visit should identify homes, playgrounds, parks, businesses, industries, or other land uses at, and in close proximity of, the release site. As appropriate, state or local zoning boards; the U.S. Census Bureau; zoning, topographic, land use, housing and other types of maps; and aerial photographs can provide information for determining land use.

Undeveloped land should be characterized by the most likely future use of that property, considering current zoning restrictions. If the undeveloped parcel is located in a predominantly nonresidential area, nonresidential classification may be appropriate. However, if the setting is more rural or land-use is mixed, the undeveloped land should be considered residential unless the owner/operator develops and implements an AUL as a part of a DEQ-approved CAP.

The exposures to be evaluated in an RE depend upon the activities that could occur under likely future uses of land and groundwater at the site. The future groundwater use should be consistent with the most likely future land use.

For example, consider property that is currently used as farmland. If the impacted farmland includes a residence, the current land use is residential. However, if the owner/operator provides information establishing clear plans to develop the residence into a nonresidential building in the near future, the likely future use may be evaluated as nonresidential.

While evaluating likely future land use(s) presents uncertainties, DEQ has identified certain factors that assist in this evaluation. These factors include, but are not limited to, local zoning ordinances; knowledge of current land use and changing land use patterns; zoning decisions; community master plans; interviews with current property owners; nonresidential appraisal

reports; proximity to wetlands, critical habitat, and other environmentally sensitive areas, such as source water protection areas; and the use of remedial action institutional controls at a site.

Assumed future land use designations other than residential must be justified and there should be a high likelihood that the land will be used for those purposes. Absent such a justification, DEQ will consider the residential land use scenario as the default future land use.

Site characterization will include a determination of the on-site and off-site areas of impact. These areas are considered in determining the pathway-specific exposure units for each type of receptor. Exposure units are discussed in more detail in section 4.3 and Appendix I.

4.1.4.2 Receptors

The objective of the RE is to quantify the adverse health effects to current and potential future receptors both onsite and offsite. For simplification, the following definitions should be used:

- On-Site –The area located within the legal property boundaries within which the source of the release is located. This includes soil, groundwater, surface water, and air within those boundaries. Adjacent property purchased subsequent to the release will be considered off-site.
- Off-Site –The areas of concern located outside the boundaries of the property where the release source is located. This includes soil, groundwater, surface water, and air located outside the property boundaries.

In a residential exposure scenario, risk is evaluated for either a child receptor or a composite receptor, depending on the specific exposure route, and whether the petroleum COI is noncarcinogenic, carcinogenic, or carcinogenic with a mutagenic mode of action. The composite receptor is based on an exposure duration of 30 years, and for some chemicals and exposure routes risk calculations incorporate modifications based on exposure occurring at different life stages.

For land uses other than residential, a typical receptor might be a commercial or industrial worker where the risk to adults is considered. Finally, under a construction scenario adult construction workers are considered. If warranted by site-specific conditions, other types of receptors may need to be defined and evaluated.

4.1.4.3 Ecological Risk Considerations

In addition to identifying potential impacts to human receptors the SCM should also attempt to identify potential pathways by which sensitive habitats, such as wetlands, surface water bodies, or other ecologically significant environments near the site, may be impacted by the release where wildlife may be the potential receptors.

Threatened and endangered species that may be exposed to site-specific chemicals should be identified. Note that within the RE process, protection of surface waters and streams is independent of ecological RE. As appropriate, a walking survey in the vicinity of the site may be necessary to identify ecological receptors.

Contact DEQ to obtain additional guidance on these issues.

4.2 Data Requirements and Evaluation

Once the SCM has been developed, an evaluation of data collection needs, data quality needs, and data collection methodology should be conducted. Depending on the amount and complexity of the proposed data collection effort, a work plan may be needed to guide the data collection process. The suggested contents of this work plan are discussed in section 4.7.

This section describes general data collection objectives and requirements for the RE process. This includes the general QA/QC considerations to help ensure the data collected is of sufficient quality and quantity to meet desired objectives, the categories of data necessary to meet these objectives, and data collection techniques.

Data collection objectives for RE include, but are not limited to:

- Accurately characterize the magnitude, nature, and extent of contamination, including the characterization of petroleum chemical concentrations for all impacted media, as appropriate,
- Allow the development and/or validation of an accurate SCM, and
- Develop sound estimates of risks posed by the release.

4.2.1 Data Collection Planning

Sound data collection planning involves a careful review of all available site information and data for its suitability in the RE. This process, in the context of the SCM, should identify any data gaps with the goal of determining the types, locations, quality, and numbers of samples or measurements needed.

Depending on what stage of the RE process is in for a given site, the relative importance of each objective described above will vary and specific data requirements will also vary. The goal of data collection for RE is to efficiently reduce uncertainty in those areas that contribute the most to potential or actual risk and for which the greatest uncertainty exists.

For example, it may be determined through the SCM that vapor intrusion represents the largest potential source of risk at a site, but little is known about subsurface conditions which may impact exposure point concentrations and only soil or groundwater data are available. In order to more realistically model this pathway, it may be most effective to better characterize subsurface stratigraphy and properties, document the conditions supporting biodegradation, and collect soil vapor data.

At many impacted sites, data collection efforts may have been conducted multiple times over an extended period of time. For example, interim corrective action measures may have been undertaken prior to planning for the RE. Soil and groundwater data collected prior to such activities may not be representative of current conditions and generally should not be used in RE. At such sites, collection of additional soil and groundwater concentration data may be needed after completion of interim corrective measures.

The exact number of samples required is a site-specific decision based on the balance between cost and representativeness and requires professional judgment and expertise. Numerous tools are available to assist in estimating the number of samples required for statistical analysis, but

none provide a definitive number and statistical analysis may not be practical in many cases. These tools include, but are not limited to, data quality objectives (DQO) and statistical and geo-statistical evaluation. Selected references to assist in developing and completing sound data collection efforts are listed in section 7.2.

4.2.2 Quality Assurance/Quality Control Considerations

The RE process relies on site-specific data to make decisions related to the magnitude of site risk, nature and extent of remedial activity, and site-closure. Thus it is very important that data be reliable, representative, complete, and of known quality.

In order to assure the data will be of appropriate quality, QA/QC activities must be applied to all environmental data collection activities throughout the RE process (site characterization, risk evaluation, remediation implementation, and monitoring).

Elements of QA/QC include:

- Using approved methodologies to collect data,
- Decontaminating field equipment as appropriate,
- Using EPA approved methods for laboratory analysis, and
- Including QA/QC samples, such as duplicates, equipment blanks, trip blanks, etc.

While the level of QA/QC applied to data collection efforts will vary (depending on factors such as site complexity, size of the release, and the immediacy of the response) all the elements of QA/QC described above that were used during a given data collection effort should be provided to DEQ when reporting the results of environmental sampling. This will allow an adequate review of the quality of the data used in the analysis.

If a work plan is submitted to DEQ for approval, it should include a QAPP. The QAPP integrates the appropriate technical and quality aspects of a project, including planning, implementation, and assessment. The purpose of the QAPP is to document planning for the collection of environmental data and to provide a project-specific "blueprint" for obtaining the type and quality of data needed for a specific decision or use. The QAPP documents the QA/QC procedures applied to various aspects of the project to assure that the data obtained are of the type and quality required.

The EPA has developed guidance for the development of QAPPs which can be obtained at: *http://www.epa.gov/quality/qs-docs/g5-final.pdf.*

To further assist in the development of a QAPP, DEQ has also developed an abbreviated QAPP template. The purpose of the template is to provide the user with an annotated outline format of a QAPP with all the required elements. From there, it is a simple matter to fill in appropriate site-specific information applicable to each element. The QAPP template is reproduced in Appendix L. This template is periodically updated. Contact DEQ for the latest version.

Documentation of all QA/QC efforts implemented during data collection, analysis, and reporting phases is important to data users, who can then consider the impact of these control efforts on data quality.

The QAPP is implemented during the data collection process. Problems can be identified and corrected at this stage. The impact of field and laboratory techniques and sampling and analysis conditions on data quality are determined using field and laboratory QC samples and periodic audits. Oversight and corrective action can prevent improper procedures or techniques from continuing.

Data verification, validation, and assessment should be performed to validate data quality and assess data quality and usability. Data verification and validation is particularly dependent on compliance with field and laboratory procedures for sample collection, identification, handling, preservation, chain of custody management, shipping, analysis, and reporting.

EPA provides several guidance documents to assist in performing data verification and validation (EPA, 1999; EPA, 2002a). The EPA Contract Laboratory Program National Functional Guidelines for Organic Data Review (EPA, 1999) provides guidance on data verification and validation of contract laboratory program (CLP) data, but may also be used as guidance for non-CLP data. EPA 2002a provides more generic guidance on conducting these tasks.

4.2.3 Documentation of the Data Collected

Once data have been collected, a field investigation report should be prepared and include:

- Dates when data were collected and names of individuals who collected the data.
- A list of data collected and reference to any work plan that may have been followed.
- All data collected, clearly tabulated, and contoured (if necessary),
- All boring logs and relevant cross-sections, where appropriate, to depict site stratigraphy,
- All QA/QC data, laboratory results, data validation and verification, assessment of data usability, and chain of custody forms,
- Contour maps of groundwater potentiometric surface indicating the predominant direction of groundwater flow, and
- A discussion of the SCM.

4.2.4 Data Collection Methods

The common categories of data that are the focus of data collection efforts for RE include:

- Vadose zone soil characteristics,
- Saturated zone characteristics, and
- Distribution of petroleum COIs in soil, soil vapor, groundwater, and surface water bodies.

DEQ has developed default values for many of the vadose and saturated zone characteristics that affect the fate and transport of petroleum COIs. These values are presented in Appendix B. For site-specific REs, these default values can be used or site-specific values can be established. This appendix describes typical collection methods for those properties of the vadose zone and saturated zone important for RE. It also addresses the collection of chemical concentration data from these media.

4.2.5 Vadose Zone Soil Characteristics

The vadose zone or unsaturated zone soil is the media through which petroleum COIs can migrate to the groundwater and vapors can move upward to the surface and into an enclosed space. Thus, characteristics of vadose zone soils have considerable impact on risk estimates and target concentration calculations. Relevant vadose zone characteristics include:

- Vadose zone thickness and depth to groundwater,
- Bulk density,
- Porosity,
- Water and air content, and
- Fractional organic carbon content.

In addition to parameters mentioned above, additional site-specific, pathway-specific parameters that may be valuable to measure include:

- Vapor permeability, effective diffusion coefficient, and building characteristics where indoor inhalation is a potentially complete pathway, and
- Infiltration rates for developing a detailed evaluation of the potential for leaching to groundwater.

4.2.5.1 Thickness of Vadose Zone and Depth to Groundwater

Vadose zone thickness is determined from boring logs. This thickness is the distance from the ground surface to the depth at which the water table is encountered, less capillary fringe thickness.

Depth to groundwater is used in estimating vapor emissions from groundwater. For indoor inhalation, depth to groundwater below the "floor" of an existing structure of concern or the most likely location of a future structure should be used.

For sites with considerable seasonal fluctuation in water table level, depending on the data available and the nature of the fluctuations, a yearly average depth or a time-weighted depth may be used. The vadose zone depth that is estimated should also form the basis for the selection of soil samples to be used in evaluation of subsurface soil vapor emissions to indoor air. Shallower water table depths often result in groundwater target levels set at lower concentrations to be protective of inhalation pathways.

4.2.5.2 Porosity

Porosity is the ratio of the volume of voids to the total undisturbed field volume of soil. Many laboratories use dry bulk density and specific gravity data to determine porosity using the following equation:

$$n = 1 - \rho_b / \rho_s \qquad (4\text{-}1)$$

where,

n = porosity (cubic centimeter per cubic centimeter [cc/cc])

ρ_b = dry bulk density (grams per cubic centimeter [gm/cc])

ρ_s = specific gravity or particle density (gm/cc)

Dry bulk density is the dry weight of a soil sample divided by the field volume of the soil sample. An accurate measurement of bulk density requires determining the dry weight and volume of an undisturbed sample. This method involves collecting a core of known volume, using a thin-walled sampler, such as a Shelby tube or similar coring device, to minimize disturbance of the sample, and transporting the core to a laboratory for analysis. This method is described in American Society for Testing and Materials (ASTM) Method D2937-00, Standard Test Method for Density of Soil in Place by the Drive-Cylinder Method (ASTM, 2000a).

The Standard Test Method for Specific Gravity of Soil, ASTM Method D854-00 (ASTM, 2002), may be used to determine specific gravity. If specific gravity is not assessed, then 2.65 gm/cc can be assumed as the particle density.

Consideration should be given to collecting multiple samples if multiple lithologies are present that might affect COI transport.

If site-specific values of porosity are not available, it should be estimated based on values provided in an appropriate literature source.

4.2.5.3 Volumetric Water Content/Moisture Content

Volumetric water content is the ratio of water volume to the total soil volume. The ASTM Method D2216-98, Standard Test Method for Laboratory Determination of Water [Moisture] Content of Soil and Rock by Mass (ASTM, 1998) is a gravimetric oven-drying method; however, the water content value used in most models is the volumetric water content.

Hence, it may be necessary to use the following equation to convert gravimetric water content to a volumetric basis:

$$\theta_{wv} = \theta_{wg} * \frac{\rho_b}{\rho_l} \qquad (4\text{-}2)$$

where,

θ_{wv} = volumetric water content (cc water/cc soil)

θ_{wg} = gravimetric water content, typically reported by the laboratory (gm of water/gm of soil)

ρ_b = dry bulk density (gm of dry soil/cc of soil)

ρ_l = density of water (gm/cc)

Volumetric water content can also be measured in the field through the use of a variety of instruments such as a neutron probe, time domain reflectometer, or gypsum block sensors. For more information on these methods, see Part VII of Wilson et al. (2000).

4.2.5.4 Fractional Organic Carbon Content in Soil

Fractional organic carbon content is the organic carbon weight in the soil divided by soil weight and is expressed either as a ratio or as a percent. The Walkley Black Method (Page et al., 1982)

is a chemical oxidation method (rapid dichromatic oxidation) while ASTM Method 2974-00 is a furnace method (ASTM, 2000b) for determining fractional organic carbon content in soil. Results are usually reported as percent organic carbon content. The reported value can be converted to a fraction by dividing by 100.

If measurements of total organic matter content are available, they should be divided by 1.724 to estimate the fractional organic carbon content. This adjusts for the portion of soil organic matter that is actually carbon. Typically, total organic carbon content is estimated using ASTM Method 2974-00. Organic carbon content should be determined using soil samples not impacted by the release.

4.2.6 Saturated Zone Characteristics

Petroleum COIs that reach the water table typically travel horizontally through the saturated zone. However, if a vertical gradient is present, chemicals may also move vertically in the direction of the gradient. Saturated zone characteristics that determine the travel time and direction for the petroleum COIs include:

- Horizontal hydraulic conductivity,
- Horizontal and vertical hydraulic gradients (magnitude and direction), and
- Saturated zone soil characteristics (fractional organic carbon content and porosity).

4.2.6.1 Hydraulic Conductivity

Hydraulic conductivity is the discharge of water per unit area per unit hydraulic gradient in a subsurface formation. Estimates of site-specific hydraulic conductivity can be obtained by conducting aquifer tests such as slug or pump tests. Data gathered during the tests are then analyzed using appropriate methods. Slug tests are easier to conduct than pump tests, generate no wastewater for treatment, and may be more appropriate for low-permeability formations. The primary disadvantages are the small aquifer volume that is explored, resulting in the need to conduct multiple tests across the site. Properly conducted pump tests will often provide better estimates of hydraulic conductivity. The simplest pump tests are single-well short-duration (2 to 4 hours) tests. The best pump tests employ a pumping well and multiple observation wells and are of longer duration (12 hours or more). These tests will identify boundary effects. Regardless of the type of test conducted, different methods of data analysis will often yield different estimates of hydraulic conductivity. ASTM Method D4043 provides guidance on the selection of aquifer test methods (ASTM, 1996).

In the absence of these tests, estimates of hydraulic conductivity may be obtained from literature, with values corresponding to the type of soil in the saturated zone, using empirical equations based on the grain size distribution of the porous formation, or they may use specific capacity data from well logs of wells in the vicinity of the site that are representative of the aquifer being investigated. In either case, adequate references and justification for the value chosen should be provided.

4.2.6.2 Hydraulic Gradient

The magnitude and direction of the hydraulic gradient is estimated by comparing water levels measured in the monitoring wells. Typically, water level contour maps are prepared based on

measured data using a computer program or manual calculations along with professional judgment. Calculations done using automated procedures should be spot-checked with hand calculations. Three wells or more are needed to adequately estimate the direction of flow and magnitude of the gradient. When drawing the contour maps, care should be taken to ensure that the measurements used are from monitoring wells that are screened in the same interval or hydrologic unit.

For sites that have seasonal variation in hydraulic gradient, estimate the average hydraulic gradient for each season. Consideration should also be given to determining any vertical gradients. This requires a comparison of adjacent water levels in wells screened in different intervals.

In areas where the shallow aquifer has been impacted and a deeper aquifer is used for drinking water, the vertical gradient should be determined. When drilling deep wells, care should be taken to avoid cross contamination.

4.2.6.3 Saturated Zone Soil Characteristics

In addition to hydraulic conductivity, other important saturated zone soil characteristics include fractional organic carbon content, porosity, and bulk density. These parameters are required to quantify the movement of chemicals within the saturated zone. The laboratory methods to measure these parameters were discussed in section 4.2.5.

4.2.7 Indicators of Biodegradation

Biodegradation of petroleum chemicals occurs in all media (soil, soil vapor, groundwater). Depending on the media, different indicators (chemical concentrations, geochemical indicators, microorganisms, oxygen, and carbon dioxide) can be measured at a site to demonstrate the occurrence of biodegradation of these organic substances.

When evaluating the potential for biodegradation in groundwater, these indicators are commonly classified into three groups: primary, secondary, and tertiary lines of evidence. Data collected under each line of evidence can be evaluated qualitatively or quantitatively to determine the occurrence of biodegradation.

The primary line of evidence demonstrates spatial stability or a reduction in chemical concentrations at a site by evaluating measured concentrations within monitoring wells, groundwater velocity, rates of contaminant transport, and time of the release.

The secondary line of evidence refers to measurement of geochemical indicators including reduction-oxidization (REDOX) potential, dissolved oxygen, dissolved nitrates, manganese, ferrous iron, sulfate, and methane. These indicators should be measured in at least three wells located along the flow line, one of which should be located at a background or up-gradient location, one within the plume near the source, and one within the plume down-gradient from the source.

The tertiary line of evidence involves microbiological studies such as identification of types of subsurface microbial populations and microbe cell counts.

Commonly used methods to estimate biodegradation rates include mass balance analysis for expanding, stable, or shrinking plumes and plots of plume concentration vs. distance. Additional details on biodegradation for petroleum COIs in groundwater are provided in Appendix H.

When evaluating the potential for, or presence of, biodegradation in soil or soil vapor, the most common indicators used are soil vapor concentrations, oxygen, and carbon dioxide. These are commonly measured at multiple depths in the subsurface and related to a potential source. More information on evaluation of biodegradation of petroleum vapors in relation to the vapor intrusion pathway is provided in Appendix G.

4.2.8 Distribution of Petroleum Chemicals of Interest

Petroleum COI may be distributed between soil, soil vapor, groundwater, surface water, and sediments present at a release location. Knowledge of contaminant distribution entails a determination of the spatial extent and magnitude of concentrations in each of these media, where they are present.

4.2.8.1 Distribution of Petroleum Chemicals of Interest in Soil

Adequate soil concentration data are necessary to estimate risk to receptors, compare representative concentrations for each complete pathway to target levels, and define the soil source dimensions. Sufficient data should be collected to define horizontal and vertical extent of impacts. The vadose zone investigation(s) should be organized to:

- Identify the horizontal and vertical extent of soil impacts. Unless otherwise directed by DEQ, the extent of impact should be defined as those areas where petroleum COI concentrations exceed screening level concentrations.
- Identify areas of maximum concentration of petroleum COIs.
- Collect samples adequate to estimate exposure point concentrations for the potentially complete exposure pathways that have been defined based on the SCM.

To determine the spatial extent of contamination, soil borings should be drilled starting from the known or suspected source area and drilling outwards until borings with sample concentrations at or below screening levels are reached in all directions. To determine the vertical extent of contamination, soil borings should be extended to the base of petroleum impact and samples collected from surface and subsurface soil zones as explained in the following sections.

The soil analytical data should help identify the soil source area. If more than one source area is identified at a site, each source area should be evaluated separately. Once the soil source(s) is identified, source dimensions can be estimated. These dimensions are used in the computational software which accompanies the guidance and rule, along with other input parameters, to estimate risk and RATL concentrations protective of indoor inhalation and to evaluate the soil to groundwater leaching pathway. Depth to subsurface soil source (used to estimate the target concentrations) should be the depth, in the source area, from the surface to the zone where concentrations are above quantification limits. Professional judgment should be used in choosing the representative depth.

4.2.8.1.1 Surficial Soil Sampling

The RE process distinguishes between surficial soil and subsurface soil zones. Surficial soil is defined as the soil zone from the ground surface to 1 foot below ground surface. Pathways that may apply to the surficial soil zone include direct contact exposure via incidental ingestion, inhalation of vapors and particulates, dermal contact, and leaching of petroleum COIs to groundwater and surface water.

Evaluation of soil exposure pathways within the surficial soil zone requires collection of an adequate number of soil samples to estimate both maximum and representative concentrations of all potential petroleum COIs. Given the small vertical depth interval of this soil zone, close attention should be given to vertical variations in contamination. The acceptability of vertical depth-composite samples versus samples from discrete depth intervals is a site-specific decision. Criteria that influence this decision include the type of petroleum COIs, vertical extent of contamination, and areal extent of the contaminated zone. Sampling within the surficial soil zone is typically done from test pits using hand samplers such as trowels or corers.

The presence of impervious (paved) surfaces poses difficulties for sampling. In some cases, very permeable material may be located 2 inches below the pavement. Residues from the paved surface may also be present. When sampling beneath impervious surfaces, sampling should begin 2 inches or deeper below concrete or asphalt pavement. Cracked areas in impervious surfaces may represent conduits for chemical migration or leaching and should be evaluated during the selection of sampling locations.

4.2.8.1.2 Subsurface Soil Sampling

Soil below the surficial soil zone (more than one foot below ground surface) and extending to the water table is termed the subsurface soil zone. Pathways evaluated for this zone include volatilization from soil to indoor air and leaching to groundwater and surface water. Most receptors will not have direct exposure to this soil. However, some construction workers may be involved in excavation activities below the surficial soil zone and subsurface soil removed during excavation may be deposited at the surface allowing greater exposure. This possibility should be considered during the development of the SCM.

To test for indoor inhalation of vapors from subsurface soils, it is preferable to collect soil vapor data however soil data can also be used. Soil samples should be collected to characterize the complete horizontal and vertical extent of contamination. Soil moisture conditions and soil vapor permeability are also important parameters affecting soil vapor transport. If petroleum contamination exists adjacent to existing structures, additional sampling should be focused in these areas. More information on evaluation of the vapor intrusion pathway is provided in Appendix G.

To test for exposure to a construction or utility worker during excavation activities, soil samples should be collected from both surface and subsurface soil zones to depths where construction-related activities are likely to occur.

To test for leaching of petroleum COIs in soil to groundwater, it is critical to determine the thickness of the contaminated soil zone, the distance from the bottom of the contaminated zone to the water table, if any, and representative concentrations of petroleum COIs within the contaminated zone.
