Fugitive dust emissions from mine wastes and mechanical processes associated with the hard rock mining industry such as crushing of sulphide ore and concentrates, and mechanical disturbance and wind erosion of uncontained mine tailings [10,53] are also associated with elevated levels of arsenic [17–19,54]. This is not surprising given that mine wastes and tailings are often characterized by extremely high arsenic concentrations. Concentrations in tailings ranging between 2250 and 21,400 $mg \cdot kg^{-1}$ have been detected in the Zimapan mining district in Mexico [55], and in some historical gold mine waste disposal areas in Victoria, Australia, concentrations of up to 15,000 $mg \cdot kg^{-1}$ have been recorded [56]. The preferential enrichment of arsenic in the finer size fraction in mine tailings [21,57] suggests that re-suspended dusts are characterized by higher arsenic content than the material from which it is suspended.

2.3. A Global Issue

The magnitude of the problems associated with arsenic contamination from mining operations is a serious ongoing issue in many localities throughout the world, and there are no indications of abatement. If the projected increase in global copper production over the next 20 years is correct [58], it could be reasonably expected that smelter emissions, and the generation of flue dust and other

associated waste products, will also increase [39]. Furthermore, despite an overall increase in the number of coal plant retirements in some localities [59], the global demand for coal is predicted to rise at a rate of 1.3% per year, from 147 quadrillion Btu in 2010 to 180 quadrillion Btu in 2020 and 220 quadrillion Btu in 2040 [60]. Expansion of coal consumption reflects substantial increases in China and India [60]. In India, arsenic-contaminated fly ash from coal combustion processes occupies more than 65,000 acres, rendering the surrounding land unsuitable for agriculture [61].

Although not increasing substantially, the number of abandoned mines worldwide runs into millions [62], and their impact is likely to increase due to population growth and urban expansion. In the United States of America, 80% of an estimated 46,000 known abandoned mine sites require further investigation and/or remediation [63]. In Australia, there are more than 50,000 registered abandoned mines ranging from isolated minor surface works to more extensive and complex sites [64,65] In Mexico, the area affected by mining activities is estimated to be over 21.7 million hectares [66]. Each year in China the mining industry produces wastes that occupy an additional 2000 ha [67], and around 4000 Mt of tailings are stockpiled on land that is urgently needed for other purposes [68].

Given the widespread geographical distribution of arsenic-rich mine wastes and the global reliance on smelting and coal combustion for various products and services, the systematic characterization and ongoing monitoring of particulate arsenic generated by mining operations are becoming increasingly important for reliably determining the impacts on human health and the environment [45].

3. Monitoring and Assessment

A number of monitoring and assessment studies have been undertaken for different purposes: (i) to identify the dominant emissions sources of arsenic; (ii) to predict the potential contribution of an identified arsenic emission source to the atmosphere; and (iii) to identify the airborne arsenic species (Table 1). For monitoring and reporting purposes, atmospheric total arsenic concentrations are often compared with the annual mean target value of 6 $ng \cdot m^{-3}$, as set by current European Union air quality standards [69]. According to the World Health Organization (WHO) [70], the excess lifetime risk of contracting lung cancer if continuously exposed to 6.6 $ng \cdot m^{-3}$ is 1:100,000.

The different methodologies used to collect PM from mining operations are reflected in the contrasting size fractions and reporting units listed in Table 1. Air monitoring programs use various types of sampling equipment to collect PM, and the arsenic content of the PM is typically reported in terms of $ng \cdot m^{-3}$. Measurement of total suspended particulates (TSP) was the United States of America standard for atmospheric aerosol until the discovery of the relationship between particle size and lung deposition of inhaled particles [71].

The smaller the particle, the deeper it will travel into the respiratory tract (RT) and PM_{10} (particulate matter $\leq$10 μm) represents the upper limit for tracheobronchial and alveolar deposition in the human lung [72]. To meet the new PM_{10} health-based standard (adopted by the USA, Europe and elsewhere during the mid to late 1980s), collection devices such as the cascade impactor and multiple orifice uniform deposit impactor (MOUDI) have been used in various atmospheric monitoring studies [10,18,54]. These sampling systems are designed to collect a pre-selected suite of aerodynamically-fractionated samples which enables a systematic investigation into the arsenic content of particulates of interest to health. The relationship between particle size and human exposure will be reviewed in detail in Section 4.

Particulate arsenic may also be measured in size-fractionated mine waste samples generated through dry sieving bulk samples [21,57]. Similar to the cascade impactor mentioned above, this method facilitates a systematic characterization of collected mine waste samples but reports the concentrations in terms of $\mu g \cdot g^{-1}$. While this technique cannot provide a quantitative assessment of atmospheric arsenic at a particular location, the data may be useful for predicting potential particulate arsenic emissions from the source.

Atmospheric arsenic concentrations vary between localities and the type of emission source (Table 1). The following sub-sections examine the contribution of each emission source to atmospheric arsenic levels in various localities throughout the world.

3.1. Smelting

Much of the atmospheric arsenic research and monitoring published to date has focused on emissions from smelting operations. This reflects the dominant contribution by smelter emissions to global anthropogenic atmospheric arsenic inputs. As reviewed in Matschulatt [3], copper and zinc smelting activities contribute of 12,800 and 2210 t of arsenic respectively into the atmosphere per year, whereas steel production contributes a comparatively lower annual quantity of 60 t per annum. It should also be noted that in some industrial localities, smelting and other processes associated with the manufacturing of ceramic materials represent important sources of arsenic in the atmosphere [27]. Smelting operations produce the greatest localized air and soil arsenic concentrations while coal combustion distributes arsenic to the air in substantially lower concentrations over a wider area [73].

In the vast majority of case studies summarized in Table 1, concentrations exceeded, and in some cases, greatly exceeded, the annual WHO-prescribed target value [70]. In one extreme case, an average concentration of 330 $ng \cdot m^{-3}$ was reported in TSP collected approximately 1 km from a complex lead-copper smelter in Belgium [4]. Similarly, a maximum arsenic concentration of 572.3 $ng \cdot m^{-3}$ (mean, 93.9 $ng \cdot m^{-3}$) was recorded in TSP collected in the vicinity of a smelter in Walsall, UK, during an air monitoring program conducted between 1972 and 1989 [26]. Interestingly, a declining trend in atmospheric arsenic levels was reported at all of the UK monitoring locations, except the Walsall smelter site [26]. The authors postulated that widespread industrial switching from coal combustion to oil and gas as a domestic energy source for space heating was the probable cause for the overall decline in atmospheric arsenic in the UK [26]. Similar results were recorded in an industrial area in Spain, whereby reductions in atmospheric arsenic concentrations were significantly associated with decreases in industrial activities, specifically the production of ceramic materials [27].

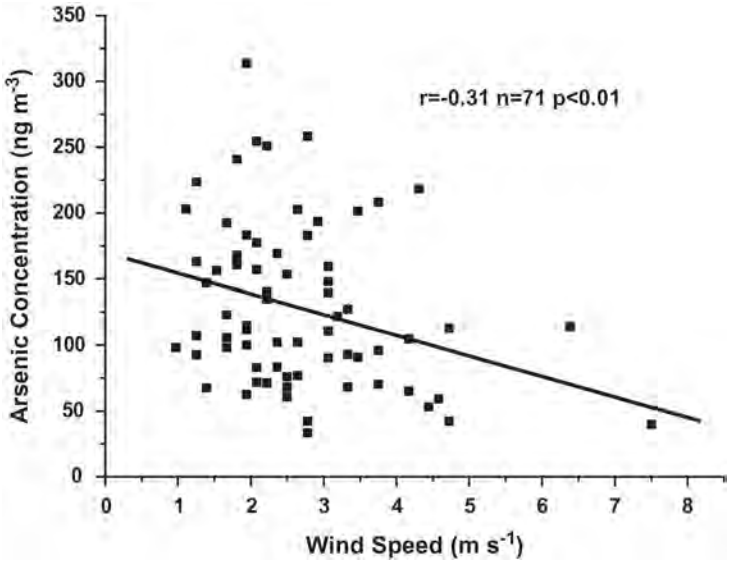
Although the quantification of arsenic in TSP provides one measurement of arsenic contamination in the atmosphere, this measurement may underestimate the respiratory health risks to nearby communities due to the inverse relationship between particle size and arsenic content. After the introduction of particle size-selective criteria, various studies have measured and compared arsenic content in the PM_{10} and $PM_{2.5}$ fractions collected in the vicinity of smelting operations (Table 1). Data from these studies suggest a general trend for preferential enrichment in $PM_{2.5}$ [74–76]. For example, an air monitoring study conducted approximately 3.5 km from the Huelva copper smelter in southwestern Spain found that 85% of the total arsenic concentration in the PM_{10} size fraction was concentrated in $PM_{2.5}$ [77]. Similar studies conducted in the same locality yielded comparable results [74,75]. In contrast to these findings, one study reported that $PM_{2.5}$ collected in the vicinity of a

copper smelter in Tacoma, WA, USA, contained only 37% of the total arsenic in the PM_{10} fraction (calculated from Polissar *et al.* [78]). These results highlight the importance of site-specific investigations during health-based risk assessments.

The greatest atmospheric arsenic levels generated by smelting operations occur in close proximity to the smelter, and decrease with increasing distance from the source [4,76,77]. Multiple reports suggest that the maximum concentrations are typically found within 1 km of the smelter site [4,78–81]. Furthermore, declines in concentrations have been observed over a relatively short distances. For example, atmospheric arsenic levels at a distance of 1 and 2.5 km from a complex copper-lead smelter in Belgium were 330 and 75 $ng \cdot m^{-3}$, respectively [4]. These results were supported by a complementary soil-based study that documented an exponential decline in soil arsenic and heavy metal concentrations within 1 km of a lead smelter in the Czech Republic, followed by a less-steep decrease between 1 and 6 km [37].

Meteorological variables, particularly surface wind circulation, play a critical role in determining the transport and spatial distribution of the pollution plume from smelting operations [82]. Contrary to the general trend between concentration and distance from the emission source, Serbula *et al.* [81] reported average arsenic levels of 131.4, 51.3 and 93.7 $ng \cdot m^{-3}$ at respective increasing distances of 0.8 (town park), 1.9 (institute) and 2.5 km (Jugopetrol) from a copper smelter in Bor, eastern Serbia. Compared with the mid-distance sampling location (institute), the farthest sampling location (Jugopetrol, which is downwind from the pollution source) experienced high-frequency exposure to the emissions as a result of dominant WNW and NW winds. To further highlight the impact of prevailing wind direction, the maximum concentration reported at Jugopetrol was equal to the maximum recorded at the sampling location closest to the smelter (Table 1). Similar relationships between atmospheric arsenic (and other metals), and surface wind characteristics in the vicinity of copper smelters have been documented [74,83]. In addition to wind direction, wind speed plays an important role in determining particulate arsenic distribution from smelting operations. The greatest concentrations of arsenic (and other metallic elements) emitted from the copper smelter in Bor occurred during calm conditions (wind speed less than 0.5 m/s) [38]. Low wind speeds inhibit the dispersal of local pollution away from the emission source and can therefore lead to very high localized concentrations of atmospheric pollutants [38].

3.2. Coal Combustion



Global coal combustion contributes an estimated 6240 t of arsenic to the atmosphere each year, equating to approximately half the contribution from copper smelting [3]. Atmospheric arsenic concentrations in coal combustion emissions are generally lower and typically distributed over a wider area. As a possible result of these two factors, coal combustion as a source of atmospheric arsenic has received less attention in the literature compared with copper/zinc/lead smelting.

Much of the research into coal combustion as a source of atmospheric arsenic has been undertaken in China (Table 1), and a recent review article listed this source as one of the key contributors to atmospheric arsenic in this country [84]. The mean atmospheric arsenic concentration for 32 localities across China was 51 ± 67 $ng \cdot m^{-3}$ (range, 0.03–200 $ng \cdot m^{-3}$). However, in heavily industrialized areas such as around Beijing, concentrations may be substantially greater [9].

Given that high temperature processes are typically associated with fine and accumulation-mode particles, arsenic levels in PM_{10} and $PM_{2.5}$ are frequently reported [85–88]. Comparable average PM_{10} arsenic concentrations were recorded in Beijing (58.3 $ng \cdot m^{-3}$) and nearby Taiyuan (43.36 $ng \cdot m^{-3}$) whereas the average $PM_{2.5}$ concentration in Ji'nan (40 $ng \cdot m^{-3}$) was almost double that of Beijing (23.08 $ng \cdot m^{-3}$ Table 1). These values greatly exceed the recommended target value of 6 $ng \cdot m^{-3}$.

Wind conditions appear to play an important role in the dispersal of atmospheric arsenic emitted by coal combustion sources [9]. Consistent with the trend found in the vicinity of smelting operations, one study [9] reported a statistically significant negative correlation between atmospheric arsenic concentration and wind speed in Beijing, China ($R = -0.31$, $p < 0.01$; Figure 2).

Figure 2. Relationship between total atmospheric arsenic concentration and wind speed in Beijing, China, for the period February 2009 to March 2011. Reprinted from Yang *et al.* [9] with permission from Elsevier.

3.3. Mine Tailings

Research into mine tailings as a source of atmospheric arsenic has gained momentum in the last decade. Mine tailings have the potential to generate high levels of dust with extremely high atmospheric arsenic concentrations, particularly in arid and semi-arid environments [10]. The Rosh Pinah lead and zinc mine and ore processing plant in Namibia reported a maximum arsenic concentration of 9140 $ng \cdot m^{-3}$ (median, 4970 $ng \cdot m^{-3}$) in wind-blown dust from tailings that cover more than 60 ha and are more than 20 m high [89]. Comparable with the trend observed around smelting operations, the impact of mine tailings on atmospheric arsenic levels are typically greatest at the source [11,17,18,54]. At the Rosh Pinah mine and ore processing plant atmospheric arsenic levels decreased from 4970 $ng \cdot m^{-3}$ at the tailings dam to 60 $ng \cdot m^{-3}$ at a distance of 2.5 km from the mine [89]. This relationship is most likely a result of the short atmospheric residence time of coarse particles (≥2.5 μm) typically found in mine tailings [10].

Arsenic enrichment in the finer fractions of size-fractionated mine tailings has been reported [19,21,57]. Although these findings are not reflective of actual atmospheric arsenic emissions from a particular source, the finer size fractions are more susceptible to wind-borne transport and are most likely to be re-suspended by wind or mechanical disturbance. Kim *et al.* [21] examined the distribution of arsenic

concentration as a function of particle size in mine tailings samples collected from two different localities in the Randsburg historic mining district in south-central California, USA. Although there were distinct differences in the arsenic distributions amongst the wastes, there were obvious inverse relationships between grain size and arsenic concentration. The high arsenic content recorded in the dust size fraction of each sample (range, 356–8210 ppm) illustrates the potential of their corresponding sources to generate potentially hazardous emissions [21].

The effects of seasonality on particulate arsenic emissions from mine tailings have also been investigated. Meteorological factors associated with different seasons, especially rainfall and temperature, have been shown to have a dramatic impact on arsenic mobility through the air [54,90]. During the dry summer months in the City of Lavrion, Greece, concentrations of arsenic in PM_{10} increased dramatically (more than 6 times) compared with concentrations during late winter [54,90]. Similarly, a study in Aznalcazar, southwest Spain, found that sporadic rainfall and low convective atmospheric dynamics during the late winter were associated with relatively low re-suspension of PM from heavy metal mining wastes [54]. During summer, the combination of intensive convective circulation and low rainfall facilitates surface drying leading to enhanced re-suspension of PM. Low rainfall and decreased humidity lead to increased atmospheric particulates, and therefore, increased atmospheric arsenic concentration [90].

3.4. Arsenic Speciation in Particulate Matter

Environmental arsenic exists in four oxidation states including As(V), As(III), As(0) and As(-III) [91,92]. The most common forms of arsenic in the environment include the trivalent (arsenite) and pentavalent (arsenate) species [93], and they are often found occurring together [94,95]. Under oxidizing conditions, such as in surface soils and water, arsenic typically occurs in the pentavalent form [92], whereas in sufficiently reducing environments, or in the presence of a reducing agent, arsenite is the dominant form [94,96]. It is widely recognized that arsenite species have greater mobility in the environment [97] and are reported to be 25 to 60 times more toxic than the corresponding pentavalent forms [98]. Since the oxidation state of arsenic in soil, water, and other environmental matrices is one of the key factors governing toxicity, speciation analysis is of interest in human exposure studies.

Speciation analysis has been used widely for the identification and quantification of arsenic species in bulk samples of surface soils and mine wastes [94,95,99,100]. However, comparatively less work has been conducted in relation to arsenic speciation in atmospheric PM generated by mining operations [9,18,44,74–76,83]. Research conducted to date indicates that both arsenate and arsenite may co-exist in smelter, coal combustion and gold roaster emissions [9,44,45,74–76,83,94] although reported levels for the trivalent species are generally much lower than those for the arsenates (Table 1). For example, arsenate and arsenite concentrations in coal combustion emissions in China were 67 and 4.7 $ng \cdot m^{-3}$, respectively [9]. Similarly, Oliveira *et al.* [83] reported respective arsenate and arsenite concentrations of 10.4 and 1.2 $ng \cdot m^{-3}$ in copper smelter emissions in Spain. The presence of arsenite in smelter emissions may result from the reduction of arsenate by aerosol sulphur dioxide S(IV) complexes during transport of the emission plume [101].

Airborne monitoring programs combined with speciation analysis demonstrate clearly that airborne arsenic is a serious and ongoing issue in mining communities and heavily industrialized areas throughout the world.

Table 1. Summary of the average, minimum and maximum total arsenic (TAs) concentrations recorded in particulate matter (PM) from various mining operations, including smelting, coal combustion and mine waste. Values for TAs are expressed as nanogram per cubic meter ($ng \cdot m^{-3}$) unless otherwise specified. Where applicable, all units of distance measurement have been converted to metric system.

Source	Location	Size Fraction (Time Period)	Distance (km)	TAs (Min–Max)	As(III) (Min–Max)	As(V) (Min–Max)	Ref.

4. Human Exposure

Communities living in the vicinity of mining operations may be exposed to airborne arsenic-contaminated particulates and be at risk of health deterioration though absorption after dermal and eye contact, or by ingestion after inhalation [28]. However, arsenic absorption through the skin following dermal and eye contact is a minor contributor compared with ingestion and inhalation exposures [25] and will not be further discussed here. Furthermore, incidental ingestion of arsenic-contaminated particulates, usually as a result of contaminated food or water supplies, has been the most thoroughly investigated pathway, and its significant range of adverse effects have been well documented following acute, intermediate and chronic exposures [25], negating the need for further detailed review here.

For the general population, ingestion is typically considered the primary exposure pathway to arsenic, and inhalation of arsenic bearing PM has been considered to be a minor exposure route [2]. The relatively neglected topic of inhalation exposure with consequent issues linked to airborne PM containing arsenic species from proximate mining industries needs to be addressed. For example, exposure assessments of communities living in the vicinity of smelting and coal combustion operations suggest that inhalation may play a similar, if not more important role than ingestion, in the overall exposure to airborne particulate arsenic [4,105–107]. In addition, it has been shown that children are particularly susceptible to inhalation exposure due to: (i) their increased likelihood of coming into contact with dust [78]; and (ii) children inhale a greater volume of air than adults relative to their size [108].

Therefore, in the following sections we will consider some of the ways in which inhaled arsenic-contaminated particulates generated by mining operations may lead to systemic absorption, toxicity, and arsenic-related disease endpoints. In order to understand how arsenic becomes mobile (or bioavailable) and exerts its toxic effects in the human body, we will begin with a discussion on the fate of inhaled particles in the RT with particular emphasis on the role that particle size plays in determining the ultimate absorption or defense mechanisms.

4.1. Deposition Location and Particle Clearance from the Respiratory Tract (RT)

The location and manner in which PM is deposited in the RT are critical for understanding how the arsenic-bearing particles might react with different lung constituents. When PM is inhaled, a proportion of the particles are retained while the remainder are expelled via exhalation. Retained particles are deposited in different regions of the RT according to their size [109–111] and as a general rule, the smaller the particle the deeper it will penetrate into the RT and the longer it will be retained (Table 2; [72,112]). To protect the body against foreign materials, the human respiratory system has developed a range of physiological lines of defense [113,114]. We will review the deposition location of inhaled particles as a function of particle size, the methods of clearance from each location, and pathways for absorption. When referring to the different "deposition regions", we use the morphometric model described by the International Commission on Radiological Protection [115]. This model divides the human RT into three major anatomical regions: (i) the extra-thoracic; (ii) the tracheobronchial, and; (iii) the alveolar, which are modeled deposition locations for the inhalable, thoracic and respirable particulate size fractions, respectively [116].

Table 2. Deposition of PM_{10} in different regions of the human respiratory tract [115,116] as a function of particle size (data from Newman [72]), including the estimated retention time of the particle size in each deposition location (data from Bailey [112]).

Anatomical Region (Corresponding Particulate Size Fraction)	PM Size (μm)	Deposition Location	Retention Time
Extra-thoracic (Inhalable)	7–10	Nasal passage	1 day; small fraction may be retained for longer
	5–7	Pharynx	Few minutes
Tracheobronchial (Thoracic)	3–5	Trachea	Few minutes
	2–3	Bronchi	Hours to weeks
	1.0–2.5	Terminal bronchioles	Hours to weeks
Alveolar (Respirable)	0.5–1.0	Alveoli	50 to 7000 days

4.1.1. Extra-Thoracic Region (Inhalable Particulate Fraction)

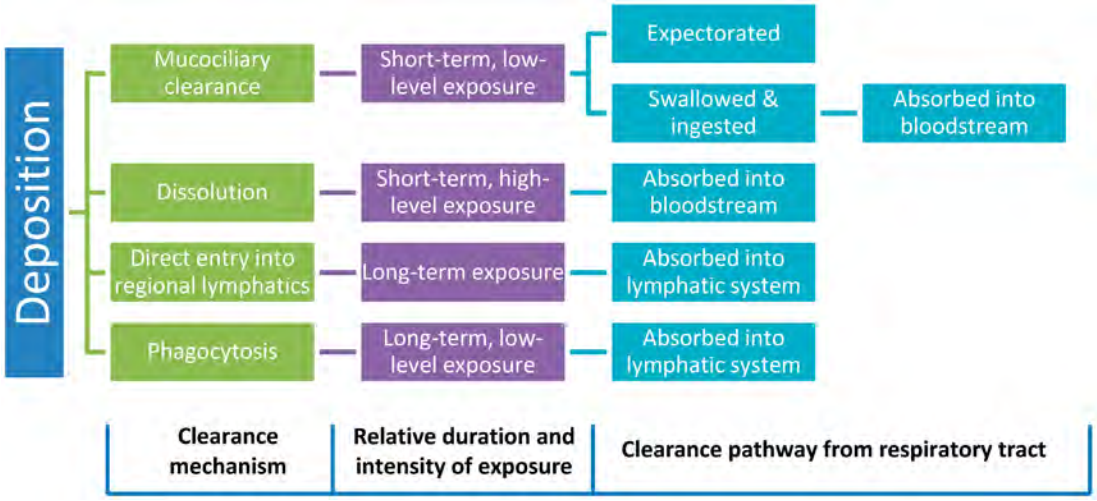
The inhalable particulate fraction (particles up to 10 μm in size) consists of particles that can be deposited into the extra-thoracic region and become trapped in the nasal cavity [109], mouth [116] and pharynx [117]. The vast majority of particles deposited in the extra-thoracic region are removed via a combination of nose-blowing, sneezing and mucociliary transport to the gastrointestinal (GI) tract [117]. Nose-blowing clears from 0.5% to 50% of particles from the front of the nose, while the remainder is slowly cleared into the GI tract [117]. Particles in the pharynx may reach the GI tract within one hour following deposition [117], and a very small proportion (around 0.05%) may be absorbed directly via the pharynx epithelium and cleared into the blood or lymphatic system [117]. Ingestion is therefore the dominant exposure pathway to particles deposited in the extra-thoracic region.

4.1.2. Tracheobronchial Region (Thoracic Particulate Fraction)

The thoracic particulate fraction is comprised of particles (1–5 μm in size) that penetrate the extra-thoracic region [116] and deposit in the tracheobronchial region. This region consists of the trachea, bronchi and terminal bronchioles [115]. Particles deposited here are of particular importance because lung carcinomas occur preferentially in the bronchial airways [110]. Particles trapped in the mucous produced by the bronchial epithelial cells are typically cleared by mucociliary transport into the throat, and then expectorated or swallowed [28,114,118]. While it is generally accepted that mucociliary transport is the principal clearance mechanism in the first 24 h [118], the rate of clearance depends upon on the clearance velocity of the mucous, particle shape, charge and surface geochemistry [119]. Furthermore, the ciliary movement is ineffective if the mucous is not of the correct viscosity due to illness or pharmacological action [109]. Other clearance mechanisms from the tracheobronchial region include coughing, absorption through airway epithelium into the blood or lymphatic system, and phagocytosis [113,118], and depending on the method of clearance, particles can be retained in the RT for weeks (Table 2; [112]). As described in sub-Section 4.2, the solubility of the particle plays an important role in determining which clearance mechanism is employed and the duration of the retention.

4.1.3. Alveolar Region (Respirable Particulate Fraction)

Airborne particles ≤1 μm can be deeply inhaled into the unciliated airways of the lung (the alveolar region) and absorbed directly into the pulmonary circulation system [113]. Alternatively, these particles may be phagocytosed and cleared by alveolar macrophages, and then either absorbed into regional lymph nodes via lymphatic vessels [120] or transported into the ciliated airways and cleared via mucociliary transport [121]. This latter process may take weeks to months to complete [122]. Alveolar macrophages are important cells of the immune system, exhibiting major phagocytic abilities and in response to inflammatory reactions, release reactive oxygen species (ROS). Under normal exposure conditions, the components of the inflammatory reaction interact synergistically with ROS to eliminate foreign material from the respiratory system [123].



4.2. Effects of Exposure Duration and Solubility

Variation in the solubility of different arsenic compounds is important for exposure and risk assessment studies [57]. In the case of short-term inhalation exposure (minutes to hours), the number of particles in the RT decreases over time until all particles have been cleared via phagocytosis and/or mucociliary transport [124]. Deposited particles containing soluble arsenic compounds may expose nearby cells to a high concentration of arsenic [125], which rapidly declines as the dissolved arsenic is removed from the lungs [126] via absorptive mechanisms through the airway epithelium [127]. Lantz *et al.* [128] proposed that this exposure regime would reduce the time for interaction with pulmonary cells and tissue. Less soluble particles on the other hand that are retained in the lung expose the target tissue to arsenic for a longer period of time (up to weeks), as observed in rodents after intratracheal instillation of inorganic arsenic compounds of varying solubility [125,126,129,130].

In the case of long-term exposure (days to years), a steady state between deposition and clearance will be reached and the retained fraction will remain in the lungs for most of the exposure period [110]. Consequently, retention of particles containing soluble and slightly soluble arsenic compounds, especially those particles deposited in the alveolar region and sequestered in the lymph nodes, may expose cells to low doses of arsenic for a prolonged period of time. It is frequently reported that long-term, low-level exposures to arsenic may be predictive of toxic effects [126,131,132] and the pathogenesis of lung diseases, such as lung carcinoma [130].

Figure 3 illustrates that following inhalation, arsenic can follow different pathways leading to systemic absorption, and each pathway is highly dependent upon particle solubility and method of clearance. Systemic exposure to arsenic may occur as a result of ingestion following mucociliary clearance, by dissolution in the lung fluid, direct entry into lymph nodes, or by phagocytosis. Systemic exposure to arsenic following inhalation of arsenic-bearing particulates could therefore be considered as a multi-pathway process with differing durations and intensities of exposure.

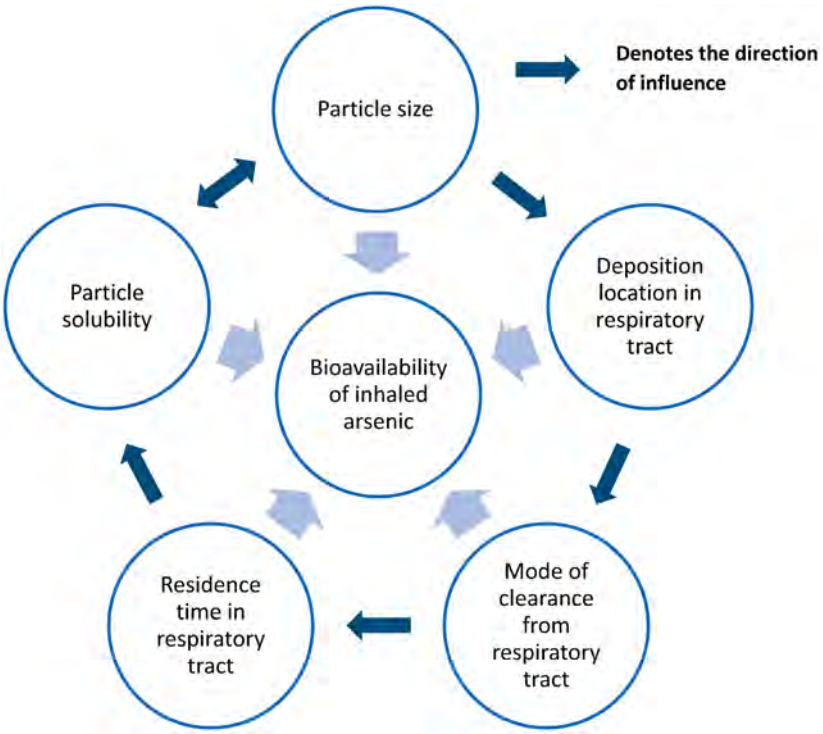
Figure 3. Potential pathways leading to systemic absorption of inhaled arsenic, including clearance mechanisms and their associated durations and intensities of exposure. Adapted from Wang [120].

4.3. Pulmonary Bioavailability of Inhaled Arsenic

The bioavailable fraction of arsenic is considered to be an important determinant of toxicity and the associated disease response [133]. The term bioavailability may be interpreted in a number of different ways [134], however and for the purposes of this review paper, the terms bioavailability and bioaccessibility will be used in accordance with the definitions prescribed by Ng *et al.* [135]. Briefly, the portion of a contaminant that is absorbed into the body following exposure is referred to as the bioavailable fraction and is typically measured *in vivo* [135]. Bioaccessibility on the other hand refers to the soluble fraction of a compound following *in vitro* gastrointestinal or pulmonary extraction, and may be used as a surrogate for estimating the bioavailability of a contaminant [135].

In order to assess the relative risk of inhalation exposure to metal-laden particles of various origins, simulated lung fluids (SLF) such as Gamble's solution and artificial lysosomal fluids (ALF) have been used in various studies [136–139]. Gamble's solution is an electrolyte fluid similar in composition to that of interstitial fluid with a pH near 7.4, and aims to mimic the aqueous component of the lung [140]. ALF is analogous to the fluid produced by macrophages during phagocytosis [141] and has a pH of around 4.5 [137]. Biological fluid pH is an important parameter governing the solubility of arsenic and other metals. For example, arsenic solubility measured as a percentage of the total arsenic concentration of mine waste, was reported as 36.6% in simulated stomach fluid (pH 1.2) and 0.4% in SLF (pH 7.5) [57], suggesting that an acid medium is required for arsenic dissolution. When determining pulmonary arsenic bioaccessibility, it may therefore be prudent to also investigate the behavior of arsenic in the more acidic ALF solution.

A limited number of studies aimed at comparing the bioaccessibility of other metallic compounds in SLF and ALF solutions reported significantly higher dissolution rates of potentially toxic metals in ALF [137,139]. Conversely, Plumlee *et al.* [142] found that SLF (near-neutral pH) was effective in leaching arsenic from dust samples collected from a dry lake, and the oral and inhalation bioaccessible arsenic fractions found in these particular dust samples were comparable. While it is important to note



that the contrasting results between these studies highlight the importance of site-specific bioaccessibility assessments, they also indicate that certain arsenic species are relatively mobile at near-neutral conditions. Furthermore, the differences may also be attributed to the contrasting dissolution times used in each study: the mine waste and the dry lake dust samples underwent dissolution times of around 2 h [57] and 24 h [142], respectively. Given that fine particles may be retained in the RT for prolonged periods of time (Table 2), incubation duration is a particularly important parameter in bioaccessibility studies.

Pulmonary bioaccessibility tests may be more reliable predictors of bioavailability than the widely-used aqueous solubility tests, since Rhoads and Sanders [125] reported that arsenic, and other metals with low aqueous solubility, were highly soluble in the lungs of rats. A more recent study observed that SLF was more effective than deionized water at leaching arsenic in the ≤20 μm size fraction of soil impacted by fire, with leachate concentrations of 19 and 2 μg/L, respectively [143].

4.4. Summary

A summary of some of the key factors governing bioavailability of inhaled arsenic-bearing particles is proposed (Figure 4). Particle size governs the deposition location of inhaled particulates in the RT. Knowledge of the location and solubility of deposited particles is important for predicting the methods of clearance from and retention time in the RT, and therefore the types of lung fluids with which the particles may interact. Contact with pulmonary fluids can then release arsenic from inhalable arsenic-bearing particulates. Since the retention of arsenic in the body is predictive of toxicity and the pathogenesis of disease [126,131,132], the long-term pulmonary bioavailability of arsenic represents important consideration in the health risk assessment of populations living in mining-affected regions.

5. Importance of Metabolic Transformation in Arsenic Toxicity

5.1. Arsenic Biomethylation

The role of metabolism in arsenic toxicity has been the subject of several detailed reviews [144–149] therefore the following discussion will provide an overview of the key concepts only. Methylation is the major metabolic pathway for ingested inorganic arsenic in most mammals, and occurs via alternating reduction of pentavalent arsenic to the trivalent state, followed by oxidative addition of a methyl group [146,150–153]. Biotransformation of inorganic arsenicals occurs primarily in the liver with an estimated 70% [154] of metabolites readily excreted in urine [147,155–157]. The remaining portion deposits differentially in other target organs and tissues including the kidneys and the lungs, as well as keratinized tissues such as skin, nails, and hair [158–161].

In terms of clearly understanding arsenic biochemistry and toxicology, arsenic methylation presents a complex problem because the metabolic sequence (Figure 5) yields at least six distinct products, each with its own unique toxicology: arsenite, monomethylarsonic acid (MMA^V), monomethylarsonous acid (MMA^{III}), dimethylarsinic acid (DMA^V), dimethylarsinous acid (DMA^{III}) and dimethylthiolarsinic acid ($DMTA^V$) [146,162,163]. Various studies have demonstrated that the unstable trivalent intermediary products, MMA^{III} and DMA^{III}, are highly reactive and substantially more toxic than the inorganic and pentavalent compounds [149,152,162,164,165]. Arsenic methylation is therefore widely considered to be a bioactivation pathway rather than a detoxification process [144], with the resulting toxicity closely linked to the methylation status and valence state of the metabolites [166]. Therefore, understanding the arsenic biomethylation pathway is critical to elucidating its subsequent action as a toxin and carcinogen [167].

5.2. Oxidative Stress as a Mode of Action for Arsenic Carcinogenesis

Although several modes of action for arsenic carcinogenesis have been presented in the literature including oxidative stress, suppressed DNA repair, altered methylation patterns, genotoxicity and cell

proliferation [144], the oxidative stress theory has been intensively investigated and is supported by a substantial mass evidence [168–171]. Oxidative stress refers to an imbalance between the production of reactive oxygen species (ROS), or free radicals, and antioxidant defense mechanisms [172]. Free radicals are characterized by the presence of unpaired electrons and the associated reactivity can lead to tissue injury [173].

The first oxidative stress theory for arsenic proposed that a minor metabolite of DMA^V, dimethylarsine (a trivalent arsenic compound), is produced via a process of reduction *in vivo* [170], possibly following a reaction between DMA^{III} and specific coenzymes important for cellular respiration [174]. Dimethylarsine is estimated to be around 100 times more toxic than DMA^{III} which is a potent genotoxin in its own right [174]. Dimethylarsine can react with molecular oxygen forming the dimethylarsenic ($(CH_3)_2As$) radical, and the superoxide anion O_2^- [175]. Through the addition of another molecule of oxygen, the dimethylarsenic radical forms the dimethylarsenic peroxyl ($(CH_3)_2AsOO$) radical. Finally, the hydroxyl radical ($HO^{\cdot}$) can be produced via reaction with cellular iron and other transition metals [170,175].

Although an excessive production of ROS, such as superoxide anion and hydroxyl radical, is commonly associated with impaired cellular functions, DNA damage and carcinogenesis [144,175,176], the dimethylarsenic and/or dimethylarsenic peroxyl radicals were found to play a crucial role in lung-specific DNA damage, tumorigenesis [169–171,174,177] and general arsenic-induced toxicity [178]. The generation of oxidative stress as a potential mode of action of arsenic for its disease endpoints is an ongoing area of research and the associated complexities have been comprehensively reviewed [145,158,175,179].

5.3. The Human Lung as a Target Organ for Arsenic Toxicity

Remarkably, arsenic is the only reported human lung carcinogen for which there is sufficient evidence of pulmonary carcinogenicity as a result of both inhalation and ingestion exposures [25,180]. Smith *et al.* [181] reported that the relative risk of lung cancer following inhalation and ingestion of arsenic was independent of the exposure pathway. Distinguishing between the different routes of exposure is complicated not only by the arsenic transformations that take place in the body, but also the common target organs following the different exposure pathways [163]. The high variability in pulmonary solubility observed for different arsenic compounds [126,129,130] also represents a confounding factor.

For systemically absorbed arsenic, via inhalation or ingestion, research suggests that the pulmonary system may function as a target tissue for toxicity based on the observation that dimethylarsine is excreted as a gas from the circulation via the lungs [170,177]. High partial pressures of molecular oxygen in the lungs may promote dimethylarsenic and dimethylarsenic peroxyl radical formation as dimethylarsine is excreted and passed through to the respiratory system [144,158,175].

Less soluble arsenic compounds can be retained in the lung as observed in humans [182] and rodents [126,129,130]. According to Styblo *et al.* [152], human lung epithelial cells have very low arsenic methylation capacity *in vitro*, which may translate to a lower capacity to convert inorganic arsenic methylate arsenicals *in vivo*. A reduced capacity to methylate arsenicals could be associated with an increased risk of toxicity due to prolonged retention of inorganic arsenic in the lung [183]. In

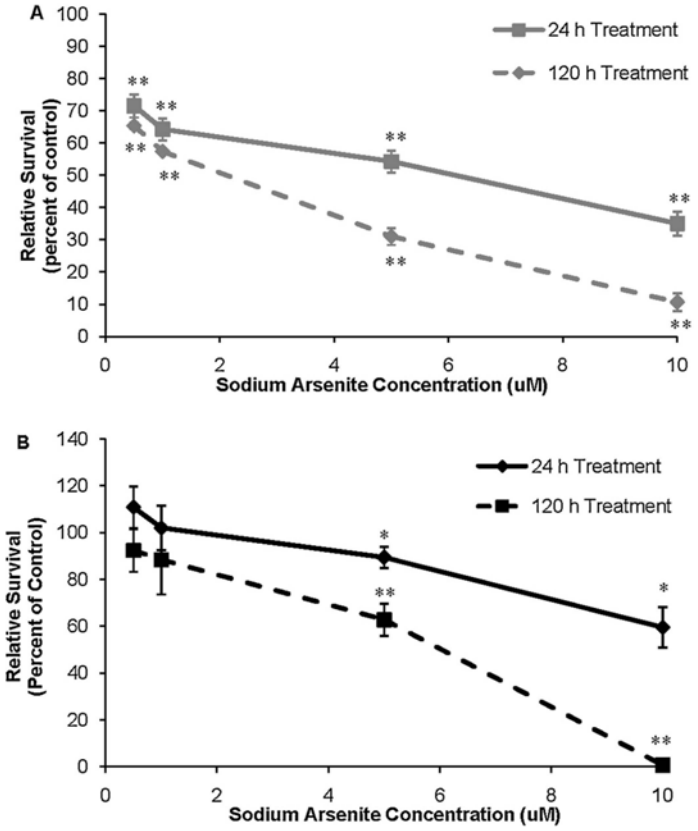
support of these observations, various *in vivo* studies have reported that arsenic toxicity is closely linked with a prolonged retention of inorganic arsenic in the lungs of rodents [129,130]. Further studies to examine the direct effects of inorganic arsenic compounds on pulmonary cells in order to elucidate the carcinogenic mode of action of retained arsenic-bearing particulates are suggested.

5.4. Direct Effects of Arsenic on Pulmonary Cells

Some of the key effects of arsenic exposure on a range of different pulmonary cell lines are summarized in Table 3. Since the dose response of arsenic can be substantially different in animal models compared with *in vivo* human exposure [184], this section will primarily focus on studies involving pulmonary cell lines, specifically human bronchial epithelial (HBE) cells derived from human lung epithelium [168], alveolar macrophage (AM) cells, which are typically harvested from animals [185], and human pulmonary fibroblast (HPF) cells. HBE and AM cells represent the first lines of defense against foreign particles [185], while HPF cells are important for regeneration and repair of chemically or mechanically damaged tissues [186]. As discussed by Dodmane *et al.* [165], although the effects of *in vitro* arsenic exposure are likely to reflect the *in vivo* effects, a cautionary approach should be adopted when interpreting the data due to the variability of effects observed amongst experimental systems.

5.4.1. Pulmonary Cytotoxicity of Arsenic

Cytotoxicity assays, and the measurement of representative parameters associated with cell pathology, are widely used to quantitatively assess the *in vitro* potency of a toxicant in the whole animal. Clear dose-response relationships between arsenic concentration and cytoxicity have been established in HBE cells [165,168,187–189], HPF cells [189–191] and AM cells [185]. Figure 6 shows a notable decrease in HPF and HBE cell survival, in a time- and concentration-dependent manner, following 24 and 120 h treatments with sodium arsenite [189]. Relative cell survival rates indicate that sodium arsenite is more cytotoxic to HPF than HBE cells (Figure 6; [189]). A similar study found that arsenic trioxide was also toxic to HPF cells, however greater concentrations were required to produce similar effects [190]. The differential cytotoxicities observed between these two trivalent arsenic compounds can be attributed to the fact that arsenic trioxide has a lower solubility in the lung than sodium arsenite [126].



Consistent with other lines of evidence presented in previous sections, recent studies confirm that methylated arsenicals are more cytotoxic to pulmonary cells than the inorganic trivalent forms [165,168,188]. For example, the respective median lethal concentrations (LC50) of As^{III}, DMA^{III} and MMA^{III} in HBE cells were reported as 5.8, 1.4 and 1.0 μM, after a 72 h exposure period [165]. $DMTA^{V}$, exhibited a similar cytotoxicity potency to DMA^{III} [168]. While little is known about the pulmonary toxic effects of $DMTA^{V}$, gene expression analysis has shown that cells exposed to $DMTA^{V}$ and DMA^{III} share a relatively high number of differentially expressed genes (DEGs) following exposure to minimally cytotoxic arsenic concentrations, indicating the existence of associated similarities in the cellular mechanism of cytotoxicity of these two arsenicals at lower concentrations [168].

A systematic assessment of the cytotoxic effects and cellular uptake of As^{III}, MMA^{III}, DMA^{III}, MMA^{V}, DMA^{V} and thiodimethylarsinic acid (thio-DMA^{V}, $[(CH_3)_2As(S)OH]$) on human alveolar

epithelial cells has been undertaken in complementary studies [187,188]. Thio-DMA^V is a human arsenic metabolite of inorganic arsenic and is formed immediately when $DMTA^V$ is added to aqueous solution [187]. Cytotoxicity was quantified by measuring reductions in cell number, cell volume and colony formation following a 24 h exposure period [187,188]. In terms of these cytotoxicity endpoints, the cytotoxic order of extracellular arsenic concentrations was reported as DMA^{III} > MMA^{III} > thio-DMA^V ≥ As^{III} ≥ MMA^V ~ DMA^V [187]. Taking into consideration the bioavailability of each arsenic species, as measured by cellular uptake, the cytotoxic order was reported to change to thio-DMA^V ~ As^{III} ~ MMA^{III} > DMA^{III} ≥ MMA^V ~ DMA^V [187]. Cellular uptake of thio-DMA^V was strongly correlated with cytotoxicity endpoints, including cell number (correlation coefficient, −0.986) and colony forming ability (correlation coefficient, −0.998) [187].

Differences in arsenic-induced cytotoxicity endpoints reported in the literature may be attributed to variability in a number of experimental parameters: (i) the arsenic species or compound; (ii) the cell exposure duration; (ii) the cell systems used in each study; and (iii) the methods for assessing cytotoxicity endpoints.

5.4.2. Effects of Arsenic-Induced Reactive Oxygen Species (ROS) Production on Human Bronchial Epithelial (HBE) Cells and Human Fibroblast (HF) Cells

Although ROS are widely recognized for their beneficial and growth-promoting effects on cells, overproduction can lead to toxic effects [192] including damage to cellular DNA and protein [144].

Studies show that HBE and HPF cells generate elevated ROS levels in a dose-dependent manner in the presence of arsenic [191,193]. Moreover, chronically exposed arsenic-transformed HBE cells constitutively generate cellular ROS (probably hydrogen peroxide) in the absence of further arsenic exposure [193]. Constitutive generation of ROS was found to be necessary for activating certain signaling pathways that regulate cell survival and cell proliferation [193].

Enhanced arsenic-induced ROS generation and accumulation have been associated with dose-dependent responses in rates of cell proliferation and colony formation in HBE cells [193–196] as well as anti-apoptotic signaling [195]. Increased cell proliferation is a distinguishing characteristic of cancer cells and is crucial for tumor formation, while apoptosis plays an important role in killing abnormal cells so that they cannot form tumors [193]. One study reported that increased cell proliferation of arsenic-exposed cells was mediated by anti-apoptotic-signaling induced by cyclooxygenase, COX-2 [197], an enzyme associated with inflammation and other pathogenesis [198]. Enhanced ROS levels play an important role in mediating COX-2 production in airway epithelial cells [199].

ROS production has also been linked with gene expression changes in HBE cells consistent with several of the proposed mechanisms for arsenic carcinogenesis [144] including oxidative stress, DNA damage and a weakened tumor-suppression response [165,168,195]. Suckle *et al.* [195] assessed the malignant potential of *in vitro* arsenic-transformed cells by injecting them into mice. The *in vivo* study identified phenotypic characteristics consistent with malignant lung epithelial cells [195], and whole genome expression profiling identified potential mitochondrial oxidative stress and increased metabolic energy output, which is indicative of increased mitochondrial energy production [195]. Importantly, chronic arsenic exposure may therefore target mitochondrial function leading to enhanced ROS generation and cancer-related gene signaling [195]. Antioxidants that target mitochondrial function could play a role in ameliorating some of the effects of arsenic in chronically-exposed populations [200].

Zhao *et al.* [201] recently discovered that long-term exposure to arsenic altered cellular energy metabolism through the induction of aerobic glycolysis (the Warburg effect), as observed in arsenite-treated HBE and other human cell lines cells. The Warburg effect is a metabolically supportive phenotype for the increased energy demands associated with the growth, proliferation and invasion of cancer cells (see the review by Vander Heiden *et al.* [202]). Unlike normal cells which produce lactate under anaerobic conditions only, the Warburg effect states that cancer cells generate large quantities of lactate regardless of oxygen availability [202]. This study was potentially the first to link an environmental toxicant with the induction of the Warburg effect, and thus this discovery may assist in identifying the role of arsenic toxicity in other diseases associated with disrupted energy metabolism, such as diabetes and atherosclerosis [201].

5.4.3. Arsenic-Induced Suppression of Alveolar Macrophage (AM) Function

Alveolar macrophages (AM) serve as the front line of cellular defence against foreign material by clearing the air spaces of any infectious, toxic or allergenic particles that have penetrated mechanical defences, such as the nasal passages and mucociliary transport system [203]. Under normal conditions, ROS are secreted by alveolar macrophages in response to phagocytosis or stimulation with specific agents, and play a key role in efficiently killing invading pathogens [204]. Various detrimental

effects of arsenic on these important cell functions have been observed (Table 3). For example, Palmieri *et al.* [185] noted concentration-dependent reductions in AM viability and size following exposure to sodium arsenite concentrations of 2 and 2.5 μM, respectively, and a notable increase in apoptosis after 5 μM. In the presence of the lower sodium arsenite concentrations (<2 μM), AM cells maintained the ability to regulate cell homeostasis whereas higher doses (≥5 μM), reduced cell viability to 50% [185]. Increasing cell culture time generally played a key role in amplifying the observed adverse effects, particularly during exposure to the higher (5 and 10 μM) sodium arsenite concentrations [185].

Contrary to the commonly-observed response by arsenic-exposed HBE and HPF cells, AM cells typically exhibit a dose-dependent reduction in ROS production in the presence of arsenic [128,185,205–208]. Soluble trivalent arsenic was notably more potent at inhibiting ROS production than the corresponding pentavalent form, with superoxide inhibition occurring at respective concentrations of 0.1 and 1 μg/mL [208]. In contrast, the slightly soluble trivalent and pentavalent forms showed similar patterns in ROS production with inhibition occurring at a concentration of 10 μg/mL arsenic [128,207]. Gercken *et al.* [205] postulated that the depression of O_2^- (superoxide anion) production by arsenic-exposed AM may be linked with high concentrations of arsenic on the particle surface. Both the studies by Lantz *et al.* [128,208] observed that a 24 h period of arsenic exposure was required to suppress ROS production.

Suppression of ROS production, or a reduction in AM function as demonstrated by others [128,185,205,207,208], may therefore inhibit phagocytosis: an important clearance mechanism of foreign particles, such as dust and bacteria, from the lung. Suboptimal phagocytosis by AM cells has been associated with a decreased ability to clear dead or dying cells from the respiratory system thereby leading to pathological inflammation [209] as well as an increased susceptibility to pulmonary infection such as pneumonia, in respiratory health-compromised individuals [210].

5.4.4. Arsenic-Induced Inhibition of the Wound Healing Response in Human Bronchial Epithelial (HBE) Cells

As the respiratory epithelium is frequently injured by inhaled pollutants or micro-organisms, the epithelial wound repair response plays a critical role in the maintenance of epithelial barrier integrity [211]. Concentration-dependent arsenic-induced inhibition of wound healing in mechanically-wounded HBE cells has been demonstrated (Table 3). In the absence of arsenic, the wounded area of an epithelial monolayer of HBE cells was largely repaired (approximately 80%) by migrating cells after a period of 4 h [212]. In the presence of 30 and 60 ppb arsenic however, the amounts of wound closure were 48% and 24%, respectively [212]. The highest concentration (290 ppb) resulted in the expansion of the wound area in the first hour, followed by 16.5% healing at 4 h [212]. Further analyses indicated that overexpression of matrix metalloproteinase (MMP-9), an enzyme important for human respiratory healing and wound closure [213], leads to dysregulated wound repair in the presence of arsenic and reductions in cellular migration [212].

Regulation of MMP-9 and migration of airway epithelial cells are linked with ATP-dependent Ca^{2+} signalling [213]. Tightly coordinated Ca^{2+} transport and activity are vital during early wound healing processes; therefore Ca^{2+} is commonly used as an immediate damage indicator [214]. Furthermore,

general interference with airway ATP signalling has been linked with chronic lung diseases, such as chronic obstructive pulmonary disease (COPD) [215]. To investigate whether arsenic disrupts Ca^{2+} signalling in mechanically-wounded HBE cells, Ca^{2+} concentrations were monitored following acute (24 h) and chronic (4–5 weeks) exposure with micromolar and nanomolar concentrations of sodium arsenite [216,217]. Significant and dose-dependent reductions in Ca^{2+} propagation in wounded cells compared to controls were observed (Figure 7; [216,217]). Arsenic-induced suppression of the wound healing response as a result of both acute and chronic exposures (well below levels typically associated with inhalation where arsenic has been linked with disease presentation) may ultimately result in a reduced ability of the lung epithelium to effectively and sufficiently close a barrier breach [212,216,217].

Figure 7. Wound healing assay of 16HBE14o- cells exposed chronically (4–5 weeks) to 0, 130, or 335 nM sodium-arsenite: (**A**) Representative images of initial wounding (left column), 30 min post-wounding (middle column), and 1 h post-wounding (right column). White scale bar represents 50 μM; (**B**) Quantification of percent wound closure over time at 30 and 60 min post-wounding. "*" indicates significant difference from untreated controls by a one-way ANOVA ($p < 0.05$). Reprinted with permission from Sherwood *et al.* [217].

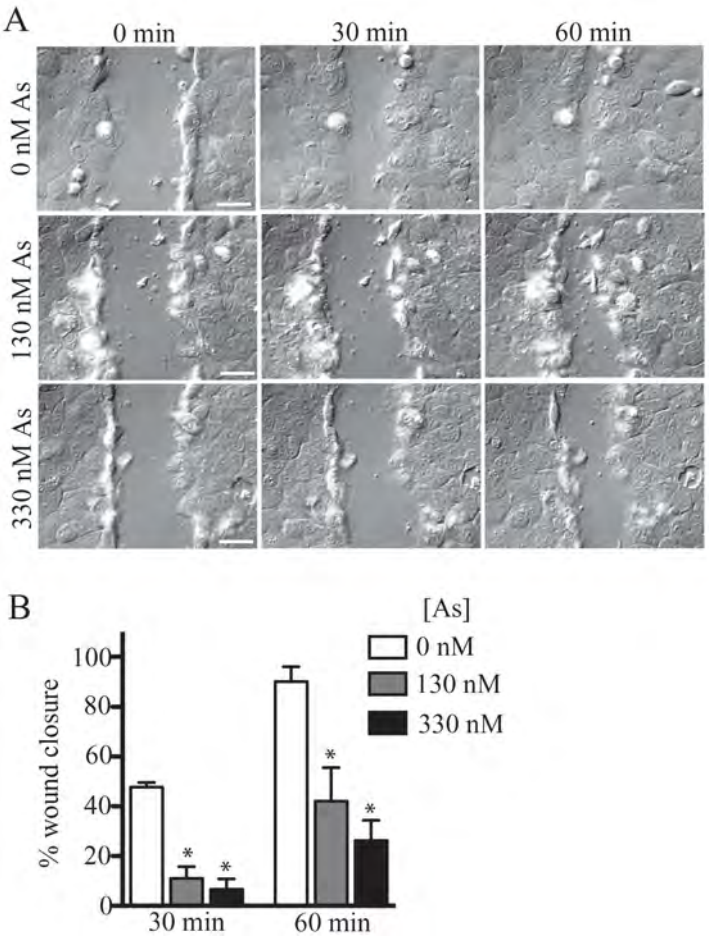

Table 3. Direct effects of arsenic exposure on human bronchial epithelial (HBE) cells, human pulmonary fibroblast (HPF) cells, and pulmonary alveolar macrophage (AM) cells. All experiments were conducted *in vitro*, unless otherwise specified. Specific cell lines are listed in accordance with the abbreviations used in each study.

As Compound	Dose	Cell Line	Pathological Effects	Potential Human Effects	Ref.
Human bronchial (or alveolar epithelial) cells					
Na-arsenite	0.5–10 μM for 24 and 120 h	NHBE	Dose-dependent reduction in cell survival; chromosomal aberrations suggestive of DNA double strand breaks	Lung cancer	[189]
Na-arsenite, MMA^{III}, DMA^{III}	Variable for 3 days	HBE	MMA^{III} & DMA^{III} were more cytotoxic; dose-dependent alteration of inflammatory response at low concentrations; alterations in oxidative stress and DNA damage repair at increasing concentrations	Pulmonary diseases linked with inflammation and increased bronchial cell proliferation	[165]
Na-arsenite	0–4 μM for 2 weeks	HBEp	Concentration-dependent increase in cellular lactate production; lactate produced via aerobic glycolysis (the Warburg effect)	Growth, proliferation and invasion of cancer cells	[201]
As-trioxide	2.5 μM for 6 months	BEAS-2B *In vivo* (Nu/nu mice) *In silico* Signalling pathway analysis	Time-dependent cell proliferation; cells exhibited a cancer-like phenotype Tumour formation; time-dependent increase in tumour volume; cells exhibited a malignant and metastatic phenotype ROS generation; DNA damage; chronic inflammation; dysregulation of pro- and anti-cancer gene signalling, anti-apoptosis and invasive signalling	Lung cancer	[195]
Na-arsenite	130 and 330 nM for 4–5 weeks and 0.8 and 3.9 for 24 h	16HBE14o-cells (wounded)	Dose-dependent reduction in the wound healing response (Ca^{2+} signalling), leading to inhibition of wound repair	Chronic lung disease, e.g., bronchiectasis	[216,217]
Na-arsenite MMA^{III}, DMA^{III}, MMA^{V}, DMA^{V}, $DMTA^{V}$	Various (μM) for 24 h	A549	DMA^{III} and MMA^{III} showed pronounced cellular uptake; differential cellular endpoints related to DNA repair	Arsenic-induced diseases	[187,188]
Na-arsenite	0.25–5 μM for 26 weeks	BEAS-2B	ROS-induced cell proliferation and colony formation; constitutive generation of ROS (probably H_2O_2); degree of effects were concentration-dependent	Primary lung tumour formation	[193]
Na-arsenite	20 nM, 200 nM, 2 μM and 20 μM for 12, 24 and 48 h	BEAS-2B	Enhanced cell growth and proliferation; up-regulation of protein, Cyclin D1, is commonly over-expressed in cancer cells	Development/progression of lung carcinogenesis	[196]
Arsenite, MMA^{III}, DMA^{III}, $DMTA^{V}$	Variable concentrations for 24 h	BEAS-2B	Arsenite was least cytotoxic; methylated forms shared similar cytotoxicities; dose-dependent increase in number of differentially expressed genes linked to carcinogenicity; minimally cytotoxic arsenic levels induced oxidative stress	Lung cancer	[168]

Table 3. *Cont.*

As Compound	Dose	Cell Line	Pathological Effects	Potential Human Effects	Ref.
Na-arsenite	30, 60, 290 ppb for 24 h	16HBE14o- (wounded)	Dose-dependent inhibition of the wound healing response	Compromised lung function	[212]
Na-arsenite	5–40 μM for 6–48 h	BEAS-2B	Overexpression of COX-2; apoptotic disruption; cell proliferation	Accumulation of genetically damaged cells leading to malignancy	[197]
Human pulmonary fibroblast cells					
Na-arsenite	0.5–10 μM for 24 and 120 h	HPF	Dose-dependent reduction in cell survival; concentration-dependent increase in chromosome damage such as DNA double strand breaks.	Lung cancer	[189]
As-trioxide	1–50 μM for 24 h	HPF	Dose-dependent reduction in cell survival between 10 and 50 μM As-trioxide		[190]
As-trioxide	1–50 μM for 0–180 h	NHBF	Dose-dependent increase in ROS (O_2^-) levels; cell growth inhibition and cell death		[191]
Alveolar macrophage cells (harvested from animals)					
Na-arsenite	1.25–10 μM for 24–96 h	Mouse AM	Dose-dependent reduction in macrophage viability and volume; time-dependent increase in apoptotic cell at higher arsenic concentrations; decrease in ROS (O_2^-) generation at low concentrations	Immunological disorders; decreased capacity to respond to toxicants	[185]
As-trioxide & Ca-arsenate (slightly soluble)	0.1–300 μg/mL for 24 h	Rat AM	Dose-dependent reduction of ROS (O_2^-) after 24 h; similar pattern for both arsenicals (around 10 μg/mL)	Alteration in AM function; compromised host defence	[128]
Na-arsenite & Na-arsenate (soluble forms)	0.1–300 μg/mL for 24 h	Rat AM	Dose-dependent reduction of ROS (O_2^-) after 24 h; As^{III} more potent than As^{V}; differential immune response between the two species	Compromised defence against infection and altered immune surveillance	[208]
Arsenic (fly ash)	50–230 ppm for 24 h	Rabbit AM	Concentration-dependent inhibition of ROS (H_2O_2 and O_2^-) production	Suppression of AM function	[206]
As-trioxide	0.1–1000 μM for 24 h	Rabbit AM	Concentration-dependent inhibition of ROS (H_2O_2 and O_2^-) production	Increased susceptibility to bacterial infections	[207]
As-trioxide (fly ash)	Industrially-relevant levels for 24 h	Rabbit AM	Suppressed ROS (O_2^-) production	Suppression of AM function	[205]

6. Epidemiological and Exposure Monitoring

Epidemiological studies provide an important link between health effects and air pollution exposure, because they provide an accurate representation of the health records and environmental conditions pertaining to a well-defined population [218]. In this regard epidemiological studies of industrially-exposed cohorts conducted during the mid-1900s have provided strong evidence of a causative role for airborne arsenic in respiratory cancer mortality. This has resulted in a diverse but important body of historical epidemiological evidence accrued on the health risks and disease outcomes associated with known, high level occupational inhalation exposures [219–221].

However, with increasing concerns regarding the effects of peripheral exposure to potential carcinogens, there is increasing attention directed at the health of communities living in the vicinity of smelting and mining operations and uncontained mine wastes and tailings. Notwithstanding the common source of the concerns, it has been observed that there are important differences between the situations of occupationally- and environmentally-exposed cohorts. Occupational studies usually differ methodologically from the environmental investigations in that there is a contained area of contamination and a restricted population who are exposed to high levels of airborne material. Whereas studies of environmental exposure in communities living in arsenic-affected areas usually start at birth, and the exposure itself may not be recognized for many years and may be intermittent, thereby rendering epidemiological studies more difficult to design and interpret, particularly since they are observational only. For these reasons, we report separately on the findings for each exposure type, since they will address different aspects of the effects of airborne particulate matter on health.

6.1. Known Occupational Exposures

An industrial hygiene study conducted between 1943 and 1965 at the Anaconda copper smelter in Montana, USA, recorded extremely high levels of airborne arsenic (≥5000 $\mu g \cdot m^{-3}$), particularly in and around the ore roasting furnace, materials crushing plant and the arsenic refinery departments [222]. Similar conditions were reported at the Ronnskar smelter in Sweden [220]. Airborne arsenic concentrations in excess of 20,000 $\mu g \cdot m^{-3}$ were not uncommon at these two smelting operations [220,222]. Lower values for airborne arsenic were typically found in areas such as the administration departments, electrical and machine workshops, outdoor environment, building department and general office area [220,222]. Significantly, airborne arsenic concentrations reported at the latter two locations are 8- and 2000-fold greater than the current target value of 6 $ng \cdot m^{-3}$ proposed by EU regulations.

Symptoms of severe arsenic exposure among smelter workers observed during the 1920s included a notable rise in the rate of sick days due to various acute and chronic respiratory disorders [223]. Arsenic trioxide-laden dust (generated as a by-product of the copper smelting process) deposited in the nose and respiratory airways forms arsenous acid on contact with moisture, resulting in necrosis of the mucous membranes [223]. Diseases reported among smelter workers during the early 1930s were bronchitis, tracheitis, ulcers, laryngitis, rhinitis, perforation of the nasal septum, atrophy of the mucus membranes in the respiratory passages and occupational arsenical dermatitis (unpublished works by Inghe and Bursell [224], translated in Gerhardsson *et al.* [225]). Emphysema and ischemic heart disease were also noted [219]. Despite the prevalence of these non-malignant respiratory disorders,

meta-analysis of the available epidemiological data did not detect any statistically significant excesses in mortality among smelter workers compared to the control cases [219,221].

The first cases of lung cancer that were traced to the work environment occurred at a Swedish smelter in the 1960s whereby a five-fold increase in lung cancer mortality compared with controls was observed [226]. Occupational health investigations at other smelting operations, as well as comprehensive reassessments and meta-analyses of previously reported data, demonstrated strong links between airborne arsenic exposure and respiratory cancer [220–222,227,228]. Lubin *et al.* [221] reported a statistically significant trend between the excess relative risk of respiratory cancer and cumulative exposure to airborne arsenic amongst a cohort of 8014 copper smelter workers in Montana, United States. Over a 50 year period, 446 deaths due to respiratory cancers were observed, comprising 428 lung cancers and 14 cancers of the larynx. No other cause of death was found to be associated with arsenic exposure, with the possible exception of COPD [221].

In addition to smelting, other studies have demonstrated a link between lung cancer and arsenic exposure at hard rock mining operations [228]. One of the most comprehensively investigated cases relates to four tin mines and three associated smelting operations in southern China, where underground miners were exposed to respirable concentrations of arsenic ranging between 0.1 and 38.3 $\mu g \cdot m^{-3}$ [229]. Chen and Chen [229] reported that the rates of lung cancer were strongly associated with cumulative dust exposure, arsenic exposure and duration of exposure. While the magnitude of risk from mining (odds ratio (OR), 8.8) was only slightly less than for smelting (OR, 12.3), exposure to both mining and smelting increased the risk to 22.0 [228]. The potential additive carcinogenic effects of inhaled crystalline silica, cigarette smoking and exposure to radon could not be ruled out [228].

To examine the distribution of arsenic in the body following long-term exposure, researchers collected and analysed tissues from deceased workers from the Ronnskar smelter in Sweden, and from various controls, and correlated these with the cause of death [225]. Post-mortem investigations discovered elevated levels of arsenic and seven other metals of concern in the lung, liver and kidneys of the deceased workers [182,225]. Median arsenic concentrations of 35 and 50 $\mu g \cdot kg^{-1}$ reported in lung tissue of the deceased smelter workers were six to seven times greater than the control cases [182,225], providing some evidence of a causative role for arsenic in respiratory cancer mortality among the exposed population [182]. Although the arsenic content diminished in liver tissue, a longer biological half-life of arsenic was observed in the lung [182]. Similar findings have been reported in animal studies [126]. An extended biological half-life and retention of arsenic in lung tissue may have implications for the development of respiratory disease. Lung cancer risk in a cohort of 107 Chinese tin miners was more dependent on the duration of arsenic exposure than then intensity [228]. Conversely, exposure intensity was more important in determining the lung cancer risk than duration in smelter workers [220,222], indicating a need for comparative studies with consistent exposure and outcome criteria.

Due to the use of exposure reduction measures by mining and mining-related industries, the number of published studies relating to rates of lung cancer and mortality in mining and mining-related industries has declined in recent years. However, occupational inhalation exposure to airborne arsenic remains a serious health issue in some localities. A recent study reported that copper smelter workers in northeastern China were exposed to airborne arsenic values that were up to 57% above the short-term exposure threshold limit value of 20 $\mu g \cdot m^{-3}$ [230]. Seven of the 38 copper smelter workers

selected for investigation had arsenic-related skin disorders including hyperkeratosis and/or hyper-pigmentation, as well as elevated urinary arsenic levels [230]. Urinary arsenic speciation analysis revealed that higher occupational exposures and skin damage cases were associated with a decreased capacity for arsenic methylation [230]. Similar results have been reported elsewhere [231]. These findings support the premise that suppressed methylation capacity results in an increased risk of arsenic toxicity due to the retention of arsenic in the body [183].

6.2. Inadvertent Environmental Exposures

It has been found that a number of populations around the world live in the vicinity of active or abandoned mining operations [28], and there exists overwhelming epidemiological evidence suggesting that there is an increased risk of arsenic exposure for these communities [4–9,78,107,232]. These studies show that children are particularly susceptible to inhalation exposure since they respire a greater relative volume of air with respect to their size, and may therefore be exposed to correspondingly higher levels of airborne contaminants than adults. Children also have an increased likelihood of coming into contact with soil and dust through playing in dirt contaminated with arsenic residues [78,233,234]. As a consequence, many human exposure monitoring studies have focussed on measuring arsenic exposure in child populations [4,7,107,233,235,236].

Measurement of arsenic in human nails, hair, urine and blood concentrations are commonly used for determining arsenic uptake in humans [78,105,232,235,236]. Blood and urine arsenic levels provide a reliable short-term measure of arsenic exposure because arsenic is readily excreted from the bloodstream via the kidneys [25]. Analysis of arsenic deposited in the toenails and hair provides useful indicators when the measurement of long-term, low-level arsenic exposure is required [234–238]. It has also been shown that analysis of the arsenic content of particles that have adhered to the hands of children can also be used as an indicator of potential exposure [4].

It is important to note that although such biological markers of arsenic exposure as those reported above are useful for predicting the degree of risk, elucidating the exact pathway to environmental uptake of arsenic in localities where multiple exposure pathways exist is not straightforward [233]. As previously mentioned in this review, airborne arsenic-contaminated particulates generated by mining operations often may be small enough to be inhaled, and have the potential to directly reach the tracheobronchial and/or alveolar regions of the RT of populations living within the reach of the industrial plume or raised dust material [19,54]. However, particles that have been deposited on the ground or other surfaces may be either ingested due to physical contact, or resuspended as dust, and then inhaled [19,105]. Many studies therefore report the existence of multiple possible pathways for human exposure to arsenic-bearing particulates in the vicinity of mining operations which contributes to the complexity of epidemiological studies of this issue [4,7,105,233,238] A recent study reported that the ingestion and inhalation exposure pathways contributed equally to the arsenic-associated carcinogenic and non-carcinogenic risks in such populations [105].

From the work reported in the above investigations, it is clear that human arsenic exposure is governed by a number of variables. There are important inverse relationships which have been frequently reported between the concentration of airborne arsenic levels and the distance from the source, and between biological arsenic levels and the distance of the home, playground or school

environment from metal smelters and other mining operations [4,7,107,233]. Buchet *et al.* [4] reported airborne arsenic concentrations of 330 and 75 $ng \cdot m^{-3}$, and dust concentrations of 1710 and 66 $\mu g \cdot g^{-1}$ at distances of 1 and 2.5 km from a lead smelter in Belgium, which are consistent with this inverse relationship. Correspondingly, the average arsenic concentration on the hands of children living within the 1 km zone was ten times greater than those children living further away [4]. Similarly, Hwang *et al.* [233] found that the urine arsenic content of children living near an extensively contaminated former copper smelter in Montana were significantly inversely correlated with distance from the smelter site.

As cautioned by Frost *et al.* [6], the assumption of a simple inverse relationship between arsenic uptake and distance from the emission source may oversimplify this phenomenon, since seasonality and wind direction are also important variables influencing exposure [9,107,231]. Milham and Strong [107] demonstrated that fluctuations in urine arsenic levels among children living near a copper smelter were closely associated with changes in prevailing wind direction. In this study, the urine arsenic concentrations of children living downwind of the smelter decreased simultaneously with shifts in wind direction [107]. Another study of children living near a former copper smelter site reported elevated biological arsenic levels during the summer, a time when seasonal factors enhance the mobilisation of dust from uncontained mine wastes, such as tailings and flue dust [233].

Carcinogenic and non-carcinogenic risks associated with inhalation exposure to atmospheric arsenic emitted by coal combustion have recently been estimated in exposed Chinese populations [9,105]. Because it has been observed that the average effective diameter of arsenic-containing aerosols from combustion processes is 1 μm [3], there exists a high potential for deposition in the terminal bronchioles and alveoli of exposed populations. Consequently, it has been estimated that more than two million residents in Beijing have an increased risk of developing cancer as a result of probable exposure to atmospheric arsenic, generated principally from coal combustion [9]. Recent measures of daily total inorganic arsenic inhalation exposure values for Beijing residents (0.3–0.8 $\mu g \cdot day^{-1}$) showed that they were 10 times greater than those in the United States (40–90 $ng \cdot day^{-1}$). These studies indicated that daily intakes of arsenite and arsenate in Beijing were 0.01–0.03 and 0.16–0.44 $\mu g \cdot day^{-1}$ by inhalation, respectively. Based on these exposures and the known effects of both arsenite and arsenate as carcinogens, an estimated excess cancer risk of $(4.2 \pm 2.0) \times 10^{-4}$ was predicted for the city's population [9]. In a similar study, Cao *et al.* [105] reported a median carcinogenic risk posed by arsenic inhalation of 2.91×10^{-3} in a community living near the largest coal refinery plant in a town of Shanxi Province, China.

6.3. Impacts of Climate Change

The effects of climate change are predicted to have an impact on mine waste chemistry and mobility. The predicted rise in global temperature is expected to increase the rate of mine waste weathering by a factor of approximately 1.3 by the year 2100 [239]. Prolonged weathering of mine waste materials will lead to the formation of a greater abundance of soluble salts [67]. Moreover, the anticipated increase in extreme weather conditions are likely to lead to a greater frequency and intensity of dust storms, as already observed in localities such as Asia, Africa, and Australia [240,241]

which in combination with the weathering, is likely to result in an increase in the occurrence and bioavailability of airborne arsenic.

7. Conclusions and Research Priorities

The potential health effects of exposure to airborne arsenic-bearing particulates generated by current and/or past mining operations are widely recognized as a growing issue of significant global importance. Investigations surveyed in this review, taken from disparate but complimentary lines of inquiry, strongly support a causative role for inhalation exposure of inorganic arsenic species in the aetiology of lung cancer and other respiratory health disorders, suggesting that a strong focus on this exposure modality is crucial for the long-term health of affected populations.

This review has highlighted the need to conclusively elucidate the exact mechanisms of arsenic-induced toxicity from exposure to PM in order to facilitate the prediction and diagnosis of adverse health consequences, and thereby enable adequate risk assessments to be undertaken.

Recent developments in various complimentary areas of research within the overarching field of medical geology including geochemistry, biomedicine, toxicology and epidemiology, have identified a number of factors that play a key role in understanding these varied phenomena. These include: (i) the effects of differing environmental variables leading to exposure; (ii) the influence of particulate characteristics on the initial deposition location in the RT; (iii) the differing toxicity levels of particulate-borne arsenicals, their species and their metabolites, and (iv) the complex pathogenesis of arsenic-induced lung disease.

While it is clear that absorbed arsenic exerts cytotoxic and genotoxic effects on pulmonary cells following both acute and chronic exposures, important species- and dose-dependent differences in toxicities between the two exposure regimes have been observed. It is also clear that particle size plays a major role in governing the deposition location, solubility, methods of clearance and retention time of arsenic-bearing species in the RT, and hence has a direct effect on the range of arsenic metabolites released to the body. Current research indicates that the exposure to arsenic and of these metabolites is predictive of the pathogenesis of lung disease, which leads to the conclusion that the long-term pulmonary bioavailability of arsenic in PM requires serious consideration in health risk assessments. Development of a series of standardized lung bioavailability assays that assess both short- and long-term exposures would be beneficial, particularly when drawing comparisons between studies.

The potential for human exposure to airborne arsenic will inevitably increase in the future due to several key factors. Increases in global copper production and coal use, with which arsenic species are intimately related, are indicators of increasing global wealth and population. With increasing wealth and population, consequent increases in urbanization will inevitably lead to encroachment on and disturbance of existing contaminated sites. In addition, it is predicted that climate change will have a considerable impact on mine waste chemistry and mobility, effectively amplifying every other risk factor, and increasing the urgency in gaining a greater understanding of all aspects of arsenic in our environment.

It is strongly recommended that future research prioritizes identifying human populations and sensitive sub-populations at risk of exposure, as well as developing long-term, cost-effective methods to adequately contain or reduce airborne emissions from known sources.

Acknowledgments

Open access publication of this article was funded by the Collaborative Research Network (CRN), Federation University Australia. The views of the authors do not necessarily represent those of the CRN. The authors would like to thank AINSE Ltd for providing financial assistance (Award-PGRA) to enable work on the original research component of this paper.

Author Contributions

All authors contributed substantially to the work presented in this manuscript. As principal researcher, Rachael Martin made a substantial contribution to this work which was undertaken in association with her PhD program. Kim Dowling provided critical analyses and commentary during the development of this manuscript, ensuring that the reviewed literature was accurately interpreted. Dora Pearce provided extensive commentary on the epidemiology and other health-related sections of this manuscript, ensuring that all findings related to health outcomes were accurately represented. With an extensive background in the field of chemistry, James Sillitoe has made substantial contributions to this paper, particularly regarding the technical aspects. Singarayer Florentine assisted with the development of the underpinning theory and conceptual framework for this manuscript, as well as assisting with major re-drafting and editing.

Conflicts of Interest

The authors declare no conflict of interest.

Attorney for Save the South Fork Salmon

BEFORE THE OFFICE OF ADMINISTRATIVE HEARINGS
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047	Agency Case No. 0101-2201 OAH Case No. 23-245-01
NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON, *Petitioners*, v. IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY, *Respondent*, and PERPETUA RESOURCES IDAHO, INC., *Intervenor*.	**DECLARATION OF ZAK SEARS**

I, ZAK SEARS, state and declare as follows:

1. My name is Zak Sears, and I am a resident of Idaho County, Idaho.

2. I have been a supporter and member of Save the South Fork Salmon ("SSFS") since 2016. I became interested in SSFS based on its work to protect the South Fork Salmon River watershed from the impacts of the Stibnite Gold Project proposed by Perpetua Resources Idaho, Inc. I continue to support SSFS's work because I support its mission to protect and preserve the ecological resources of the South Fork Salmon River watershed. In 2020, I started a fundraiser where I donated large canvas framed photographs of the South Fork Salmon River watershed to SSFS for use at its events and to auction off to raise funds to support its work. I took some of the photographs; the rights to use other images were donated by other photographers. The fundraiser raised several thousand dollars. I am currently working on a map project of the lower South Fork Salmon River that I will donate to SSFS for its use to raise funds to support its work. The map is intended to be a navigational and informational tool that could be used by a wide variety of recreationists interested in recreating in the South Fork Salmon River watershed. I am also a member of SSFS.

3. I have also supported work that protects the South Fork Salmon River watershed by participating as an informal liaison for recreational non-motorized boaters during the Payette National Forest's development of a river recreational management plan for the lower South Fork Salmon River corridor. As a result of that involvement, two action plans were implemented (Waste Alleviation and Gelling, or WAG, bags and a self-issued permit box), and I continue to engage with the Payette National forest on how to best manage use in that river corridor.

4. I have a deep personal and professional connection to the South Fork Salmon River watershed, including many of the rivers in the area. The area's landscape is remarkable and some stretches of river boast the largest bull trout I have ever seen. It provides a diverse recreational experience during both summer and winter. It is one of the most spectacular places to visit in Idaho.

5. I currently work as a river and steelhead fishing guide, primarily on the Middle Fork Salmon River ("Middle Fork"), which is located in the South Fork Salmon River watershed and downwind of the proposed mine. As part of my guided trips, I fly my clients into the Middle Fork area, and we use areas adjacent to Indian and Little Indian Creeks for camping and for accessing drinking water from the creeks. I spend up to 90 days a year on the Middle Fork as a river and fishing guide.

6. I personally recreate in the South Fork Salmon River watershed, including areas in and around the site of the proposed Stibnite Gold mine. I spend a significant time in the area hiking, photographing, mushroom hunting, fishing, backcountry skiing, birding, and kayaking and snorkeling in the rivers. I have visited the South Fork Salmon River ("South Fork") and the East Fork of the South Fork Salmon River ("East Fork") area at a minimum annually since 2006. For about three years, I made approximately 10 trips each year to the area to kayak, snorkel, fish, and visit Yellow Pine. My most recent visit to the area was in May 2023, where I visited the East Fork near the mouth of Johnson Creek and the lower South Fork canyon. My next planned visit is in June 2023, where I plan to go to the East Fork near Yellow Pine and the lower South Fork canyon.

7. I have reviewed Perpetua's map that depicts the proposed mine site and the ambient air boundary. A true and correct copy is attached as Exhibit 1. I have recreated both within the blue line that depicts the ambient air boundary, and just outside of that boundary. I have also traveled on the existing road through the proposed mine site to access recreational sites, which corresponds roughly to the green line on the map.

8. I have snorkeled in the East Fork below the confluence of Johnson Creek to view the fish and observe their behaviors in their natural habitat. When snorkeling in the lower river, I can get very close to the largest bull trout I've ever seen.

9. In June 2021, I traveled to the proposed mine to access the East Fork downstream of the Yellow Pine Pit with the intent of snorkeling in the deep pools to view the fish. As I drove up the East Fork into the proposed mine area, the river area feels like it is an intact ecosystem. There is large woody debris that creates good fish habitat. Even from the road, you can see deep pools in the river holding large fish. I am drawn to the area to explore these pools and snorkel with the fish. The East Fork downstream of the Yellow Pine Pit is the most incredible stretch of river that I have ever seen in Idaho or anywhere in the world. On this particular trip, I forgot my snorkeling gear. However, I intend to go back to snorkel in the pools south of the Yellow Pine Pit in the future.

10. In March 2020, I did a backcountry ski trip that started in the area on the map that is labeled "Hanger Flat Pit." I toured across the area that is labeled "Hanger Flat TSF" on the map. I intended to continue my ski trip by climbing out of Meadow Creek to reach Pistol Ridge, which would have taken me outside of the ambient air boundary depicted on the map, and return to Warm Lake where I had parked my car. However, I had to turn around because of significant

downed trees and I did not have enough of a window of good weather to take the time I would have needed to complete the loop. I intend to ski that same route in the near future.

11. In June 2021, I drove through the proposed mine site by entering the road from the north (labeled "North Entry" on the map). I exited at the South Gate of the road, and continued to Monumental Summit. Once at Monumental Summit, I hiked from there to the area under the label "South Entry" on the map, which is just outside of the blue ambient air boundary line. From there, I could see several peaks in the distance: the Sawtooths, Mount Borah, the Beaverheads. The view was incredible. I could visually and mentally connect the topographical features on my map to the real landscape to understand where I was situated in this vast ecosystem. I intend to return to this area in the future.

12. As stated above, since 2006, I have visited the South Fork Salmon River watershed area, including the area around the proposed Stibnite Gold Project on a yearly basis, at a minimum. I intend to continue to visit and recreate in this area in the future as long as I am able to do so. I also anticipate that my future trips will require me to travel on the road through the proposed Stibnite Gold Project, and I intend to travel on that road in the future.

13. I understand that in June 2022, the Idaho Department of Environmental Quality ("DEQ") issued Perpetua Resources an air permit for the proposed Stibnite Gold Project, called a Permit to Construct, under the authority of the Clean Air Act. I understand that the proposed mining operations will emit significant amounts of air pollutants, such as particulate matter, and cancer-causing air pollutants, such as arsenic. I also understand that inside the ambient air boundary line and including over the public road going through the mine site, the impacts to air quality from the emission of air pollutants is not analyzed or regulated. I also understand that

outside of the ambient air boundary, the air quality is supposed to meet certain standards, and that these are health-based standards set to protect the public health.

14. I am concerned that the air permit that DEQ issued to Perpetua for the proposed mine will not sufficiently protect air quality as is required under the Clean Air Act and under Idaho's rules and regulations. I am concerned that the air permit does not ensure that the air quality outside the ambient air boundary where I recreate will meet the criteria necessary to comply with the laws and regulations and ensure that it protects my health or does not injure me or negatively impact my health.

15. I am greatly concerned that the air quality outside of the ambient air boundary in areas where I have recreated and plan to recreate in the future will contain air pollutants that exceed the health-based standards. I am greatly concerned about using the road going through the mine site that I have used and plan to use to access public lands to recreate. I am concerned that the pollutants emitted into the air, and the air quality above the road are not regulated at all.

16. I am concerned that if the air pollutants exceed these health-based standards, that it can have a negative impact on my health. I have a family history of esophageal cancer. My father lived downwind of the hanford nuclear waste repository, and died from cancer.I believe that the poor air quality and pollution from the nuclear waste site may have been a factor in my father getting cancer.

17. Many of the areas that I recreate in and take clients to on guided fishing trips, including the Middle Fork, are outside of but close to the ambient air boundary and are downwind of the proposed mine. The area downwind of the proposed mine site is naturally an extremely windy area. I am concerned that the prevailing wind pattern will carry air pollutants,

including particulate matter and arsenic, out of the ambient air boundary and into the areas that I personally recreate in, as well as areas that I take clients to on guided fishing trips.

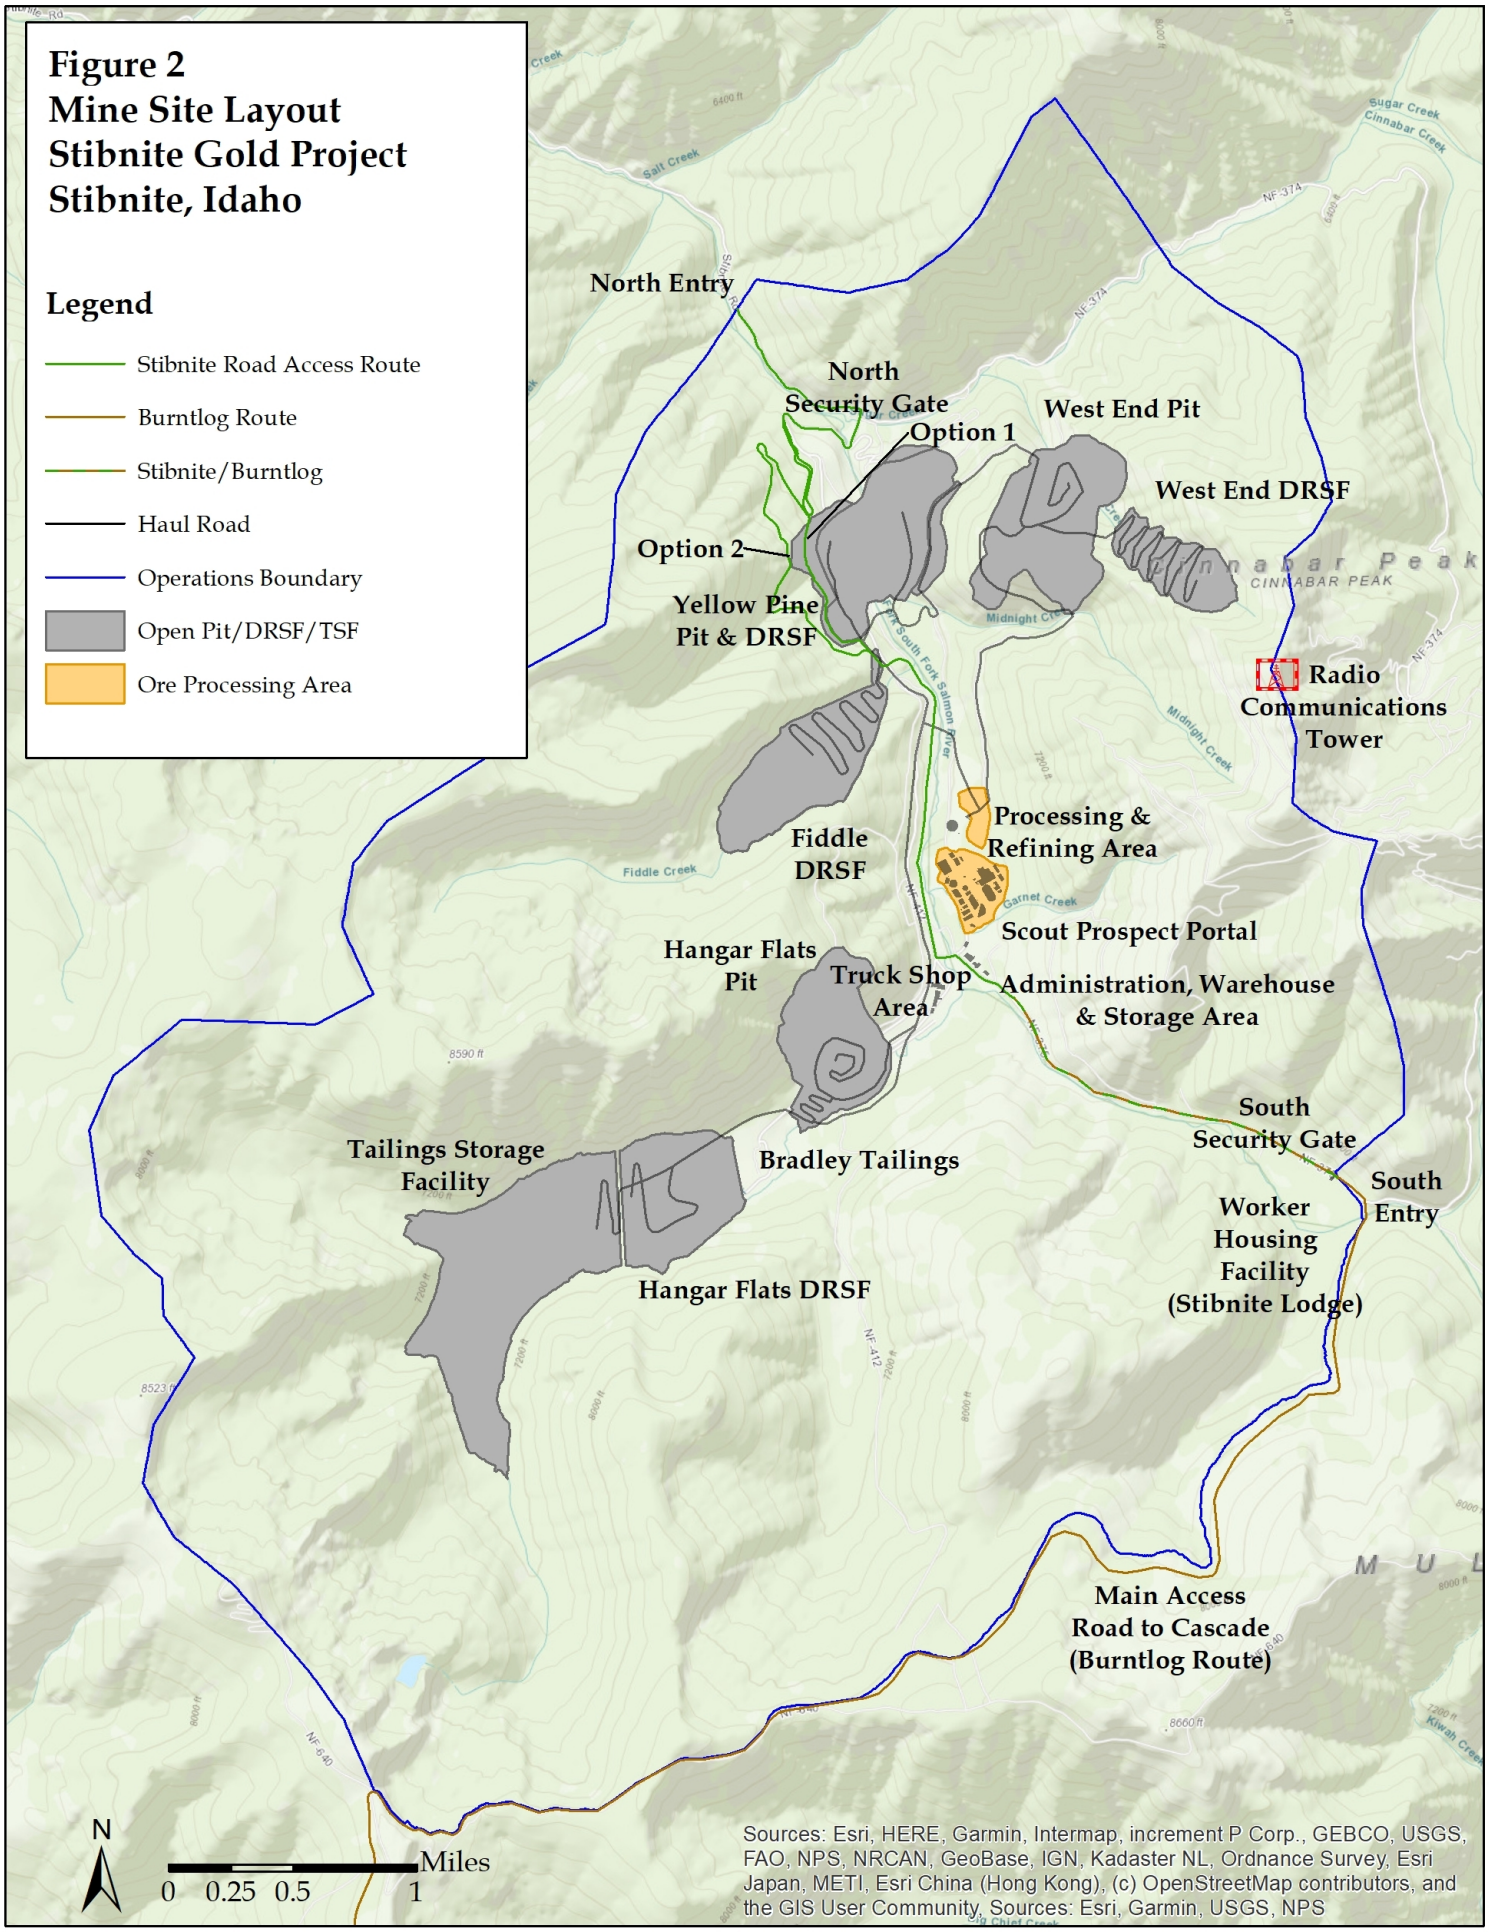
18. Most of my personal recreational activities are very strenuous aerobic activities. I breathe hard when engaging in these activities. I am concerned that if this air permit does not sufficiently protect the air quality outside of the ambient air boundary where I recreate, that through my strenuous activities, I will be breathing in more air pollutants than I would if the air permit ensured that the air quality outside of the ambient air boundary complied with health-based standards.

19. I would like to continue recreating in the South Fork Salmon River watershed, and in the areas within and outside of the ambient air boundary, but if the air quality is degraded by air pollutants emitted from the mine, then my experiences will be harmed by operation of this mine. I am extremely concerned about how reduced air quality may impact my health. Because the mine will operate year round, degraded air quality will impact both my summer and winter recreational activities in the area. As a result, places I currently enjoy kayaking, hiking, birding, photographing, snorkeling, and skiing, I will no longer feel comfortable enjoying them knowing that I am breathing in carcinogenic air pollutants. I will stop recreating in certain areas that are close to or downwind of the ambient air boundary. I will stop recommending this area as a place for friends to visit. I will be extremely uncomfortable bringing clients to the area to fish, and this would have a significant impact on my business.

20. I am also concerned that air pollutants emitted from the mine, including arsenic, will fall onto the ground and will leach into the rivers, or fall directly onto the water, and increase the arsenic concentration in the rivers where I kayak, fish, snorkel in, and drink water

from. I am concerned that if I continue to recreate in these areas once mine operations start, that I will be exposed to these pollutants. I understand that arsenic is a carcinogen, and if the rivers were more polluted with arsenic, I am concerned how that could impact my health. I would be less likely to kayak in these rivers, and would no longer snorkel. I would lose the ability to see the bull trout and this amazing aquatic habitat up close and personal.

21. I am also concerned how arsenic in the air, and arsenic falling on the ground and polluting the water will impact the bull trout and other aquatic species, terrestrial wildlife, migratory birds, and vegetation.



22. It is my understanding that the Clean Air Act and the rules or regulations that DEQ follow in issuing an air permit are designed to protect air quality by imposing pollution limits, best management practices, and restrictions on how the mine can operate, and that DEQ may impose monitoring and reporting requirements to ensure that ambient air quality is maintained. Therefore, a decision from the Office of Administrative Hearings and/or the Board of Environmental Quality that finds that the air permit is in compliance with all laws and regulations will help redress these harms. I would feel better recreating in the area and taking clients to the area if the air permit could ensure that the amount of air pollutants emitted from the mine do not exceed air quality standards at the ambient air boundary.

Pursuant to Idaho Code 18-5409, I declare under penalty of perjury that the foregoing is true and correct.

Executed this 6th day of June 2023, at Idaho County, Idaho.

Attorneys for Nez Perce Tribe and Idaho Conservation League

BEFORE THE OFFICE OF ADMINISTRATIVE HEARINGS
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047	)	Agency Case No. 0101-2201
	)	
	)	OAH Case No. 23-245-01
NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON,	)	**DECLARATION OF EMMIT TAYLOR JR.**
Petitioners,	)	
v.	)	
IDAHO DEPARTMENT OF ENVIORNMENTAL QUALITY,	)	
Respondent,	)	
and	)	
PERPETUA RESOURCES IDAHO, INC.	)	
Intervenor.	)	

I, EMMIT TAYLOR, JR., state and declare as follows:

1. My name is Emmit Taylor, Jr. I am a resident of Lapwai, Idaho, and am over 18 years of age. The following statements are based on my personal knowledge, and if called as a witness, I would and could testify thereto.

2. I am an enrolled member of the Nez Perce Tribe ("Tribe"), a federally recognized tribe, and am the Director of the Tribe's Department of Fisheries Resources Management ("DFRM"), Watershed Division. I hold a Bachelor of Science Degree in Civil Engineering from Colorado State University and a Master of Natural Resources Degree from the University of Idaho.

3. I grew up on my family's land on the Nez Perce Reservation in north-central Idaho.

4. Since time immemorial, members of the Nez Perce Tribe have used and enjoyed their aboriginal lands, which include portions of the present-day states of Idaho, Oregon, Washington, and Montana and the Columbia and Snake River basins.

5. My family continuously engaged in Nez Perce culture and the exercise of Nez Perce treaty-reserved hunting, gathering, and fishing rights throughout our aboriginal homeland, including in the South Fork Salmon River ("SFSR") watershed.

6. I have direct oral knowledge of my family's history in the SFSR watershed—a history that traces back to time immemorial. My family has countless stories, passed down through enumerable generations, of using the SFSR watershed to gather, hunt, and, mostly, fish. My late uncle, Elmer Crow, described to me how our family annually traveled throughout our aboriginal territory for a three- to five-month fishing and gathering journey. Each year's journey

ended on the SFSR. My grandpa, Ron Oatman, taught me the Nez Perce names for rivers and locations in the SFSR watershed and their place and use in traditional Nez Perce culture. My dad, Emmit Taylor, Sr., and my uncle, Dave Penney, have also shared with me countless stories of my family fishing in the SFSR watersheds streams, including the East Fork SFSR (among others), as well as fishing in Big Creek, which is accessed via the East Fork SFSR.

7. This heritage is who I am and its importance to me and my family cannot be overstated. I continue to take my family to the SFSR area on an annual basis. We hunt, gather, and, most importantly, fish in order to express our culture and identity and connect to our history, ancestors, and the land and rivers themselves. These practices are the heart of who we are as Nez Perce people and are vital to our health and well-being.

8. Today, my family and other Nez Perce Tribal members typically fish in the SFSR and its tributaries from mid-June through August. The SFSR tributaries my family and other Nez Perce Tribal members seasonally fish include the Secesh River, Lick Creek, Johnson Creek, and East Fork SFSR. While there, we also gather our traditional food and medicine.

9. I have personally engaged in treaty fishing within the boundaries of the proposed Stibnite Gold Project ("SGP"). I have fished for steelhead and bull trout which are culturally significant species to the Tribe. My family and I also plan to engage in treaty fishing, hunting, and gathering within and adjacent to the proposed SGP area in the future. I am very concerned about the adverse effects resulting from Idaho Department of Environmental Quality's issuance of the air permit for the proposed SGP on my family's ability to safely exercise our treaty rights in, and use and enjoy, the area. My understanding is that the SGP would generate air pollutants, including dust with arsenic, that are unhealthy to breathe. This air pollution also reduces

visibility which impairs my cultural and ceremonial practices and reduced my enjoyment of these special places. I am also deeply concerned that the arsenic can enter waterways and soil in the area and adversely affect culturally-significant fish and wildlife and the habitat on which those treaty resources depend. Dust with arsenic can also collect on, and can adversely affect, culturally-significant plants and medicines that my family and I gather in the area and use for cultural, subsistence, ceremonial, and spiritual purposes.

10. In addition to personally exercising treaty rights and using and enjoying the area, I also honor my heritage through my professional work as Director of the Tribe's Fisheries Department, Watershed Division.

11. The Tribe established DFRM in the early 1980s after the federal courts acknowledged the Tribe's role a co-manager of its fisheries. Since then, DFRM has devoted substantial time, effort, and resources to recovering and sustaining the Tribe's fishery. Today, the Tribe's Fisheries Department is one of the largest and most successful tribal fisheries programs in the United States with six divisions (Administration, Conservation Enforcement, Harvest, Production, Research, and Watershed), 180 employees, and an annual budget in excess of $24 million. The Fisheries Department works throughout north-central Idaho, northeastern Oregon, and southeastern Washington, with funding primarily provided by the Bonneville Power Administration, to mitigate for the harm caused to anadromous fish by the Columbia River Basin hydropower system.

12. DFRM established an office in McCall, Idaho, in the mid-1990s to maintain the Nez Perce Tribal fishery in the SFSR watershed due to its cultural and biological significance to the Tribe and to Chinook salmon recovery in Idaho. DFRM currently expends $2.79 million

annually in the SFSR watershed on hatchery supplementation, fishery research, and habitat restoration.

13. Among other production and research projects, DFRM biologists in McCall have conducted a unique, long-running study that provides information on the effects of using a hatchery supplementation program to increase a naturally spawning population of fish listed under the ESA. DFRM staff trap and spawn natural/wild-returning salmon in Johnson Creek, a tributary of the East Fork SFSR, to provide the eggs, which are reared to smolts at the McCall Fish Hatchery. DFRM biologists then release approximately 130,000 smolts back into Johnson Creek each year. DFRM monitors these juvenile releases to determine their survival through various stages of their journey out to the ocean and back to spawn. Returns are compared with non-supplemented fish to determine genetic, behavior, and morphological differences in an effort to evaluate how the use of a hatchery affects, and whether a hatchery can be a benefit to, a natural spawning population.

14. Each year, DFRM staff also collect Pacific lamprey from downriver dams, hold them at the Tribe's hatchery on the Clearwater River until the spring, and then release them to spawn in various tributaries within the Tribe's aboriginal territory, including the SFSR, to ensure their continuing presence in these streams. DFRM also moves some Chinook salmon above the fish passage blockage created by the legacy mine pit, known as the Glory Hole, at the historical Stibnite mine site to spawn. The resulting juvenile production from above the Glory Hole helps boost overall returns to the SFSR.

15. I have worked for DFRM, Watershed Division since 1996 and have been the Director for the last twelve years. As Director, I am responsible for developing and

implementing a regional aquatic ecosystem restoration and protection program for anadromous and resident fish habitat. As part of this work, I direct the Tribe's efforts to protect and restore aquatic ecosystems within the SFSR watershed.

16. DFRM Watershed Division first began working out of the McCall Fisheries Department office in 2007, when it applied for, and received, a grant for the specific purpose of reestablishing fish passage in the East Fork SFSR above the Glory Hole and of rehabilitating one mile of spawning habitat above the Glory Hole, in the headwaters of the East Fork SFSR.

17. Unfortunately, the McCall Fisheries Watershed Division was unable to complete this work. Before the Tribe could begin restoring fish passage, the private land owner of the Glory Hole reach of the East Fork SFSR entered into a lease-to-purchase option with Perpetua Resources' predecessor corporations. The Tribe was then told that it could not move forward with the project because of the possibility of re-opening a mine. Consequently, the McCall Fisheries Watershed Division moved its restoration efforts to other parts of the SFSR watershed.

18. Since 2007, DFRM Watershed Division has been able to complete numerous aquatic ecosystem restoration and protection projects in conjunction with the U.S. Forest Service, Idaho Department of Fish and Game, and private landowners. The Watershed Division has planted over 8,000 plants, removed nine fish passage barriers (opening 46 miles of blocked salmon habitat), decommissioned 214 miles of road, and improved 26.7 miles of road to reduce sediment in the SFSR that is detrimental to fish species listed under the federal Endangered Species Act.

19. In addition to this on-the-ground restoration and protection work, DFRM Watershed Division also critically evaluates and comments on other activities proposed within

the Tribe's aboriginal territory that may negatively affect the health of the aquatic ecosystem, undermine DFRM's work in the SFSR watershed, and/or harm the Tribe's treaty-reserved rights and resources and its members.

20. The proposed SGP is currently the biggest ecological threat to the SFSR watershed. The proposed mining activities under the SGP could undermine the Tribe's fisheries and fishery restoration work by degrading or polluting the East Fork SFSR and SFSR, as well as upland terrestrial habitat. Consequently, DFRM Watershed Division, along with Tribe's Cultural Resources Program, Wildlife Department, Water Resources Department, and Air Quality Program have been deeply engaged in review of the SGP. Throughout the process, the Tribe has submitted numerous written comments to federal and state permitting agencies, including written comments to Idaho Department of Environmental Quality on October 12 and November 10, 2020, March 8, 2021, and March 14, 2022. The Tribe has also engaged extensively in staff-to-staff meetings, many of which I participated in personally, and convened government-to-government consultations with federal permitting agencies.

I declare under penalty of perjury that the foregoing is true and correct.

Attorney for Save the South Fork Salmon

BEFORE THE OFFICE OF ADMINISTRATIVE HEARINGS
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047	Agency Case No. 0101-2201 OAH Case No. 23-245-01
NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON, *Petitioners*, v. IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY, *Respondent*, and PERPETUA RESOURCES IDAHO, INC., *Intervenor*.	**DECLARATION OF JULIA THROWER**

DECLARATION OF JULIA THROWER

I, JULIA THROWER, hereby declare as follows:

1. The following facts are personally known to me, and if called as a witness, I could and would competently testify thereto. I am over eighteen years of age.

2. I am counsel of record representing Save the South Fork Salmon in this matter.

3. The attached Exhibits 15-17 are true and correct copies of the following documents, which were produced during discovery in this matter:

Doc. No.	Bates No.	Document Description
15	PET 838-839	Stantec Memo to Ramanathan (May, 12, 2021)
16	PET 840-885	U.S. EPA Office of Inspector General Report (July 8, 2021)
17	PET 885-1265	Stibnite Gold Project Air Quality Specialist Report (Aug. 2022)

4. The attached declarations are true and correct copies of the following documents, which are filed with Petitioners' Response to DEQ's and Perpetuta's Motions for Summary Judgment and Reply in Support of Petitioners' Motion for Summary Judgment:

- Declaration of Allison Fowle
- Declaration of Drew Hollenback
- Declaration of Asa Menlove
- Declaration of Joseph Oatman
- Declaration of Jonathan Oppenheimer
- Declaration of Zak Sears
- Declaration of Emmit Taylor Jr.

I declare under penalty of perjury that the foregoing is true and correct to the best of my knowledge, information, and belief, and based on my personal experiences.

Signed this 9th day of June 2023, in McCall, Idaho.

Stantec

Memo

To:	Brinda Ramanathan USFS Bridger-Teton NF	From:	Eric Clark, PE Boise, Idaho Office
File:	203721981	Date:	May 12, 2021

Reference: Access Road and Ambient Air Boundary Applicability – Stibnite Gold Project EIS

Ms. Ramanathan:

Stantec Consulting Services, Inc. (Stantec) and the United States Forest Service (USFS) held a conference call on March 26th, 2021 to discuss air quality elements of the Stibnite Gold Project (SGP) draft EIS and appropriate updates or changes to be completed for the final EIS. Several questions arose from that meeting, which prompted Stantec to develop a "path forward" document to address specific points of concern. These included potential differences in modeling techniques/requirements between the Idaho Department of Environmental Quality (DEQ) state-regulated air permit and the modeling approach applied for the EIS, whether the proposed dust control efficiencies (93.3%) are attainable and will be monitored appropriately and to explore the applicability of the proposed public access road through SGP being excluded from ambient air. The following discussion focuses on the access road and the rationale for exclusion from ambient air.

Public Road Description and Restricted Access Approach

The road is described, and access control measures outlined by Midas Gold Idaho, now Perpetua Resources, in the December 18th, 2020, Refined Proposed Action – ModPro2 document as follows:

A new 12-foot-wide gravel road would be constructed to provide public access from Stibnite Road (FR 50412) to Thunder Mountain Road (FR 50375) through the mine site (Figure 3-2). The road would be constructed on a widened bench within the Yellow Pine pit. South of the Yellow Pine pit, this road would parallel a mine haul road and use a partially revegetated portion of the former Bradley mine haul road. This road would be approximately 4 miles in length. The public access road would be constructed concurrent with the removal of development rock from Yellow Pine pit.

During operations, the public access road would be used to travel through the mine site and would provide seasonal use, open to all vehicles. Vehicles passing through the mine site would be required to check-in with mine personnel at the North or South mine site entry points and would receive a safety briefing. For safety purposes, vehicles on the public access road would be required to pass through the mine site without stopping or deviating from the public access road and would be required to check-out with mine site personnel upon exiting the mine site. Midas Gold would restrict mine site access to any vehicles due to concerns related to public or employee health and safety, such as during blasting, mining in the immediate area of the road and other similar operations.

Berms, security fencing, and an underpass to allow the public road to pass beneath the mine haul road, would separate the public access road from other mine site roads; the underpass would be located north of Fiddle Creek. The public access road would be temporarily closed during construction and maintenance of the public access road, and other mining activities that would be considered public safety hazards (e.g., high wall scaling, blasting). The public access road would be maintained to the current standards (i.e., not plowed in the winter) and signs would be placed to inform the public of seasonal and temporary closure.

During the operations phase (and during closure and reclamation) public access by foot or on roads would be restricted from entering the operations boundary shown in the SGP DEIS on Figure 2.3-2. Security personnel,

Reference: **Access Road and Ambient Air Boundary Applicability – Stibnite Gold Project EIS**

fencing (including wildlife exclusion fencing), and signs would restrict public access to the designated public access roadway within the operations boundary.

Idaho DEQ Approach to Access Road

Prior to completion of the EIS, Perpetua also applied for a Permit to Construct with Idaho DEQ. This application proposed to exclude the public road on the basis of restricted access and that people traveling on the road would be considered "guests of the mine" and maintain full control. The current draft permit and associated statement of basis (as of February 18th, 2021) states that "receptors on the Stibnite Road access road were not included in the SGP air quality analysis as this road is not considered ambient air". Response to comments on February 18th, 2021 also states that the roadway between Stibnite Road at Sugar Creek and Thunder Mountain Road at Meadow Creek was appropriately excluded from ambient air. Lastly, direct communication with DEQ permitting staff has also confirmed this determination.

EPA Approach to Access Road

The Environmental Protection Agency (EPA) to Stantec's knowledge has never explicitly stated that the public access road is excluded from ambient air, but they have insinuated as such on numerous occasions by referring their 2019 guidance memorandum or deferring to DEQ on the matter. For example, on a November 18th, 2020 response to comments of the DEIS, Region X acknowledges, and it is accepting of DEQ's findings and states on page 25 of the response letter they are "recognizing that this control access road would not be ambient air". Additionally, on an April 15th, 2021 conference call with Stantec and the USFS, EPA representatives affirmed that controlled public access road is consistent with the December 2nd, 2019 Revised Policy on Exclusions From "Ambient Air" memorandum.

The memo states "*the atmosphere over land owned or controlled by the stationary source may be excluded from ambient air where the source employs measures. which may include physical barriers. that are effective in precluding access to the land by the general public".* The measures to-be employed by Perpetua, as discussed above, would qualify under the revised broader definition.

Conclusion

After review of all pertinent information associated with other cooperating agencies, it is Stantec's understanding that the public access road can be justifiably excluded from ambient air consideration. The State agency responsible for issued air permits has excluded the road because of restriction measures put in place consistent with their rules and requirements in the permit. Also, EPA Region X has accepted DEQ's conclusions. Dispersion modeling conducted by DEQ has demonstrated compliance with applicable National Ambient Air Quality Standards given higher production rates than will be allowed in the EIS and Record of Decision.

At a Glance

EPA Should Conduct More Oversight of Synthetic-Minor-Source Permitting to Assure Permits Adhere to EPA Guidance

Why We Did This Audit

We conducted this audit to determine whether the U.S. Environmental Protection Agency and state and local agencies provide sufficient oversight to assure that synthetic-minor sources of air emissions comply with the limits in their air permits.

Synthetic-minor sources are facilities that agree to restrictions in their permits to reduce their actual emissions below major-source thresholds to avoid being major sources of air pollution under Clean Air Act permitting programs. Major sources are the largest emitters of air pollution and are subject to stringent permitting and compliance requirements.

This audit addresses the following:

- *Improving air quality.*

This audit addresses a top EPA management challenge:

- *Overseeing states implementing EPA programs.*

Address inquiries to our public affairs office at (202) 566-2391 or OIG_WEBCOMMENTS@epa.gov.

List of OIG reports.

What We Found

While the EPA oversees state and local compliance monitoring for synthetic-minor-source permits, the EPA conducts only limited oversight of the permits themselves. The EPA has issued guidance to state and local agencies to develop enforceable permit limitations in synthetic-minor-source permits, but the Agency does not review permits to assure the agencies meet this guidance.

Without clear and enforceable limitations in synthetic-minor-source permits, facilities may emit excess pollution that would otherwise subject them to the more stringent requirements of the Clean Air Act major-source permitting programs.

We reviewed 16 natural gas extraction industry synthetic-minor-source permits from Colorado and Oklahoma and found that many of the permit limitations did not adhere to the EPA's guidance. For example, in those permits, we found that 102 of 529 permit limits did not have sufficient information within the permit or the permit's supporting documentation to determine whether the limits were technically accurate. We also found that 26 limits did not specify the method for assessing compliance. In addition, 55 limits did not have sufficient monitoring requirements to determine whether the facility's assumed pollution reduction from pollution control devices was being achieved. This could result in a synthetic-minor facility emitting pollutants at or above major-source levels without being detected.

In addition, we found that the EPA had not communicated several key expectations for synthetic-minor-source permitting to state and local agencies via guidance. Further, Oklahoma does not allow the public to participate in its permitting process for certain synthetic-minor-source permits, as required by EPA regulations. EPA staff said this may be the case in other states as well.

Recommendations and Planned Agency Corrective Actions

We recommend that the EPA (1) develop and implement an oversight plan for synthetic-minor-source permitting; (2) update its practical enforceability guidance; (3) assess EPA studies and other relevant information on enclosed combustion devices during its next review of applicable regulations to determine whether revisions to monitoring, record-keeping, and reporting requirements are needed; (4) develop and issue new guidance that includes key EPA expectations for synthetic-minor-source permitting; and (5) take steps to assure that all states adhere to public participation requirements for synthetic-minor permits. All recommendations are resolved with corrective actions pending.

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
WASHINGTON, D.C. 20460

THE INSPECTOR GENERAL

July 8, 2021

MEMORANDUM

SUBJECT: EPA Should Conduct More Oversight of Synthetic-Minor-Source Permitting to Assure Permits Adhere to EPA Guidance
Report No. 21-P-0175

FROM: Sean W. O'Donnell

TO: Joseph Goffman, Acting Assistant Administrator
Office of Air and Radiation

This is our report on the subject audit conducted by the Office of Inspector General of the U.S. Environmental Protection Agency. The project number for this audit was OA&E-FY19-0093. This report contains findings that describe the problems the OIG has identified and corrective actions the OIG recommends. Final determinations on matters in this report will be made by EPA managers in accordance with established audit resolution procedures.

The Office of Air and Radiation is responsible for the recommendations presented in this report.

In accordance with EPA Manual 2750, your office provided acceptable planned corrective actions in response to all five OIG recommendations. All recommendations are resolved, and no final response to this report is required. If you submit a response, however, it will be posted on the OIG's website, along with our memorandum commenting on your response. Your response should be provided as an Adobe PDF file that complies with the accessibility requirements of Section 508 of the Rehabilitation Act of 1973, as amended. The final response should not contain data that you do not want to be released to the public; if your response contains such data, you should identify the data for redaction or removal along with corresponding justification.

We will post this report to our website at www.epa.gov/oig.

Chapter 1
Introduction

Purpose

The Office of Inspector General for the U.S. Environmental Protection Agency conducted this audit to determine whether the EPA and state and local agencies provide sufficient oversight to assure that synthetic-minor sources of air emissions comply with the limits in their air permits. Specifically, we focused on emission, operational, and production limits in the permits.

Top Management Challenge

This audit addresses the following top management challenge for the Agency, as identified in OIG Report No. 20-N-0231, *EPA's FYs 2020–2021 Top Management Challenges*, issued July 21, 2020:

- Overseeing states implementing EPA programs.

Background

The Clean Air Act, or CAA, permitting programs cover three types of facilities:

- **Major sources**, which are facilities that emit regulated pollutants over certain levels measured by tons per year or TPY, referred to as major-source thresholds. Major-source thresholds differ by permitting program and type of pollutant.
- **True-minor sources**, which are facilities that have the potential to emit regulated pollutants below major-source thresholds.
- **Synthetic-minor sources**, which are facilities that have the potential to emit regulated pollutants at or above major-source thresholds but that agree to enforceable restrictions to limit their emissions below these thresholds to avoid being subject to more stringent major-source requirements.[1] Such enforceable restrictions, also called limitations, are included in a facility's air permit.

Enforceable restrictions or limitations are conditions in air permits. If a facility does not adhere to its limitations, the state, local, or tribal permitting agency or the EPA may take administrative, civil, or criminal enforcement actions. This includes issuing a notice of violation, an order for the facility to come into compliance, or a fine. Citizens may also file a civil action suit against a facility for permit limitations violations.

[1] Synthetic-minor sources are referred to as "synthetic" because they would be major sources if not for their enforceable permit restrictions. Thus, they have "synthetically" become a minor source by accepting those restrictions.

Examples of enforceable restrictions are limiting a facility's operating hours or operating pollution control equipment to reduce emissions to a specified level. Figure 1 illustrates how a potential major source may choose to accept enforceable permit restrictions to avoid major-source permitting requirements.

Figure 1: New facility chooses to accept enforceable restrictions to avoid major-source-permitting requirements

Source: EPA OIG analysis of enforceable permit restrictions. (EPA OIG image)

By implementing enforceable permit restrictions on their potential to emit regulated pollutants, synthetic-minor sources can avoid certain costly requirements of CAA permitting programs that apply to major sources. These programs include Title V, Nonattainment New Source Review, and Prevention of Significant Deterioration. Appendix A summarizes these permitting programs and the corresponding levels of emissions that make a facility a major source under each program.

Based on data in the EPA's Integrated Compliance Information System for Air, known as ICIS-Air, there were 27,498 synthetic-minor sources and 12,282 major sources operating in the United States in 2019. The ratio of synthetic-minor sources to major sources has changed slightly over the last decade, with the proportion of synthetic-minor sources being 2 percent higher in 2019 than in 2011 and major sources being 2 percent lower.

State and local agencies conduct most permitting and oversight activities of synthetic-minor sources through permitting programs that have been approved by the EPA. This includes developing or writing facilities' specific permit limitations, as well conducting activities such as inspections to assure that facilities are in compliance with their permit limitations. The EPA is responsible for overseeing state and local agencies' permitting programs through support and evaluation activities by clearly describing objectives and expectations, such as

PET-847
REC 2566

through guidance documents, to increase state and local agencies' ability to successfully implement program requirements.

Some synthetic-minor sources operate under a general permit rather than an individual, facility-specific permit. A general permit is a single permit that establishes terms and conditions that all facilities subject to that permit must comply with. The establishment of a general permit provides for emission limitations in a one-time permitting process and thus avoids the need to issue separate permits for each facility operating under the general permit. A state or local agency may develop general permits for a specific industry when there are a large number of facilities within that industry that need to be permitted.

Types of Synthetic-Minor-Permit Limitations

There are several types of limitations that can be used in a permit to restrict a synthetic minor's potential to emit below major-source thresholds. These include:

- **Emission limits**, which are restrictions over a given period of time on the amount of a pollutant that may be emitted from a source into the outside air.

- **Production limits**, which are restrictions on the amount of final product that can be manufactured or otherwise produced at a source.

- **Operational limits**, which include all other restrictions on the manner in which a source is run, including hours of operation, amount of raw material consumed, fuel combusted, or conditions that specify that the source must install and maintain add-on controls that operate at a specified emission rate or efficiency.

It is important to assure that the limitations in synthetic-minor-source permits are clear and enforceable and that synthetic-minor sources comply with these limitations. If a synthetic-minor-source permit did not have permit limitations, the facility would be considered a major source and subject to the more stringent requirements of the major-source permitting programs. Although these facilities are not major sources, they may still be significant emitters of regulated pollutants. This is particularly the case for synthetic minors considered to be SM-80 sources, which are a subset of synthetic-minor facilities that emit or have the potential to emit pollutants at 80 percent or more of major-source thresholds.

EPA Guidance on Synthetic-Minor Sources

The EPA has issued guidance for state agencies to use in developing synthetic-minor-source permits. Of particular importance in the guidance are two related concepts:

- **Federal enforceability** refers to whether the limitations placed on a source's potential to emit are enforceable by the EPA and private citizens as a legal and practical matter, thereby providing the public with credible assurances that otherwise major sources are not avoiding applicable CAA requirements.

- **Practical enforceability** refers to whether the permit provisions readily allow regulators to assess a facility's compliance with its permit limitations.

The EPA has also issued guidance for conducting compliance monitoring activities at synthetic minors considered to be SM-80 sources. The EPA's 2016 *Clean Air Act Stationary Source Compliance Monitoring Strategy*, known as the *CAA CMS*, describes the recommended frequency of full compliance evaluations at SM-80 sources, as well as the activities that inspectors should complete to assess compliance during full compliance evaluations.

Responsible Offices

Within the Office of Air and Radiation, or the OAR, the Office of Air Quality, Planning, and Standards, known as the OAQPS, is responsible for developing regulations and guidance related to air permitting, as well as providing high-level oversight of state and local air permitting programs. The Office of Enforcement and Compliance Assurance is responsible for developing guidance for state and local agencies to use in conducting compliance monitoring at permitted sources of air pollution and for overseeing state and local compliance monitoring programs. The EPA regions are also responsible for overseeing state and local air permitting and compliance monitoring programs.

Scope and Methodology

We conducted this performance audit from November 2019 to April 2021 in accordance with generally accepted government auditing standards. Those standards require that we plan and perform the audit to obtain sufficient, appropriate evidence to provide a reasonable basis for our findings and conclusions based on our audit objective. We believe that the evidence obtained provides a reasonable basis for our findings and conclusions based on our audit objective.

As detailed in Appendix B, we assessed the internal controls necessary to satisfy our audit objective.[2] In particular, we assessed the internal control components and underlying principles—as outlined in the U.S. Government Accountability

[2] An entity designs, implements, and operates internal controls to achieve its objectives related to operations, reporting, and compliance. The U.S. Government Accountability Office sets internal control standards for federal entities in GAO-14-704G, *Standards for Internal Control in the Federal Government* (also known as the Green Book), issued September 10, 2014.

Office's Green Book—significant to our audit objective. Any internal control deficiencies we found are discussed in this report. Because our audit was limited to the internal control components and underlying principles deemed significant to our audit objective, our audit may not have disclosed all internal control deficiencies that may have existed at the time of the audit.

To address our objective, we reviewed EPA policies and guidance related to synthetic-minor-source permitting and compliance monitoring. We also interviewed staff and managers in the OAQPS and the Office of Enforcement and Compliance Assurance.

We also reviewed synthetic-minor facilities in the natural gas extraction sector to assess whether synthetic-minor-source permit limitations and provisions adhered to EPA guidance and whether the facilities' inspections were consistent with EPA guidance. Specifically, we reviewed eight facilities in Oklahoma in Region 6 and eight facilities in Colorado in Region 8. We selected these states because they have among the highest number of synthetic-minor facilities in the natural gas extraction industry, according to the 2017 National Emissions Inventory. For each of the 16 facilities, we reviewed each active permit and the associated technical support documentation, referred to as the permit record, to assess whether permit limitations and associated provisions adhered to EPA guidance on synthetic-minor-source permitting. This included a total of 30 permits covering the 16 facilities. In total, we reviewed 523 limits, including:

- 310 unit-specific emission limits.
- 42 facilitywide emission limits.
- 171 production and operation limits.

For each of the 16 facilities, we also reviewed documentation related to full compliance evaluations conducted at the facilities to determine whether the facilities were inspected in accordance with EPA guidance on compliance monitoring activities.

We interviewed staff and managers from the OAQPS; the Office of Enforcement and Compliance Assurance; Regions 6 and 8; the Colorado Department of Public Health and Environment, known as CDPHE; and the Oklahoma Department of Environmental Quality, known as ODEQ.

Appendix C provides more details on our scope and methodology. Appendix D provides background information on the natural gas extraction industry.

PET-850
REC 2569

Chapter 2
EPA Should Conduct Additional Oversight to Assure That Synthetic-Minor-Source Permits Meet Guidance

While the EPA oversees compliance monitoring activities at synthetic-minor facilities to assure that facilities comply with their permits, the EPA conducts minimal oversight of the permits themselves. The EPA has issued guidance for state and local agencies to use in developing synthetic-minor-source permit limitations to assure that the limits are enforceable as a practical matter, but the EPA does not assess whether state and local agencies have developed permit limits in accordance with this guidance. We found that 23 of the 30 synthetic-minor-source permits we reviewed in the natural gas extraction industry did not adhere to all elements of the EPA's guidance on practical enforceability. In cases where practical enforceability guidance was not met due to insufficient monitoring requirements, it could be more difficult to detect when a synthetic-minor source has violated its permit limitations or is actually emitting pollutants at a major-source level. The EPA should increase its oversight of synthetic-minor-source permits to better assure that limits adhere to EPA guidance and are practically enforceable.

EPA Policy Requires Oversight of Permitting Programs

Under the 1984 *EPA Policy on Oversight of Delegated Environmental Programs*, the Agency is responsible for overseeing state and local programs. The policy states that EPA oversight of delegated state programs should, among other things, enhance state capabilities to administer sound environmental protection programs through increased communication and a combination of support and evaluation activities. In addition, the policy calls for the EPA to clearly describe objectives and expectations for state environmental programs to increase the ability of state agencies to successfully implement program requirements and to increase the EPA's ability to provide appropriate assistance and evaluation. Examples of tools provided in the EPA's policy include detailed, up-front guidance on how program work should be performed.

In December 2020, the EPA issued its *National Permitting Oversight Policy*. The policy states that the EPA is responsible for ensuring permits and permitting programs conform with applicable laws and regulations. Additionally, the policy states that the EPA's regular oversight of permits and permitting programs is designed to identify and resolve emerging issues collaboratively with the permitting authority, such as a state or local agency, long before the issues pose a significant risk to the effectiveness of the program. This way, the EPA can avoid invoking procedures to withdraw program delegation, authorization, or approval.

EPA Conducts Oversight of Compliance Monitoring Activities at Synthetic-Minor Sources to Assure Facilities Comply with Permits

The Office of Enforcement and Compliance Assurance oversees state and local compliance monitoring activities including at SM-80s. According to the *CAA CMS*, states should conduct a full compliance evaluation of each SM-80 source once every five fiscal years and report the data to the ICIS-Air database.

Office of Enforcement and Compliance Assurance staff said that the EPA regional offices meet regularly with state and local agencies, and one of the issues they discuss is whether state and local agencies are having any problems meeting the requirements of the *CAA CMS*. Further, Office of Enforcement and Compliance Assurance staff receive a monthly *CAA CMS* report that identifies sources that are overdue for a compliance evaluation and contact the responsible EPA regional office for resolution.

The EPA regional offices audit state performance against *CAA CMS* goals through the State Review Framework reviews, which are completed every five years for each state. The following State Review Framework metrics are relevant to overseeing synthetic-minor sources: full compliance evaluation coverage of SM-80s, documentation of full compliance evaluation elements, and timeliness of high-priority violation determination and identification.

We found that Colorado and Oklahoma conducted compliance monitoring activities at the synthetic-minor natural gas production facilities we reviewed in accordance with the *CAA CMS*. All the facilities we reviewed had at least one full compliance evaluation conducted by the state between fiscal years 2015 and 2020, in accordance with the *CAA CMS*. In addition, reports from states' full compliance evaluations show that the CDPHE and the ODEQ generally included all activities that are supposed to be conducted during such evaluations. Further, compliance monitoring reports contained all the elements required by the *CAA CMS*.

EPA Conducts Limited Oversight of Synthetic-Minor-Source Permits

The EPA developed numerous guidance documents in the late 1980s and throughout the 1990s for state and local agencies to use in developing synthetic-minor-source permit limits so that the limits are practically enforceable. The guidance, however, has not been consolidated and lacks clarity on how to effectively limit facilities' potential to emit air pollution. In fiscal year 2020, the OAQPS issued training slides, titled "Setting Enforceable Potential to Emit Limits in Permits," that present important criteria from various EPA guidance documents. These slides were intended to promote consistency in how state and local agencies develop synthetic-minor-source permit limits, but they are not considered to be official guidance.

Neither EPA headquarters nor regional offices conduct regular or routine evaluations or review synthetic-minor-source permits and the limitations adopted by facilities to avoid major source status. The OAQPS only reviews synthetic-minor-source-permit limitations in cases where a Title V permit under review contains such limitations. This may occur when the Agency receives a petition to review a specific Title V permit. Title V permits are issued for major sources and some minor sources of air pollution and impose certain record-keeping and reporting requirements on facilities. Synthetic-minor limitations may be included in some Title V permits if the facility is a major source for some pollutants and a synthetic-minor source for other pollutants. Beyond Title V permits, OAQPS staff stated that they do not review synthetic-minor limitations, and the office does not receive synthetic-minor-source permits from the state and local agencies.

Region 8 staff told us that they do not oversee minor sources, synthetic or otherwise, because that is not considered to be one of their responsibilities. According to Region 8 staff, EPA headquarters has directed regions to focus their oversight activities on major sources. The only Region 8 responsibilities that relate to synthetic-minor oversight are (1) reviewing State Implementation Plans to modify state permitting programs and (2) assisting states with problems or issues, such as ones brought up during a permit's public comment period or in the media.

A State Implementation Plan is an EPA-approved plan that is made up of various air pollution control measures and activities that a state will implement to meet certain air quality standards.

Region 6 staff told us that the region does not routinely review synthetic-minor-source permits but that states notify the region when a synthetic-minor-source permit is released for public comment. Region 6 does not focus on synthetic-minor permits but may review a permit if the media reports a problem with the permit, the state received a significant comment on the permit, or a citizen complains about the permit.

Many Permits Reviewed Did Not Adhere to EPA Guidance on Practical Enforceability

EPA guidance on practical enforceability states that a permit's provisions should specify:

- A technically accurate limitation and the portions of the source subject to the limitation.
- The time period for the limitation, such as hourly, daily, monthly, or annually. A rolling annual limit, for example, is based on 12 consecutive months rather than a calendar year. When the month changes, the most recent prior 12 months, regardless of the calendar year, are used to determine compliance.

- The method to determine compliance, including appropriate monitoring, record-keeping, and reporting. Examples of this include monitoring and maintaining records on a facility's hours of operation and the amount of product produced.

We identified instances for each of these three elements where permits did not adhere to the EPA's guidance. Practical enforceability is key to permitting because it helps assure that a permit's provisions are written in such a way that regulators and citizens can assess a facility's compliance with its permit limitations. This helps assure that synthetic-minor-source facilities are not actually emitting pollution at major-source levels.

Many Synthetic-Minor-Source Permits or Permit Records Reviewed Did Not Include Sufficient Documentation to Verify Technical Accuracy of Limitations

To assure a synthetic-minor-source permit is practically enforceable, the state or local agency must establish technically accurate permit limitations that include the portions of the facility subject to the limitation. A technically accurate permit limitation is one that is "sound," "appropriate," and based on the most representative data available. We have concluded, based on EPA guidance and interviews with EPA staff, that in order for a reviewer to determine whether a limit is technically accurate, the permit or permit record should include information that supports the different elements that are relied upon to determine the limitation.

The technical accuracy of emission limits that rely on pollution control equipment, such as an enclosed combustion device—known as an ECD—or an engine catalyst system, is verifiable when the permit or permit record includes supporting information about the specific control equipment used. ECDs are intended to reduce volatile organic compounds, known as VOC, and hazardous air pollutant emissions that are known or suspected to cause cancer and other serious health problems. Engine catalyst systems are intended to reduce nitrogen oxides and carbon monoxide emissions.

These pollution control devices are included in air permits with an associated control efficiency, which can vary depending on the specific equipment and pollution control device used. The control efficiency is the percent of pollution emission reduction obtained from pollution control equipment. For example, the CDPHE generally assumes that ECDs reduce VOC and hazardous air pollutant emissions with a 95 percent control efficiency. For the technical accuracy of emission limits that rely on ECDs and engine catalysts to be verifiable, the assumption that the device obtains a specific control efficiency should be supported in the permit or permit record. Based on EPA guidance and interviews, such support could include emissions data from compliance tests, other source tests, or equipment vendor emissions data and guarantees.

PET-854
REC 2573

Limits Reviewed Lacked Sufficient Supporting Documentation

In the permits we reviewed, 96 of the 523 limits were not adequately supported by documentation, such as underlying information about pollution control equipment with an assumed control efficiency, in the permit or permit record. This lack of critical supporting information prevented us from determining whether the limits contained errors and properly prevented the synthetic-minor source from operating at major-source levels.

Of the 96 limits that lacked adequate support, 35 relied on assumed control efficiencies from pollution control equipment designed to restrict emissions, such as ECDs and engine catalysts. In 20 of these 35 cases, the assumed control efficiency was 95 percent or greater, but neither the permit nor permit record provided documentation to support this assumption. Specifically, the permit and permit record did not include a manufacturer's guarantee of control efficiency, testing data, model inputs, or other information that could be used to validate this control efficiency assumption. Staff and managers from the CDPHE told us that the 95 percent control assumption efficiency for ECDs is based on the manufacturer's guaranteed control efficiency and anecdotal field testing in Colorado, but we found no support in the permit or permit record for that assumption in these cases.

We found that 41 of the 96 limits could not be verified because there was insufficient underlying support for the basis of the emission factor used. An emission factor is a representative value designed to relate the quantity of a pollutant released to the atmosphere with an activity associated with the release of that pollutant. Such factors facilitate the estimation of emissions from various sources of air pollution. For example, one permit simply cited "Conservative [Texas Commission on Environmental Quality] … emission factors" as the source of the emission factor, but there was no other citation in the permit or permit record that would allow a third party to identify what the emission factor is based on or where to find that information.

Information on which permit limits are based needs to be as complete and transparent as possible so that permit writers, the public, and the EPA can assess whether pollution reductions are likely to occur as intended. Not providing sufficient underlying support for what permit limits are based upon undermines the ability to conduct such an assessment.

Instruction on Documentation Has Not Been Clearly Communicated in EPA Guidance

EPA guidance from the 1980s and 1990s does not provide permitting authorities with instruction on what supporting information should be included in the permit or permit record. The guidance is decades old, not specific to any particular industry or synthetic-minor-source permitting,

PET-855
REC 2574

contained within multiple discrete documents, and, in one case, only available in draft form. The training slides that the EPA developed in fiscal year 2020 present criteria from various guidance documents. It also provides information and examples of technically accurate limitations that are not included in prior guidance. The EPA, however, has not updated its guidance documents to include, or expand upon, the information in the training.

In addition, we found that OAQPS permitting staff and managers have expectations for assuring limits are practically enforceable, but those expectations have not been clearly communicated to state agencies. For example, during one interview, OAQPS staff and managers told us that supporting documentation, such as a manufacturer specification sheet for an ECD, should be contained within the permit record. This expectation is not stated in any formal guidance document.

Some Synthetic-Minor-Source Permit Limits Did Not Include Time Period That Was Consistent with EPA Guidance

To assure a synthetic-minor-source permit is practically enforceable, the permit must specify a time period for the limitation—generally, hourly, daily, or monthly—but not exceed an annual limit on a 12-month rolling basis. The time periods for all limits should readily allow for demonstration of compliance.

The time periods associated with 25 of the 523 permit limits we reviewed did not adhere to EPA guidance. Of the 25 permit limits, 11 were for facilities in Colorado. We found nine emission limits in one permit that were annual limits with no rolling monthly averages. The CDPHE told us that this was a permit-writer error rather than a systemic issue in Colorado permitting. We agree with that assessment, given that we did not find any evidence to contradict this explanation. Separate from this permit-writer error, two Colorado permits contained an operational limit for which the time period did not adhere to EPA guidance.

We found that 14 of the annual emission limits in the Oklahoma permits we reviewed did not adhere to EPA guidance on time periods. In these cases, the permits did not clearly state that the emission limits were to be based on a 12-month rolling total or provide corresponding short-term limits, such as pounds per hour, that would make the limit easier to enforce. The permit writers used a template that labeled annual emission limits as TPY rather than on a rolling annual basis.

It is more difficult for inspectors to determine compliance with limits that have longer time periods. For example, EPA guidance explains that an inspector could not verify compliance for an emissions unit with only monthly and annual production, operational, or emission limits if the inspection occurred at any time except at the end of a month. Further, if there is a compliance problem, such as

excess emissions from a particular piece of equipment, longer time periods could mean that the issue is not detected by the facility or an inspector until months after the problem began. The sooner a violation is identified, the less likely excess emissions will occur.

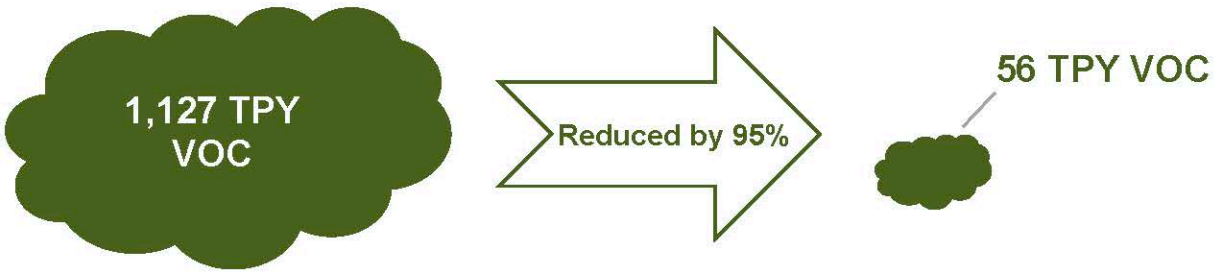
Some Synthetic-Minor-Source Permits Did Not Specify Method to Determine Compliance with Certain Limitations or Lacked Sufficient Monitoring Requirements

The final component of establishing a practically enforceable limit requires the permit writer to specify the method to determine compliance, including appropriate monitoring, record-keeping, and reporting requirements, for each limit in the permit. Based on 1990 draft EPA guidance, limitations must be easily measurable and allow no subjectivity in their compliance determinations. In particular, when permits include a requirement to operate a control device at a particular control efficiency level, the permits should also contain monitoring requirements for the specific parameters cited in the permit or those which ensure the efficiency of the unit as required in the permit. A parameter, such as temperature, is a key indicator of system performance that is correlated with the control efficiency obtained by the pollution control device. Such requirements allow a permitting agency to instantaneously verify a source's compliance with its limits.

In Oklahoma, 26 Permit Limits Lacked Specified Method to Determine Compliance

For 26 of the 230 limits we reviewed in Oklahoma permits, the permits did not specify a method for determining compliance. The majority of these 26 limits are VOC emission limits associated with engines in a permit that does not require VOC emissions testing. Other limits are based, in part, on production limits, such as limits on throughput. The production limits are required to be tracked and monitored monthly, but the permits did not clearly explain how monthly tracking of production limits demonstrates compliance with emission limits. In these instances, the connection between the production limits and the emission limits were not described.

Vague permitting conditions, such as unclear or missing statements on the method for determining compliance, can allow facilities unintended flexibility. For example, a facility may discover that its typical method for determining compliance with an emission limit generates emissions estimates in excess of the emission limit during a compliance period. If the method of compliance is not stated, the facility has the option to use a more favorable estimation technique that may not show the facility has exceeded its permit limit.



Fifty-Five Limits Did Not Contain Sufficient Monitoring Requirements to Assure That Assumed Control Efficiency Was Being Met

Based on the permits we reviewed, synthetic-minor-source permits often rely on the assumed control efficiencies of add-on control devices, such as an ECD or engine catalyst system, to achieve emission reductions below major-source thresholds. For 55 of the 523 permit limits we reviewed, we found that the permit lacked sufficient direct testing or parametric monitoring to assure that the assumed control efficiency of control devices was being met.

Parametric monitoring measures key indicators of system performance that are correlated with the control efficiency obtained by the pollution control device. These parameters are generally operational or design parameters of the process or the air pollution control device that are known to affect the emissions levels from the process or the control. An example of a potential way to conduct parametric monitoring for ECDs is measuring combustion chamber temperature, as this is considered to be a design parameter that impacts ECD combustion efficiency. Examples of parametric monitoring for engine catalysts include measuring temperature, changes in pressure, and the presence of oxygen.

Figure 2 shows how the assumed control efficiency of a control device, such as an ECD, reduces a facility's potential to emit below major-source thresholds, based on one of the permits we reviewed. In this example, a facility emits 1,127 tons of VOC if it operates for an entire year, which would subject the facility to major-source requirements. Facility management may choose to install an add-on control with an assumed 95 percent VOC control efficiency, which would theoretically reduce the facility's emissions to 56 tons of VOC per year. If the facility emits less than 100 tons of VOC per year, it would be considered a synthetic-minor-source and would not have to follow major-source requirements. If the ECD did not achieve 95 percent VOC control efficiency, the facility could be emitting at major-source levels without having to follow major-source requirements.

Figure 2: How permitting authorities may use a 95 percent control efficiency assumption for an emissions control device to reduce potential emissions

Source: OIG analysis of potential VOC emission reduction from a pollution control device. (EPA OIG image)

Fifty emission limits we reviewed were established based on an ECD operating at a 95 percent or greater control efficiency. Most of the applicable permits included requirements to periodically verify that a pilot light was operating and to check for visible emissions. The pilot light is necessary to combust waste gas flowing to the combustion device and is the difference between achieving a 0 percent (no pilot) and potential 95 percent control. Visible emissions indicate incomplete combustion and demonstrate that the device is not operating correctly. Verifying that the pilot light is operating and checking for visible emissions may indicate whether an ECD is operating properly, but we conclude that these are not parametric measures that accurately show what control efficiency the device is actually achieving. Thus, these measures do not assure that the device is continuously meeting its assumed control efficiency of 95 percent.

In addition, many emission limits we reviewed were established based on an engine catalyst operating at a specific control efficiency. While reviewing Colorado permits containing engine catalysts, we found that facilities were required to conduct daily, weekly, or monthly parametric monitoring, depending on the parameter being monitored and the facilities' permitted emissions. This was in addition to quarterly or semiannual engine emissions testing. Therefore, these facilities were subject to emissions testing and frequent parametric monitoring to help assure the assumed control efficiency of the catalyst was being met.

Facilities operating under Oklahoma's general permit, on the other hand, were required to conduct quarterly testing and to install parametric monitoring equipment, but the general permit did not require frequent parametric monitoring. The Oklahoma individual permits we reviewed did not contain monitoring or record-keeping requirements beyond quarterly testing. While quarterly testing assures that catalyst systems are operating as intended four times per year, the lack of frequent parametric monitoring means that short-term excess emissions from engines may go undetected.

Challenges Exist to Parametric Monitoring

Significant challenges exist to direct testing and parametric monitoring of ECDs. Natural gas extraction facilities tend to be in remote, unmanned locations and may be far from an adequate power source necessary to run monitoring equipment. Further, testing and monitoring can be expensive, difficult, and unsafe given the design of ECDs and their placement at natural gas extraction facilities. The EPA is aware of these challenges and is studying alternatives to existing compliance methods in EPA Region 8.[3] In the meantime, the EPA has pointed to the New Source Performance Standards,

[3] The study Region 8 is conducting is called *Measuring Enclosed Combustion Device Emissions Using Portable Analyzers - Phase 1: Test Summaries*. The EPA is conducting this research in conjunction with the Wyoming Department of Environmental Quality.

known as the NSPS, that cover sources in the natural gas extraction industry as containing visible emissions and pilot light monitoring as the existing requirements for assuring compliance with the assumed control efficiency.[4] EPA staff stated that they would not expect states to have more stringent requirements than what is in EPA regulations.

The standards reflect the "best system of emission reduction" which the EPA determines has been adequately demonstrated. They are subject to revisions given the potential for process improvements and technology advances that would alter the best system of emission reduction. CAA Section 111(b)(1)(B) requires the EPA to review and, if appropriate, revise the NSPS at least every eight years unless the EPA administrator determines that the review is not appropriate in light of readily available information on the efficacy of the standard.

The NSPS in 40 C.F.R. Part 60 Subpart OOOO were due for review under CAA section 111(b)(1)(B) in 2020. The Agency has not reviewed the standards because it has been engaged in reconsideration and revisions of Subparts OOOO and OOOOa standards. EPA staff also told us that the EPA has until 2024 to review the standards in Subpart OOOOa and that, since the types of sources regulated by Subparts OOOO and OOOOa are within the same industry sector, a review of Subpart OOOOa could be planned and executed to also include review of Subpart OOOO.

Lack of Parametric Monitoring Could Result in Unidentified Violations of Permit Limitations

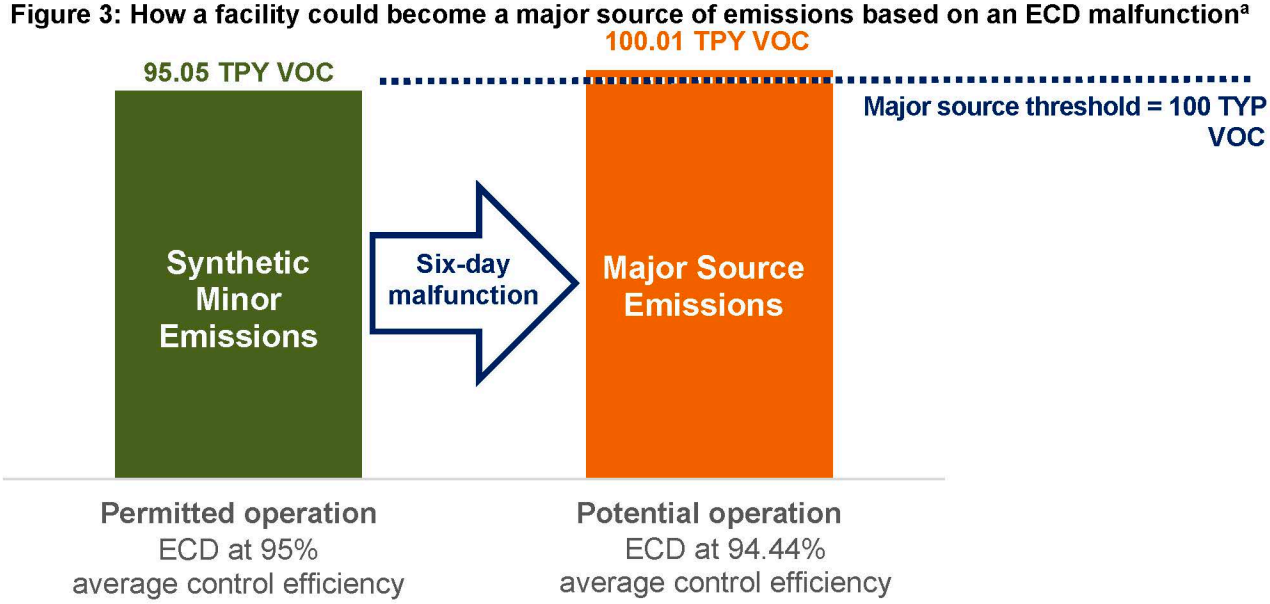
Ultimately, when there is no monitoring associated with a limitation or when the monitoring is insufficient to describe the actual control efficiency of a control device, the state may not be able to obtain sufficient evidence to determine whether a limitation is being violated. In addition, depending on the severity of a violation, the facility could unknowingly be operating as a major source.

Region 8, in conjunction with the Wyoming Department of Environmental Quality, is conducting a study to better understand ECDs and develop an alternative method for demonstrating compliance with permitted control efficiency requirements. Preliminary results from this ongoing study, along with results from a 2014 EPA study, indicate that the control efficiency of these devices can vary and that the devices may fall far below their assumed 95 percent efficiency for unknown periods of time.[5] In the 2014 study, EPA

[4] 40 C.F.R. Part 60 Subparts OOOO and OOOOa. The title of 40 C.F.R. Part 60 Subpart OOOO is "Standards of Performance for Crude Oil and Natural Gas Production, Transmission and Distribution for which Construction, Modification or Reconstruction Commenced After August 23, 2011, and on or before September 18, 2015." The title of 40 C.F.R. Part 60 Subpart OOOOa is "Standards of Performance for Crude Oil and Natural Gas Facilities for which Construction, Modification or Reconstruction Commenced After September 18, 2015."

[5] The title of the 2014 study is *Advancing Understanding of Emissions from Oil and Natural Gas Production Operations to Support EPA's Air Quality Modeling of Ozone Non-Attainment Areas.*

PET-860



REC 2579

researchers found that an ECD at one of the eight sites they studied was operating at a 60 percent control efficiency.

If a facility's actual control efficiency falls below the assumed control efficiency, it could cause the facility to unknowingly exceed its permit limits and become a major source of emissions. As an example, for one facility we reviewed, if only one of the four permitted ECDs malfunctioned and achieved a maximum 60 percent control efficiency for approximately six days, the facility would violate its permit limits and become a major source of emissions. The violation may not be detected without sufficient monitoring. This is depicted in Figure 3.

If the facility experiences a small malfunction, such as a 94 versus a 95 percent control efficiency over the majority of the compliance period, the facility could become a major source of emissions, perhaps without being detected. The CDPHE told us that facility-conducted field testing in Colorado shows ECDs meet a 95 percent control efficiency most of the time.

Figure 3: How a facility could become a major source of emissions based on an ECD malfunction[a]

Source: OIG analysis of potential VOC emission increases due to a short-term ECD malfunction. (EPA OIG image)

[a] Example is based on a hypothetical situation where a short-term malfunction at one of the facilities we reviewed could result in an ECD control efficiency of 60 percent and cause the facility to release major-source levels of emissions. Values are rounded. Emissions presented in the above columns are based on multiple pieces of permitted equipment, with a malfunction at only one piece of permitted equipment.

Appendix E provides a case study of the wood biomass industry, in which synthetic-minor facilities without sufficient monitoring requirements were found to be emitting pollution over major source thresholds.

Conclusions

The EPA is responsible for overseeing state and local permitting and compliance monitoring activities. The EPA oversees state and local compliance monitoring activities for synthetic-minor sources through the *CAA CMS* and State Review Framework reviews, but it conducts limited oversight of state and local synthetic-minor-source permitting. Neither EPA headquarters nor EPA regional offices regularly review synthetic-minor-source permitting. Existing guidance for establishing synthetic-minor-source permits is dated, scattered across numerous documents, and lacks clarity on how to effectively limit the potential to emit.

In our reviews of Colorado and Oklahoma synthetic-minor-source permits, we found that state and local agencies are largely meeting EPA expectations for compliance monitoring, but many synthetic-minor-source permit limits do not adhere to EPA guidance on practical enforceability. In particular, the Agency should provide better guidance on how state and local agencies can establish limits that are technically accurate. For synthetic-minor-source permits in the natural gas extraction sector, the Agency should place additional emphasis on how state and local agencies can assure that assumed control efficiencies from pollution control devices are being achieved.

Recommendations

We recommend that the assistant administrator for Air and Radiation:

1. Update Agency guidance on practical enforceability to more clearly describe how the technical accuracy of a permit limit should be supported and documented. In updating such guidance, the Office of Air and Radiation should consult and collaborate with the Office of Enforcement and Compliance Assurance, the Office of General Counsel, and the EPA regions.

2. In consultation with the EPA regions, develop and implement an oversight plan to include:

    a. An initial review of a sample of synthetic-minor-source permits in different industries that are issued by state, local, and tribal agencies to assess whether the permits adhere to EPA guidance on practical enforceability, including limits that are technically accurate; have appropriate time periods; and include sufficient monitoring, record-keeping, and reporting requirements.

    b. A periodic review of a sample of synthetic-minor-source permits to occur, at a minimum, once every five years.

PET-862
REC 2581

c. Procedures to resolve any permitting deficiencies identified during the initial and periodic reviews.

3. Assess recent EPA studies of enclosed combustion device performance and compliance monitoring and other relevant information during the next statutorily required review of 40 C.F.R Part 60 Subparts OOOO and OOOOa to determine whether revisions are needed to monitoring, record-keeping, and reporting requirements for enclosed combustion devices to assure continuous compliance with associated limits, and revise the regulatory requirements as appropriate.

Agency Response and OIG Assessment

The Agency agreed with all three recommendations and provided acceptable corrective actions and completion dates. The recommendations are resolved with corrective actions pending. The Agency's full response is in Appendix F.

For Recommendation 1, the OAR will update Agency guidance on the practical enforceability of permit limitations, including, but not limited to, the EPA's June 13, 1989 *Guidance on Limiting Potential to Emit in New Source Permitting*, to describe how the technical accuracy of a permit limit should be supported and documented. In updating its guidance, the OAR will consult and collaborate with the Office of Enforcement and Compliance Assurance, the Office of General Counsel, and the EPA regions. We agree that these planned actions address our recommendation. Recommendation 1 is resolved with corrective actions pending.

For Recommendation 2, the OAR, in consultation with EPA regional offices, will develop and implement an oversight plan for synthetic-minor-source permits in accordance with statutory and EPA regulatory requirements. The OAR's plan will include the specific elements identified in Recommendation 2. We agree that these planned actions address our recommendation. Recommendation 2 is resolved with corrective actions pending.

For Recommendation 3, we initially recommended that the OAR develop technical support information for natural gas production facilities that includes defining the parameters upon which the control efficiency for ECDs is based and methods for measuring those specific parameters so that permitting authorities can verify compliance with permit limits. The OAR agreed that monitoring, record-keeping, and reporting requirements associated with synthetic-minor permit emission limitations serve to ensure that the established enforceable limits are being met and are important to meet the ongoing compliance requirement in EPA regulations. The OAR also agreed that facilities under synthetic-minor status should generate records to demonstrate continuous compliance with permit emission limits.

The OAR disagreed with the OIG's implication in the original recommendation that inadequate technical information regarding monitoring, record-keeping, and

reporting for ECDs was an impediment to verifying emission limits associated with the oil and gas industry. The OAR pointed to federal regulations in 40 C.F.R Part 60 Subparts OOOO and OOOOa and 40 C.F.R Part 63 Subpart HH as evidence that properties related to effective combustion are well-understood and depend on gas composition, gas flow, residence time in the combustion zone, and the continuous presence of a pilot light to ensure ignition. The OAR further pointed to Subpart OOOOa requirements for initial testing of ECDs by the owner or operator—or a certification test by the manufacturer—for continuously monitoring for a pilot flame, for monthly visible emissions testing, and for continuously monitoring gas flow to the unit for certain ECDs.

The OAR was amenable to revising the existing monitoring, record-keeping, and reporting requirements for pollution control equipment at oil and gas facilities if new data and information warrant changes. The OAR cited the statutorily mandated technology review for the NSPS under Subpart OOOOa, to occur by 2024, as an appropriate time to determine whether additional or different monitoring requirements for ECDs are necessary, practicable, and cost-effective.

After reviewing the cited regulations, we still believe that the EPA has not presented adequate technical information to assure that permitting authorities can continuously verify compliance with ECD-related emission limitations. As noted in our report, verifying that the pilot light is operating and checking ECDs periodically for visible emissions are not compliance actions that accurately demonstrate the assumed control efficiency is being met on a continuous basis. In addition, monitoring the flow rate does not guarantee the assumed control efficiency is being met.

We acknowledge that there may be cost and logistical constraints, such as a lack of electricity at some oil and gas production facilities, which make continuous compliance monitoring difficult. Further, the Region 8 study is ongoing, and it may be inappropriate for the EPA to issue supplemental technical information or guidance prior to obtaining complete data or when the applicable NSPS is not under review. Therefore, we agree with the EPA that the upcoming review of standards under Subparts OOOO or OOOOa is an appropriate time to reconsider the monitoring, record-keeping, and reporting requirements for ECDs. As such, we have revised Recommendation 3 to focus on the EPA's review of EPA studies and other relevant information during the statutorily mandated review in 2024.

The Agency concurred with our revised recommendation and provided an acceptable proposed corrective action plan and planned completion date. The planned completion date is the date by which the Agency plans to initiate its statutorily required review of 40 C.F.R Part 60 Subparts OOOO and OOOOa. The Agency's full response to the revised recommendation is in Appendix G. Recommendation 3 is considered resolved with corrective actions pending.

Chapter 3
EPA Has Not Clearly Communicated Key Synthetic-Minor-Source Permitting Expectations in Official Guidance

We found that the EPA has several key expectations for synthetic-minor-source permitting that are not clearly communicated in official guidance. EPA policy requires the Agency to clearly describe objectives and expectations for state environmental programs, such as permitting. Without clear guidance, states may develop their own practices that do not align with EPA expectations.

Key Expectations Have Not Been Clearly Communicated in Official Guidance

The *EPA Policy on Oversight of Delegated Environmental Programs* states that the EPA must clearly describe objectives and expectations for state environmental programs to increase the ability of state agencies to successfully implement program requirements and to increase the ability of the EPA to provide appropriate assistance and evaluation. One way this can be accomplished is by providing detailed, up-front guidance on how program work should be performed. We found through discussions with OAQPS staff and managers that the EPA has key expectations for synthetic-minor-source permitting that it has not clearly communicated to state and local agencies in official guidance, such as:

- The terms of a synthetic-minor limitation, such as the limit itself and the methods for demonstrating compliance with the limit, should be in the permit itself. These terms, along with calculations necessary to demonstrate compliance with synthetic-minor limits, need to be included in the permit or incorporated by reference from another source. It would also be appropriate to include calculations and model inputs used to estimate the potential to emit or to set an emission limit in the permit record, such as the permit's technical support documentation.

- Regarding the technical accuracy of limits that depend on pollution control equipment, the vendor or manufacturer information and specifications for the control equipment should be part of the permit record. One way to better assure that a pollution control device obtains its intended pollution reductions over time is to require a source to follow the manufacturer specifications.

- Synthetic-minor-source permits for facilities with emergency generators, which are devices that are intended to serve solely as backup sources of power in the event of a loss of the normal power source, should include a

limitation for the emergency generator as part of the permit. OAQPS staff stated that an emergency generator would be expected to operate approximately 500 hours under worst-case conditions. Permitting authorities should include this figure when assessing the facility's potential to emit calculations. For a synthetic-minor source permit that contains emission sources other than the emergency generator, the permitting authority should include the emergency generator in the permit itself and establish corresponding limits, such as an emission limit and an operational limitation. For example, the facility may not operate the emergency generator for more than 500 hours per year.

These expectations have not been clearly communicated in official guidance, in part because the EPA has not prioritized revising guidance documents to include the Agency's expectations. The 2020 training slides discussed in Chapter 2 include most aspects of the first two expectations, but they are not official guidance.

Without Clear Guidance, States May Adopt Their Own Practices

In the absence of clear, national guidance, state and local permitting programs may develop their own practices for addressing these issues, which do not align with EPA expectations. For example, based on the permits we reviewed and discussions with CDPHE staff, Colorado does not include emergency generators in the permits themselves or establish corresponding emission or operational limits unless the generator's potential emissions put the facility over the major source threshold.

Conclusions

As part of its oversight of state and local environmental programs, the EPA should clearly describe objectives and expectations so that state and local agencies can successfully implement program requirements. During our audit, EPA staff and managers described to us expectations regarding three important aspects of synthetic-minor-source permitting that are not currently reflected in EPA guidance documents. Rather than updating guidance from the 1980s and 1990s to formalize these expectations, the EPA has developed training materials for state and local agencies. Given the importance of establishing effective limits on the potential to emit—that is, limits that are both federally and practically enforceable—the EPA should communicate all key expectations through formal guidance. Without clear guidance, states may adopt their own practices that do not adhere to EPA expectations or assure synthetic-minor-source permit enforceability.

PET-866
REC 2585

Recommendation

We recommend that the assistant administrator for Air and Radiation:

4. Revise the Agency's guidance to communicate its key expectations for synthetic-minor-source permitting to state and local agencies.

Agency Response and OIG Assessment

The Agency agreed with Recommendation 4 and provided an acceptable corrective action and completion date. The OAR will revise the Agency's guidance to include the key expectations above and may, at least in part, integrate this work with the updates to guidance on practical enforceability in response to Recommendation 1. The recommendation is resolved with corrective actions pending. The Agency's full response is in Appendix F.

PET-867

REC 2586

Chapter 4
ODEQ Does Not Currently Include Synthetic-Minor-Source Permits in Its Public Participation Process

The ODEQ does not currently issue its individual synthetic-minor-source permits for public comment before they are finalized, as required by EPA regulations. Staff in the EPA's OAQPS told us that this may be the case for other state and local agencies as well. ODEQ staff told us that Oklahoma's legislature passed new state rules that will require public comment on synthetic-minor-source permits and that these rules will go into effect in September 2021. Although this deficiency is being addressed in Oklahoma, the EPA has not ensured that all states include public participation in their synthetic-minor-source permitting process.

Without the opportunity to review permit materials and provide comments on proposed synthetic-minor-source permits, citizens are deprived of the ability to assess information and provide input on facilities that may impact air quality where they live. The EPA should regularly confirm that states adhere to requirements on public participation for synthetic-minor-source permits.

EPA Regulations Require Opportunity for Public Review and Comment on Synthetic-Minor-Source Permits

EPA regulations require certain permitting information to be available to the public for review and comment, generally for 30 days. Per 40 C.F.R. § 51.161, permitting authorities must make the following information public:

- Information submitted by owners and operators.
- An analysis of the effect of the construction or modification of the facility on ambient air quality.
- The permitting authority's proposed approval or disapproval of the permit.

Staff from both Region 6 and the OAQPS told us that these requirements apply to synthetic-minor-source permits, and EPA guidance states that public participation is a central tenet of federal enforceability.

ODEQ Does Not Currently Provide Opportunity for Public Review and Comment on Individual Synthetic-Minor-Source Permits

The ODEQ does not currently issue its individual, facility-specific synthetic-minor-source permits for public comment before they are finalized because Oklahoma's current regulations lack such a requirement. Region 6 staff told us that the region is aware of this issue and has communicated with the ODEQ about the need to revise this in Oklahoma's state permitting rules. In November 2020,

ODEQ staff told us that the state's air advisory council had approved new state rules to require an opportunity for public comment. In June 2021, ODEQ staff told us that the rules had been passed by the state legislature and will be going into effect on September 15, 2021. OAQPS staff told us that they are aware that lack of public participation for synthetic-minor sources may be a problem in other states as well.

Lack of Public Participation Precludes Citizen Input on Facility Permits

Synthetic-minor permit limitations are intended to limit emissions from facilities and, as such, have an impact on local air quality. Public participation requirements are intended to assure that citizens have the ability to provide input on the permit limitations, the pollutants that are emitted, and the quantity of emissions that will affect their communities. Not providing the opportunity to review permit materials and provide comments on proposed synthetic-minor-source permits hinders citizens' ability to weigh in on facilities that may impact air quality where they live.

Conclusions

The ODEQ is not currently adhering to EPA regulations that require state and local environmental programs to allow public review of and comment on proposed synthetic-minor-source permits, and this may be the case in other states as well. These requirements were established by the EPA to allow citizens the opportunity to analyze and understand environmental impacts in their communities. Individual synthetic-minor-source permits were approved by the ODEQ without any forewarning or input from the citizens who may be impacted by the permitted emissions. This lack of public participation can undermine permit quality and limits the opportunity for citizens to weigh in on facilities that may be located in their communities. The EPA should work with all state, local, and tribal agencies that do not provide the opportunity for public comment on synthetic-minor-source permits to assure opportunities for public participation, as required by law.

Recommendation

We recommend that the assistant administrator for Air and Radiation:

5. Identify all state, local, and tribal agencies in which Clean Air Act permit program implementation fails to adhere to the public participation requirements for synthetic-minor-source permit issuance and take appropriate steps to assure the identified states adhere to the public participation requirements.

Agency Response and OIG Assessment

The Agency agreed with Recommendation 5 and provided acceptable corrective actions and completion dates. The OAR, with EPA regional office support, will identify state, local, and tribal agencies whose program regulations do not meet the public participation requirements contained in the applicable EPA regulations and guidance with respect to synthetic-minor-source permitting. For the identified agencies, the OAR will take appropriate corrective steps, potentially to include informal engagement. The recommendation is resolved with corrective actions pending. The Agency's full response is in Appendix F.

Status of Recommendations and Potential Monetary Benefits

RECOMMENDATIONS

Rec. No.	Page No.	Subject	Status[1]	Action Official	Planned Completion Date	Potential Monetary Benefits (in $000s)
1	17	Update Agency guidance on practical enforceability to more clearly describe how the technical accuracy of a permit limit should be supported and documented. CAA Major-Source-Permitting Programs

The CAA major-source-permitting programs are Title V, Nonattainment New Source Review, and Prevention of Significant Deterioration. The requirements and major-source thresholds vary by program, and Nonattainment New Source Review and Prevention of Significant Deterioration permitting depend upon whether the area in which the source is located complies with National Ambient Air Quality Standards. These health-based standards are set by the EPA for certain pollutants so that the level of the pollutant in the air is protective of human health and the environment. Areas that comply with these standards are known as attainment areas, while areas that do not comply are known as nonattainment areas. The table below summarizes these permitting programs and the corresponding levels of emissions that make a facility a major source under each program.

Table A-1: CAA programs and their corresponding major-source thresholds of air emissions

	Title V permitting	NNSR permitting	PSD permitting
Summary of program and requirements*	Permitting program for all operating major sources of air pollution. Title V permits contain all CAA requirements to which a facility is subject and impose certain monitoring, reporting, and record-keeping requirements.	Permitting program for new or modified major sources in areas that are in nonattainment with the NAAQS. NNSR permits require sources to install control equipment that obtains the lowest achievable emission rate to reduce emissions.	Permitting program for new or modified major sources in areas that are in attainment with the NAAQS. PSD permits require sources to use the best available control technology to limit emissions.
Major-source threshold	100 TPY of a regulated pollutant, but can be lower in nonattainment areas for the pollutant for which the area is in nonattainment; 25 TPY of total hazardous air pollutants; and 10 TPY of a single hazardous air pollutant.	100 TPY of a regulated pollutant, but can be lower depending on the severity of the air quality problem in the nonattainment area.	250 TPY of a regulated pollutant, except for facilities within 28 specific industries for which the threshold is 100 TPY.
Pollutants covered	VOC, NO_x, CO, SO_2, NO_2, $PM_{2.5}$, and PM_{10}, lead, and hazardous air pollutants, such as benzene, formaldehyde, and n-hexane.	Ozone (including VOC and NO_x, which react in the atmosphere to form ozone), CO, SO_2, NO_2, $PM_{2.5}$, PM_{10}, and lead.	Ozone (including VOC and NO_x, which react in the atmosphere to form ozone), CO, SO_2, NO_2, $PM_{2.5}$, PM_{10}, lead, hydrogen sulfide, and sulfuric acid.

Source: OIG summary of EPA information. (EPA OIG table)

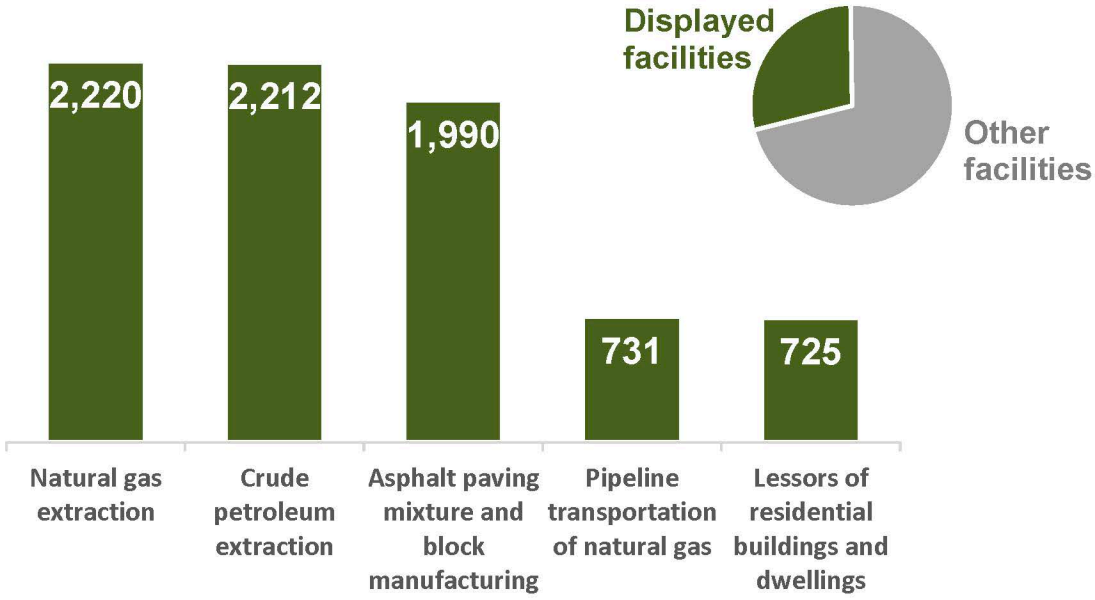
* This table is intended for summary purposes and does not include all requirements of the permitting programs.

Note: CO is carbon monoxide, NAAQS is National Ambient Air Quality Standards, NNSR is Nonattainment New Source Review, NO_2 is nitrogen dioxide, NOx is nitrogen oxides, PM is particulate matter, PSD is Prevention of Significant Deterioration, and SO_2 is sulfur dioxide.

Internal Control Assessment

This table identifies which internal control components and underlying principles are significant to our audit objective.

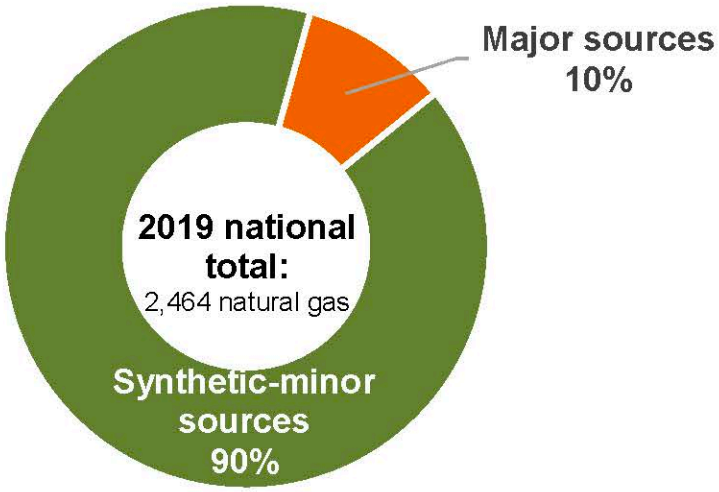
Which internal control components are significant to the audit objective?		Which internal control principles are significant to the audit objective?	
X	**Control Environment** The foundation for an internal control system. It provides the discipline and structure to help an entity achieve its objectives.		1. The oversight body and management should demonstrate a commitment to integrity and ethical values.
		X	2. The oversight body should oversee the entity's internal control system.
			3. Management should establish an organizational structure, assign responsibilities, and delegate authority to achieve the entity's objectives.
			4. Management should demonstrate a commitment to recruit, develop, and retain competent individuals.
			5. Management should evaluate performance and hold individuals accountable for their internal control responsibilities.
X	**Risk Assessment** Management assesses the risks facing the entity as it seeks to achieve its objectives. This assessment provides the basis for developing appropriate risk responses.	X	6. Management should define objectives clearly to enable the identification of risks and define risk tolerances.
		X	7. Management should identify, analyze, and respond to risks related to achieving the defined objectives.
			8. Management should consider the potential for fraud when identifying, analyzing, and responding to risks.
		X	9. Management should identify, analyze, and respond to significant changes that could impact the internal control system.
X	**Control Activities** The actions management establishes through policies and procedures to achieve objectives and respond to risks in the internal control system, which includes the entity's information system.	X	10. Management should design control activities to achieve objectives and respond to risks.
			11. Management should design the entity's information system and related control activities to achieve objectives and respond to risks.
		X	12. Management should implement control activities through policies.
X	**Information and Communication** The quality information management and personnel communicate and use to support the internal control system.		13. Management should use quality information to achieve the entity's objectives.
			14. Management should internally communicate the necessary quality information to achieve the entity's objectives.
		X	15. Management should externally communicate the necessary quality information to achieve the entity's objectives.
X	**Monitoring** Activities management establishes and operates to assess the quality of performance over time and promptly resolve the findings of audits and other reviews.	X	16. Management should establish and operate monitoring activities to monitor the internal control system and evaluate the results.
		X	17. Management should remediate identified internal control deficiencies on a timely basis.



Source: Based on internal control components and principles outlined in GAO-14-704G, *Standards for Internal Control in the Federal Government* (also known as the "Green Book"), issued September 10, 2014.

Details on Scope and Methodology

To address our objective, we reviewed EPA policies and guidance related to synthetic-minor-source permitting and compliance monitoring. We also interviewed staff and managers in the OAQPS and the Office of Enforcement and Compliance Assurance.

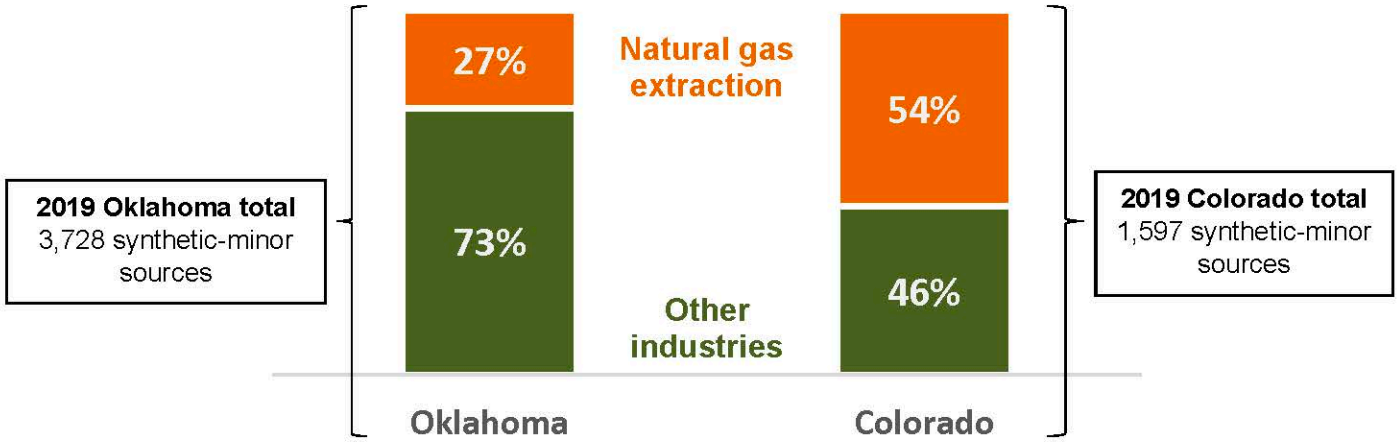


We reviewed synthetic-minor facilities in the natural gas extraction sector to assess whether synthetic-minor-source permit limitations and provisions adhered to EPA guidance and whether the facilities' inspections were consistent with EPA guidance. The natural gas extraction sector is covered by the North American Industry Classification System Code 211130 and involves activities related to the production of natural gas. To select this industry, we used data from the EPA's ICIS-Air database and the National Emissions Inventory. This selection was based on the natural gas extraction sector's disproportionally high (1) cumulative emissions from synthetic-minor sources, (2) number of synthetic-minor facilities within the industry, and (3) prevalence of synthetic minor emissions in areas with relatively poor air quality. Anecdotal statements from permitting and compliance subject matter experts also supported the selection of this industry. Background information on the natural gas extraction industry is included in Appendix D. Figures C-1 and C-2 provide more information about the selection of the natural gas extraction sector for review.

Figure C-1: Top five industries with the most permitted synthetic-minor sources in 2019

Source: OIG analysis of data from ICIS-Air and the EPA's Enforcement and Compliance History Online database. (EPA OIG image)

Figure C-2: Percentage of synthetic-minor sources compared to major sources in natural gas extraction industry[a]

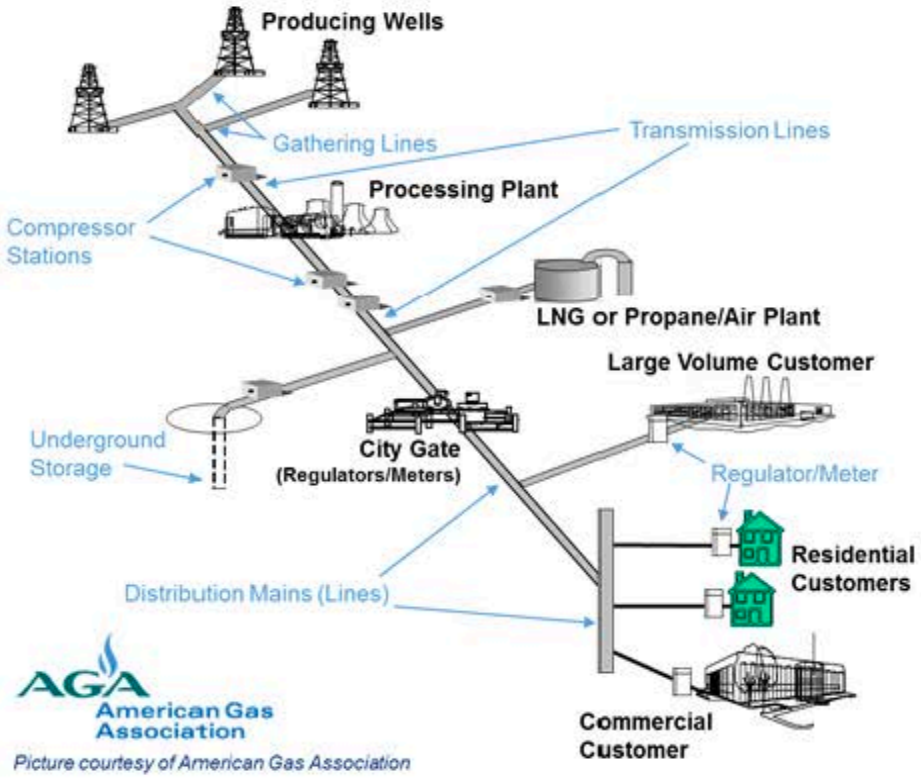


Source: OIG analysis of data from ICIS-Air and the EPA's Enforcement and Compliance History Online database. (EPA OIG image)

[a] Analysis does not include true-minor sources because those data are not required to be submitted to the EPA.

We selected a judgmental sample of two states from which to review natural gas extraction permits. Specifically, we selected to review permits in Colorado and Oklahoma because these states have among the highest number of synthetic-minor facilities in the natural gas extraction industry, according to the 2017 National Emissions Inventory. These states also contain among the most synthetic-minor facilities with actual emissions that potentially exceed major-source thresholds, according to the 2017 National Emissions Inventory. According to ICIS-Air and the EPA's Enforcement and Compliance History Online database, Colorado had 859 facilities identified as synthetic-minor sources in the natural gas extraction industry in 2019, and Oklahoma had 999. Figure C-3 shows the percentage of synthetic-minor sources in Oklahoma and Colorado that are in the natural gas extraction industry compared to other industries.

Figure C-3: Percentage of Oklahoma and Colorado synthetic-minor sources in natural gas extraction industry compared to other industries



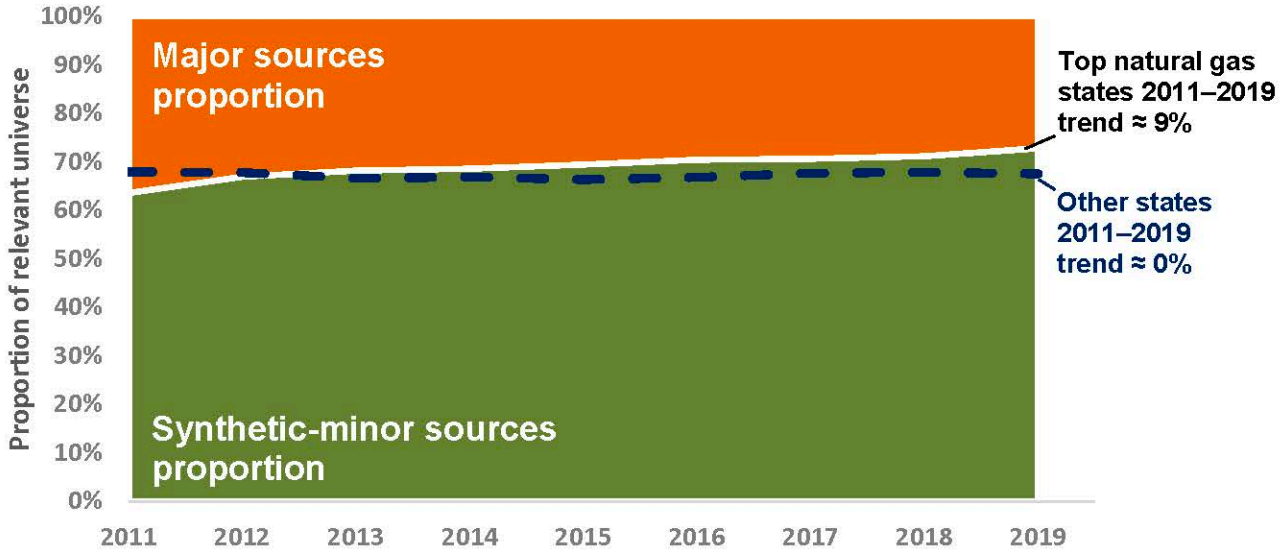
Source: OIG analysis of data from ICIS-Air and the EPA's Enforcement and Compliance History Online database. Data are based on state-submitted information. (EPA OIG image)

In each of these states, we randomly selected eight natural gas extraction facilities that are characterized as SM-80s in ICIS-Air for in-depth review. In Colorado, we selected facilities operating in the Denver and Northern Front Range—located north of Denver and east of the Rocky Mountains—metropolitan areas where the air does not meet EPA air quality standards for ozone. Natural gas extraction facilities contribute to ground-level ozone formation by emitting VOC and nitrogen oxides, which react in sunlight to form ozone. Breathing elevated concentrations of ozone can trigger a variety of health problems, including chest pain, coughing, throat irritation, and airway inflammation. It also can reduce lung function and harm lung tissue. Ozone can worsen bronchitis, emphysema, and asthma, leading to the need for increased medical care. Oklahoma does not have any areas where the air does not meet the EPA's standards for ozone.

Background on Natural Gas Extraction Industry

The natural gas extraction industry includes the production of natural gas. This includes well-production sites, where natural gas is extracted from the ground. It also includes compressor stations, which help maintain the pressure of the gas and move the gas from the individual well-production sites to natural gas processing plants and ultimately the end user. The facilities we reviewed include both well-production sites and compressor stations. Figure D-1 shows where well-production sites and compressor stations are located within the overall natural gas lifecycle—from extraction to distribution to the end user.

Figure D-1: Natural gas industry from production to distribution



Source: American Gas Association. (American Gas Association image)

Natural gas production facilities emit several types of pollutants, including VOC, nitrogen oxides, carbon monoxide, and hazardous air pollutants. VOC and nitrogen oxides interact in sunlight to form ground-level ozone. Breathing elevated concentrations of ozone can trigger a variety of health problems, including chest pain, coughing, throat irritation, and airway inflammation. It also can reduce lung function and harm lung tissue. Ozone can worsen bronchitis, emphysema, and asthma, leading to a need for increased medical care. Hazardous air pollutants are toxic pollutants known or suspected to cause cancer or other serious health problems.

Colorado and Oklahoma are both among the ten states with the highest amount of natural gas extraction and production. In 2019, Colorado produced 1,988,714 cubic feet of natural gas, while Oklahoma produced 3,175,008 cubic feet.

Based on EPA data, the proportion of synthetic-minor sources compared to major sources in top natural gas producing states was 9 percent higher in 2019 than in 2011, while it remained relatively constant in states that are not top producers of natural gas. This is shown in Figure D-2. This shift could be an indication that more facilities in the natural gas production industry are choosing to implement synthetic-minor limits to avoid major-source permitting requirements than in other industrial sectors.

Figure D-2: Proportion of synthetic-minors and major-sources in top natural gas producing states versus all other states between 2011 and 2019[a]

Source: OIG analysis of data from ICIS-Air and the U.S. Energy Information Agency. (EPA OIG image)

[a] The top ten natural gas producing states, based on our analysis of data from the U.S. Energy Information Administration, include Alaska, Arkansas, Colorado, Louisiana, New Mexico, Ohio, Oklahoma, Pennsylvania, West Virginia, and Wyoming. The analysis does not cover states or U.S. territories that have no synthetic-minor sources identified in ICIS-Air. Although Texas is a top natural gas producing state, it was not included in the analysis for this reason.

Case Study: Synthetic-Minor-Source Permitting in Wood Biomass Industry

As detailed in its 2018 report, *Dirty Deception: How the Wood Biomass Industry Skirts the Clean Air Act*, the nonprofit organization Environmental Integrity Project examined air permits and emission information in federal and state records for 21 wood pellet plants in the United States. Wood pellet facilities convert trees into pellets to be burned for electricity. The Environmental Integrity Project found that seven out of 21 facilities violated their permit limits by releasing too much pollution, while another four plants had state-issued permits that failed to require necessary pollution-control equipment. The report explains that most wood pellet facilities are permitted as synthetic-minor sources under the EPA's Prevention of Significant Deterioration permitting program, but they only have a blanket emission limit in their permits, such as "the facility shall emit less than 249 TPY of VOCs," rather than an actual production limit that is directly associated with emissions. An EPA guidance document from 1989 cites a 1988 court decision, *United States vs. Louisiana-Pacific Corporation,* which found that blanket limits are not enforceable as a practical matter. The Environmental Integrity Project concluded that many large wood pellet plants were in fact exceeding their 249 TPY limits because many units emitted much more VOC than states and the industry anticipated.

Source: Biomass manufacturing in the United States as of August 2020, including facilities operating (green), under construction or planned (yellow), and temporarily not in operation (red). (U.S. Energy Information Administration image)

OAQPS and EPA regional staff confirmed to us that there are potential problems with permitting wood biomass sources and that the industry is under increased scrutiny on a national level. OAQPS staff explained that the wood pellet industry is an emerging industry, so the emissions and emissions sources are not well understood. For example, a Region 6 branch chief explained that an issue with these facilities has been the use of unproven emission factors to characterize emissions from pellet coolers. The branch chief said that Louisiana's Department of Environmental Quality reprocessed two permits after further testing and is requiring the facilities to obtain major-source permits. One OAQPS staff person suggested that states could make synthetic-minor permits, including those for wood pellet facilities, more enforceable by requiring source-specific stack testing to confirm expected emissions. In order for a reviewer to know whether the permitted emission limit is enforceable, the staff person said, the permit must include a way to measure emissions.

AIR AND RADIATION

MEMORANDUM

SUBJECT: EPA Response to OIG Draft Report titled: "EPA Should Conduct More Oversight of Synthetic-Minor-Source Permitting to Assure Permits Adhere to EPA Guidance" - Project No. OA&E-FY19-0093, April 29, 2021

FROM: Joseph Goffman
Acting Assistant Administrator
Office of Air and Radiation

TO: Renee McGhee-Lenart
Acting Air Director
Office of the Inspector General

The Office of Air and Radiation (OAR) welcomes the opportunity to provide comment on the draft report titled: "*EPA Should Conduct More Oversight of Synthetic-Minor-Source Permitting to Assure Permits Adhere to EPA Guidance*" and its recommendations. Based on our review, we find the draft report to be factually accurate overall. Our responses to the draft report recommendations are provided below.

OIG Recommendation 1: Update Agency guidance on practical enforceability to more clearlydescribe how the technical accuracy of a permit limit should be supported and documented. In updating such guidance, the Office of Air and Radiation should consult and collaborate with theOffice of Enforcement and Compliance Assurance, the Office of General Counsel, and the EPA regions.

Response 1: OAR concurs with this recommendation. OAR will update Agency guidance on the practical enforceability of limitations, including but not limited to EPA's June 13, 1989 *Guidance on Limiting Potential to Emit in New Source Permitting*, to describe how the technicalaccuracy of a permit limit should be supported and documented. Specifically, the updated guidance will address the practical enforceability of limitations on potential to emit. In updating our guidance, we will consult and collaborate with the Office of Enforcement and Compliance Assurance, the Office of General Counsel, and the EPA regions.

PET-880
REC 2599

Planned Completion Date: October 2023

OIG Recommendation 2: In consultation with the EPA regions, develop and implement an oversight plan to include:

- An initial review of a sample of synthetic-minor-source permits in different industries that are issued by state, local, and tribal agencies to assess whether the permits adhere toEPA guidance on practical enforceability, including limits that are technically accurate; have appropriate time periods; and include sufficient monitoring, recordkeeping, and reporting requirements.
- A periodic review of a sample of synthetic-minor-source permits to occur, at a minimum,once every five years.
- Procedures to resolve any permitting deficiencies identified during the initial and periodicreviews.

Response 2: OAR concurs with this recommendation. In consultation with EPA Regional offices, OAR will develop and implement an oversight plan in accordance with current statutoryand EPA regulatory requirements and, as appropriate, including the specific elements identified.

Planned Completion Dates:

1. Develop plan: April 2024
2. Complete initial review: October 2024

OIG Recommendation 3: Develop technical support information for natural gas production facilities that includes defining the parameters upon which the control efficiency for enclosedcombustion devices is based and methods for measuring those specific parameters so that permitting authorities can verify compliance with permit limits.

Response 3: We agree with the OIG that monitoring, recordkeeping and reporting requirements(MRR) associated with synthetic minor permit emission limitations serve to ensure that the established enforceable limits are being met and are important to meet the ongoing compliance requirement in the CAA. We also agree with the OIG that facilities under synthetic minor statusshould generate records to demonstrate continuous compliance with permit emission limits.

However, the OIG's recommendation implies that the impediment to verifying compliance with emission limits associated with the oil and gas industry is inadequate technical information regarding MRR permit conditions for pollution control equipment for use by permitting authorities. We disagree that permit authorities do not have the technical tools to effectively establish appropriate MRR in synthetic minor permits. As described below, the technical supportinformation in existing air rules fully addresses the need identified by the OIG.

Federal regulations covering air emissions from oil and gas facilities (40 CFR part 60 subparts OOOO and OOOOa (NSPS OOOO and OOOOa) and 40 CFR part 63 subpart HH (NESHAP HH)) contain provisions requiring control of VOC and HAP at these facilities.

PET-881
REC 2600

Combustion, including enclosed combustors for the natural gas production segment, is a common control option to meet these provisions. As we discussed with the OIG during interviews and reiterated in our written response to the initial draft report, the properties related to effective combustion are well-understood and depend on gas composition, gas flow, residence time in the combustionzone, and the continuous presence of a pilot light to ensure ignition. These parameters are not unique to the natural gas production sector and are standard across multiple rules in a number ofindustries. To ensure proper use and efficacy of combustion control devices by oil and gas facilities, each subpart covering the industry contains targeted MRR requirements. For example,to ensure high combustion efficiency, NSPS OOOOa requires initial testing of enclosed combustion devices by the owner or operator or a certification test by the manufacturer; periodically, the combustor must be retested by the owner, or the owner may continuously monitor the gas flow to the unit. Additionally, owners and operators must continuously monitorfor the presence of a pilot flame and ensure residence time in the combustion zone through design analysis. On a monthly basis, the operator must perform a visible emissions test with Method 22 of appendix A-7 to part 60 to detect smoke, which would indicate less than 95 percent control efficiency.

Continuous Monitoring Systems (CMS), consisting of both continuous emissions monitoring systems and continuous parameter monitoring systems, create continuous electronic data recordsthat can be used to verify continuous compliance. These systems rely on site infrastructure such as shelters, electricity on site, and data acquisition systems. In the oil and gas industry, not all production sites are electrified for support equipment. Well pads and related sites are often powered by the gas itself, through pneumatic pumps and pneumatic controllers. This lack of electrification of all sites limits the blanket use of CMS for continuous compliance.

Looking ahead, OAR is open to revising the existing MRR requirements and adding others if future data demonstrate a need for further action. EPA is currently reviewing NSPS OOOOa under Executive Order 13990. The scope of the action and the timeline for compliance with this EO foreclose EPA's ability to consider additional monitoring provisions in this NSPS to address enclosed combustor compliance assurance issues beyond existing MRR requirements. However, as more data and information become available, and the required technology reviews for both NSPS OOOOa and NESHAP HH approach, EPA may receive data and information that can be analyzed to determine whether additional or different monitoring requirements for these devices are necessary, practicable, and cost effective. In the meantime, by maintaining enforcement of existing MRR requirements and addressing other recommendations stated in the draft report, EPA will be assisting permitting authorities to establish permit parameters that meet the practicalenforceability requirements for synthetic permit limitations.

OIG Recommendation 4: Revise the Agency's guidance to communicate its key expectationsfor synthetic-minor-source permitting to state and local agencies.

Response 4: OAR concurs with this recommendation. OAR will revise the Agency's guidance tocommunicate its key expectations for synthetic-minor-source permitting to state and local agencies. This will include an expectation that synthetic minor permit terms and conditions

ensure that the potential to emit of the source is less than the applicable major source threshold by meeting legal and practical enforceability criteria. Our work related to this recommendation may, at least in part, be integrated with the updated guidance on practical enforceability in response to OIG Recommendation 1.

Planned Completion Date: October 2024

OIG Recommendation 5: Identify all state, local and tribal agencies in which state Clean Air Act permit program implementation fails to adhere to the public participation requirements for synthetic-minor-source permit issuance and take appropriate steps to assure the identified states adhere to the public participation requirements.

Response 5: OAR concurs with this recommendation. With EPA Regional office support, OAR will identify state, local and tribal agencies whose program regulations, including but not limited to minor new source review and federally enforceable state operating permit program regulations and corresponding practices, do not meet the public participation requirements contained in the applicable EPA regulations, e.g., 40 CFR 51.161, and guidance with respect to synthetic minor source permitting. For the identified agencies, OAR will take appropriate corrective steps, which may include constructive, informal engagement.

Planned Completion Dates:
1. Identify target agencies and program regulations with public participation requirement deficiencies: July 2022
2. Take appropriate steps to resolve identified deficiencies: December 2023

AIR AND RADIATION

MEMORANDUM

SUBJECT: EPA Revised Response to OIG Draft Report titled: "EPA Should Conduct More Oversight of Synthetic-Minor-Source Permitting to Assure Permits Adhere to EPA Guidance" - Project No. OA&E-FY19-0093, April 29, 2021

FROM: Joseph Goffman
Acting Assistant Administrator

TO: Renee McGhee-Lenart
Acting Air Director
Office of the Inspector General

The Office of Air and Radiation (OAR) welcomes the opportunity to provide comment on the revised recommendation 3 found in the draft report titled: "*EPA Should Conduct More Oversight of Synthetic-Minor-Source Permitting to Assure Permits Adhere to EPA Guidance*". Based on our review, we find the revisions to the draft report to be factually accurate overall. Our response to the revised recommendation 3 is provided below.

OIG Revised Recommendation 3: Assess recent EPA studies of enclosed combustion device performance and compliance monitoring and other relevant information during the next statutorily-required review of 40 C.F.R part 60 subparts OOOO and OOOOa to determine whether revisions are needed to monitoring, record-keeping and reporting requirements for enclosed combustion devices to assure continuous compliance with associated limits, and revise the regulatory requirements as appropriate.

OAR Revised Response: OAR concurs with this revised recommendation. OAR will assess EPA studies of enclosed combustion device performance and compliance monitoring and other relevant information during the next statutorily-required review of 40 C.F.R part 60 subparts OOOO and OOOOa and determine whether revisions are needed to monitoring, record-keeping and reporting requirements for enclosed combustion devices to assure continuous compliance with associated limits, and revise the regulatory requirements as appropriate.

Planned Completion Date: EPA intends to initiate review of subparts OOOO and OOOOa, in accordance with our statutory obligations under CAA section 111(b)(1)(B), by no later than 2024.

We make every effort to create documents that are accessible to individuals of all abilities; however, limitations with our word processing programs may prevent some parts of this document from being readable by computer-assisted reading devices. If you need assistance with any part of this document, please contact the Payette National Forest at (208) 634-0700.

In accordance with Federal civil rights law and U.S. Department of Agriculture (USDA) civil rights regulations and policies, the USDA, its Agencies, offices, and employees, and institutions participating in or administering USDA programs are prohibited from discriminating based on race, color, national origin, religion, sex, gender identity (including gender expression), sexual orientation, disability, age, marital status, family/parental status, income derived from a public assistance program, political beliefs, or reprisal or retaliation for prior civil rights activity, in any program or activity conducted or funded by USDA (not all bases apply to all programs). Remedies and complaint filing deadlines vary by program or incident.

Persons with disabilities who require alternative means of communication for program information (e.g., Braille, large print, audiotape, American Sign Language, etc.) should contact the responsible Agency or USDA's TARGET Center at (202) 720-2600 (voice and TTY) or contact USDA through the Federal Relay Service at (800) 877-8339. Additionally, program information may be made available in languages other than English.

To file a program discrimination complaint, complete the USDA Program Discrimination Complaint Form, AD-3027, found online at http://www.ascr.usda.gov/complaint_filing_cust.html and at any USDA office or write a letter addressed to USDA and provide in the letter all of the information requested in the form. To request a copy of the complaint form, call (866) 632-9992. Submit your completed form or letter to USDA by: (1) mail: U.S. Department of Agriculture, Office of the Assistant Secretary for Civil Rights, 1400 Independence Avenue, SW, Washington, D.C. 20250-9410; (2) fax: (202) 690-7442; or (3) email: program.intake@usda.gov.

USDA is an equal opportunity provider, employer, and lender.

REC 2615

1.0 Introduction

The United States (U.S.) Department of Agriculture Forest Service (Forest Service) received the Stibnite Gold Project (SGP) Plan of Restoration and Operations, (Midas Gold Idaho, Inc. 2016) for review and approval in accordance with regulations at 36 Code of Federal Regulations (CFR) 228 Subpart A for the proposed SGP in central Idaho. A revised Plan, also known as ModPRO[1], was submitted to the Forest Service in 2019 (Brown and Caldwell 2019). A further modified Plan, also known as ModPRO2[2], was then submitted in October of 2021 (Perpetua 2021a). Midas Gold changed their name to Perpetua Resources Idaho Inc. (Perpetua[3]) in February 2021.

The SGP would consist of mine operations, including an open pit hard rock mine and associated processing facilities, located within Valley County in central Idaho on federal, state, and private lands (**Figure 1-1**). The SGP would produce gold and silver doré, and antimony concentrate, for commercial sale by Perpetua. The SGP would have a life (construction, operation, closure, and reclamation), not including post-reclamation monitoring, of approximately 20 years, with active mining and ore processing occurring over approximately 15 years.

Air quality is the degree to which the ambient air is pollution-free and protective of public health and is assessed by measuring a number of indicators of pollution. Air quality conditions are important from a human health and aesthetic (i.e., visual) perspective, and they also are subject to specific regulations, which are enforced to protect human health. Local and regional air quality may be affected by the SGP.

The affected environment area for the SGP for the air quality analysis is defined by two regions or "fields" for which different assessment tools are applicable. These regions are defined by the requirements of an air quality analysis, and the capabilities of the regulatory models provided for the assessments. The air quality impact analyses presented for the SGP adopt the U.S. Environmental Protection Agency (EPA) recommendations contained in 40 CFR Part 61, Appendix W for the analysis approach as defined for the two fields.

The first region is the "near field," which is defined as a 50-kilometer (km)[4] radius from the proposed SGP, as shown on **Figure 1-1**. Dispersion modeling (i.e., modeling that simulates how air pollutants disperse in the atmosphere) to identify air quality impacts in the near-field region utilize Gaussian plume dispersion models. The near-field analysis focused on comparison of predicted concentrations of air pollutants with federal standards, and screening assessments of air pollutant deposition.

The second region is the much larger "far field," which is defined as a 300-km radius from the SGP that encompasses more distant Class I and Class II areas as described in **Section 3.0**, Relevant Laws, Regulations, Policies, and Plans, and shown on **Figure 1-1**. Mandatory federal Class I areas are national parks and wilderness areas afforded special air quality and visibility protections under the Clean Air Act. To meet the requirements of the far-field analysis for these protected areas, specialized air quality modeling was conducted to support the analysis. The far-field analysis for selected Class I and selected

[1] Associated project documents may reference the Revised Plan as the ModPRO.

[2] Associated project documents may reference the Modified Plan as the ModPRO2.

[3] Documents provided by Perpetua prior to the February 2021 name change will still be cited and referenced as Midas Gold.

[4] Metric units, including kilometers (km), are used predominantly in this section because of permit and modeling standards. 1 km=0.6mi; 1mi=1.6km.

Class II areas assessed the SGP's contribution to regional haze and screened for air pollutant deposition impacts. Dispersion modeling is discussed in **Sections 5.4** and **5.5**.

Modeling within the near-field region included an analysis of potential impacts to "ambient air" as defined for the SGP. The term "ambient air," for modeling purposes, refers to a defined area where the public has access that is subject to the National Ambient Air Quality Standards (NAAQS). The NAAQS are promulgated to protect public health and welfare. Long-standing EPA policy has defined "ambient air" as "that portion of the atmosphere, external to buildings, to which the general public has access," and further that "the exemption from ambient air is available only for the atmosphere over land owned or controlled by the source and to which public access is precluded by a fence or other physical barriers" (EPA 2018c). More recent EPA policy expanded the range of measures that could be implemented to exclude the public from access, such as signage, monitoring of access, security surveillance, and similar effect measures (EPA 2019a). In this case, the SGP public exclusion area is understood to be defined as the limits of the SGP Operations Area Boundary. The Operations Area Boundary establishes the inner boundary of the surrounding "ambient air" that represents the modeling domain for quantifying air quality effects in **Section 7.2**, Direct and Indirect Effects. As part of the air modeling analysis supporting the Stibnite Gold Environmental Impact Statement, and the air permit application to the Idaho Department of Environmental Quality (IDEQ), the Operations Area Boundary was set by the Perpetua air modeling contractor, and subsequently reviewed and approved by the Forest Service and IDEQ (Air Sciences 2018a).

A refined dispersion modeling analysis was conducted within a 10-km radius of the Operations Area Boundary (OAB), as shown on **Figure 1-2**. It was confirmed through preliminary modeling that the 10 km domain size was sufficient to characterize worst-case near-field air quality impacts for the SGP. Air quality effects would decrease at distances beyond the modeled 10 km range. The refined model used a "grid" of defined receptor points at which air pollutant concentrations are predicted by the model calculations. Receptor grids of 25-meter (m)[2], 50-m, 100-m, 500[5]-m, and 1-km spacing beyond the Operations Area Boundary out to the 10-km extent of the modeled domain followed accepted standard U.S. Environmental Protection Agency's (EPA) regulatory modeling protocol. Tighter spaced receptors closer to the OAB allowed the model to map the predicted highest predicted concentrations in more detail.

To develop the far-field air quality analysis area, several agencies were consulted and included: National Park Service (NPS), U.S. Fish and Wildlife Service, EPA, IDEQ, Nez Perce Tribe air quality staff and the Pacific Northwest and Northern regions of the Forest Service. Based upon this group's initial review of the plan, the four Class I areas (as shown in **Figure 1-3**) that far-field modeling results were reported for are: Sawtooth Wilderness [SAWT], Selway-Bitterroot Wilderness (SELW), Hells Canyon Wilderness [HECA]), and Craters of the Moon National Monument (CRMO). Table 1-1 illustrates the distance from the SGP boundary to the various Class I areas. There are additional Class I areas within the 300-km radius; however, these are farther from the proposed SGP and in the same general cardinal directions as the four closer Class I areas. A tiered approach was adopted to initially analyze the closer Class I areas that would likely have greater potential for air quality or visibility impacts. If the impacts predicted at the four closer Class I areas indicated potential for impacts at greater distances, then additional analyses would have been conducted for the more distant Class I areas.

[5] 1 meter (m)=3.3 feet; 1 foot=0.3 meter.

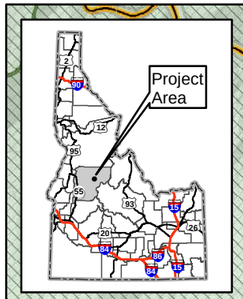
Class II wilderness areas are public lands outside of Class I protection that are maintained in its natural state protected against the introduction of intrusive artifacts such as buildings. Four of which are shown in **Figure 1-3** and were selected by the Forest Service for far-field evaluation: Frank Church River of No Return Wilderness (FCRNRW), Gospel Hump, Hemingway-Boulders, and Cecil D. Andrus—White Clouds. The FCRNRW area is a large wilderness adjacent to the Operations Area Boundary and extends more than 50 km from the boundary. For purposes of far-field analysis, only the portion of the FCRNRW that is located more than 50 km from the Operations Area Boundary was considered. Also, at the request of the Nez Perce Tribe, a fifth far-field region was included. This area is identified on **Figure 1-3** as "Nez Perce Requested Analysis Area."

2.0 Alternatives, Including the Proposed Action

The SGP 2021 Modified Mine Plan (MMP) Alternatives Report (Forest Service 2022a) contains the details of the alternatives that are being considered and fully analyzed in this report. For reader convenience, the alternatives are briefly summarized here.

2.1 No Action Alternative



The No Action Alternative provides an environmental baseline for comparison of the action alternatives. Under the No Action Alternative, the mining, ore processing, and related activities under the 2021 MMP or the Johnson Creek Route Alternative would not take place. In addition, certain legacy and existing mining impacts would be addressed as directed in the 2021 Administrative Settlement Agreement and Order on Consent (ASAOC), including installation of stream diversion ditches designed to avoid contact of water with sources of contamination and removal of development rock and tailings currently impacting water quality. However, existing and approved activities (i.e., approved exploration activities and associated reclamation obligations) would continue and Perpetua would not be precluded from subsequently submitting another plan of operations pursuant to the General Mining Law of 1872 (U.S. Congress 1872).

2.2 2021 MMP

The 2021 MMP is based upon Perpetua's Revised Plan (ModPRO2) and is considered the Proposed Action. The description of this alternative has been updated per the Revised Plan submitted in 2021 (Perpetua 2021a). The proposed SGP operations footprint has been modified but would still be within the previously identified Operations Area Boundary (Midas Gold 2016) (**Figure 2-1**).

The following mine components would be common to the action alternatives:

- Mine pit locations, areal extents, and mining and backfilling methods
- Transportation management on existing and proposed roads
- Pit dewatering, surface water management, and water treatment
- Ore processing
- Lime generation
- Tailing storage facility (TSF) construction and operation methods
- TSF Buttress construction methods
- Water supply needs and uses

Surface Land Management

- Management of mine impacted water and stormwater runoff
- Stibnite Gold Logistics Facility (SGLF)
- A road maintenance facility
- Surface and underground exploration
- Stibnite Gold Project worker housing facility

For access, the 2021 MMP would utilize Warm Lake Road, Johnson Creek Road, and Stibnite Road during construction of the proposed Burntlog Route; then once constructed, the Burntlog Route would be utilized during operations and reclamation. The actions proposed under the 2021 MMP would take place over a period of approximately 20 to 25 years, not including the long-term, post-closure environmental monitoring or potential long-term water treatment.

2.3 Johnson Creek Route Alternative

The Johnson Creek Route Alternative was developed to evaluate potential reductions in impacts to various resources. The mining portion of this alternative would be the same as under the 2021 MMP. Therefore, the primary focus of the Johnson Creek Route Alternative would be using an existing road for mine access through operations and reclamation instead of the Burntlog Route that would require new road construction in Inventoried Roadless Areas. The Johnson Creek Route Alternative would require upgrades to both Johnson Creek Road and Stibnite Road. Construction schedule for upgrading the roads and construction of the SGP would increase from 3 years to 5 years under this alternative.

The action alternatives are summarized in **Table 2-1**.

Table 2-1 Action Alternatives Summary

SGP Phase	Component/ Subcomponent	2021 MMP	Johnson Creek Route Alternative
All Phases	SGP timeline	• Construction: Approximately3 years. • Operations: Approximately 15 years. • Exploration: Approximately 17 years (during construction and operations). • Reclamation: Approximately 5 years (except for the TSF which would require an additional 9 years for tailings dewatering and consolidation). • Closure/Post-Closure Water Treatment: Approximately through Mine Year 40. • Environmental Monitoring: As long as needed.	Same as 2021 MMP except: • Construction: Approximately 5 years (upgrading the existing Johnson Creek and Stibnite Roads to provide permanent mine access).

SGP Phase	Component/ Subcomponent	2021 MMP	Johnson Creek Route Alternative
All Phases	Access Roads	Construction/Operations: • Warm lake road from State Highway (SH) 55 to Johnson Creek Route intersection (34 miles). • Johnson Creek Route for SGP access during early construction with minor improvements within the road prism. • Burntlog Route (38 miles) for SGP access during last year of construction, mining and ore processing operations, and closure and reclamation. Includes improvements of existing segments (23 miles) and road construction for new segments (15 miles). • Up to eight borrow areas developed along Burntlog Route for materials needed for road improvements and maintenance. • Access route around the Yellow Pine pit for public access. Closure and Reclamation: • New sections of Burntlog Route to be reclaimed after the closure and reclamation period.	• Warm lake road from SH 55 to Johnson Creek Route intersection (34 miles). • Johnson Creek Route (39 miles: Johnson Creek Road 25 miles, Stibnite Road 14 miles) upgraded and used for access throughout life of mine (LOM) instead of the Burntlog Route. • Access route around the Yellow Pine pit for public access, employee access, and deliveries of supplies and equipment to the processing, warehouse, worker housing facility, and administration areas. • No improvements or construction of new segments for Burntlog Route. • Up to seven borrow sources developed along the Johnson Creek Route for materials needed for road improvements and maintenance. Closure and Reclamation: • Improved Johnson Creek and Stibnite roads would not be reclaimed to pre-existing conditions.
All Phases	Public Access	Construction: • Temporary groomed over-snow vehicle (OSV) trail on the west side of Johnson Creek from Trout Creek to Landmark while Burntlog Route is constructed (8 miles). • OSV trail on west side of Johnson Creek from Wapiti Meadows to Trout Creek campground closed during construction (9 miles). • OSV trail from Warm Lake to Landmark closed during construction through operations (8.5 miles). • Cabin Creek Road Groomed OSV trail (11 miles).	Construction and Operations: Same as 2021 MMP except: • OSV trail on the west side of Johnson Creek from Wapiti Meadows to Trout Creek campground would be closed from construction through mine closure (9 miles). • Groomed OSV trail on the west side of Johnson Creek from Trout Creek to Landmark lasting from construction through mine closure. Closure and Reclamation: Same as 2021 MMP.

PET-0904

REC 2624

SGP Phase	Component/ Subcomponent	2021 MMP	Johnson Creek Route Alternative
		• Public roads remain open through the SGP with temporary closures as needed to accommodate construction. Operations: • Groomed OSV trail moves from west side of Johnson Creek Road to Johnson Creek Road from Landmark to Wapiti Meadows (16.7 miles). • Stibnite Road (County Road [CR] 50-412) / Thunder Mountain Road (FR 50375) closed through the SGP. • Seasonal public access through the Operations Area Boundary provided by constructing new road through Yellow Pine pit and below mine haul road to link Stibnite Road (FR 50412) to Thunder Mountain Road (FR 50375). • Public access allowed on Burntlog Route to Thunder Mountain Road (FR 50375). Closure and Reclamation: • New road constructed over the Yellow Pine Backfill (backfilled Yellow Pine pit) connecting Stibnite Road (FR 50412) to Thunder Mountain Road (FR 50375).	
Operations	Utilities – Transmission Lines	• Upgrade approximately63 miles of the existing 12.5 kilovolt (kV) and 69 kV transmission lines. • New approximate 9-mile, 138 kV line would be constructed from the Johnson Creek substation to a new substation at the mine site. • Upgrade the substations located at Oxbow Dam, Horse Flat, McCall, Lake Fork, and Warm Lake. • Reroute approximately 5.4 miles of transmission line to avoid the Thunder Mountain Estates subdivision.	Same as 2021 MMP.

PET-0905

REC 2625

SGP Phase	Component/ Subcomponent	2021 MMP	Johnson Creek Route Alternative
		• Reroute approximately 0.9 miles of transmission line between Cascade and Donnelly to use an old railroad grade on private property. • Installation of approximately 3 miles of new underground distribution line along Johnson Creek Road from the Johnson Creek substation south to Wapiti Meadows.	
Operations	Utilities - Communication Towers and Repeater Sites	• One cell tower located north of the Hangar Flats pit. • Locations along Burntlog Route for very high frequency (VHF) repeater sites. • Use existing access roads to repeater site locations along Burntlog Route. • Communication site at the SGLF. • Upgrades to existing communication site.	Same as 2021 MMP except: • Cell tower sites constructed and maintained using helicopter (instead of constructing access roads) for sites within IRAs managed for Backcountry/Restoration. • Locations along Johnson Creek route for repeater sites.
Operations	Off-site Maintenance Facility	• SGLF located along Warm Lake Road. • Burntlog Maintenance Facility located at one of the borrow source locations 4.4 miles east of the junction of Johnson Creek Road and Warm Lake Road along the proposed Burntlog Route.	• SGLF same as 2021 MMP • Landmark Maintenance Facility located at junction of Warm Lake Road at Johnson Creek Road.
Closure and Reclamation	Access road segments	• Removal and reclamation of new road segments constructed for Burntlog Route. • Return of previously existing road segments to pre-construction width and condition.	• No removal or reclamation of pre-existing access routes.

Source: Perpetua 2021a

2.4 Applicable Environmental Design Features

The SGP must comply with all laws and regulations that apply to the proposed activities (Forest Service 2021a). Standards and guidelines in the Payette and Boise National Forest Land and Resource Management Plans (Forest Service 2003, 2010) that are designed to reduce or prevent undesirable impacts resulting from proposed management activities are incorporated into all the action alternatives by reference. In addition, best management practices outlined in the Best Management Practices for Mining

in Idaho (Idaho Department of Lands 1992) would be implemented where appropriate and applicable for operations to minimize site disturbance from mining and drilling activities.

In the design of the 2021 MMP, Perpetua has already considered many of the potential environmental impacts that might be caused by the SGP. This has led to an internal evaluation of project design features and operational characteristics that may have the effect of reducing and/or eliminating potential environmental impacts of the SGP. Such project-specific measures intended by a proponent to inherently reduce and/or avoid potential environmental impacts of a proposed action are referred to as environmental "design features."

Based on the application of permits and regulatory compliance requirements (Forest Service 2022a) to the project, regulatory requirements, standards and guidelines, best management practices, and likely permit conditions are listed in **Table 2-2**. The environmental design features that have been proposed and committed to by Perpetua are listed in **Table 2-3**. All of these environmental design measures have been assumed to be effective in conducting the environmental analysis presented in **Section 7.0**.

Table 2-2 Prominent Regulatory and Forest Plan Requirements for Air Quality

Description	Type	Reference
Deploy a satellite or network connected visibility web camera as part of the FS visibility network aimed from the boundary of FCRNRW south of mine across to FCRNRW boundary north of mine and/or from north to south on the FCRNRW boundary looking to the opposite boundary to document frequency of plume blight and visibility impacts to the wilderness area. Work with Perpetua to employ additional controls (likely dust mitigation and speed limits) if Forest Supervisor deems visibility impact magnitude or frequency unacceptable.	Design Feature	
Dust abatement chemicals would be used in accordance with the applicable road maintenance Biological Assessment. Apply dust- abatement additives and stabilization chemicals (typically MgCl2, CaCl2, or lignin sulphonates) to avoid run-off of applied dust abatement solutions to streams. Spill containment equipment would be available during chemical dust abatement application. Where the road surface is within 25 feet (slope distance) of surface water, dust abatement would only be applied to a 10-foot swath down the centerline of the road. The rate and quantity of application would be regulated to insure all of the chemical is absorbed before leaving the road surface.	Design Feature	
Perpetua will prepare a dust mitigation plan with appropriate schedule or triggers for control deemed adequate by IDEQ to achieve the level of control of 93 percent of dust (as submitted in Perpetua's application for Permit to Construct from IDEQ). Alternatively, Perpetua could employ particulate matter or opacity monitors deemed adequate by IDEQ and the Forest Service and immediately apply water or chemical dust control when PM or opacity monitors reach levels within 10 percent of the threshold determined by IDEQ.	IDEQ Permit	IDEQ Permit to Construct
To further ensure the intended high level of control, the FS requires an adaptive management plan as dust is a major component of emissions and air quality impacts affecting the near-field area. See also IDEQ dust control plan outline and EPA AP42 Chapter 13: Miscellaneous Sources, Section 2.2: Unpaved Roads pp. 13.2.2-12 – 13.2.2-17.	Design Feature	

Table 2-3 Proponent Proposed Environmental Design Features for Air Quality

Description
Following crushing, the crushed ore would be transported via conveyor to a dome-shaped, covered stockpile.
All off-highway diesel engines would conform to EPA Tier IV standards for off-highway diesel engines or better.
Perpetua would encourage employees to use company provided shuttle buses as transport to the SGLF from towns along SH 55.
Busing and/or vanpooling would be provided for Perpetua and contractor employees. The associated parking area would accommodate approximately 300 vehicles. To the degree practicable, Perpetua would mandate the use of busing and vans for employee and contractor transportation to the SGP and the worker housing facility.

In addition to the environmental design features listed in **Table 2-3** that are specific to air quality, Perpetua has proposed additional environmental measures for the SGP as described in the following documents:

- Stibnite Gold Mitigation Plan (Perpetua 2021b)
- Fugitive Dust Control Plan (Perpetua 2021c)
- State of Idaho Permit to Construct (IDEQ 2022)

3.0 Relevant Laws, Regulations, and Policy

The Clean Air Act (CAA) of 1970 (42 United States Code 7401 et seq.), as amended in 1977 and 1990, regulates air emissions and protects air quality and air quality related values across the U.S. Provisions of the CAA that are relevant to the analysis of SGP air quality effects are listed below:

- NAAQS
- Attainment and Non-Attainment Area Designations
- New Source Review Permitting
- New Source Performance Standards (NSPS)
- Mobile Source Regulations
- Visibility and Regional Haze
- Greenhouse Gas (GHG) Reporting Rule

Certain areas also may be designated for special protection of air quality. All U.S. lands are categorized as either “Class I” or “Class II,” under the CAA, which determines the level of protection from air pollution impacts provided by regulations. Mandatory federal Class I areas include international parks, wilderness areas, and national memorial parks that exceed 5,000 acres, as well as national parks that exceed 6,000 acres, which were in existence prior to August 7, 1977. All other areas were initially classified as Class II. The CAA also gives states and Tribes the ability to request re-designation from Class II to Class I status.

3.1 Land and Resource Management Plan

Physical, social, and biological resources on National Forest System lands are managed to achieve a desired condition that supports a broad range of biodiversity and social and economic opportunity. National Forest Land and Resource Management Plans embody the provisions of the National Forest Management Act and guide natural resource management activities on National Forest System land.

In the SGP area, the Payette National Forest Land and Resource Management Plan (Payette Forest Plan; Forest Service 2003), and the Boise National Forest Land and Resource Management Plan (Boise Forest Plan; Forest Service 2010) provide management prescriptions designed to realize goals for achieving desired condition for air quality and include various objectives, guidelines, and standards for this purpose.

3.2 Federal Laws, Regulations, and Policy

3.2.1 National Ambient Air Quality Standards

The EPA, in Title 40 CFR 50, established NAAQS for six criteria pollutants: carbon monoxide (CO), lead, nitrogen dioxide (NO_2), ozone (O_3), particulate matter (PM) including PM less than 10 microns in diameter (PM_{10}) and PM less than 2.5 microns in diameter ($PM_{2.5}$), and sulfur dioxide (SO_2). The NAAQS set two levels of standards for each criteria pollutant: primary standards are health- based atmospheric concentration levels, across specific averaging times, and are protective of public health; secondary standards are in comparable form, and are established to protect commercial and natural resources, and public welfare.

The following regulated air pollutants comprise the criteria pollutants covered by NAAQS:

- Ozone: Ground-level O_3 is a secondary pollutant formed in the atmosphere by a series of complex chemical reactions involving precursor pollutants nitrogen oxides (NO_X) and volatile organic compounds in the presence of sunlight. In relatively high concentrations, O_3 is a powerful oxidant capable of destroying organic matter, including human lung and airway tissue.

- Nitrogen dioxide: NO_2 can be emitted directly from combustion sources, such as fuel-fired stationary sources and vehicle exhaust. These are generally the largest source categories for nitric oxide and NO_2, collectively termed NO_X. Nitrogen dioxide is also formed in the atmosphere primarily by the rapid reaction of the colorless gas, nitric oxide, with atmospheric oxygen. Over longer-term exposures, NO_2 can irritate and damage the lungs, cause bronchitis and pneumonia, and lower resistance to respiratory infections such as influenza.

- Carbon monoxide: CO is a colorless, odorless, and potentially toxic gas. It is produced by natural and anthropogenic (caused by human activity) pathways such as combustion processes. The major source of CO is incomplete combustion of carbon-containing fuels (primarily gasoline, diesel, natural gas, and coal). However, it also results from combustion of vegetation such as forest fires and agricultural burning. The potential health impact from CO is that at relatively high concentrations it diminishes the ability of blood to carry oxygen to the brain, heart, and other vital organs, which especially affects sensitive populations and those with respiratory or heart disease.

- Sulfur dioxide: SO_2 is a colorless gas with a sharp, irritating odor. It reacts with moisture in the atmosphere to produce sulfuric acid and sulfates, which contribute to acid deposition and atmospheric visibility impairment. At longer exposures to low concentrations, SO_2 causes

constriction of the airways and poses a respiratory tract infection hazard to sensitive individuals, such as asthmatics and children.

- Respirable PM: PM_{10} consists of airborne PM, fine dusts, and aerosols that are 10 microns or smaller in diameter. The primary sources of PM_{10} include combustion processes, dust from paved and unpaved roads, and earthmoving construction operations. As a regulated pollutant, PM_{10} encompasses different constituents and, therefore, varying effects on health. PM_{10} particles can accumulate in the upper portion of the respiratory system, affecting the bronchial tubes, nose, and throat.

- Fine PM: $PM_{2.5}$ is a mixture of very fine particulate dusts and condensed aerosols that are 2.5 microns or smaller in aerodynamic diameter. $PM_{2.5}$ particles are emitted directly from activities such as industrial and residential combustion processes, wood burning, and from diesel- and gasoline-powered vehicles. They also are formed in the atmosphere by reactions of "precursor" gases, such as SO_2, NO_X, ammonia, and volatile organic compounds that create discrete secondary particulate. $PM_{2.5}$ can enter the deepest portions of the lungs where gas exchange occurs between the air and the blood stream, and where the lungs have no efficient mechanism for removing them. These fine particles can be retained in the lungs permanently, which increases the risks of long-term respiratory disease, cancer, and premature death.

- While the EPA sets the NAAQS, most states, including Idaho, are responsible for implementing, attaining and maintaining the standards and this process is done through the State Implementation Plans (SIPs). The IDEQ is the regulatory agency for air pollution control for the State of Idaho. The CAA allows states to adopt their own standards if they are at least as stringent as the NAAQS. The State of Idaho has adopted the NAAQS by reference in Idaho Administration Procedures Act (IDAPA) 58.01.01(107) in lieu of setting its own standards. In addition, Idaho has adopted an ambient air quality standard for fluorides in IDAPA 58.01.01(577). Literature surveys and published air pollutant emissions inventories for gold mining do not list fluoride as a potential emissions concern, and therefore SGP fluoride emissions are considered to be negligible. **Table 3-1** lists the primary and secondary NAAQS that would apply to the SGP.

Table 3-1 National Ambient Air Quality Standards

Pollutant and Averaging Time	Primary NAAQS	Secondary NAAQS	Exceedance Criteria
CO, 8-Hour	9 ppm	N/A	Not to be exceeded more than once per year
CO, 1-Hour	35 ppm	N/A	Not to be exceeded more than once per year
Lead, 3-month	0.15 $\mu g/m^3$	0.15 $\mu g/m^3$	Not to be exceeded by the rolling 3-month average
NO2, Annual	53 ppb	53 ppb	Not to be exceeded by the average of the 1-hour concentration in a calendar year
NO2, 1-Hour	100 ppb	N/A	98th percentile of 1-hour daily maximum concentration, averaged over 3 years
O3	0.070 ppm	0.070 ppm	Annual 4th highest daily maximum 8-hour concentration, averaged over 3 years
PM2.5, Annual	12 $\mu g/m^3$	15 $\mu g/m^3$	Annual mean, averaged over 3 years
PM2.5, 24-Hour	35 $\mu g/m^3$	35 $\mu g/m^3$	98th percentile, averaged over 3 years

Pollutant and Averaging Time	Primary NAAQS	Secondary NAAQS	Exceedance Criteria
PM10, 24-Hour	150 µg/m3	150 µg/m^3	Not to be exceeded more than once per year on average over 3 years
SO2, 3-Hour	NA	0.5 ppm	Not to be exceeded more than once per year
SO2, 1-Hour	75 ppb	N/A	99th percentile of 1-hour daily maximum concentration, averaged over 3 years

Source: EPA 2018a
µg/m^3 = micrograms per cubic meter
CO = carbon monoxide
m^3 = cubic meters
N/A = not applicable
NAAQS = National Ambient Air Quality Standards
NO_2 = nitrogen dioxide
O_3 = ozone
PM = particulate matter
ppb = parts per billion
ppm = parts per million
SO_2 = sulfur dioxide

The EPA determines and publishes air quality attainment status in the EPA Green Book (USEPA based on whether the air quality in the area consistently meets the NAAQS. Areas that persistently do not meet this standard are designated as nonattainment areas. The geographic areas considered in the air quality analysis area are in attainment of the NAAQS for all pollutants and averaging times (IDEQ 2019).

3.2.2 Federal Air Permitting

The New Source Review process requires facilities to undergo an EPA pre-construction review if they propose building new facilities or modifying existing facilities that would result in a "significant increase" of criteria pollutants per 40 CFR § 52.2376. The New Source Review is further broken down into Major Source Permits for stationary sources that emit criteria pollutants at levels that exceed the defined thresholds for the source type and Minor Source Permits for sources that have emissions below those thresholds. In Idaho, New Source Review air permitting is administered by IDEQ through an EPA approved State Implementation Plan.

Prevention of Significant Deterioration (PSD) permitting applies to new major sources or major modifications at existing sources for specific pollutants in cases where location of the source is in an attainment or maintenance area. For these sources, the PSD program requires an assessment of best available control technology and expanded analysis of air quality impacts in Class I areas in 40 CFR 52.21. Areas surrounding the SGP are in attainment with the NAAQS. Applicability of the PSD program depends on the magnitude of annual emissions for criteria pollutants.

For new or modified major sources subject to the PSD program, ambient concentrations in Class I and Class II areas also are compared to criteria air pollutant concentration increments that specify the maximum increase of ambient air concentrations of pollutants, or the "consumption of increment," over the legally established baseline for an area per 40 CFR § 52.2376. The analysis of increment consumption was promulgated under the CAA, and the available increment levels are specific to a given location. The allowable increment levels are more stringent in Class I areas, compared to Class II areas. It is the responsibility of the individual states, through their permitting programs, to ensure that the increments are not exceeded due to the development of new or modified facilities. While an increment analysis is required for new or modified major sources, it is recognized that new or modified minor sources also may

consume increment. Because the assessment of increment consumption is part of state new source review programs, such an analysis is normally not included in air quality reviews under federal National Environmental Policy Act. However, a simple comparison of modeled pollutant concentrations to the increments for Class I and Class II areas was conducted as part of the SGP air quality analysis. Disclosure of the SGP impacts in comparison to PSD increments helps to inform decision makes and the public regarding the significance of impacts to local air quality.

A Title V operating permit is required for major stationary sources under the Federal Operating Permits Program provided in CAA implementing regulations at 40 CFR 70. Whether a source meets the definition of "major," depends on the type and amount of air pollutants the source could potentially emit on an annual basis.

A determination would be made by the IDEQ whether the SGP would require a Title V permit, due to potential emissions. This will be based on the complete air emissions inventory for stationary sources that would be submitted by Perpetua as part of its application for an air quality permit. On June 17, 2022 IDEQ issued a final Permit to Construct (PTC) and Statement of Basis (SOB) stating that the SGP will not require a Title V permit.

3.2.3 Federal New Source Performance Standards

The NSPS are codified at 40 CFR 60 and are incorporated in Idaho air regulations by reference. These rules establish requirements for new, modified, or reconstructed emission units in specific source categories. NSPS requirements include emission limits, monitoring, reporting, and record keeping. Applicable NSPS for the SGP emission sources are:

- 40 CFR 60 Subpart A – General Provisions. Subpart A contains the general requirements applicable to all emission units subject to 40 CFR 60.
- 40 CFR 60 Subpart LL – Standards of performance for metallic mineral processing facilities. All facilities located in underground mines are exempted from the provisions of this subpart. All surface facilities at which construction or modification commenced after August 24, 1982, are subject to this subpart.
- 40 CFR 60 Subpart IIII – Standards of Performance for Stationary Compression Ignition Internal Combustion Engines. This subpart applies to diesel-fueled reciprocating engines, which would include the compressor and generator engines included in the SGP sources.
- 40 CFR 60 Subpart OOO – Standards of Performance for Nonmetallic Mineral Processing Plants. This subpart applies to the proposed limestone processing plant in Alternative 2.

3.2.4 National Emission Standards for Hazardous Air Pollutants

The federal National Emission Standards for Hazardous Air Pollutants (NESHAP) rules are codified at 40 CFR 61 and 63 and are incorporated in Idaho air regulations by reference. As part of the NESHAPs program, federal maximum achievable control standards are enacted to reduce the emissions of Hazardous Air Pollutants (HAPs) from both major source and area source categories.

Consideration of NESHAP Subparts in 40 CFR 63 indicates that there are three regulations and general provisions applicable to the SGP's air emission sources:

- 40 CFR 63 Subpart A – General Provisions. Subpart A contains the general requirements applicable to all emission units subject to 40 CFR 63.

- 40 CFR 63 Subpart EEEEEEE (7E) - NESHAPs for Gold Mine Ore Processing and Production Area Source Category. The rule was promulgated in February 2011, and this NESHAP applies generally to gold ore processing and production of gold-bearing products. This NESHAP is applicable to minor or "area sources" of HAP, and so would apply to the SGP emission sources. Specifically, this NESHAP applies to gold recovery and refining that use carbon processes, non-carbon processes, and mercury retorts. Therefore, the "carbon-in-pulp" process included in the SGP process sequence that adsorbs dissolved gold into the carbon particles is subject to this subpart. The regulation establishes mercury emissions limitations and work practice standards to control mercury emissions from gold production processes.

- 40 CFR 63 Subpart ZZZZ – National Emissions Standards for Hazardous Air Pollutants for Stationary Reciprocating Internal Combustion Engines. This subpart applies to the proposed diesel combustion engines at the SGP.

- 40 CFR 63 Subpart CCCCCC – National Emission Standards for Hazardous Air Pollutants for Source Category: Gasoline Dispensing Facilities. This subpart applies to the proposed gasoline storage tanks at the SGP.

3.2.5 Wilderness Act

The Wilderness Act of 1964 requires that wilderness areas be administered to preserve their wilderness character. The agencies managing wilderness further defined wilderness character in Keeping It Wild 2 (Forest Service 2015a): "Wilderness character is a holistic concept based on the interaction of (1) biophysical environments primarily free from modern human manipulation and impact, (2) personal experiences in natural environments generally free from the encumbrances and signs of modern society, and (3) symbolic meanings of humility, restraint, and interdependence that inspire human connection with nature." The Wilderness Act also created the National Wilderness Preservation System (NWPS) to identify and preserve designated wilderness areas (NWPS 2019a). Further, the Wilderness Act contains specific provisions for managing and protecting these pristine areas (NWPS 2019b). The Forest Service included additional wilderness areas in the air quality screening and modeling for the SGP to evaluate potential impacts on the areas' natural quality of wilderness character.

3.2.6 Greenhouse Gas Reporting Rule

GHGs are natural or anthropogenic gases that trap heat in the atmosphere and contribute to the greenhouse effect. In October 2009, the EPA issued the Mandatory Reporting of Greenhouse Gas Rule (MRR) in 40 CFR 98, which required reporting of GHG data and other relevant information from large sources and suppliers in the U.S. The gases covered by 40 CFR 98 are carbon dioxide, methane, nitrous oxide, hydrofluorocarbons, perfluorocarbons, sulfur hexafluoride, and other fluorinated gases. Implementation of the MRR includes the greenhouse gas reporting program applicable to facilities for which actual emissions of GHG are greater than 25,000 metric tons per year. Facilities subject to the MRR are required to submit annual reports to the EPA (CFR 2016). The Climate Change Specialist Report (Forest Service 2022b) addresses climate change and applicability of the MRR in further detail, but SGP GHG emission estimates would require MRR.

3.2.7 Mobile Source Federal Regulations

Mobile source air pollution control requirements for gasoline and diesel on-road engines are codified in 40 CFR 80, 40 CFR 85, and 40 CFR 86. These standards are designed to reduce emissions from passenger cars, light trucks, and large passenger vehicles (including sport utility vehicles, minivans, vans, and pickup trucks) and to reduce the sulfur content of diesel and gasoline fuels. Under these provisions, the EPA initially established Tier 1 and Tier 2 emissions standards for the purpose of minimizing emissions from these sources. For the on-road vehicles that would be owned and operated by Perpetua, the regulatory criteria indicate that EPA's Tier 2 emission standards program would apply.

Provisions for non-road diesel engines are codified in 40 CFR 89, 40 CFR 90, and 40 CFR 1039. Starting in 1996, manufacturers of non-road engines became subject to the EPA's increasingly stringent Tier 1 through Tier 4 emissions standards, depending on model year and engine size (CFR 2011). All new diesel engines have been required to meet Tier 4 standards since 2015.

EPA's mobile source regulations in 40 CFR 80 Subpart I - Motor Vehicle Diesel Fuel; Non-Road, Locomotive, and Marine Diesel Fuel; and U.S. Emissions Control Area Marine Fuel contains provisions restricting diesel fuel sulfur content for fuel used in mobile sources, in order to prevent damage to the emission control systems. These restrictions would apply to the fuels that would be used by the SGP, as they were phased in for highway diesel fuel starting in 2006 and for non-road diesel fuel in 2007.

3.3 State and Local Policy

3.3.1 Idaho Minor Source Air Permitting

The State of Idaho has enacted air quality regulations that are administered by the IDEQ. With respect to new source review permitting, IDEQ uses a PTC program (codified in IDAPA 58.01.01.200-228) that applies to new and modified sources. In this manner, the PTC program serves to protect ambient air quality from impacts due to major and more-numerous non-major stationary emission sources.

The IDEQ requires minor source permits for new facilities that are subject to federal NSPS and/or NESHAP regulations. A determination would be made by the State of Idaho whether the SGP satisfies the requirements of the PTC program, based on demonstration of the SGP's potential emissions and controls. This would be based on the complete air emissions inventory of stationary sources that would be submitted by Perpetua as part of its application for an air quality permit. Perpetua applied to IDEQ for an air permit under the PTC program. IDEQ issued a final PTC and SOB were issued on June 17, 2022 for the SGP.

3.3.2 Idaho Visibility Protection Requirements and Regional Haze Rule

Atmospheric visibility is defined as the ability of the human eye to distinguish an object from the surrounding background. In 1980, the EPA adopted regulations requiring states to update their State Implementation Plans for protection of visibility in Class I areas in 40 CFR 51 Subpart P (40 CFR 51.300 through 40 CFR 51.307). As a federal land manager of Class I areas, the Forest Service also has affirmative responsibilities to protect air quality and air quality-related values, such as visibility, in the Class I areas.

The federal Regional Haze Rule, adopted by the State of Idaho in IDAPA 58.01.01.665-668, requires states to develop long-term, regional haze, State Implementation Plans for reducing human-caused pollutant emissions that contribute to visibility degradation and to establish goals aimed at improving visibility in Class I areas. Sources of haze-causing pollutants include emissions from industrial sources,

tailpipes, agricultural equipment, and practices; and from natural sources such as volcanic emissions, windblown dust, and smoke from wildfires.

According to IDEQ, regional haze in Idaho's natural parks and scenic areas is attributable to a variety of natural and human source of air pollution and is greatly impacted by the effects of climate, such as drought, increased wildfires, and reduced precipitation (IDEQ 2017).

3.3.3 Idaho Toxic Air Pollutant Program

The State of Idaho's Toxic Air Pollutant Program is a stand-alone risk-based program that regulates approximately 350 pollutants determined by their nature to be toxic to human or animal life or vegetation. The program prohibits emissions of these pollutants in amounts that would injure or unreasonably affect human or animal life or vegetation. Toxic Air Pollutant emissions from industrial sources are compared to screening levels and limited by acceptable ambient concentrations for carcinogenic (i.e., having the potential to cause cancer) and non-carcinogenic pollutants. An air impact modeling analysis is required for projects having Toxic Air Pollutant emissions that exceed screening emission levels provided in IDAPA 58.01.01.585 for non-carcinogens, and IDAPA 58.01.01.586 for carcinogens. The modeling analysis must show that the acceptable ambient concentrations for non-carcinogens are not exceeded on a 24-hour average basis, and on a longer-term average for carcinogens.

IDAPA 58.01.210.14(a) requires control technologies for toxic pollutants as required to demonstrate compliance with appropriate AAC/AACC values. This is known as T-RACT or Toxic Reasonably Available Control Technology. During the development of the IDEQ permit, specific controls were evaluated and determined to be acceptable and compliant with the standards. As a result, IDEQ is requiring the use of "low-arsenic" quartzite (90 ppm arsenic or less) development rock to be applied for capping haul roads excluding those with the various pits and rock storage facilities. In addition, the drill rigs will include a dust control system with a minimum efficiency of 90 percent. Perpetua's PTC application included emissions subject to the Toxic Air Pollutant Program. IDEQ issued a final PTC and SOB for the SGP demonstrating compliance based on the air emissions inventory submitted in the application. The T-RACT analysis requirements outlined above were incorporated into the final PTC.

4.0 Issues and Resource Indicators

4.1 Significant Issues

Significant issues are those which are used to formulate alternatives to the Proposed Action and to develop mitigation measures. The SGP may affect air quality characteristics and resources that are affected by air pollutants. Arsenic emissions are of concern for air quality. For information pertaining to the potential impacts refer to **Section 7.2.2.3** Hazardous Air Pollutant Modeling. Note that Hazardous Air Pollutants (HAPs) are a federally regulated subset of the Idaho state regulated TAPs discussed above. HAPs are identified under the CAA Section 112. Idaho regulates all HAPs and an extended number of toxic pollutants under their TAPs program. HAPs modeling was conducted for this analysis because of this being a federal NEPA action. All other TAPs were analyzed during the PTC permitting process with IDEQ.

4.2 Resource Issues and Indicators

The indicators for the air quality resource reflect four components of air quality impact: magnitude or intensity, duration, geographic extent, and context. The issue and indicators analyzed for air quality are as follows:

Issue: The SGP may affect air quality characteristics and resources that are affected by air pollutants.

Indicators:

- Geographical extent of pollutant concentrations and deposition.
- Type and volume of air pollutants emitted, including haze precursors, airborne dust, and HAPs.
- Criteria air pollutant ambient air concentrations outside the Operations Area Boundary anywhere the public is allowed unrestricted access.
- Comparison of predicted ambient concentrations to Class I and Class II PSD increments and Significant Impact Levels.
- HAPs (including mercury [Hg]) emissions and Hg deposition.
- Deposition of nitrogen and sulfur compounds in Class I and specified Class II areas.
- Near-field plume blight and far-field regional haze in protected areas.

5.0 Methodology

Environmental consequences related to air quality are evaluated by comparing to objective, usually numerical, standards. In this case, the assessment of potential air quality impacts relies on a quantification of the emissions from the construction and operations phase of the action alternatives. It is typical practice for analysis of air quality effects to evaluate the period during which emissions are predicted to be highest. If the resulting indicators for that period are below the appropriate standards, then impacts for other periods can be reasonably concluded to be of lower magnitude and extent. Estimated construction, mining, and processing emissions for the 2021 MMP are presented in **Appendix A**, reproduced from the report entitled Air Quality Analysis, prepared for Perpetua (Air Sciences 2021a) and from an updated modeling analysis submitted to support the air quality permitting process (Air Sciences 2020).

The assessment of potential effects regarding the air quality issue and indicators is analyzed for each action alternative in its entirety (i.e., the combined emissions of the SGP construction/operation, transmission line construction/operation, and access road activities). The methodology for analysis of air quality-related effects is detailed in the following sections. **Section 7.2** presents the results of the quantitative assessment of the impacts of emissions from the action alternatives, including fugitive emissions from surface mining activities, roadway dust, and tailpipe exhaust. For the air quality impacts analysis, the basis for emissions of pollutants, including criteria air pollutants, HAPs, sulfuric acid mist, Hg, and hydrogen cyanide, was the year of mine operations with the highest level of overall emissions.

5.1 Analysis Area

An air quality analysis usually relies on defined geographic regions that represent the areas for which different types of modeling would be conducted. First, a "near field" was examined using appropriate models to quantify the effects of action alternative sources. The near-field modeling domain for the ambient air quality analysis, which extends 10 kilometers (km)[6] from the SGP, is depicted in **Figure 1-2**. Other aspects of the near-field modeling such as nitrogen and sulfur deposition used a domain of 50 km from the SGP. Federal modeling rules (40 CFR 51, Appendix W) stipulate that near-field models may be applied for distances of 50 km or less from the emission sources. For the SGP, preliminary modeling confirmed that the 10-km domain size was adequate to characterize worst-case near-field air quality impacts. Air quality effects would typically decrease at distances beyond the modeled 10 km range. For further detail pertaining to near-field modeling refer to **Section 5.4**.

The refined model uses a "grid" of defined receptor points at which air pollutant concentrations are predicted by the model calculations. Receptor tiers were used starting at 25 m[7] along the Operations Area Boundary (OAB) and transitioning to 1 km spacing out to the 10-km extent of the modeled domain to follow accepted regulatory modeling practice. Tighter spaced receptors were used closer to the OAB to allow the model to map in more detail the predicted close-in concentrations that are generally the highest.

Second, a much larger "far-field" region was defined within an area up to 300 km-radius from the SGP that encompassed more-distant Class I areas, wilderness areas, Tribal reservation and other areas requested by Tribes that were considered in the analysis as shown in **Figure 1-1**, with the Class I areas identified. As described in the following sections, specifically **Section 5.5**, specialized air quality modeling in the far-field region examined SGP source contributions to regional haze, nitrogen deposition, and sulfur deposition.

5.1.1 Direct/Indirect Effects Boundaries

A key concept in air quality analysis is the definition of "ambient air" as a defined area in which air pollutant effects to ambient air are to be compared to the national and state ambient air quality standards because that area is accessible to the general public (U.S. EPA 2019a). For the SGP, the area outside the area of Operations Boundary is defined as ambient air for modeling analyses is the OAB. This area is illustrated in **Figure 1-2** and the limit of the area that is closed to unrestricted public access. In this area, public access would be prohibited, or restricted through such measures that are accepted as means to control public access (EPA 2019a) as Perpetua security checkpoints, physical barriers at points of potential access road and trail entry, and security surveillance patrols.

A May 12, 2021, memorandum developed for the USFS by Stantec Consulting Services, Inc. outlines the rationale to exclude a portion of the proposed seasonal through-site controlled public access road through the mine operations from the public as approved by the Idaho DEQ and accepted by the EPA from ambient air for dispersion modeling purposes (Stantec 2021). This stretch of road is from Stibnite Road (FR 50412) to Thunder Mountain Road (FR 50375). The EPA Region X has indicated that the access road could possibly be excluded from ambient air if sufficient enforceable measures are taken to comply with the 2019 revised policy (EPA 2019a). To comply with this measure, Perpetua has developed a Transportation Management Plan that is included as **Appendix D**. The memorandum provides details that Idaho DEQ, who is responsible for issuing air permits in the state have excluded the road because of

[6] Metric units, including kilometers (km), are used predominantly in this section because of permit and measuring requirements. 1 km = 0.6mi; 1 mi =1.6 km

[7] 1 meter (m) = 3.3 feet; 1 foot = 0.3 meter.

PET-0917

REC 2637

restriction measures put in place consistent with their rules and requirements in the permit Lastly, DEQ issued a final PTC on June 17, 2022, that requires an Access Management Plan to be developed outing specific requirements relating to access control. Further information regarding IDEQ's ambient air interpretation is available in the PTC, condition 2.7 and the Response to Comments document, Comment 16.

5.1.2 Cumulative Effects Boundaries

For the far-field air quality impact analysis, a suitable far-field modeling domain was defined as an area 420 km by 420 km in extent, centered on the SGP, as shown in **Figure 1-3**. This area encompasses the closest Class I areas and Class II wilderness areas that are most likely to have impacts. The four Class I areas for which far-field modeling results were reported are SAWT, SELW, HECA, and CRMO.

5.2 Analysis Area Methodology

There are several Class I areas within a 300-km radius of the SGP Operations Area Boundary; however, many of these are farther from the SGP, and in the same general cardinal directions as the four closer Class I areas. A tiered approach was adopted to analyze the closer Class I areas that would have greater potential for air quality or visibility impacts. If the impacts predicted at the four closer Class I areas indicated potential for impacts at greater distances, then additional analyses would have been conducted for the more-distant Class I areas.

Four Class II wilderness areas, also shown in **Figure 1-3**, were selected by the Forest Service for far-field evaluation: FCRNRW, Gospel-Hump (GOSPEL), Hemingway-Boulders (HEMBLD), and Cecil D. Andrus - White Clouds (WHTCLD). Also, at the request of the Nez Perce Tribe, a fifth far-field region was included: the Nez Perce Requested Analysis Area.

The FCRNRW area is a large wilderness adjacent to the SGP Operations Area Boundary and extends more than 50 km from that boundary. For purposes of far-field analysis, only the portion of the FCRNRW that lies beyond 50 km from the Operations Area Boundary was considered. The regions of the FCRNRW that are within 50 km of the SGP were included in the near-field analysis area, which allows the impacts to be evaluated using dispersion models that are suitable for such distances.

5.3 Air Emissions Inventory Methodology

Direct effects are defined as those which are caused by the action and occur at the same time and place. Indirect effects are those that are caused by the action and occur later in time or are farther removed in distance but are still reasonably foreseeable. Because the direct and indirect air quality effects related to concurrent construction and operations are not distinguishable, a complete air emission inventory is to consider mine operations, ore processing (including refining), ongoing development of the SGP, support facilities, access roads, utilities (transmission line construction), and off-site facilities. For purposes of these analyses and IDEQ permitting, separate air pollutant emission inventories have been assembled for:

- Criteria air pollutants addressed by NAAQS: CO, NO_2, $PM_{2.5}$, PM_{10}, SO_2, O_3, and ozone precursors (e.g., NO_X and volatile organic compounds [VOCs]);
- HAPs, including Hg, As, Sb and hydrogen cyanide (HCN);
- Non-criteria pollutants: total PM, sulfuric acid mist (H_2SO_4), hydrogen sulfide; and
- Greenhouse gases.

The detailed emission inventories in **Appendices A** and **B** provide the source and selection rationale for the various factors that were used. Additional evaluation regarding the selection of emission factors for the specific sources included in the SGP is provided in **Appendix C**. This methodology applies to criteria, non-criteria, and HAP emissions estimates. The emission factors and estimation techniques are provided in regulatory and industry technical documents, including, but not limited to:

- EPA Document AP-42: "Compilation of Air Pollutant Emission Factors" and associated background documents (EPA 1995);
- Published emission estimation reports, including reports from the EPA and other environmental experts (EPA 1994; Schmidt and Card 2010; Eckley et al. 2010);
- EPA emission estimation models, such as MOVES (Motor Vehicle Emission Simulator) (EPA 2015a), and TANKS for hydrocarbon storage tanks (EPA 1999);
- Applicable regulatory emission requirements from Title 40 of the CFR (CFR 2011a, 2011b, 2016a, 2016b);
- EPA reference method performance test data or permit limits from similar gold ore processing operations (Nevada Division of Environmental Protection 2006, 2015, 2016; Schmidt and Card 2010);
- Manufacturer emissions certification data (Caterpillar 2019); and
- Other technical documents (Air Sciences 2018a, 2021a, 2021b; EPA 2003, 2012; Nevada Division of Environmental Protection 2017).

The air emissions inventory for the 2021 MMP is based on calculations for each emission source, for each life-of-mine (LOM) year. Perpetua timelines in the Plan of Restoration and Operations (Midas Gold 2016) and supporting documents, including the Air Quality Analysis (Air Sciences 2018a, 2021a), are based on a timeline that starts with construction years listed as negative years to Year 1 which is the first mine operational year. This specialist report assumes Year 1 is the first year of any type of disturbance associated with the SGP, including construction and does not use negative years in discussing mine timelines[8]. Timelines in the air quality discussion are based on the EIS timelines but some figures may be taken from reports using the Perpetua timelines; in these cases, explanatory notes are added.

5.3.1 Criteria Pollutant Inventory Methods

Mine operations involve numerous emission source categories characterized by the type of process, material processed, and equipment used. Most of the methods used to estimate emissions follow the accepted techniques that are described in EPA Document AP-42, Compilation of Air Pollutant Emission Factors (EPA 1995). This compilation is the largest single reference used to develop air emission estimations and is maintained as an EPA website resource. It provides methodologies, emission model equations, and emission factors for a broad range of process equipment and industrial sources. An emission factor is usually a well-supported, representative value that reasonably relates the quantity of a pollutant released from some activity or process to a quantitative measure of the intensity or rate of the

[8] Note that Perpetua's Plan of Restoration and Operations (Midas Gold 2016) includes a schedule that reports SGP construction as negative years (-3, -2, and -1) counting down to when operations begin at the SGP in year 1. This differs from the timeline presented in this report which begins at year 1 aligning with the first year of SGP construction-related activity.

activity. Examples of the measure of activity rate are acres disturbed, tons processed, gallons of fuel combusted, or thermal content of fuel used. An evaluation of the selected emission factors for the SGP sources is provided in **Appendix C**.

In general, Document AP-42 emission factors represent a broad average of emissions data available for a specific source type. A single tabulated emission factor usually encompasses data from several actual operations and a relatively large range of actual emission rates per unit of activity. Therefore, the Document AP-42 emission factors should be considered as representing an average of the range of measured or calculated emission rates. When the individual factors are applied to a specific operating unit, the resulting emissions estimate is therefore subject to some level of uncertainty. In EPA Document AP-42, the level of uncertainty in each factor is indicated by an "emission factor rating" with values ranging from "A" for best accuracy, and "E" for greater uncertainty.

To illustrate the level of confidence in judging emission estimates, it can be noted that nearly all the emission factor values in Section 11.19.2 of Document AP-42, which is relied on for many Perpetua sources, have emission factor ratings of "D" or "E." To compensate for this uncertainty, the accepted practice applied in this analysis is to over-estimate the activity rates for a given operation. This tends to avoid under-reporting the final estimates used for air quality analyses (Air Sciences 2018a).

As described in **Section 5.3.3**, inventories were developed for two different mine operating scenarios. One inventory was applied to support the range of non-regulatory analyses prepared for the 2021 MMP, and a second inventory applied to the NAAQS analysis by IDEQ that supported the PTC for the SGP (**Appendix B**). For each inventory, activity-specific (e.g., drilling, blasting, material crushing and conveying, refining, and other ancillary sources and activities) emissions were estimated based on the maximum activity rates for mining and production sources, coupled with applicable emission estimation techniques. Emissions were calculated on a short-term (hourly) and a long-term (annual) basis for ore processing, mine operations, and construction activities.

During full production, the daily ore-milling and processing rate would range from 20,000 to 25,000 tons per day (tpd). To ensure a conservative analysis, maximum daily ore processing emissions for the two inventories were based on the maximum design rate of 25,000 tpd, and this rate was assumed to be maintained for each annual operating scenario. Maximum annual emissions for the processing sources were based on the maximum daily emissions and multiplied by 365 days per year. Both the 2021 MMP and New Source Review (NSR) inventories from a processing perspective are essentially identical. Slight variations are due to differences of requirements between the EIS and the PTC process. These are discussed in further detail in **Section 5.3.3**.

5.3.2 Non-Criteria and HAP Inventory Methods

Most of the non-criteria and HAP emissions from operations come from the combustion of fossil fuels, processing of gold-bearing ore, and fugitive dust containing trace metals. For the SGP, emission estimates from these sources include:

- Organic and inorganic HAP from combustion of propane and diesel fuel in stationary sources, non-road engines, and vehicles
- Hg from gold ore refining sources (e.g., autoclave, carbon kiln, retort, and induction furnaces);
- Hg from exposed surfaces (stockpiles, development rock, tailings, and pits);
- Fugitive dust containing Hg released from mining and ore processing activities;

- HCN volatilization from the dilute cyanide solution in leach tanks, carbon-in-pulp tanks, and HCN detoxification tanks; and
- Release of trace amounts of residual HCN contained in tailings storage facility (TSF) impoundment of process tailings.
- As emissions from mining dust derived from development rock and ore concentrations

Combustion of propane and diesel fuels in stationary and mobile sources comprise a substantial source of HAP emissions for the SGP. For each category of fuel combustion equipment, published emission factors were used to relate the short term and annual emission rates of HAPs to the rate of fuel consumption. As discussed in **Section 5.3.3**, different categories of fuel combustion sources were included in the two inventories compiled for air quality assessments. Most notably, in line with permitting procedures, the mobile engine tailpipe emissions were not considered in the IDEQ new source review regulatory inventory. The non-regulatory inventory for EIS analyses did include these mobile source tailpipe criteria and HAP emissions.

Emissions of Hg result from mine operations due to the natural Hg content in mined materials and from several thermal steps in the refining of extracted gold (e.g., retort, carbon regeneration kiln, induction furnaces). Estimates of these emissions were based on regulatory compliance emission test results available for several gold mines in Nevada that use the same type of extraction process (Nevada Division of Environmental Protection 2006, 2015, 2016).

Evaluation of potential Hg emission impacts was conducted, in part, to verify that emissions would comply with the EPA Hg emission standards provided in 40 CFR 63, Subpart EEEEEEE, for gold ore processing and production facilities. The SGP would be subject to these federal standards because of the use of a carbon-in-pulp process for capturing gold that has been extracted from the ore using dilute HCN solutions and the use of a retort for purifying the gold-laden precipitate from electrowinning.

Sources of HCN emissions include volatilized HCN from several types of tanks used to extract gold from crushed ore (leach tanks, carbon-in-pulp tanks, HCN detoxification tanks). Process tailings that contain trace amounts of residual HCN impounded in the TSF are the largest source of volatized HCN. These emissions were estimated using published EPA field test data derived from HCN flux measurements at active gold processing facilities in Nevada and estimated physical properties specific to the SGP gold-refining processes (i.e., area, temperature, pH, HCN concentration) (Schmidt and Card 2010).

5.3.3 Comparison of 2021 MMP and NSR Inventories

As described in **Section 7.2**, different mine operational scenarios were used to develop separate emission inventories for the 2021 MMP, and for the modeling that supported the PTC application to IDEQ.

The 2021 MMP inventory examined projected levels of mine development and operation for each LOM year. Emissions from mine operations (drilling, blasting, material extraction and movement, mobile machinery use, lime kiln and other ancillary sources) vary significantly year to year. Therefore, annual emissions were calculated based on the maximum annual activity/production rates for each LOM year. The year with the highest level of overall criteria pollutant emissions, LOM Year 6, has been used for the non-regulatory analyses presented in this specialist report, namely, near-field plume blight (visibility), increment comparison and deposition analyses, and for the far-field air analyses, as discussed in **Section 7.2.2**.

IDEQ, as the regulatory authority for the NAAQS compliance analysis, has approved an alternative emissions inventory to support the NSR process. This inventory, referred to here as the PTC NSR inventory, included the same emissions sources (both fugitive and stationary), but excludes mobile source tailpipe emissions. Additionally, the PTC NSR inventory is the basis for a multitude of hypothetical operating scenarios for NAAQS modeling.

The full inventories of emissions for the 2021 MMP and for the operating scenario comprising the approved PTC NSR inventory are provided in **Appendices A** and **B**, respectively. There are a number of differences to note between the emissions inventories. The inventories used for the 2021 MMP include fugitive dust emissions from the Burntlog Route, as well as mobile tailpipe emissions from on-site mobile equipment. These sources were not included in the PTC NSR inventory because state regulations do not require mobile sources to be covered by the PTC. Other emission levels have been revised in the PTC NSR emissions inventory in accordance with IDEQ's engineering review specific operating condition assumptions. Further, the PTC NSR inventory assumed a specific hypothetical operating scenario that assumed the highest maximum daily mine activity would occur in just a single pit, and that all development rock disposal would use a single development rock storage facility. This resulted in an inventory with generally larger emission rates for the SGP for the PTC NSR inventory than those reflected in the 2021 MMP inventory, which provided a more conservative regulatory assessment of NAAQS compliance (Air Sciences 2020). For further detail refer to **Section 5.4**. **Table 5-1** summarizes the different source categories and action alternatives that were considered in each of the emission inventories.

Table 5-1 Comparison of 2021 MMP and PTC NSR Inventories

Emission Inventory	Used for 2021 MMP Analyses	Used for IDEQ NAAQS Analysis	Action Alternative Basis	Mobile Source Tailpipe Emissions	Burntlog Route Fugitive Dust
2021 MMP [2]	Yes	No	2021 MMP	Included	Included
PTC NSR [1]	No	Yes	2021 MMP	Not Required	Not Required

Sources:
[1] From Perpetua PTC application (Air Sciences 2020)
[2] Air Sciences 2021a

The 2021 MMP inventory includes both dust and tailpipe emissions from vehicle travel for mine construction and operation periods. The traffic emissions included projected workforce, supply, and haulage vehicles (buses, light and heavy trucks) and road maintenance equipment (graders and dozers). Emissions from construction activities during LOM years 1 to 3 (site preparation, temporary power generation to support construction, mobile machinery use, transportation, etc.) vary within each year of the construction period. The maximum overall operations phase criteria pollutant emissions from this source would occur during the peak in mine throughput in LOM Year 6.

5.4 Near Field Air Quality Analyses

This section provides an overview of the air dispersion modeling methods, procedures, and datasets used for the near-field assessment. Additional details are provided in the Air Quality Analysis (Air Sciences 2018a, 2021a). **Figure 1-2** illustrates the extent of the near-field modeling domain. The near-field air quality analyses were conducted in accordance with EPA Guidelines for regulatory air modeling (40 CFR 51, Appendix W) and included the following:

- Ambient air quality analyses to evaluate compliance with NAAQS and compare to Class II increments and Significant Impact Levels (SILs);
- Ozone and secondary fine particulate formation analysis;
- Screening visibility and plume blight analysis;
- Screening Hg deposition analysis; and
- Screening nitrogen and sulfur species deposition analysis.

The PTC NSR inventory prepared for the state of Idaho permit application indicates that the SGP would qualify as a minor source for NSR applicability (based on IDEQ review and approval). In this case, the state air permit application for a minor source is not required to provide a full analysis to show compliance with the Prevention of Significant Deterioration (PSD) criteria in Class I areas within the near-field analysis area. However, an analysis was required to ensure that the new emission sources do not cause or contribute to an exceedance of ambient air standards provided in the NAAQS. The PTC emissions are based on a hypothetical maximum possible production mining rate of 180,000 tons/day of ore and development rock. This is higher than the 2021 MMP emissions inventory that proposes a highest realistic annual production of 36.3 million ton or approximately 99,500 tons per day (Air Sciences 2021a). Additionally, the PTC evaluated numerous scenarios where all 180,000 daily tons were allocated to specific locations throughout the mine. This approach was performed to ensure ease of permitting and are not representative of real-world operations.

SILs are defined concentrations of criteria pollutants in the ambient air that are considered inconsequential in comparison to the NAAQS. Each SIL varies by pollutant and averaging period. In the case of the SGP, an assessment of project impacts in comparison to Class II area PSD increments and SILs for informational purposes provides an additional gauge of the air quality impacts. In addition, comparison of maximum modeled impacts to the SILs for Class II areas can be used, as provided in EPA Guidance, as a measure of the significance of impacts from major or minor sources. A project impact shown to be below a SIL can be presumed to not cause or contribute to the violation of a NAAQS.

5.4.1 Ambient Air Quality Refined Modeling

Refined modeling techniques using the air quality model were used to estimate pollutant concentrations using the 2021 MMP air emissions inventory (except for lead and ozone) at receptor locations. The current version at the time of analysis (19191) of the American Meteorological Society/Environmental Protection Agency Regulatory Model (AERMOD) dispersion analysis modeling system was used for this air quality analysis. The AERMOD modeling system is listed as the recommended model for short-range analysis (up to 50 km) in federal regulations (40 CFR 51, Appendix W).

Modeling of background sources was not warranted for this near-field analysis, because the region is generally rural, and large sources of air emissions are absent. A review of state air quality permits showed that there are no permitted facilities located within a 50 km area (extent of near-field analysis area), of the OAB. The contribution to air quality conditions from background sources is accounted for in the selected baseline concentrations for the NAAQS analysis. These baseline concentrations were added to the highest modeled off-site concentrations due to the SGP sources, as represented in the PTC NSR inventory.

Monitored background or baseline concentrations should reflect the existing air pollutant concentrations in the modeling domain. The total ambient concentrations were estimated by aggregating existing baseline concentrations to the modeled future ambient concentrations resulting from the SGP. In

accordance with IDEQ recommendations, the CO, NO_X, and SO_2 baseline concentrations were derived from the Northwest International Air Quality Environmental Science and Technology Consortium online tool (NW AIRQUEST), for monitored years 2014 to 2017, as provided through Washington State University (2018). These baseline concentrations were derived by photochemical modeling methods, which are allowed under EPA Guidelines (40 CFR 51, Appendix W). The O_3 concentration used as the baseline level was provided by IDEQ as representative backgrounds. The baseline concentrations for particulate species were derived from on-site monitoring data provided by Perpetua, obtained by operation of an IDEQ-approved monitoring program (IDEQ 2015). The pollutant baseline concentrations accepted by IDEQ for the NAAQS air quality demonstration, in units of micrograms per cubic meter ($\mu g/m^3$), are listed in **Table 5-2**.

AERMOD requires an input of hourly meteorological data to estimate pollutant concentrations in ambient air resulting from modeled source emissions. For this analysis, one year (January 1, 2014 to December 31, 2014) of site-specific hourly surface meteorological data collected at the Stibnite monitoring station was used. When site-specific data are available, as in this case, use of a single year of meteorological data can be deemed sufficient for the analysis. A full 12 months of data are the minimum required for air quality assessments under EPA Guidelines (40 CFR 51, Appendix W) to account for seasonal effects. The methods and procedures used to collect this dataset were reviewed by IDEQ and approved in December 2013 (IDEQ 2013) based on the PSD meteorological data quality requirements specified in the EPA Appendix W Guidelines. The EPA-recommended preprocessor, AERSURFACE, was used to estimate surface parameters for use in AERMOD that are dependent on the land use and vegetative cover of the area being evaluated.

Table 5-2 Background Pollutant Concentrations for IDEQ PTC Air Quality Analysis

Pollutant	Averaging Time	Background Conc. ($\mu g/m^3$)	Primary NAAQS[1]
CO	8 hours	1110	10,000 $\mu g/m^3$
	1 hour	1740	40,000 $\mu g/m^3$
NO_2	Annual	0.9	100 $\mu g/m^3$
	1 hour	4.3	188 $\mu g/m^3$
O3	8 hours	117.7	137 $\mu g/m^3$
PM10	24 hours	37.0	150 $\mu g/m^3$
PM2.5	Annual	3.5	12 $\mu g/m^3$
	24 hours	15.0	35 $\mu g/m^3$
SO_2	1 hour	12.3	196 $\mu g/m^3$
	3 hours	16.8	1300 $\mu g/m^3$

Source: Air Sciences 2021a, WSU 2018

[1] The NAAQS units are shown to agree with the modeling analysis approved by IDEQ. Gaseous pollutant $\mu g/m^3$ to ppb conversion 1 ppb equals: NO_2: 1.88 $\mu g/m^3$; SO_2: 2.62 $\mu g/m^3$; CO: 1.145 $\mu g/m^3$; O_3: 2.0 $\mu g/m^3$.

$\mu g/m^3$ = micrograms per cubic meter;
CO = carbon monoxide
NO_2 = nitrogen dioxide
O_3 = ozone
PM_{10} = particulate matter 10 microns in diameter and smaller
$PM_{2.5}$ = particulate matter 2.5 microns in diameter and smaller.
SO_2 = sulfur dioxide

Several source categories are defined in AERMOD to reflect different release characteristics. Processing, refining, and ancillary sources with exhaust stacks, such as baghouse-equipped sources, fuel-burning equipment, and the refinery autoclave, retort, smelting furnace, carbon kiln, etc., were modeled as "point" sources. In general, the sources without exhaust stacks, but where emissions have some inherent velocity on release (such as blasting, haul road dust, mechanical transfer of material, and ore screening and crushing) were modeled as "volume" sources. Unlike point sources, emissions from the numerous fugitive sources in the mining pits and process area (e.g., drilling, blasting, material loading, unloading, hauling, and wind erosion of exposed surfaces) were not modeled individually; rather, they were grouped together as combined "area" sources for these activity locations. The haul road network was divided into 22 sections, and these were sub-divided into 65-meter-long segments. Each segment was represented as an individual "volume" source in AERMOD.

Default particulate modeling methods, including deposition were used for estimating $PM_{2.5}$ and PM_{10} impacts. To account for particulate settling, published references were relied on for the particle properties and size distribution for combustion sources (Khalizov et al. 2012; University of Minnesota 2002). The ore and waste material particle densities were provided by Midas Gold (Air Sciences 2018a).

Pollutant emissions from combustion sources are partially composed of nitric oxide (NO) and NO_2. Once in the atmosphere, the NO can be converted to NO_2 through chemical reactions with ambient ozone. An approved conversion method (ozone limiting method) to mathematically estimate the ambient NO_2 concentrations from EPA Guidelines (40 CFR 51, Appendix W), was used to estimate the 1-hour and annual NO_2 impacts for this analysis (EPA 2015b).

The 2021 MMP was characterized in AERMOD by a series of "line" sources laid along the actual route. These sources were assigned a release height of 3 m, and an initial vertical dispersion of 2.8 m. These release parameters were based on an assumed 3.5 m vehicle height, which is representative of an overall approximation of anticipated vehicle heights (grader – 3.7 m, heavy- duty truck – 3.6 m, and pickup truck – 3.2 m [Caterpillar 2019]), and the area source parameter recommendations provided in the EPA Haul Road Workgroup Report (EPA 2012). The Burntlog Route emissions were evenly distributed along the full route by dividing the total road emissions by the total road total area (i.e., the complete Burntlog Route length (60,378 m = 37.5 miles) multiplied by the road width (6.1 m) (as described in Air Sciences [2018b]).

As the SGP is considered a minor source for NSR, it is not required to show compliance with the PSD increments as part of its minor NSR air permit application unless requested by IDEQ to do so. However, due to its proximity to the FCRNRW area and the Nez Perce Requested Analysis Area, the Class II air quality analysis performed for the 2021 MMP analysis did include an assessment of the significance of SGP air quality impacts by comparison to the Class II PSD increments (Air Sciences 2018b). The near-field modeling performed using the 2021 MMP inventory was used to compare predicted ambient concentrations to the Class II increments at the areas of interest. This assessment does not represent a PSD increment compliance demonstration, which is a more detailed evaluation.

REC 2645

5.4.2 Ozone and Secondary $PM_{2.5}$ Analyses

A quantitative evaluation of the impacts of ozone and secondary $PM_{2.5}$ resulting from action alternative sources was performed, applying recent guidance issued by the EPA (Air Sciences 2018b). These two criteria air pollutants are formed through chemical reactions in the atmosphere, so they are referred to as "secondary pollutants." Ozone is not emitted directly from mining activities or processes, but rather is formed by reactions involving NO_X and VOCs in the atmosphere. Therefore, ozone direct effects cannot be evaluated by air dispersion modeling of emissions from a single source or facility. Warm temperatures, clear skies (abundant levels of solar radiation), and stagnant air masses (low wind speeds) increase the potential for ozone formation (EPA 2016).

In January 2017, the EPA promulgated an update to its Guideline on Air Quality Models (EPA 2017) in 40 CFR 51, Appendix W (1978), to incorporate a tiered demonstration approach to address the secondary chemical formation of ozone and $PM_{2.5}$ associated with precursor emissions from single sources. The 2017 Guideline on Air Quality Models outlined a two-tiered approach for addressing single-source ozone and secondary $PM_{2.5}$ impacts:

- Tier 1: The first tier of assessment involves those situations where existing technical information is available, such as the results from existing photochemical grid modeling, published empirical estimates of source-specific impacts, or reduced-form models. In combination with other supportive information and analyses for the purposes of estimating secondary impacts from a particular source. According to the EPA, the existing technical information should provide a credible and representative estimate of the secondary impacts.

- Tier 2: If appropriate information for a Tier 1 analysis is not available, then a Tier 2 analysis would be conducted involving the application of a case-specific air quality modeling analysis using chemical transport models.

5.4.2.1 Tier 1 Assessment Approach – Ozone

According to the EPA guidance, air quality modeling of hypothetical industrial sources that have similar source characteristics and emission rates of ozone precursors, and which are in similar atmospheric environments, are generally suitable for comparative Tier 1 assessments. To evaluate ozone impacts for the SGP analysis, a Tier 1 assessment was performed based on review of the EPA's Modeled Emission Rates for Precursors (MERPs) guidance document, which includes the EPA's hypothetical source photochemical grid model (PGM) results (EPA 2019b). The PGM is a regional-scale atmospheric model that accounts for ozone-forming reactions and assigns the predicted ozone results as background to hypothetical sources of ozone precursors. This selected PGM source used in this case (number 18 in the PGM source roster) is the geographically closest to the SGP—210 miles (336 km) west-northwest of the SGP—in northeastern Oregon. Ozone impacts reported for the selected hypothetical source at a specified emission level were scaled to reflect the action alternative emission levels to estimate ozone impacts. The PGM-based estimates for ozone concentration changes were added to the baseline ozone concentrations to determine total estimated SGP ozone impacts for comparison to the NAAQS (Air Sciences 2018b).

5.4.2.2 Tier 1 Assessment Approach Secondary $PM_{2.5}$

Particulates smaller than 2.5 microns in diameter present in the atmosphere due to combustion or process sources consist of primary particulates, condensable particulates, and secondary particles. Primary particulates are the fraction of emissions that originates as solid particles (e.g., soot). Condensable particulates originate as gaseous chemical emissions and condense to form particles after exposure to the

cooler temperatures of the atmosphere. Secondary particulates can be formed when exhaust gases, the most notable example being NO_x and SO_2 emissions from a process stack, interact with other chemical species in the downwind atmosphere to form fine particles (e.g., nitrates and sulfates).

To evaluate SGP secondary $PM_{2.5}$ impacts, a Tier 1 assessment was performed based on the EPA MERPs guidance document (EPA 2019b). The same modeled hypothetical source in northeastern Oregon that was selected for the ozone assessment based on similarity in source characteristics, emission rates of precursors, and similar atmospheric environment, was selected to evaluate secondary $PM_{2.5}$ impacts. The PGM-based estimates for $PM_{2.5}$ concentration changes were added to the baseline $PM_{2.5}$ concentrations to determine total estimated SGP $PM_{2.5}$ impacts for comparison to the NAAQS (Air Sciences 2018b).

The Tier 1 assessment approach was accepted by both EPA and Idaho DEQ reviewers.

5.4.3 Plume Visibility Screening Analysis

Plume visibility analysis is a means of quantifying the ability of a viewer to discern a visible plume released from a source and is usually evaluated for an observer at the closest point on the boundary of a Class I or Class II wilderness area of concern. For the SGP plume visibility analysis, the most recent version of the EPA visibility impairment screening model (VISCREEN, version 13190) (EPA 1992) was used to determine if a plume released from the 2021 MMP sources could potentially be visible by a human observer. Plume blight occurs when a coherent plume from a source is perceptible to a casual observer against either a terrain or sky background. The VISCREEN model considers the absolute plume contrast and the difference in color contrast, which together provide a measure of the visible difference between a plume and background as perceived by humans.

The VISCREEN model was run using site-specific wind data to estimate the worst-case visibility impacts for worst-case meteorological conditions (wind speed and stability) (EPA 1992). The annual background visual range of 270 km for the SGP location was provided by the Forest Service and is representative of IMPROVE visual range data in the region. Additional details of the VISCREEN analysis procedures are provided in Air Sciences (2018a).

To operate VISCREEN, the aggregated emissions from the action alternative sources were arranged to be released from a single point. This creates some uncertainty, because the emissions from the SGP and process operations area would spread out over several miles. To account for dispersed emission sources, accepted modeling practice is to determine a theoretical single-point plume origin correction distance. The calculated distance in this case was 17.8 km. Subsequently, this distance was added to the hypothetical observer distance at the FCRNRW area boundary, and the combined observer distance was used in the VISCREEN inputs.

VISCREEN results provide a comparison of the two calculated plume contrast parameters with criteria thresholds to determine the plume perceptibility by an observer. Contrast that the is a measure of the difference in the transmitted light intensity without regard for color. Color contrast (ΔE) measures the difference in wavelength of perceived light rather than intensity. For this plume visibility assessment, VISCREEN results for both C and ΔE were evaluated for a plume against a backdrop of sky or terrain, and at solar angles of 10 degrees and 140 degrees. A result that exceeds the criteria thresholds for either C or ΔE indicates that a plume would be visible. Both daytime and nighttime hours were included in this analysis, although it should be recognized that any plume that occurs at night would not have sunlight to illuminate it.

Following the DEIS release it was requested that the VISCREEN modeling be updated with two distinct changes. First, the portion (1.8 percent) of PM emissions from combustion are now categorized as soot in the model rather than PM_{10}. Second, PM emissions larger than PM_{10} have been added to the model. For details refer to Appendix C of the Air Quality Analysis Addendum ModPro2 memorandum (Air Sciences 2021a) and **Section 7.2.2.3**.

5.4.4 Mercury Deposition Analysis

In the atmosphere, the forms of Hg that contribute to the deposition to land and surface waters are gaseous Hg (Hg^{2+}), particulate-borne Hg (HgP), and gaseous elemental Hg (Hg0). Further speciation of the particulate forms of Hg is possible such as fine HgP, which is analogous to filterable and condensable PM_{10}. Essentially, the PM_{10} associated with HgP is the mercury bound within the particles of the particulate smaller than 10 microns. Appropriate particle distribution of mercury can be established using proper test methods and techniques, but the overall percentage of HgP compared to total Hg is small, with HgP PM_{10} being even less (~14.1 percent vs 2.4 percent from a coal boiler as an example) (Peng 2021). However, as discussed below, and in further detail in **Section 7.2.2.3** the approach applied for this analysis did not speciate HgP. The assessment of Hg deposition for the locale of the SGP was conducted using two different tools. EPA computer simulation results based on the Regional Modeling System for Aerosols and Deposition (REMSAD) are available to quantify Hg deposition in each of the lower 48 states (EPA 2008).

This modeling was based on Hg emission inventory data obtained from 2000 through 2006, so would be expected to be higher than more-recent Hg emission levels that reflect regulatory limitations. The REMSAD results were used to estimate background deposition in the locale of the SGP area. Sources of Hg deposition included in the EPA REMSAD modeling analysis were:

- Point- and area-source emission sources in the lower 48 U.S.;
- Emissions from sources in Canada and Mexico; and
- Global background deposition from the Chemical Transport Model, the Global/Regional Atmospheric Heavy Metals model, and the GEOS-Chem model (EPA 2008).

The second analysis tool to assess the contribution to Hg deposition due to the 2021 MMP sources was screening-level dispersion simulation using AERMOD. It is recognized that AERMOD does not simulate the key physical processes affecting Hg in the environment (e.g., chemical transformation, re-emission, wet deposition, etc.) that are included in other models of Hg deposition. However, AERMOD was used in this case as a screening tool, to quantify the potential for increases in deposition of Hg species that could lead to impacts to biota. Complete discussion of the AERMOD method details and calculations are provided in the Air Quality Analysis report (Air Sciences 2018b).

5.4.5 Nitrogen and Sulfur Deposition Screening Analysis

To evaluate near-field deposition due to action alternative sources of NO_x and SO_2, screening-level modeling was conducted using AERMOD for nitrogen and sulfur species. As in the case of Hg deposition, it is recognized that AERMOD does not include several physical processes involved in chemical deposition (e.g., atmosphere chemical transformation of NO_2 and SO_2) found in traditional acid deposition models. However, for purposes of this assessment, it served as a screening tool to conservatively identify potential for adverse deposition effects.

This screening analysis was conducted using the Level 2 procedures prescribed in the draft interagency near-field deposition modeling guidance (U.S. National Park Service [NPS] 2011). The Level 2 analysis assumes that 100 percent of the NO/NO_2 emissions are promptly transformed into soluble nitric acid on release to the atmosphere. This assumption results in a significant overestimation of potential nitrogen species deposition close to the facility and is viewed as conservative.

5.5 Far-Field Air Quality Analyses

Another area of air quality impacts was analysis of potential effects in Class I and Class II areas surrounding the SGP area. The Class I areas within 300 km of the Operations Area Boundary are shown in **Figure 1-3**. The distances and direction between the proposed SGP and the closest boundary of these Class I areas are listed in **Table 5-3**. As described below, a less extensive area was defined as the far-field modeling domain, and several Class II wilderness areas were considered along with the selected Class I areas.

The far-field analysis focused on four Class I areas that were among the closest to the SGP, and in different cardinal directions relative to the SGP area: SAWT, SELW, HECA, and CRMO. The adopted approach was to discern if potential impacts above thresholds were predicted in these areas. Assessment of impacts in these closer Class I areas are conservatively representative of impacts in the areas not included in the model. **Table 5-3** identifies the Class I areas that were not included in far-field modeling; however, if significant impacts had been identified in the closer Class I areas, then additional analysis would be warranted to determine if there were potential impacts also could affect the more distant Class I areas (Air Sciences 2018a).

Table 5-3 Class I Areas in the Far-Field Analysis Area

Class I Area	Included in Far-Field Modeling	Distance, miles (km) and Direction
SAWT	Yes	48.1 (77.5), South
SELW	Yes	53.6 (86.5), North
HECA	Yes	62.0 (100.0), Northwest
Eagle Cap Wilderness	No	84.1 (135.6), West
Anaconda-Pintler Wilderness	No	98.6 (159.0), Northeast
CRMO	Yes	132.8 (214.2), Southeast
Flathead Reservation	No	156.7 (252.7), North-Northeast
Strawberry Mountain Wilderness	No	165.0 (266.1), West-Southwest
Red Rock Lakes National Wildlife Refuge	No	169.6 (273.5), East
Mission Mountains Wilderness	No	177.7 (286.7), North-Northeast

Source: Air Sciences 2018b

Four Class II wilderness areas also were included in the far-field analysis: FCRNRW, GOSPEL, HEMBLD, and WHTCLD. The FCRNRW area is a large wilderness adjacent to the Operations Area Boundary that extends well beyond 50 km from this boundary. For purposes of the far-field analysis, only the portion of the FCRNRW that lies beyond 50 km was considered in far- field modeling. The Nez Perce Requested Analysis Area also was included in the far-field analysis of visibility effects and chemical deposition impacts. The locations of these Class II areas of concern within the modeling domain are illustrated in **Figure 1.3**.

5.5.1 Modeling Methodology for Far-Field Analyses

For the far-field analyses, the CALPUFF dispersion model was selected. The CALPUFF model is a non-steady state, Lagrangian "puff" model that simulates the transport and chemical transformation of discrete puffs of pollutants released into the atmosphere. As wind flow changes geographically from hour to hour after the release, the path of each puff is altered by the model to follow the changing wind direction.

The CALMET processor, which simulates a three-dimensional wind field required by CALPUFF, was not used in this case. Rather, this analysis used a location-specific, 3-year wind field dataset generated by the Weather Research and Forecasting Model (WRF) in accordance with the federal Guideline on Air Quality Models (40 CFR 51, Appendix W). The WRF data was processed with the Mesoscale Model Interface (MMIF) program to prepare the meteorological fields for use in CALPUFF. This wind field spanned the entire modeling domain (420 km by 420 km, at a 4 km resolution [105 by 105 grid cells]) and was based on 3 years of regional data (2015 to 2017) (Air Sciences 2018b).

To assess data quality, the CALPUFF-ready wind field was evaluated against observational data from 15 established monitoring stations distributed throughout the CALPUFF modeling domain using the MMIF statistics program (MMIFStat). From the WRF meteorological data set, the MMIFStat package derives a few data quality metrics for air temperature, relative humidity, and winds. These computed metrics were compared to data quality benchmarks that have been commonly reported for mesoscale model evaluation. These benchmarks are available for both simple and complex terrain and are viewed as indicators of data adequacy and quality but are not used alone to accept or reject datasets.

In this case, the applicable complex terrain benchmarks for temperature and humidity data were generally met by the WRF dataset. However, some divergences from benchmarks were noted for wind speed and direction data. This was attributed to the elevated and complex terrain surrounding the various data monitoring sites, which can cause errors in wind direction simulation. Additional details of the meteorological data assessment procedures for operation of CALPUFF are presented in the Air Quality Analysis report (Air Sciences 2018b).

Sources from the near-field AERMOD modeling files were used to build the CALPUFF inputs, with some significant differences. For point sources having exhaust at ambient air temperature (e.g., dust control baghouses), the CALPUFF model differs from AERMOD, because it sets a constant release temperature approximating ambient air temperature (293.15 degrees Kelvin). In AERMOD, the mine pit sources were modeled as rectangular volume sources (OPENPIT routine), with individual lateral dimensions and release heights for each pit used to calculate initial vertical dispersion parameters. In CALPUFF, the pit sources were modeled as square area sources located with a release height at the top of the pit opening, with the pit located from the AERMOD lateral dimensions. The primary SGP plant access road (Burntlog) was modeled in AERMOD using several defined "line" sources. In CALPUFF, this access road was modeled as a set of widely spaced "volume" sources (Air Sciences 2018a).

Receptors for each Class I area were downloaded from the NPS Class I Area Receptors website (NPS 2018). For the Class II wilderness areas, receptor elevations were determined using the AERMAP program. Receptors were placed in the interior of each wilderness area at a 2-km grid spacing starting at 50 km from the SGP.

5.5.2 Far-Field Regional Haze Assessment Procedures

For the far-field assessments of regional haze impacts, the MESOPUFF II five-pollutant (nitric acid [HNO_3], NO_x, nitrate species, SO_2, and sulfate species [SO_4]) conversion algorithm was applied in CALPUFF to simulate atmospheric chemistry effects and contribution to regional haze. Action alternative source emissions were set at the LOM Year 7 of the DEIS Alternative 2 maximum daily 24-hour emissions of NO_X, SO_2, SO_4, and fine and coarse PM. Additional details of the CALPUFF processing and post-processing methods are presented in the far-field modeling protocol and the Air Quality Analysis report (Air Sciences 2018a, 2018b). Note that Far-Field modeling was not completed a second time, rather a validation comparison was performed to demonstrate that no significant changes to impact concentrations resulted between the DEIS and the 2021 MMP. For further details refer to **Section 7.2.2.4 Direct and Indirect Effects - Fair Field Analysis**.

Use of the annual average natural visual range conditions and visibility background values are usually recommended by federal land manager guidance for Class I areas. The average natural conditions for the four Class I areas in this analysis were obtained from the IMPROVE sites representing those areas (Copeland 2018). For the Class II wilderness areas, Forest Service- recommended HECA background values were used for the Nez Perce Requested Analysis Area, and median background values from the four nearest Class I IMPROVE sites were used for the remaining Class II wilderness areas (Copeland 2018).

5.5.3 Far-Field Comparisons with Class I and Class II Increments

As the SGP is considered a minor source for NSR, it is not required to show compliance with the PSD increments in either Class II or Class I areas. In view of proximity of the SGP to the FCRNRW area and the Nez Perce Requested Analysis Area within a 50 km distance, a comparison of SGP air quality impacts with the Class II PSD increments was conducted as part of the near-field analysis (refer to **Section 5.4**). Similarly, the far-field CALPUFF modeling was used to perform a comparison between maximum ambient concentrations with Class I and Class II increments for the areas of interest in the far-field domain beyond 50 km.

It should be noted that this modeling was based on the 2020 DEIS Alternative 2 inventory. This inventory was shown to have somewhat higher overall criteria pollutant emissions, generally due to the added combustion emissions of the lime kiln. Therefore, it was considered more conservative to perform this increment comparison for the action alternative with the higher quantified emissions. Alternative 2 inventory includes fugitive tailpipe emissions from vehicles operating at the SGP, in common with other non-regulatory modeling analyses such as the regional haze contributions and deposition screening modeling.

5.5.4 Far-Field Deposition Assessments

Total potential annual nitrogen (N) and sulfur (S) deposition from action alternative sources was determined as part of the air quality far-field analyses. The POSTUTIL routines in the CALPUFF model predict the deposition fluxes for both these chemical species at the receptors placed in the areas of concern. These post-processing routines were used to calculate the nitric acid/nitrite concentrations levels at each receptor, accounting for the hourly-occurring humidity and temperature conditions. Similarly, POSTUTIL routines in CALPUFF were applied to predict sulfuric acid/sulfate concentrations at each receptor. The modeling results for total potential N and S deposition are expressed in terms of the quantity of those two elements. Both dry and wet deposition were considered. Deposition impacts were compared to the Deposition Analysis Thresholds (DAT) as outlined in federal land manager guidance on N and S

deposition (NPS 2011). In this guidance, the significance level for N and S deposition rates in Class I areas is listed as 0.005 kilogram per hectare-year.

6.0 Affected Environment

6.1 Existing Conditions

The air quality in a given location is characterized by a number of properties that can be physically monitored and evaluated. The existing conditions that may be affected by the SGP include ambient air quality in comparison to the NAAQS, visibility as impacted by regional haze and visible plumes emitted from mine activities, and current rates of atmospheric deposition of mercury, nitrogen, and sulfur compounds. The description of the affected environment addresses these issues and several other parameters that pertain to regional air quality.

6.1.1 Criteria Air Pollutants

For SGP-specific baseline concentrations, Perpetua (then Midas Gold) collected 20 months (November 2013 to June 2015) of PM_{10} and $PM_{2.5}$ air concentration data at the approved Stibnite monitoring station (IDEQ 2013). The Stibnite monitor is in the same airshed as the SGP; characterized as mountain valley terrain with little or no industry. Additionally, this SGP particulate monitor is located within the near-field analysis area and was deemed by IDEQ to be representative of background conditions in the locale. The IDEQ formally approved the Monitoring Protocol and Quality Assurance Project Plan in December 2013 (IDEQ 2013). Both the meteorological and air quality monitoring began in November 2013 (Trinity Consultants 2017). After reviewing the data and associated quality control procedures, IDEQ concluded that the calendar year 2014 data for PM_{10} and $PM_{2.5}$ data collected at the Stibnite monitoring station satisfied the applicable regulatory requirements and approved the data as representative for analysis (IDEQ 2015).

For the ambient air NAAQS demonstration, IDEQ identified the source for gaseous pollutant background data as the NW AIRQUEST database for years 2014-2017 (Washington State University 2018) to be used in conjunction with particulate matter data collected at the Stibnite monitoring station. **Table 6-1** displays these data along with the applicable NAAQS. The areas considered in the analysis of air quality impacts are in attainment of the NAAQS for all pollutants and averaging times (IDEQ 2019).

Table 6-1 Ambient Air Data – Perpetua and NW Airquest Consortium Background Values

Pollutant and Averaging Time	Monitored Value and Units	NAAQS	Source and Period
PM_{10}, 24-Hour	37 µg/m^3 [1]	150 µg/m^3	Onsite monitor 1/1/14-12/31/14
$PM_{2.5}$, Annual	3.5 µg/m^3 [6]	12 µg/m^3	J Onsite monitor 1/1/14-12/31/14
$PM_{2.5}$, 24-Hour	15 µg/m^3 [3]	35 µg/m^3	Onsite monitor 1/1/14-12/31/14
SO_2, 3-Hour (Secondary)	6.4 ppb [1]	500 ppb	NW Airquest Consortium 7/1/14-6/30/17
SO_2, 1-Hour	4.7 ppb [4]	75 ppb	NW Airquest Consortium 7/1/14-6/30/17
CO, 8-Hour	0.97 ppm [1]	9 ppm	NW Airquest Consortium 7/1/14-6/30/17
CO, 1-Hour	1.52 ppm [1]	35 ppm	NW Airquest Consortium 7/1/14-6/30/17

Pollutant and Averaging Time	Monitored Value and Units	NAAQS	Source and Period
NO_2, Annual	0.5 ppb [2]	53 ppb	NW Airquest Consortium 7/1/14-6/30/17
NO_2, 1-Hour	2.3 ppb [5]	100 ppb	NW Airquest Consortium 7/1/14-6/30/17

[2] Annual mean value for the data collection period.
[3] 98th-percentile for the data collection period.
[4] Average of the 99th-percentile daily maximum 1-hour values for the data collection period.
[5] Average of the 98th-percentile daily maximum 1-hour values for the data collection period.
[6] Weighted average of quarterly means for the data collection period.

6.1.2 Hazardous Air Pollutants

There are no permitted sources of HAP emissions in the vicinity of the SGP area. One source, the Tamarack Mill, LLC is 75 km away, and reported minor source level emissions of 5.9 tons per year of HAPs in 2014 (Trinity Consultants 2017). Due to absence of permitted HAP emission sources in the air quality analysis area, it can be assumed that baseline ambient concentrations of HAPs are low and less than more industrialized or heavily populated areas.

6.1.3 Ozone

For purposes of identifying a baseline value for NAAQS assessment of O_3 impacts due to SGP sources, the IDEQ selected the baseline value from the NW AIRQUEST database for years 2014 through 2017 (Washington State University 2018).

The National Park Service has been operating a continuous O_3 monitor at CRMO from 1992 to present. This monitor is the only O_3 data source in the region that is not located in an urban area, therefore, it is likely representative of conditions near the SGP and surrounding rural area. The highest 1-hour maximum O_3 concentration recorded at the monitor was 91 ppb recorded in July 1996 and again in August 2008. However, there is no 1-hr NAAQS for O_3. The highest O_3 concentration measured at CRMO that is comparable to the 8-hour average NAAQS, (i.e., annual fourth-highest daily maximum 8-hour average) was 69 ppb which occurred in 2018. The annual trend of the fourth-highest 8-hour average for recent years is shown in **Table 6-2**.

Table 6-2 Annual Ozone Concentrations for Comparison to 8-Hour NAAQS Criteria Values – Craters of the Moon National Monument, 2012-2020

Annual O_3 Conc. for NAAQS Comparison [1]	NAAQS 8-hr Standard	2012	2013	2014	2015	2016	2017	2018	2019	2020
8-hour O_3 Conc.(ppb)[2]	70	65	60	62	61	58	63	69	58	66

Source: EPA 2021b
[1] The annual 4th highest 8-hour average averaged over a 3-year period is the NAAQS averaging criteria; these data are annual values, without rolling 3-year averaging.
[2] These values can be compared to the 2015 8-hour average O_3 NAAQS of 70 ppb.

6.1.4 Air Quality Related Values

Air Quality Related Values (AQRVs) are resources sensitive to air quality and include a wide array of resources including, but not limited to, vegetation, soils, water, fish, wildlife, and visibility. Visibility may be affected by impairment due to plume blight or increase in regional haze levels. Plant growth and survival may be adversely affected due to increased ozone concentrations. Deposition of acidic air pollutants may cause episodic or chronic acidification of surface waters and may alter soil chemistry. Elevated deposition of nitrogen or phosphorus can drive species composition changes in both aquatic and terrestrial environments and can change growth and survival rates of plants. Mercury deposition can impact aquatic and riparian dependent species and can bioaccumulate causing health risks to humans and other species.

The CAA gives federal land managers the affirmative responsibility to protect against degradation of air quality and AQRVs in Class I areas. There are several Class I areas within a 300-km radius of the SGP which were considered for AQRV impact assessments. The nearest Class I areas are SAWT (approximately 80 km south-southeast of the SGP Operations Area Boundary) and Selway-Bitterroot

Wilderness (approximately 90 km northeast of the SGP Operations Area Boundary). The Class I areas within a 300-km radius of the SGP Operations Area Boundary are shown in **Figure 1-1**.

The monitoring stations in the far-field analysis area that provide representative background data are listed in **Table 6-3**, and the station locations are mapped in **Figure 6-1**. The Interagency Monitoring of Protected Visual Environments (IMPROVE) monitoring network stations measure chemical constituents that contribute to regional haze and visibility impairment. The National Trends Network (NTN), operated by the National Atmospheric Deposition Program (NADP) provides data on wet atmospheric deposition. The Clean Air Status and Trends Network (CASTNET), provides information on dry atmospheric deposition, including sulfur and nitrogen compounds, as well as ozone. The Mercury Deposition Network (MDN), also operated by NADP, monitors the atmospheric mercury concentration in wet deposition.

6.1.4.1 Visibility

The CAA sets specific goals for protecting Class I areas from human-caused visibility impacts. Scattering of light by aerosols is the main process that limits visibility in the troposphere (ground level to approximately 10 km) degrading the clarity and color of what can be seen. Some airborne particles are naturally occurring (biogenic) and include seeds, pollen, spores, fragments of plants and animals, sea salt, dust, and smoke. They also are generated from anthropogenic sources, which include dust from roads, wind erosion of tilled land, biomass burning, fuel combustion, and industrial processes. In addition, emissions of sulfur, nitrogen, and carbon compounds, which are emitted from industrial sources burning fossil fuels, or from natural sources (e.g., wildfire or dust storms), can be precursors of condensed aerosol particles. In Class I wilderness areas and parks, the Regional Haze Rule requires states to address human-caused sources of air pollution degrading visibility on a regional scale. States use the "impairment" metric to factor out natural sources, such as wildfire smoke, and international contributions outside their control, in tracking their progress in improving visibility in the Class I areas.

One unit used to quantify visibility deterioration is the "visual range," which is a measurable parameter of atmospheric clarity at a specific monitoring location. A shorter visual range corresponds to more impaired long-range visibility through the atmosphere. Visibility has generally improved in Class I areas across the country, in part due to mandated sulfur restrictions on fuels, and controls on industrial sources of air pollution. Average monthly visual range values in the four Class I areas included in the far-field analysis area are between 223 and 278 km, with significant seasonal fluctuation (Air Sciences 2018a; Federal Land Managers' Air Quality Related Values Work Group 2010).

IMPROVE is a cooperative visibility monitoring effort managed by the EPA, with assistance from multiple U.S. agencies, state agencies, Indian tribes, and associated members in Canada and South Korea. The IMPROVE program measures current and long-term trends in visibility by monitoring, on 3-day intervals, the pollutants that contribute to reduction in visual range. Historic visibility parameters are presented in **Table 6-4** for the four IMPROVE stations in Class I areas in the SGP far-field analysis area. The IMPROVE network is designed so that some monitoring sites are used to represent multiple Class I areas in a region.

The visibility data in **Table 6-4** illustrate how observed impairment can vary seasonally and with local conditions in a given locale. Two different measures of impairment are listed. The "most impaired days" represent the portion of days that exhibit the highest 20 percent of observed visibility impairment and reflects only anthropogenic contributions to haze. Another visibility metric, the "monthly average visual range" includes effects of anthropogenic and natural (e.g., wildfire) contributions to haze, and a higher visual range reflects better clarity. The distribution of most impaired days at the Sawtooth (SAWT1) and Selway-Bitterroot (SULA1) wilderness areas tend to have a greater portion of the most impaired days during the warmer summer months. In contrast, the most impaired days occur more frequently during the winter months at Craters of the Moon National Monument (CRMO1) and Hells Canyon Wilderness (HECA1).

REC 2658

Plume visibility is a condition that is caused by a source or combination of sources and is the presence of a plume that is visible to an observer some distance from the source.

Assessment of plume visibility is a means to quantify the ability of a viewer to discern a visible plume and is usually evaluated for an observer at the closest point on the boundary of a Class I area of concern. Plume blight occurs when a coherent plume from a source is perceptible against a viewing background (e.g., the sky, or a terrain feature such as a mountain) to a casual observer. The primary parameters of plume blight are the change in visible contrast and color contrast between a plume and background.

6.1.4.2 Atmospheric Deposition

There are two types of deposition that can affect AQRVs: 1) wet deposition, which involves the scavenging of particles and gases in the air by clouds and precipitation; and 2) dry deposition, which involves the direct collection of gases and particles in the air by vegetation and solids and liquid surfaces (Wallace and Hobbs 2006). Atmospheric deposition may be due to distant sources or local sources of pollution.

As described in this section, data for the existing conditions at the monitoring stations nearest the SGP area indicate that both wet and dry nitrogen deposition either show no clear trend or are trending higher. Nationwide, it has been reported that deposition of oxidized nitrogen species has declined between 2006 and 2016, which may reflect improved NO_x emission control technologies for vehicles and power plants. However, over the same period, deposition rates of reduced forms of nitrogen, such as ammonia, have increased or remained unchanged (NADP 2019). The data presented in this section show that no clear trend is evident in wet or dry sulfur species deposition between 2005 and 2015 at the monitoring sites closest to the SGP area. However, nationwide SO_2 emissions have decreased by 76 percent between 2010-2020 (EPA 2022).

Two complementary monitoring networks that collect deposition data are CASTNET and NTN, which collect data related to dry and wet deposition, respectively. Total deposition estimates are provided nationwide by NADP's Total Deposition Science Committee. They use a hybrid approach combining ambient measurements from CASTNET, NTN, and other air concentration monitoring data with model output to provide gridded estimates of total deposition (NADP 2022; Schwede and Lear 2014). Nearly all CASTNET sites are co-located or are near a corresponding NTN site, which together provide the data needed to track temporal and spatial trends in total deposition.

Deposition of nitrogen and sulfur compounds impact the environment through several pathways. In the atmosphere, NO_x reacts with moisture and oxygen to form nitric acid, nitrates, and nitrous oxide, while SO_2 reacts to form sulfuric acid, sulfates, and sulfites, which can be transported to the surface by wet deposition. Nitrogen and sulfur compounds formed in the atmosphere are conveyed by dry and wet deposition and can affect soils, water, and biota far from the origination of the precursor emissions. Excessive nitrogen deposition can cause reduction in plant biodiversity and eutrophication (excessive plant and algae growth) in surface waters. This has the effect of reducing the oxygen content of the water, and therefore reduces the population of animal life the water can sustain.

Of somewhat less concern in the Pacific Northwest is acid deposition, which occurs when SO_2, NO_X, and ammonia in the atmosphere react to form sulfuric acid, nitric acid, and ammonium. These compounds can enter surface waters, primarily through wet deposition. These pollutants originate from anthropogenic sources (e.g., burning of fossil fuels in power plants and motor vehicles, and agricultural practices), and to a lesser degree from natural sources (e.g., forest fires and volcanoes).

National Trends Network

The NTN provides a nationwide historic record of precipitation chemistry that is reflected in wet deposition rates to soil and surface water. The NTN is part of the NADP that operates several atmospheric monitoring programs. NTN sites are typically located away from urban areas and large point sources of pollution, and many stations are in Class I areas. While stations cannot be established and operated in protected wilderness areas, NTN sites are in many cases located near, or are considered representative of, nearby wilderness area deposition conditions at similar elevations. Each monitoring site measures the quantity of precipitation, and automatically captures samples only during precipitation events. Samples are retrieved from the field on a weekly interval, and analyzed for calcium, magnesium, potassium, sodium, ammonium, nitrate, total nitrogen species, chloride, sulfate, and free acidity (as H^+) (NADP 2022). Wet deposition data is expressed in units of kilograms per hectare per year (kg/ha-yr)[9].

Annual data for three NTN sites closest to the SGP is presented in **Tables 6-5** through **Table 6-7**. These three sites are located at the CRMO (213 km distant, southeast) Reynolds Creek (264 km distant, south-southwest), and Lost Trail Pass (142 km distant, northeast). Trends in the wet deposition rates of the primary nitrogen and sulfur species (nitrate [NO_3], ammonium [NH_4], and sulfate [SO_4]) are plotted in **Figures 6-2** through **6-4** for the three NTN sites. These trends show the wide variability in annual wet deposition rates in the region, with no clear long-term trend.

Clean Air Status and Trends Network Data

CASTNET is a long-term, dry deposition national monitoring network managed by EPA. The CASTNET sites measure nitrogen and sulfur species, chloride, and base cations (i.e., a positively charged ion) that are used to calculate dry deposition rates. The network was established under the 1990 CAA Amendments to provide accountability for emission reduction programs by reporting trends in pollutant concentrations and acidic deposition (EPA 2018b). **Table 6-8** shows dry nitrogen compound and dry sulfur compound deposition rates at the two CASTNET monitoring sites closest to the SGP and located in Idaho. These are stations on Nez Perce Tribal Reservation land (82 km distant, north-northwest, and at Reynolds Creek (264 km distant, south-southwest). Like wet deposition, dry deposition is typically expressed in units of kg/ha-yr. **Figure 6-5** illustrates the trends in annual dry deposition rates at these sites, with dry deposition of sulfur species generally higher than nitrogen species.

Mercury Deposition Network

Inorganic Hg in gaseous and particle-bound forms and mercury oxide are emitted from many mine operations and fossil fuel combustion sources, most notably coal-fired electrical-generating units. Each form has specific physical and chemical properties that determine how far it travels in the atmosphere before depositing to the landscape.

Atmospheric deposition of mercury is of particular concern where the potential exists for transfer to riparian areas and/or surface waters through precipitation and runoff. Although gaseous oxidized Hg and particle-bound Hg deposition are prevalent, all forms of Hg may deposit to local or regional watersheds (Zhang 2009). National Hg emissions from domestic anthropogenic sources declined from about 63 tons in 2008 to about 55 tons in 2014, the latest data year available in the EPA National Emissions Inventory (EPA 2017). More than 75 percent of this decline (5.9 tons per year) can be attributed to reductions in Hg emissions from fossil-fueled electric generation plants (EPA 2017). Once deposited in a body of water, inorganic forms of mercury are converted to a chemical form (methyl mercury) that can become concentrated in fish and can harm the health of individuals who consume these fish, particularly children.

[9] 1 kilogram = 2.2lbs; 1 hectare = 2.5 acres.

In relatively arid regions, such as Idaho, dry Hg deposition may be a larger contributor to atmospheric deposition of mercury compared to wet deposition.

Annual averages of sampling data are available from the MDN in the region corresponding to the SGP far field analysis area. Three MDN sites have been located at CRMO, Deer Flats (294 km distant, south-southwest), and McCall, Idaho (59.5 km distant, west). The most recent measurements were between 2007 and 2010 and are provided in **Table 6-9** to serve as an estimate of historical Hg deposition in the region surrounding the SGP area. Total Hg deposition in precipitation (organic + inorganic) is calculated for the MDN in units of micrograms per square meter per year ($\mu g/m^2$-yr) based on measured mass of Hg deposited over a known sample area (NADP 2018).

Mercury Ambient Concentrations

In addition to deposition data, ambient mercury concentrations are measured via the NADP, specifically the Atmospheric Mercury Network (AMNet). AMNet has captured concentration data throughout North America beginning in 2006. AMNet has been in 39 sites throughout the years and 12 currently active locations. Each site measures hourly gaseous elemental mercury (GEM) and also measures 2-hour gaseous oxidized mercury (GOM) and particulate bound mercury ($PBM_{2.5}$). The nearest geographic site to the SGP area is no longer active but was active from December 2008 to August 14, 2017. **Table 6-10** illustrates the annual average concentrations of each component from December 2008 through November 2015. Only a very limit percentage of data was available from December 2015 through August 2017. For further information and concentrations for other locations please refer to http://nadp.slh.wisc.edu.

2010	Craters of the Moon NM (ID03)	3.91	14.03	5.48
Mean	All Stations	3.95	11.65	4.29

Table Source: NADP 2018
[1] Individual annual measurements for precipitation and mercury deposition data available for three sites: ID03 Craters of the Moon National Monument; ID98 Deer Flats, Idaho; ID99 McCall Idaho.
[2] The three MDN sites within the far field analysis area ceased operation by 2010.
µg/m^2-yr = deposition rate as micrograms mercury per square meter per year.
dm = decimeter (1 decimeter = 3.94 inches).
ng/L = nanograms per liter precipitation.

Table 6-10 Annual Average Mercury Concentration – Salt Lake City AMNet Site

Year	GEM Hourly Average Concentration (ng/m^3)	GOM Average Concentration (pg/m^3)	PBM2.5 Average Concentration (pg/m^3)
Dec 2008 – Nov 2009	2.15	20.14	15.22
Dec 2009 – Nov 2010	2.07	26.63	6.35
Dec 2010 – Nov 2011	1.83	17.06	8.44
Dec 2011 – Nov 2012	1.80	18.68	16.45
Dec 2012 – Nov 2013	1.87	16.80	22.22
Dec 2013 – Nov 2014	1.73	14.52	12.82
Dec 2014 – Nov 2015	1.74	15.17	8.87
Overall Mean	12.91	18.43	1.88

Table Source: NADP 2022
ng/m^3 = nanograms per cubic meter.
pg/m^3 = picograms per cubic meter
GEM = Gaseous elemental mercury
GOM = Gaseous oxidized mercury
PBM2.5 = particle bound mercury

6.1.5 Climate and Meteorology

The SGP is located in the central portion of the Salmon River Mountain Range, in central Idaho, approximately 10 air miles east of the village of Yellow Pine. The SGP Operations Area Boundary and the broader analysis area are classified as a Warm-Summer Continental Climate (Weatherbase.com). In this region, the climate typically ranges from warm, dry summers to cold, wet winters. However, the locale of the SGP is semi-arid as a result of the Cascade and Sierra Nevada mountains to the west and the Bitterroot and Rocky Mountains to the north, which effectively prevents large scale intrusion of Pacific moisture.

As described by the Western Regional Climate Center (WRCC), organized storm fronts frequently move through the region during winter, resulting in cold outbreaks, and can produce snowfall over 2 feet or more. Cloudy and unsettled weather is common during the winter with measurable precipitation occurring roughly a third of the days. The summer months are typically dominated by high pressure over the Great Basin resulting in warm days with very little precipitation. In general, temperatures in the cooler months average below 30 degrees Fahrenheit (°F) and average above 50°F during the warmer months (WRCC 2018a, 2018b).

Spring months are normally wet and windy with periods of high winds that may persist for days at a time. Weather conditions fluctuate quickly during the spring. Afternoon temperatures in the range of 30 to 50°F with precipitation in the form of rain or snow may occur interspersed with periods of sunny skies and afternoon temperatures between 50 to 70°F. Thunderstorms are not uncommon and are usually accompanied by rain showers and occasional snow. Low elevation snowpack usually melts quickly during the spring, but high elevation snowpack can persist into June or later in the year (WRCC 2018a, 2018b).

The nearest location with a long-term climatological data record is the McCall, Idaho, municipal airport station, which is located approximately 37 air miles west and 1,575 vertical feet below the SGP. The McCall National Weather Service station also monitors surface temperature, dew point and wind speed, direction, and highest gust speed (National Oceanic and Atmospheric Administration 2018). While regionally representative, it can be assumed that the McCall airport data will be slightly warmer with lower amounts of precipitation due to its lower elevation compared to the SGP. The average maximum annual temperature is 54ºF and during the warmest month (July) the average maximum monthly temperature is 81ºF. The average minimum annual temperature is 27ºF and during the coldest month (January) the average minimum monthly temperature is 11ºF (National Oceanic and Atmospheric Administration 2018). **Table 6-11** provides the daily average temperature range parameters for the McCall station for the years 1997 to 2008 (WRCC 2018b). The daily average minimum and maximum temperatures for each month recorded in for McCall also are plotted in **Figure 6-6.**

Table 6-11 Average Temperature Data from McCall National Weather Service Site

Data	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Avg.

°F = degrees Fahrenheit; Avg. = average

The Big Creek Summit Site is operated by the National Water and Climate Center's Snow Telemetry (SNOTEL) network. The site is located 28 miles southwest of the SGP at approximately the same elevation and latitude. The site provides data for surface temperature, precipitation, snow water equivalent, and snow depth. The monthly average precipitation and snowfall information for the Big Creek Summit Site can be considered representative of the SGP and is shown in **Table 6-12** (National Resources Conservation Service [NRCS] 2018). Although the climatological data is quoted for different spans of years, this available data provides covers sufficiently long periods to provide representative average values for historical climate description.

Table 6-12 Average Precipitation Data from Big Creek Summit SNOTEL Site

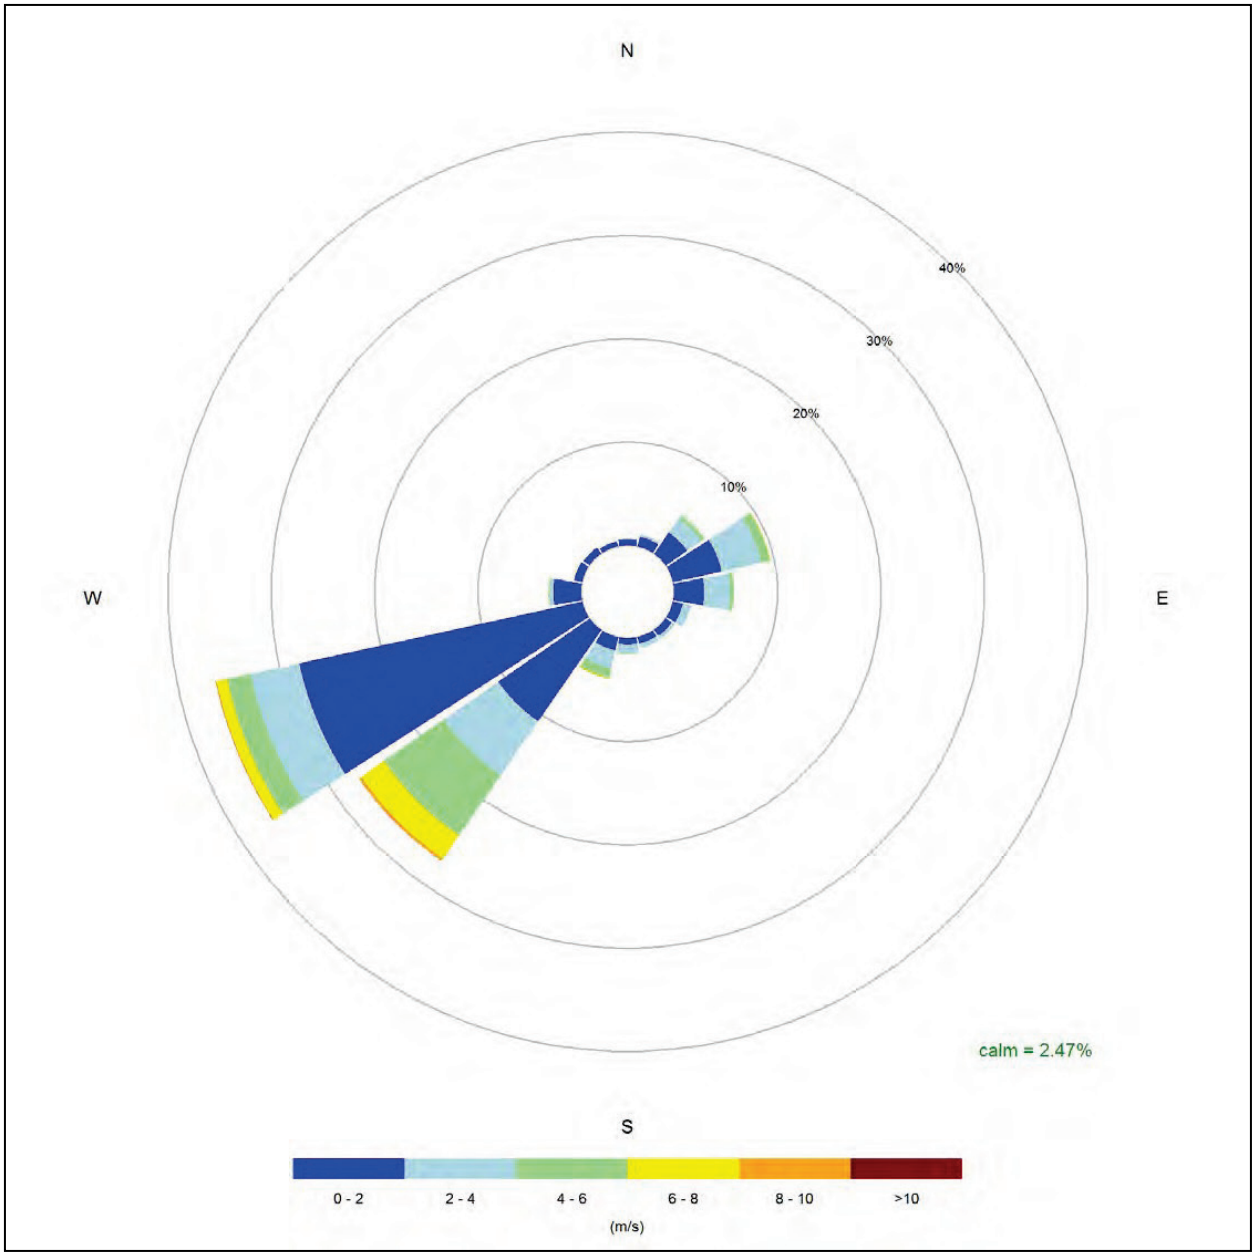
Figure 6-6 Temperature Range Data for McCall, Idaho, and Monthly Precipitation for Big Creek Summit SNOTEL Site

6.1.5.1 Temperature

Between 2010 and 2014, the maximum hourly temperature recorded at the McCall site was 95°F during 2013. Typically, the maximum hourly temperature occurred during July or August. The minimum hourly temperature recorded at the McCall site was -18°F during 2010. In winter, the minimum hourly temperature occurred on numerous days between December and February. Diurnal temperature ranges were the largest in the warmer months (April to September) and decreased during the cooler months (WRCC 2018b). The maximum and minimum daily average temperatures between 1997 and 2008 are shown on **Figure 6-6**.



The hourly temperatures recorded at the Big Creek Summit site would be comparable to the SGP, as this station is at the same elevation. Between 2010 and 2014 highest hourly temperature was 90°F, recorded during 2013. Typically, the maximum hourly temperature occurred during July or August. The minimum hourly temperature recorded at the Big Creek Summit site was -13°F during 2010. Typically, the minimum hourly temperature occurred on numerous days between December and February. Diurnal temperature ranges were the largest in the warmer months (April to September) and decreased during the cooler months (National Oceanic and Atmospheric Administration 2018).

6.1.5.2 Precipitation

Precipitation data for the Big Creek Summit SNOTEL site over the period 1991 to 2020 show that monthly average totals range from 5 to 8 inches per month during the cool months (November - March) primarily in the form of snow. The summer is dry, with monthly average precipitation typically less than 2 inches per month from June through September. Annual precipitation accumulation recorded at the Big Creek Summit site was approximately 51.4 inches in 2010, 47.1 inches in 2011, 54.9 inches in 2012, 35.6 inches in 2013, and 52.8 inches in 2014.

6.1.5.3 Wind

Baseline wind speed and direction data at the Stibnite monitoring station were collected from November 2013 to June 2015. During this period, the strongest winds were from the southwest and from the west-southwest. The mean wind speed was 2.3 meters per second (5.2 miles per hour). Wind directions had a strong tendency from the southwest. Speeds varied widely but tended to be strongest from the southwest. The Stibnite wind distribution data collected at the on-site meteorological station from January 2014 to December 2014 are shown in **Figure 6-7** (Air Sciences 2018a).

Source: Air Sciences 2018a

7.0 Environmental Consequences

7.1 Impact Definitions

The impacts definitions for intensity, duration (FSH 1909.15, 152b), and context are provided in **Table 7-1** (Forest Service 2012).

Table 7-1 Impact Definitions

Attribute	Term	Description
Intensity	Negligible	Impacts would result in a change in current conditions that would be too small to be physically measured using normal methods or would not be perceptible. There is no noticeable effect on the natural or baseline setting. There are no required changes in management or utilization of the resource.
Intensity	Minor	Impacts would result in a change in current conditions that would be just measurable with normal methods or barely perceptible. The change may affect individuals of a population or a small portion of a resource, but it would not result in a modification in the overall population, or the value or productivity of the resource. There are no required changes in management or utilization of the resource.
Intensity	Moderate	Impacts would result in an easily measurable change in current conditions that is readily noticeable. The change affects a large percentage of a population, or portion of a resource which may lead to modification or loss in viability, value, or productivity in the overall population or resource. There are some required changes in management or utilization of the resource.
Intensity	Major	Impacts are considered significant. Impacts would result in a large, measurable change in current conditions that is easily recognized. The change affects a majority of a resource or individuals of a population, which leads to significant modification in the overall population, or the value or productivity of the resource. This impact may not be in compliance with applicable regulatory standards or impact thresholds, requiring large changes in management or utilization of the resource.
Duration	Temporary	Impacts that are anticipated to last no longer than 1 year.
Duration	Short-Term	Impacts that are anticipated to begin and end within the first 3 years during the construction phase.
Duration	Long-Term	Impacts lasting beyond 3 years to the end of mine operations and through reclamation, approximately 20 years.
Duration	Permanent	Impacts that would remain after reclamation is completed.
Context	Localized	Impacts would occur within the analysis area or the general vicinity of the Operations Area Boundary.
Context	Regional	Impacts would extend beyond the Operations Area Boundary and local area boundaries.

Intensity is the severity or levels of magnitude of an impact.
Duration is the length of time an effect would occur.
Context is the effect(s) of an action that must be analyzed within a framework, or within physical or conceptual limits).

7.2 Direct and Indirect Effects

7.2.1 No Action Alternative

In the No Action Alternative, there would be no surface (open-pit) mining or ore processing to extract gold, silver, and antimony, as described for the action alternatives. Therefore, the air emissions described in **Section 7.2.2** for the 2021 MMP or similar emissions for other action alternatives, would not occur. Perpetua may continue to implement surface exploration and associated activities that have been previously approved on NFS lands as stated in the Golden Meadows Environmental Assessment (Forest Service 2015b). Air emissions and related minor impacts for these activities, which are much lower than emissions under the action alternatives, would continue. These approved activities include construction of several temporary roads (approximately 0.32 mile of temporary roads) to access drill sites (total of 28 drill sites), drill pad construction (total of 182 drill pads) and drilling on both NFS and private lands at and in the vicinity of the SGP. Construction of these facilities in the future would result in temporary air quality effects due to earthmoving and equipment tailpipe emissions, which are described in the Golden Meadows Exploration Project Environmental Assessment (Golden Meadows EA) (Forest Service 2015b).

Perpetua would be required to continue to comply with reclamation and monitoring commitments included in the Golden Meadows EA, which include reclamation of the drill pads and temporary roads by backfilling, re-contouring, and seeding using standard reclamation practices, and monitoring to ensure that sediment and stormwater best management practices are in place. These construction and reclamation activities would result in temporary and intermittent air quality effects due to earthmoving and equipment tailpipe emissions.

In January 2021 Midas Gold (now Perpetua) entered into an ASAOC with the Forest Service and USEPA for removal actions at the Stibnite legacy mining site. Phase 1 of this agreement includes removal of tailings and other mining wastes from the stream channels of lower Meadow Creek and East Fork SFSR and placing the excavated wastes in selected, on-site locations where they would no longer impact water quality in these streams. It also includes construction of three stream diversions to avoid contact of runoff with legacy mining wastes. There would be temporary air quality effects related to the earthmoving and tailpipe emissions from the construction equipment and vehicles used to access the site. This work is planned to occur between 2022 and 2024.

If none of the action alternatives proceed, the current uses by Perpetua and other users on patented mine/mill site claims and on the Payette National Forest and Boise National Forest would continue to follow all existing applicable air quality regulations. Uses of NFS lands that may result in air pollutant emissions include mineral exploration, dispersed off-highway-vehicle use, snowmobiling, and other forms of recreation.

7.2.2 2021 MMP

7.2.2.1 Construction and Operations Description

The construction of the 2021 MMP includes building power transmission, access roads, and mining/processing facilities. These operations are to be performed during LOM 1 through LOM 3. Mine operations would begin in LOM 4 through LOM 18. Access road construction would consist of development of the Burntlog Route for mine access and minor improvements for the Johnson Creek route. Also, while the Burntlog Route is being developed, a temporary groomed OSV trail would be constructed on the west side of Johnson Creek from Trout Creek to Landmark for public access. Other public access

construction would be a Cabin Creek Road groomed OSV trail. Eight borrow sources along the Burntlog Route would also be constructed.

During operations, public access through the site would be provided by constructing a new road around the Yellow Pine pit and below the mine haul road to link Stibnite Road to Thunder Mountain Road. Public access would also be allowed on the Burntlog Route.

Lastly, operations would include communication towers and an offsite logistics and road maintenance facility. A cell tower would be located north of the Hangar Flats pit with very high frequency repeater sites. There would also be a communication site at the SGLF with upgrades to the existing site. The Burntlog maintenance facility would be located approximately 4.4 miles east of the junction of Johnson Creek Road and Warm Lake Road along the proposed Burntlog Route.

7.2.2.2 Construction and Operations Air Emissions Inventory

Air pollutant emissions were initially estimated for activities and process sources included in the 2021 MMP for each LOM year. The LOM years presented in this discussion are based on years starting with LOM 1 as the first year of construction. As discussed in **Section 5.3.3**, LOM 6 is expected to produce the highest overall annual total of criteria pollutant emissions.

Air pollutant emission point sources for the construction phase would include engine-driven generators, portable conical crusher and screens, diesel-fired heaters, and engine-driven air compressors. The fugitive sources related to mine construction and operations would be haul, access, and construction road dust from vehicle travel during the pre-production years, as well as earth-moving equipment, material transfers, storage in several construction stockpiles and waste rock piles, tailpipe emissions and exploratory activities. The use of ammonium nitrate/fuel oil explosives also would be considered a mine construction phase source, as well as an ongoing operations phase source.

In the air emissions inventory, mining and ore processing operations are assumed to be capable of continually operating 365 days per year, so annual emissions, and ambient air and visibility impacts, were derived for that schedule. Most of the construction activities also are assumed to occur at a consistent rate for 355 days per year. Consideration of these schedules allowed emissions to be estimated on a daily-average and hourly bases for modeling purposes. This assumed schedule may produce an overprediction as weather conditions would affect the construction schedule and would suggest higher daily activity during the months of May through November, and higher short-term emission rates at these times. Details regarding the emission source roster, operating assumptions, and resulting emissions estimates are provided in **Appendix A**.

Starting in LOM 4 (after up to 3 years of construction and pre-production activities), construction and mining activity emission sources would consist of conventional open-pit methods to extract ore and waste rock, including drilling, blasting, excavating, limestone production and hauling. The point sources for the operations phase, generally beginning in LOM 4, include many of the same sources that would be used during mine construction. Added emission sources beyond the construction phase would consist of portable and stationary engine-driven generators, two propane-fired heaters for intake vent air, the primary jaw crusher system, and the mill building sources (Midas Gold 2016).

Control measures for air pollutant emissions are incorporated at each step of the mining and processing operations. Air pollution control measures that were proposed by Perpetua are common to both action alternatives. For the 2021 MMP, emission control devices and designs would be put in place to abate emissions of particulate matter, Hg, and criteria pollutant emissions from internal combustion engines.

Assessments of near-field and far-field impacts take these measures into consideration by applying emission factors based on data that include emission controls in compiling the SGP inventory. For off-highway truck travel, the efficiency of dust suppressants was based on vendor information (Air Sciences 2018c).

Tailpipe emissions for off-highway diesel engines included in the SGP are controlled by use of engines that meet Tier IV or better EPA performance standards (e.g., stationary internal combustion new source performance standards, 40 CFR 60, Subparts IIII and JJJJ). Roadway dust and tailpipe emissions from vehicle travel on Burntlog Route from the SGP to Landmark also were calculated for both construction and operation periods. The traffic emissions included projected workforce, supply, and haulage vehicles (buses, light, and heavy trucks) and road maintenance equipment (graders and dozers).

Perpetua would design, construct, and operate SGP facilities with air pollution controls stipulated in applicable regulations and the air quality permit issued by IDEQ. The Idaho PTC issued June 17, 2022, includes stipulations that are based on applicable state and federal regulations, and that are consistent with best available control technology for new surface mining and processing operations. Details on the control measures and estimated control effectiveness for the action alternatives, including additional measures that would be stipulated by the Forest Service, are provided in **Section 2.4**. Specific examples include:

- Adherence to a robust fugitive dust control plan, containing standard operating procedures for dust control, surveillance, record-keeping, and reporting as may be required under best operating practices and/or conditions of air permits under IDEQ.
- The main ore processing facility building, and coarse ore stockpile would be enclosed.
- Water sprays and dust collection systems for ore processing facility material handling activities would be installed.
- Water sprays and/or bag house dust collectors would be installed at the ore-crushing system and at ore reclaim feeders that deliver ore to the grinding circuit.
- Hg emission controls, including particulate filters and carbon adsorption filters, would treat exhaust from the precipitate retort, autoclaves, carbon regeneration kiln, and induction furnaces.
- Internal combustion engines used for the construction and operational phases (diesel- or gasoline-powered) would be maintained in a manner that would promote fuel-efficient operation, and thereby reduce tailpipe emissions.
- Off-highway diesel engines would be rated for EPA Tier IV or better emission performance; operated in compliance with federal air quality applicable to internal combustion engines (e.g.,40 CFR 60, Subparts IIII and JJJJ); and would observe limitations required by IDEQ air quality rules.
- Ultra-low sulfur diesel fuel would be used for mobile sources and stationary diesel engines, to comply with state regulations.

Figure 7-1 presents the annual emissions inventory used in the 2021 MMP air analyses for the criteria pollutants for each LOM construction and operation year as derived from the maximum operating schedule for each type of operation. The construction emissions occur primarily in the pre-production year years (LOM 1 through LOM 3), the mining emissions and ore processing emissions occur from

LOM 4 through LOM18. Emissions from certain mine construction components that continue during the mine operation years are included with the applicable LOM year mining emissions. Note that the maximum potential ore processing emissions would not vary over the life of the mine. This is because ore processing emissions were calculated conservatively based on constant operation at the maximum daily ore production rate of 25,000 tpd, regardless of actual yearly ore production rates each day of the year. The maximum emission rate LOM 6 shown in **Figure 7-1** was selected as the emission inventory basis for detailed 2021 MMP assessment. Note that NAAQS compliance dispersion was conducted for all criteria pollutant for both LOM 6 and LOM10. A separate full regulatory assessment was completed for the IDEQ PTC process and will not be discussed in this report (refer to the State of Idaho SOB on the IDEQ website for details).

The maximum annual pollutant emissions for the 2021 MMP analyses for each LOM year are further detailed in **Table 7-2**. The highest aggregated controlled criteria pollutant annual emissions (including fugitives) would be approximately 1,260 tons per year (tpy) and are predicted to occur in LOM 6, which would be the highest ore production year (289.7 PM_{10}, 65.9 $PM_{2.5}$, 535.4 CO, 335.3 NO_x, 7.3 SO_2 and 26.1 VOC). The corresponding individual source emissions were taken as the basis for the air dispersion modeling analyses described in **Sections 5.4** and **7.2.2.2**. The variation in annual emissions reflects the progression in levels of mining activity in different open pits, and differing levels of haul road transport for the pits during their development (Air Sciences 2018a).

The predicted annual emissions summaries by source category for each criteria pollutant are provided in **Table 7-3**. It should be recognized that the stationary sources represented by the process and auxiliary category are the sources used to determine the applicability of Title V and PSD major source permitting status (mobile sources are excluded from the applicability analysis). As shown in **Table 7-3**, these emissions are less than the annual threshold of 100 tpy that would trigger Title V or 250 tpy for PSD permitting status. Emissions of particulate matter (total suspended particulate [TSP], PM_{10}, and $PM_{2.5}$) from fugitive sources represent the largest contributor to overall emissions. The operation of off-highway trucks and fuel-combusting equipment would constitute the largest sources of CO and NO_x. Due to the low sulfur content of liquid fuels that would be used for the equipment at the SGP, and the more stringent federal emission standards for the recent model-year diesel engines, the emissions of SO_2 and VOC are relatively low.

Dust and tailpipe emissions due to the travel of off-highway trucks and other vehicles were accounted for in the dispersion modeling within the SGP Operations Area Boundary, in the mined pits, and along the Burntlog Route from the SGP. As listed in **Table 7-3**, these emissions were based on the access road and mine road configuration proposed in the 2021 MMP. The estimated operations phase emissions for SGP vehicle travel alongWarm Lake Road (CR 10-579) from Landmark to Cascade also are estimated (**Appendix A**).

The level of traffic and related vehicle emissions impacts beyond the town of Cascade, such as the transportation of supplies and personnel to the SGP or the shipping of antimony concentrate from the SGP, are not sufficiently predictable to be quantified. Nor is that potential unique to the SGP. The vehicles involved in this off-site transportation activity have separate utility only related to the SGP and are operating in relatively large areas where any potential emissions are relatively small compared to the baseline conditions. Based on current estimates, transport of concentrate would require two truck trips per day, so the contribution to SGP emissions would be minimal (~2.9 percent or 2 of 68 AADT during mine operation traffic). However, for informational purposes, emission factors per mile of travel for fully-loaded heavy transport trucks are provided in the Air Quality Analysis report for the 2021 MMP emission inventory (Air Sciences 2021a).

[1] The LOM Years presented on the table represent LOM Years as numbered in this report. Perpetua Resource's Refined Proposed Action ModPro2 (Perpetua 2021) portrays the pre-operation years as negative numbers, so LOM years are numbered as -3, -2, -1, 1 through 15.

[2] LOM 1 through LOM3 represent construction and pre-production period. Mining and processing operations are fully active in LOM 4.

[3] Total 2021 MMP emissions are the sum of PM_{10}, CO, NO_X, SO_2, and VOC emission rates. $PM_{2.5}$ is a portion or subset of PM_{10}. TSP is not a criteria pollutant per the EPA and is more of a nuisance pollutant.

[4] The highest overall annual emissions would occur in LOM 6, which corresponds to the year of highest predicted annual mine output.

Table 7-3 Maximum Annual Criteria Pollutant Emissions Summary – LOM 6

Source Category	CO (tpy)	NO_X (tpy)	TSP (tpy)	PM_{10} (tpy)	$PM_{2.5}$ (tpy)	SO_2 (tpy)	VOC (tpy)
Processing & Refining	30.6	38.0	86.7	55.8	35.9	6.5	5.3
Mining Pit/Tailings Activity[1]	157.0	107.7	51.9	13.0	6.2	0.3	8.8
Blasting[2]	240.1	6.5	20.6	10.7	0.6	0.01	--
Stockpiles[3]	--	--	0.6	0.3	0.04	--	--
Process Area	5.7	4.3	0.3	0.2	0.1	0.01	0.3
Hauling	96.7	173.8	721.9	180.7	20.0	0.5	11.1
Access Roads/Heliport	5.3	4.9	113.2	29.1	3.1	0.02	0.6
Mining Activity Total (does not include Processing/Refining)	504.9	297.2	908.6	233.9	30.0	0.8	20.8
Total (Mining, Processing and Refining)[4]	535.4	335.3	995.3	289.7	65.9	7.3	26.1

Source: Air Sciences 2021a

[1] Mining pits include: the Yellow Pine, Hangar Flats and the West End pits. The Tailings include Bradley Tailings and the tailings storage facility.

[2] Blasting emissions are the aggregate total from the three pits mentioned above.

[3] Emissions are the aggregate total from the Hangar Flats and Limestone stockpiles.

[4] Mobile sources and fugitive sources are included in the total emissions. Mobile sources are not included in the permit applicability and fugitive emissions are not considered unless the project is one of 27 PSD list Source Categories. SGP is not a PSD listed source category.

Most of the HAP emissions from operations come from the combustion of fossil fuels and fugitive dust containing trace metals. Other HAP emissions include:

- Hg from gold ore refining sources (e.g., autoclave, carbon kiln, retort, and induction furnaces);
- Hg from exposed surfaces (stockpiles, development rock, tailings, and pits);
- Fugitive dust containing Hg released from mining and ore processing activities;
- HCN volatilization from the dilute cyanide solution in leach tanks, carbon-in-pulp tanks, and HCN detoxification tanks; and
- TSF impoundment of process tailings that would contain trace amounts of residual HCN.

The annual HAP and toxic pollutant emissions for LOM 6 are listed in **Table 7-4**, with Hg reported in pounds per year, and the other toxics in tpy. Details regarding the HAP and air toxics operating assumptions, and resulting emissions estimates for the 2021 MMP, are provided in **Appendix A**. Additionally, facility-wide dispersion modeling was conducted for all HAPs and compared to the IDEQ acceptable ambient non-carcinogenic and carcinogenic concentrations (AAC/AACC) as defined in IDAPA 58.01.01.585/586. Please refer to **Section 7.2.2.2** for further details.

Regarding HCN emissions from gold mines, the EPA has examined U.S. gold ore processing and production facilities and concluded that measurements of HCN concentrations at these gold facilities "showed ambient concentrations below levels of public health and environmental concerns" (EPA 2010a). The latter determination was based on several fence-line monitoring studies directed by EPA to measure HCN concentrations downwind of the gold facilities, and comparison with the applicable HCN reference

concentration. The estimated SGP HCN emissions (1.9 tpy), which is based the area and type (tailings, tanks), the appropriate mass transfer coefficient, snow cover adjustments and solution characteristics. The appropriate emissions factors were derived from the final report from a 2009 fugitive HCN report from three Nevada gold mines (Cortez, Gold Quarry and Rocky Mountain). For further detail, see **Appendix A** and EPA 2010b. This group of existing facilities reported HCN emission rates ranging from 0.2 to 8.8 tpy, with an average of 3.8 tpy (EPA 2010a). Therefore, the SGP estimates are approximately one half the average rate as determined by the study.

Hg is introduced to the ore processing system through the Hg content of the ore itself. Evaluation of potential Hg emission impacts was conducted, in part, to verify that emissions would comply with the EPA Hg emission standards provided in 40 CFR 63, Subpart EEEEEEE, for gold ore processing and production facilities. The SGP would be subject to these federal standards using a carbon-in-pulp process for capturing gold that has been extracted from the crushed ore using dilute NaCN solutions and use of a retort for purifying the gold-laden precipitate from electrowinning. The projected Hg emissions from the gold ore processing sources would be controlled to 20 percent of the Subpart EEEEEEE federal standards for Carbon Processes with Mercury Retorts and less than 1 percent of the pretreatment standard of 84 lb/MMton (autoclave control). Control of the autoclave and its corresponding emissions are derived from SysCad Mercury modeling performed by M3 Engineering that includes the uses of a venturi scrubber, vent gas cleaning tower, vent gas stream condensing tower and at least one sulfur-impregnated activated carbon filter. These controls are also included in the IDEQ PTC. The retort emissions are based on an average of two Refinery reports in 2015/2016 (NDEP 2015, 2016). The corresponding calculations are 20 percent of the retort standard of 0.8 lb/ton. The emissions released from gold-refining processes are controlled as listed below to mitigate particulate and gaseous Hg emissions. These process exhaust control technologies are accounted for in the maximum emissions estimates in **Table 7-4**:

- Activated carbon regeneration kiln – wet scrubber and activated carbon filter;
- Retort – activated carbon canisters and filter pack; and
- Induction furnaces – baghouse filter and activated carbon filter pack.

Table 7-4 Maximum Annual HAP and Air Toxics Emissions Summary

Source Category	HCN (tpy)	H_2SO_4 (tpy)	As[1] (tpy)	HAP (tpy)	Hg (lbs/yr)
Process and Auxiliary	1.9	8.9	0.02	4.7	5.8
Mining fugitive	0.0	0.0	0.374	4.0	7.8
Total[2]	1.9	8.9	0.394	8.7	13.6

[1] Arsenic is also included in the total HAPs calculation. For more information specific to arsenic emissions and the corresponding modeling conducted, refer to **Section 7.2.2.3**.
[2] All emission calculations are derived from methods provided in **Appendix A**.

7.2.2.3 2021 MMP Near-Field Analysis NAAQS

Assessment of conformance to the NAAQS is based on the highest receptor concentration in the modeling domain for the pollutants and averaging times corresponding to the standards. The modeled maximum concentration at each receptor is added to the selected background concentrations that represent current existing conditions (**Table 5-2**). If the results from this computation are below the NAAQS, then impacts at other locations in the domain would be below the NAAQS as well.

For NAAQS modeling inputs, the highest emissions of each pollutant during any LOM year were determined and provided in **Table 7-5**. For the 2021 MMP, the highest criteria pollutant emissions occur during two different years, LOM Year 6 (CO, NO_X, and SO_2) and LOM Year 10 ($PM_{2.5}$ and PM_{10}). Therefore, to capture the highest modeled concentration for each pollutant, separate modeling was performed for LOM Years 6 and 10 (i.e., two models). Note that VOC emission maximums from LOM 3 were not modeled because there is no specific NAAQS for these emissions, however VOCs are addressed as part of the secondary $PM_{2.5}$ analysis discussed in **Section 5.4.2**.

Table 7-5 LOM Years for Pollutant-Specific Maximum Annual Emissions

Pollutant	LOM Year	SGP Total Annual Emissions (tpy)
CO	6	535.5
NO_2	6	335.2
PM_{10}	10	320.1
$PM_{2.5}$	10	69.2
SO_2	6	7.3
VOC	3	27.4
HAPs	10	8.5
Hg	10	13.3 (lb/yr)

The 2021 MMP would include a 12-foot-wide gravel road to provide public access from Stibnite Road (FR 50412) to Thunder Mountain Road (FR 50375) through the SGP. Perpetua received a final PTC from IDEQ on June 17, 2022. This application proposed to exclude the public road on the basis of restricted access and maintaining full control, and that people traveling on the road would be considered "guests of the mine". IDEQ accepted the private road concept proposed by Perpetua (see PTC Condition 2.7, Response to Comments #16 and Statement of Basis on the IDEQ website) and in response to comments on February 18, 2021, also states that the roadway between Stibnite Road at Sugar Creek and Thunder Mountain Road at Meadow Creek was appropriately excluded from ambient air. Additionally, the EPA Region X has indicated that the access road could possibly be excluded from ambient air if sufficient enforceable measures are taken to comply with the 2019 revised policy (EPA 2019a). To comply with this measure, Perpetua has developed a Transportation Management Plan that is included as **Appendix D**.

A November 18, 2020 response to comments letter authored by the EPA states that Region X acknowledges and is accepting of DEQ's findings. On page 25 of the EPA response letter, it states they are "recognizing that this control access road would not be ambient air" (Stantec 2021). This is also consistent with the December 2, 2019, Revised Policy on Exclusions From "Ambient Air" memorandum (EPA 2019a). The memo states "*the atmosphere over land owned or controlled by the stationary source may be excluded from ambient air where the source employs measures. which may include physical barriers. that are effective in precluding access to the land by the general public."* The measures to be employed by Perpetua, as discussed in the 2021 MMP (Perpetua 2021a) would qualify under the revised broader definition of ambient air. As a result, because of IDEQ's decision and the EPA general acceptance given an acceptable Transportation Management Plan (**Appendix D**), the public access road was excluded for the NAAQS analysis.

The AERMOD dispersion modeling results for the 2021 MMP emissions and comparison with the applicable NAAQS are provided in **Table 7-6**. The geographic location of the maximum impacts amongst the criteria pollutants and averaging periods between LOM 6 and LOM 10 are provided in Figure 4 of the

Air Quality Analysis Addendum ModPro2 (Air Sciences 2021a). The results demonstrate compliance with all NAAQS and would be considered to have a moderate impact locally and minor impact regionally. Additionally, **Table 7-7** provides geographic locations of the NAAQS maximums.

Table 7-6 Near-Field NAAQS Compliance Demonstration

Pollutant	Averaging Time	Maximum Modeled Conc. (µg/m³)	Background Conc.[3] (µg/m³)	Total Impact Conc. (µg/m³)	NAAQS (µg/m³)	NAAQS Compliance
CO	8 hours	404.6	1,110	1,515	10,000	Yes
	1 hour	495.5	1,740	2,236	40,000	Yes
Lead	3-month rolling	Not Required[1]				
NO_2	Annual	19.8	0.9	20.7	100	Yes
	1 hour	129.8	4.3	134.1	188	Yes
O_3	8 hours	3.0	117.7	120.7	137	Yes
PM_{10}	24 hours	15	37.0	51.9	150	Yes
$PM_{2.5}$ [2]	Annual	1.1	3.5	4.6	12	Yes
	24 hours	2.7	15.0	17.7	35	Yes
SO_2	1 hour	3.0	12.3	15.3	196	Yes
	3 hours	1.8	16.8	18.6	1,300	Yes

1 Lead modeling is not required per IDEQ as the facility-wide emissions are less than 10 percent of the lead significant emission rate of 0.6 tpy and considered "Below Regulatory Concern".
2 Includes the secondary impacts.
3 All background concentrations are derived from the NW Airquest data (WSU 2018).

Table 7-7 Near-Field NAAQS Maximum Geographic Locations

Pollutant	Averaging Time	Easting (m)	Northing (m)	Distance to Boundary (mi)	Nearest Boundary Direction
CO	8 hours	634,478.09	4,972,209.38	0	East Boundary
	1 hour	634,493.79	4,972,189.94	0	East Boundary

	3 hours	634,999.52	4,975,933.79	0.56	East

Comparison of Maximum Pollutant Impacts with PSD Class II Increments

Comparison of the maximum modeled impacts to PSD Class II increments and SILs is typically required as part of the PSD evaluation for major source ambient air quality assessments. However, for informational purposes relative to the SGP such comparisons provide an additional indicator of the relative significance of air quality impacts. The results in **Table 7-8** based on the 2021 MMP maximum annual inventory show the near-field maximum modeled ambient concentrations derived from the 2021 MMP, near-field analysis. For all pollutants, the modeled concentrations are less than the Class II increments. For pollutants other than SO_2, the maximum modeled concentrations are above the SILs. In the case of a major source, this outcome would indicate that more detailed analysis is warranted to confirm compliance with the NAAQS, and other criteria. For any new source, a project impact shown to be below a SIL is recognized as not causing or contributing to the violation of a NAAQS or PSD increment. The geographic location of the maximum impacts amongst the criteria pollutants and averaging periods between LOM 6 and LOM 10 are provided in Figure 3 of the Air Quality Analysis Addendum ModPro2 (Air Sciences 2021a).

In general, instances of modeled project impacts that exceed a SIL may warrant a refined analysis to investigate whether a project will cause or contribute to a PSD increment violation. Given there are no substantial existing minor or major sources in the immediate vicinity of the SGP, it is viewed as unlikely that significant consumption of the PSD increment occurs in this area. Due to the relatively low maximum concentrations from near-field modeling for SGP, which are well below the PSD increment for all pollutants, it also is unlikely the SGP would cause or contribute to a violation of a PSD increment. If the IDEQ were to have sufficient concern that a PSD increment violation could occur, a full regulatory PSD increment compliance demonstration could be warranted even for a minor source under the state's NSR air permitting process. The impact would be considered minor to Class II PSD areas as the SGP is well below the significance levels for all pollutants and averaging periods.

Table 7-8 Near-Field Class II PSD Increment Comparison

Pollutant	Averaging Time[1]	Maximum Conc. (µg/m^3)	Class II Significant Impact Level[3] (µg/m^3)	Maximum Allowable Increase (µg/m^3)	PSD Increment Compliance
NO_2	Annual	19.8	1.0	25	Yes
PM10	Annual	6.5	0.2	17	Yes
	24 hours	14.9	1.0	30	Yes
PM2.5[2]	Annual	1.1	0.2	4	Yes
	24 hours	3.3	1.0	9	Yes
SO_2	Annual	0.2	1.0	20	Yes
	3 hours	1.8	25	512	Yes
	24 hours	0.7	5.0	91	Yes

Source: Air Sciences 2021a; EPA 2018

[1] Design Value Rank For any period other than an annual period, the applicable maximum allowable increase may be exceeded during one such period per year at any one location.

[2] Includes secondary, condensable $PM_{2.5}$ impacts. The annual SIL was revised as described in EPA Guidance issued in April 2018 (EPA 2018).

[3] These results show that, except for SO_2, the near-field modeled maximum concentrations are above the Significant Impact Levels, which would be relevant if SGP were a major source.

REC 2686

Hazardous Air Pollutant Modeling

A supplemental air quality dispersion modeling analysis was conducted based on federally regulated HAP emissions associated with the 2021 MMP. The analysis consisted of several metal HAPs which were: antimony, arsenic, beryllium, cadmium, chromium, cobalt, manganese, nickel, and selenium from all potential emitting sources at SGP. The main source of metals emissions was from dust produced in mining and hauling/handling ore and development rock. The metals were present in this dust in natural mineral forms. Note that lead and mercury were not assessed in this modeling exercise because lead emissions are considered less than significant (see **Table 7-6**). Mercury is discussed in the Deposition Screening section below and other resource reports (Air Sciences 2018a and 2021a).

The highest LOM emissions in terms of tons/yr were evaluated to establish the status of SGP from a HAP perspective, which was determined to be LOM Year 10. **Table 7-9** illustrates all HAP emissions from LOM Year 10. The only federal requirement pertaining to HAPs is to determine whether the facility would be categorized as a Major or Area source facility for HAPs. If a source is less than 10 tpy of any single HAP and less than 25 tpy of all HAPs in aggregate, the facility is considered to be an Area Source. Based on the information provided in **Table 7-9**, SGP is an Area Source or a minor source for HAPs. For further details regarding the methodology for determining the emissions associated with each applicable emission source, please refer to the Supplemental HAP Air Quality Analysis Addendum – ModPro2 (Air Sciences 2021a).

IDEQ developed a toxics air pollutant program in the early 1990's. The program is based upon health and risk standards that would apply to potential new sources and implemented with appropriate ambient levels. In addition to ambient levels, it was decided to incorporate a stack-based emission levels at or below which it could be reasonably expected that the ambient standard would not be exceeded. The reason the stack-based levels were incorporated was that often stack emissions are easier to calculate than it is to model for ambient concentrations (IDEQ 2001).

The AAC values were based on the American Conference of Government Industrial Hygienists (ACGIH) threshold limit values (TLV). IDEQ equates the ACC to the Occupational Exposure Limit (OEL) divided by 20. For carcinogens (AACC) the unit Risk Factors (URF) from EPA (IRIS) was used and set them equal to a risk level of a one in a million (IDEQ 2001).

Note that only those pollutants mentioned above were modeled because they were the only pollutants that exceeded the State of Idaho screening Emissions Levels as defined by IDAPA 58.01.01.585/586. All other HAPs did not exceed the screening level and were therefore deemed to meet state permitting requirements without further evaluation. It should be noted that the state regulations were applied as a surrogate for the analysis because no federal standards applied. **Table 7-10** identifies the State of Idaho AAC/AACC as defined by the IDAPA rules referenced above. All mining years from LOM Year 3 through LOM Year 18 were modeled as discussed below.

7782-49-2	Selenium	No	24 hours	10

Source: Air Sciences 2021b
Carcinogenic pollutants are averaged annually; non-carcinogenic pollutants are averaged daily (24-hrs). Both emissions rates applied to the model are lb/hr or g/s averages based on the applicable timeframe 24-hr or annually.

AERMOD Modeling was conducted for the HAPs in identical fashion to the 2021 MMP NAAQS modeling (Air Sciences 2021a and 2021b). A unit g/s emission rate approach was applied for each modeled source group. All the haul road segments were modeled as a single source group — with unit emission rate proportioned among the individual haul road segments relative to associated particulate emissions within the source group. The access road segments were also modeled as a single source group, like the haul road segments. AERMOD generated modeled concentration tables (plot file) for each source group and all source groups combined. The other input parameters for AERMOD, including source characterization, building downwash, receptor locations, and meteorological data, were consistent with the July 2021 NAAQS analysis (Air Sciences 2021b). A HAP-specific modeled concentration at each receptor was estimated by adding the products (sum-product) of a source group-specific unit concentration and a potential emission rate in g/s for each HAP. Lastly, default particulate deposition method was applied based on the mass fraction, mass mean diameter and density by various source category. For further detail refer to the Supplemental HAP Air Quality Analysis Addendum – ModPro2 (Air Sciences 2021b).

The potential ambient concentration was calculated at each receptor for LOM 3–18. The estimated total concentrations were then compared with the Idaho AACs. For each acute HAP with a 24-hour averaging time AAC, the highest estimated ambient concentration across all modeled receptors and modeling scenarios was compared with the applicable AAC, provided in **Table 7-11**.

PET-0969

REC 2689

Table 7-11 Acute AAC Comparison

CAS #	Pollutant	Averaging Time	AAC (µg/m³)	HMC[1] (µg/m³)	HMC < AAC
7440-36-0	Antimony	24 hours	25	0.0002	Yes
7440-47-3	Chromium	24 hours	25	0.0004	Yes
7440-48-4	Cobalt	24 hours	2.5	0.0001	Yes
7439-96-5	Manganese	24 hours	250	0.0103	Yes
7782-49-2	Selenium	24 hours	10	0.00004	Yes

Source: Air Sciences 2021b
[1] HMC = highest modeled concentration amongst all mining years

Table 7-11 shows that the highest modeled 24-hour concentrations are less than the applicable acute AACs. The location of the maximum 24-hour modeled concentration for each acute HAP is shown in Figure 2 of the Supplemental HAP Air Quality Analysis Addendum – ModPro2 (Air Sciences 2021b).

The annual AACC values are based on IDAPA 58.01.01.586 and were developed "*based on the probability of developing excess cancers over a seventy (70) year lifetime exposure to one (1) microgram per cubic meter (1 µg/m³) of a given carcinogen and expressed in terms of a screening level or an acceptable ambient concentration for a carcinogenic toxic air pollutant.*"

Each HAP with an annual averaging period AACC was evaluated for a 70-yr lifetime exposure, calculated as follows, on a receptor-by-receptor basis:

$$70\ yr\ exposure\ \frac{\mu g}{m^3} = \frac{\sum LOM\ Yrs\ 3\ to\ 16\ annual\ conc\ \frac{\mu g}{m^3}}{70(yrs, exposure)}$$

The highest estimated 70-year lifetime exposure across all receptors was compared with the chronic AAC for each HAP modeled for the annual averaging time, as shown in **Table 7-12**.

Table 7-12 Chronic AACC Comparison

CAS #	Pollutant	Averaging Time	AACC (µg/m³)	HMC[1] (µg/m³)	HMC < AACC
7440-38-2	Arsenic	Annual	0.00023	0.00015	Yes
7440-41-7	Beryllium	Annual	0.0042	0.00001	Yes
7440-43-9	Cadmium	Annual	0.00056	0.000003	Yes
7440-02-0	Nickel	Annual	0.042	0.00001	Yes

Source: Air Sciences 2021b
[1] HMC = highest 70-yr exposure concentration amongst all mining years

Table 7-12 shows that the estimated highest 70-year lifetime exposure concentrations are less than chronic AACCs. The location of the 70-year lifetime exposure concentration for each chronic HAP is shown in Figure 3 of the Supplemental HAP Air Quality Analysis Addendum – ModPro2 (Air Sciences 2021b). The results illustrate that the overall impact from the associated HAPs would be moderate, but well below the IDEQ permitting thresholds.

Ozone and Secondary $PM_{2.5}$ Impact Assessment

To evaluate ozone impacts from VOC and NO_X precursor emissions, a Tier 1 assessment as described in **Section 5.4.2** was performed based on the SGP emissions inventory for LOM year 6, the year of highest projected mine production. For that inventory, the facility-wide potential ozone precursor emissions were estimated in that inventory to be 335 tpy of NO_X and 26.1 tpy of VOCs. This assessment used the 2021 MMP emissions inventory, therefore, SGP mobile source tailpipe emissions were included. Additional discussion regarding the ozone and secondary $PM_{2.5}$ analysis is provided in the Air Quality Analysis report (Air Sciences 2021a).

Following Tier 1 procedures, a representative industrial source as modeled by EPA was selected from the PGM roster to assess ozone impacts. This modeled source (number 18 in the PGM source roster) is geographically the closest to the SGP; 210 miles (336 km) west-northwest of the SGP, in northeastern Oregon. Given the location of number 18 downwind from the coal-fired (550 megawatts) Boardman Power Plant (17 miles (27 km) to the west-southwest), it can be expected that this PGM source would experience higher ozone concentrations than would be expected at the undeveloped SGP area. For hypothetical source 18, ozone contributions from precursor pollutant emissions of NO_X and VOCs (500 tpy each) were predicted to be 1.94 ppb and 0.46 ppb for NO_X and VOCs, respectively (Air Sciences 2018a; EPA 2019b).

On this basis, the corresponding ozone impact due to the 2021 MMP sources was estimated by linearly scaling the source number 18 ozone impact by the relative precursor emission rates of the PGM source and the 2021 MMP. The result is provided in **Table 7-13**. This table also shows the baseline ozone concentration and the estimated total concentration for the highest modeled receptor. This analysis shows that the maximum modeled contribution to ozone levels is a small fraction of the existing baseline conditions. The overall project ozone impact is considered negligible relative to the baseline.

Table 7-13 Maximum 8-hour Ozone Impact

Pollutant	Averaging Time	Maximum Concentration	Baseline Concentration	Total Concentration
Ozone	8 hours	1.4 ppb	60.0 ppb	61.4 ppb
Ozone	8 hours	0.003 µg/m³	0.129 µg/m³	0.131 µg/m³

Source: Air Sciences 2021a
µg/m³ = micrograms per cubic meter
ppb = parts per billion air concentration

To evaluate secondary $PM_{2.5}$ impacts resulting from emissions of secondary $PM_{2.5}$ precursor emissions, a Tier 1 assessment was performed based on the 2021 MMP emissions inventory. For this inventory, the maximum facility-wide potential emissions of secondary $PM_{2.5}$ precursor emissions would be 335 tpy of NO_X and 7.3 tpy of SO_2. This assessment used the same EPA- modeled hypothetical industrial source (number 18 in northern Oregon) for $PM_{2.5}$ precursor emissions and corresponding $PM_{2.5}$ maximum impacts.

Results of the analysis of primary and secondary $PM_{2.5}$ impacts are shown in **Table 7-14**. The PGM industrial source results provided both the primary (as emitted) $PM_{2.5}$ impacts and secondary $PM_{2.5}$ impacts that were scaled to represent the 2021 MMP sources. For this analysis, the concentrations of both forms of $PM_{2.5}$ were added together and combined with the baseline $PM_{2.5}$ concentration. This comparison indicates that predicted primary and secondary $PM_{2.5}$ impacts from the 2021 MMP would be about one-third or less of existing background conditions. The overall secondary $PM_{2.5}$ project impact is considered negligible relative to the baseline.

Table 7-14 Primary and Secondary $PM_{2.5}$ Impact

Pollutant	Averaging Time	Max. Primary $PM_{2.5}$ Concentration ($\mu g/m^3$)	Max. Secondarily- Formed $PM_{2.5}$ Concentration ($\mu g/m^3$)	Baseline Concentration ($\mu g/m^3$)	Total $PM_{2.5}$ Impact ($\mu g/m^3$)
Total $PM_{2.5}$	Annual	1.1	0.01	3.5	4.7
Total $PM_{2.5}$	24 hours	2.6	0.15	15.0	17.7

Source: Air Sciences 2021a
$\mu g/m^3$ = micrograms per cubic meter
$PM_{2.5}$ = Particulate matter less than 2.5-micron diameter

Class II Wilderness Area Plume Visibility Screening Results

Plume visibility modeling is a means of quantifying the ability of a viewer to discern a visible plume from a source and is usually evaluated for an observer at the closest point on the boundary of an area of concern. The model used in this case, VISCREEN, outputs a comparison of two calculated plume parameters to determine the possibility of plume perceptibility by an observer using thresholds based on human visual perception (EPA 1992). The two parameters are C and ΔE. Contrast is a measure of the difference in the light intensity without regard for color. Color contrast measures the difference in wavelength of light rather than intensity.

Applying the Level 2 screening approach as described in **Section 5.4.3**, VISCREEN results for both C and ΔE wereevaluated for a modeled plume against a backdrop of sky or terrain, and at two solar angles (θ) of 10 degrees and 140 degrees. These solar angles generally correspond to a low angle at dawn and dusk, and a high angle that represents mid-day. A result that exceeds the threshold for either C or ΔE indicates that a plume would be visible.

EPA's guidance for using the VISCREEN model for PSD Class I analyses is intended to provide a conservative, worst-case screening model for plume visibility impacts (EPA 1992). Following EPA's VISCREEN guidance, both daytime (6 a.m. to 6 p.m.) and nighttime (6 p.m. to 6 a.m.) are included in this analysis. Therefore, during the summer, the nighttime hours would include some hours when sunlight illuminates any plume and, conversely, during the shorter wintertime daylight hours, some hours analyzed as daytime would occur after the sun has set.

Perpetua performed a revised VISCREEN analysis in October 2020 which is based on combined NOx, PM, and soot emissions of 8,953 lbs/day. Updates included the addition of non-point and mobile equipment emissions; the background visual range was increased to 270 km and large-diameter particle matter emissions were incorporated. However, there was a slight variation in total emissions from the analysis and those emissions produced by the 2021 MMP. The 2021 MMP is expected to produce a combined emissions of 8,204 lbs/day, approximately an 8 percent reduction. The October 2020 analysis was not redone and is considered conservative.

A summary of the VISCREEN results is provided in **Table 7-15** for daytime and nighttime hours, and for combinations of terrain or sky background and two solar angles (Forest Service 2019). These results show the frequency of visible plumes expressed as the highest percentage of time a plume could be visible for a given combination of viewing background and solar angle. The potential for a plume being visible to an observer at the FCRNRW is determined by comparing the modeled result for either C or ΔE to the appropriate perception screening threshold calculated by VISCREEN for each modeled hour during a year. A plume is deemed to be visible during each hour when modeled values of either C or ΔE would exceed the perception thresholds. **Table 7-16** provides the magnitude of the visible plumes.

Table 7-15 Frequency of Modeled Visible Plumes – Screening Results for FCRNRW: Percent of Time when Perceptibility Threshold is Exceeded

Plume Parameter	Background	% Day Hours: 10 Degrees[1]	% Night Hours: 10 Degrees	% Day Hours: 140 Degrees[2]	% Night Hours: 140 Degrees
Plume Contrast (C)	Terrain	0	0	0	0
Color Contrast (ΔE)	Terrain	0.02	2.9	0	0
Plume Contrast (C)	Sky	0	0	0	0.38
Color Contrast (ΔE)	Sky	0	2.3	0	0

Source: (Forest Service 2019) based on Level 2 VISCREEN modeling (Appendix C of Air Sciences 2021a)
[1] The 10-degree solar angle reflects conditions after sunrise (day), and before sunset (night).
[2] The 140-degree solar angle reflects mid-day conditions.
C = modeled plume parameter that quantifies overall contrast or light impeded by a plume.
ΔE = modeled plume parameter that reflects the color difference or contrast with viewing background.
Results tabulated combine the stability classes and wind speed conditions that exhibit plume parameters above perception thresholds. Stability classes are not adjusted for elevation difference.

Table 7-16 Magnitude of Modeled Visible Plumes – Screening Results for FCRNRW: Ratio of Maximum Impact when Perceptibility Threshold is Exceeded

Plume Parameter	Background	Day: 10 Degrees[1]	Night: 10 Degrees	Day: 140 Degrees [2]	Night: 140 Degrees
Plume Contrast (C)	Terrain	--	--	--	--

Results tabulated combine the stability classes and wind speed conditions that exhibit plume parameters above perception thresholds. Stability classes are not adjusted for elevation difference.

Mercury Deposition Screening Results

Hg emissions can occur from both mine operations and ore processing, as a consequence of the processing methods used, and the naturally occurring Hg content of the ore and overburden material. This section describes the predicted Hg deposition flux rates in the near-field modeled area surrounding the SGP. The analysis combines the impacts of both existing background sources and the SGP sources.

As described in **Section 5.4.4**, one tool that describes the background effects for Hg deposition is the REMSAD. This model has been implemented by the EPA across the continental 48 states to quantify Hg deposition on a regional basis. The inventory information for this model was gathered between the years 2000 and 2006; therefore, it is likely higher than current emissions levels due to regulatory controls on Hg emissions (e.g., on coal-fired power plants) implemented since 2006, and the trend to replace coal-fired

generation with gas-fired units. The sources of Hg deposition used in the EPA REMSAD modeling analysis included sources in the U.S., Mexico, and Canada; and contributions from global background deposition from Chemical Transport Model, the Global/Regional Atmospheric Heavy Metals model, and the GEOS-Chem model (EPA 2008).

The EPA REMSAD model was used to estimate the background Hg deposition in the SGP area, and three immediately surrounding hydrographic "sub-basins" that extend approximately 20 to 50 miles (32 to 80 km) from the SGP. Results of the REMSAD include both wet and dry deposition mechanisms. As listed in **Table 7-17**, total annual Hg deposition flux rate in the three hydrographic sub-basins ranges from 12.7 to 13.9 grams per square km per year (g/km^2-yr).

An AERMOD screening assessment included the point and fugitive Hg emissions from the SGP that are in the form of elemental, Hg^{2+}, and HgP. Gaseous elemental Hg0 emission sources are controlled by activated carbon absorbers. A source of bias in the analysis is the use of this screening level modeling approach that does not account for recent findings showing the importance of Hg0 deposition to plants, and this flux being the largest point of entry for atmospheric Hg into terrestrial environments. Taking these factors into account suggests that total Hg deposition predicted by the model is likely biased low.

The results of the AERMOD screen modeling of Hg deposition based on the 2021 MMP inventory are listed in **Table 7-17**. This analysis indicates a maximum estimated increase in Hg deposition rate of 0.4 percent or less of the existing background rate. However, it should be recognized that this rate underestimates the total Hg deposition, as the mechanism of Hg0 flux is not included in the screening model.

The range of increased deposition is less than 5 miles (8 km) from the SGP, covering the area generally east of the SGP Operations Area Boundary. Outside of this area, Hg deposition contribution due to 2021 MMP sources is estimated to be less than the minimum value that can be quantified by AERMOD. Additional details and mapping of the Hg deposition rates from REMSAD and the AERMOD analysis are provided in the Air Quality Analysis report (Air Sciences 2021a). The mercury impact associated with the project is negligible compared to the RESMAD past modeling.

Table 7-17 SGP Contribution Above Estimated Hg Background

Hydrographic Sub-basin	REMSAD Background (g/km^2-yr)	AERMOD Screen Results[1] (g/km^2-yr)	2021 MMP Contribution to Existing Background
Within SGP area and the sub-basin east of the SGP	13.9	0.056	0.40%
Sub-basin northeast of the SGP	13.6	0	0.00%
Sub-basin southeast of the SGP	12.7	0	0.00%

Source: Air Sciences 2021a; EPA 2008

[1] Modeled maximum result is at the SGP Operations Area Boundary; screening results show close to zero deposition at any location beyond 5 miles from the SGP.

g/km^2-yr = grams per square kilometer per year

Nitrogen/Sulfur Screening Acid Deposition Analysis

A screening analysis using the AERMOD dispersion model was performed following the approach described in **Section 5.4.5** to predict the near-field deposition of nitrogen and sulfur species from NOX and SO_2 precursor emissions as estimated in the 2021 MMP inventory. Although AERMOD is not designed to simulate several natural processes that affect chemical deposition (e.g., atmospheric chemical

transformations to acid compounds), it was used in this case as a conservative screening tool. As described in **Section 5.4.5**, this screening analysis was conducted using the Level 2 procedures prescribed in the draft interagency near-field deposition modeling guidance (NPS 2011). The Level 2 analysis assumes that 100 percent of the NO_X emissions would be completely transformed into NO_2, and then HNO_3 on release to the atmosphere. This assumed extent of conversion is expected to result in a conservative over-estimation of nitrogen deposition.

The NO_2 dry deposition flux estimated by AERMOD was converted to the potentially absorbed nitrogen at the surface by multiplying the predicted NO_2 flux by the ratio of nitrogen to NO_2 molecular weights (equals 0.304). Similarly, the SO_2 dry deposition flux estimated by AERMOD was converted to sulfur by multiplying with the ratio of sulfur to SO_2 molecular weights (equals 0.5). For purposes of this analysis, deposition of SO_2 was converted to the equivalent amount of SO_4.

The resulting range of predicted screening-level nitrogen and sulfur deposition rates at the SGP Operations Area Boundary and at receptors approximately 10 km beyond that boundary are listed in **Table 7-18** in units of grams per square meter per year.

Table 7-18 Summary of Predicted Near-Field Nitrogen and Sulfur Deposition Rates

Chemical Element	Receptor Locations	Deposition Flux Rate (g/m^2-yr)
Nitrogen (N)	OAB	0.00081 – 0.0039
Nitrogen (N)	10 km from OAB	0.00011 – 0.0098
Sulfur (S)	OAB	0.00001 – 0.0043
Sulfur (S)	10 km from OAB	0 – 0.0002

g/m^2-yr = grams per square meter per year

Stibnite Public Access Route

As discussed in **Section 7.2.2.2**, the SGP public access route (Figure 1 of Air Sciences 2021a) was excluded from the ambient boundary. However, Perpetua did conduct a NAAQS compliance demonstration by applying 25-m spacing receptors along the public access route which was completed as part of a feasibility assessment. The 2021 MMP analysis was completed using the Bulk Richardson Number method (BULKRN) to preprocess the meteorological data (Air Sciences 2018a). This is consistent with the IDEQ recommendations and to ensure maximum conservative. The public access route analysis was evaluated for LOM Year 6 and Year 10. The difference between the NAAQS outlined in **Section 7.2.2.2** and the public access route was that the BULKRN method was not used, but rather the EPA default approach of Qian and Venkatram method (Air Sciences 2018a). **Table 7-19** illustrates the NAAQS impact results at the public access route through the SGP.

Table 7-19 SGP Public Access Route Receptor Results and NAAQS Compliance Demonstration

Pollutant	Averaging Time	Maximum Modeled Conc. ($\mu g/m^3$)	Baseline Conc. ($\mu g/m^3$)	Total Impact Conc. ($\mu g/m^3$)	NAAQS ($\mu g/m^3$)	NAAQS Compliance
CO	8 hours	201.9	1,110	1,312	10,000	Yes
	1 hour	486.8	1,740	2,227	40,000	Yes
NO_2	Annual	39.0	0.9	39.9	100	Yes

PET-0975

REC 2695

Pollutant	Averaging Time	Maximum Modeled Conc. (µg/m³)	Baseline Conc. (µg/m³)	Total Impact Conc. (µg/m³)	NAAQS (µg/m³)	NAAQS Compliance
	1 hour	124.4	4.3	128.7	188	Yes

	3 hours	6.0	16.8	22.8	1,300	Yes

7.2.2.4 Direct and Indirect Effects – Far-Field Analysis

The far-field analysis for regional haze contributions, increment, and chemical deposition was performed for four selected Class I areas: SAWT, SELW, HECA, and CRMO. In addition, four Class II wilderness areas were evaluated in the same manner: FCRNRW (beyond 50 km), GOSPEL, HEMBLD, and the WHTCLD. The nearby Nez Perce Requested Analysis Area also was included in this analysis. The far-field analyses described in this section are based on the 2021 MMP inventory for criteria pollutant emissions.

Additionally, the 2018 modeling report (Air Resources 2018b) conducted far-field NAAQS analysis from 50 km to 300 km. Due to slight differences between the 2018 modeling report and the 2021 MMP a verification analysis was conducted to ensure no significant far-field impact changes.

50-km Ring NAAQS Verification

Additional AERMOD modeling was completed to estimate concentrations at receptors located on a 50-km radius ring around the SGP; the maximum approved range of AERMOD. The 50-km ring modeling was performed for the applicable AQRV pollutant averaging time combinations. The 50-km ring modeling result comparison for 2018 modeling and the 2021 MMP modeling is provided in **Table 7-20**.

Table 7-20 50-km Ring AERMOD Results for 2018 Modeling and 2021 MMP

Pollutant	Averaging Time	2018 Modeling (µg/m³)	2021 MMP (µg/m³)
NO_2	Annual	0.53	0.50
$PM_{2.5}$	Annual	0.09	0.09
	24 hours	0.40	0.38
PM_{10}	Annual	0.14	0.11
	24 hours	0.51	0.57
SO_2	Annual	0.01	0.01
	24 hours	0.07	0.06
	3 hours	0.23	0.20

Source: Air Sciences 2021a

Table 7-20 shows that the 50-km ring results are nearly identical for the 2018 modeling and the 2021 MMP modeling.

The 50-km ring AERMOD analysis demonstrates that the 2021 MMP changes are not expected to affect the far-field analysis results, and therefore, the 2018 far-field analyses are representative of the 2021 MMP. **Table 7-21** illustrates a summary of the far-field impacts.

Table 7-21 Far-Field Impacts Summary

[1] Maximum results are shown, g/ha-yr = grams per hectare-year
[2] See Table 7-22
[3] There are no regulatory standards or thresholds to compare to the results provided in these columns.

SILs are defined concentrations of criteria pollutants in the ambient air that are considered inconsequential in comparison to the NAAQS. A project impact shown to be below a SIL can be presumed to not cause or contribute to the violation of a NAAQS. **Table 7-22** shows the Class I and Class II Area SILs for comparison to the results provided in **Table 7-21**. As shown by these two tables, the far-field impacts of criteria pollutants on Class I and II areas are below the SIL. **Table 7-20** also shows that the Class I visibility and deposition impacts are below the regulatory thresholds (Air Sciences 2021a).

Far-Field Evaluation of Regional Haze Impacts

The methodology for the analysis of the impairment of atmospheric clarity, or regional haze,is described in **Section 5.5.2**. For this analysis, maximum 24-hour the 2021 MMP source emissions of SO_2, NO_X, SO_4, and fine and coarse PM were modeled using CALPUFF for the roster of Class I and Class II wilderness areas of interest. To account for atmospheric chemistry, the MESOPUFF II five-pollutant (SO_2, SO_4, NO_X, HNO_3, nitrate) conversion scheme was used. The POSTUTIL routine in CALPUFF was used to calculate concentrations of these chemical species that can act as haze precursors (Federal Land Managers' Air Quality Related Value Work Group [FLAG] 2010).

As described in **Section 5.5**, the CALPUFF-ready wind field was evaluated against 15 regional station observational data benchmarks for a span of 3 calendar years (2015 to 2017) using the MMIFStat statistics program. MMIFStat compiles statistics for air temperature, relative humidity, wind speed, and direction. Because much of the modeling domain is in mountainous terrain the "complex conditions" benchmarks were applied to evaluate whether the CALPUFF datasets were acceptable. These evaluations demonstrated that the meteorological data sets generally met acceptance benchmarks that have been commonly reported for mesoscale model evaluation for air quality modeling (Air Sciences 2018b).

The Class I and Class II wilderness area visibility analysis results are presented in **Tables 7-23** and **7-24**, respectively. These results show the modeled 98th percentile highest daily change in extinction parameters in each analyzed area. The net predicted reduction in atmospheric visibility is less than the 5 percent change in extinction threshold that is considered the significance criteria for Class I areas (FLAG 2010). Using the same stringent Class I criteria for the Class II wilderness areas included in this analysis demonstrates that the level of regional haze impact in these areas is predicted to be minor.

Table 7-23 Predicted Regional Haze Contributions in Class I Areas Due to SGP Sources

Class I Areas	98th Percentile 2015	98th Percentile 2016	98th Percentile 2017	Maximum 98th Percentile	Class I Extinction Threshold	Below Threshold (Yes/No)

Far-Field Nitrogen and Sulfur Deposition

Total potential annual N and S deposition from SGP sources was determined through the same model, CALPUFF, used to assess regional haze effects. The total potential N and S deposition were assumed to be composed only of the N or S component of the different compounds included in the model. Both dry and wet deposition modes were considered. The maximum pollutant emission rates for the ModPro inventory were applied to modeling for three meteorological data years, 2015 through 2017.

Predicted deposition impacts, in grams of pollutant per hectare per year, were compared to the DAT as outlined in the 2011 interagency guidance on N and S deposition as an indicator of significance (NPS 2011). The DAT for N and S in the Class I area are listed as 5 g/ha-yr.

For the three modeled years of 2015 through 2017, the maximum predicted annual deposition rates were below the DAT in each Class I and Class II area evaluated. The estimated maximum N and S deposition in g/ha-yr for the Class I areas evaluated for this analysis are provided in **Tables 7-25** and **7-26**. Predicted deposition rate in SELW is the highest, with N deposition rate of 1.13 g/ha-yr at the highest receptor location. This is well below the DAT of 5 g/ha-yr and indicates that deposition impacts from the SGP in Class I areas would likely be undetectable.

Table 7-25 Summary of Predicted Nitrogen Deposition Rates in Class I Areas Due to SGP Sources

Class I Area	Max. Receptor N Deposition Rate 2015 (g/ha-yr)	Max. Receptor N Deposition Rate 2016 (g/ha-/yr)	Max. Receptor N Deposition Rate 2017 (g/ha-yr)	3-Year Maximum N Deposition Rate (g/ha-yr)	Class I DAT (g/ha-yr)	Below Threshold (Yes/No)
CRMO	0.06	0.11	0.11	0.11	5	Yes
HECA	0.21	0.13	0.09	0.21	5	Yes
SAWT	0.44	0.44	0.48	0.48	5	Yes
SELW	1.00	0.99	1.18	1.18	5	Yes

Source: Air Sciences 2021a; NPS 2011
g/ha-yr = grams per hectare per year
DAT = Deposition Analysis Threshold

Similarly, the estimated maximum N and S deposition in g/ha-yr for the four Class II areas and closest Tribal lands evaluated for this analysis are provided in **Tables 7-27** and **7-28**.

Predicted deposition rate in FCRNRW is the highest, with N deposition rate of 4.63 g/ha-yr at the highest receptor location. This reflects the position of the FCRNRW as the closest area of concern, essentially adjacent to the SGP area. Despite the proximity to the SGP, the highest deposition rate contribution is still predicted to be below the protective Class I DAT of 5 g/ha-yr.

Table 7-27 Summary of Predicted Nitrogen Deposition Rates in Class II Wilderness Areas and Nez Perce Requested Analysis Area

Class II Wilderness Area	Max. Receptor N Deposition Rate 2015 (g/ha-yr)	Max. Receptor N Deposition Rate 2016 (g/ha-yr)	Max. Receptor N Deposition Rate 2017 (g/ha-yr)	3-Year Maximum N Deposition Rate (g/ha-yr)	Class I DAT (g/ha-yr)	Below Threshold (Yes/No)

7.2.3 Johnson Creek Route Alternative

The Johnson Creek Route Alternative would be used for access during mine construction, operations, and closure and reclamation (the Burntlog Route would not be constructed). The approximately 36-mile Route consists of Johnson Creek Road (CR 10-413) and McCall-Stibnite Road (CR 50-412) from the village of Yellow Pine to the SGP. The road design and maintenance for the Johnson Creek Route would be similar to the road design and maintenance described for the 2021 MMP. Construction material borrow sources would be developed along the Johnson Creek Route ROW. Several changes to water and wildlife habitat management also would be included, but these would only affect air quality impacts during the construction phase.

Controlled public access through the SGP during mine operations would be provided by an access road connecting McCall-Stibnite Road (CR 50-412) to Thunder Mountain Road (FR 50375) through the mine area. Similar to this same feature described under the 2021 MMP, this public access road would be constructed during the first year of mine operation and public access to this road would be carefully controlled; fences would prohibit public visitors on this road from having access to the SGP mining or support activities.

7.2.3.1 Construction

The Burntlog Route would not be constructed. Using the Johnson Creek Route for mine access would avoid disturbance-related air quality impacts from construction of approximately 20 miles of new road for the Burntlog Route. This would have the effect of decreasing overall roadway construction phase vehicle tailpipe and airborne dust emissions. The topographic features of the route (e.g., a portion of the route is along a river through a canyon) do not affect the nature of the air emissions during construction. However, the location of air pollutant concentrations may differ because construction activities would take place along a different ROW compared to other action alternatives.

No road widening or straightening of curves would be required for the Johnson Creek Road (CR 10-413) portion of the alternative. The Stibnite Road (CR 50-412) portion would be improved by widening curves to accommodate 55-foot semi-truck trailers. Approximately one mile of road past the village of Yellow Pine would be paved. Based on relative roadway length affected, these changes in roadway construction to improve the Johnson Creek Route would represent a decrease of overall construction phase emissions. However, the magnitude of the emissions difference would be small compared to total construction

emissions during the first three LOM years. Also, the construction phase emissions for these upgrades to the Johnson Creek Route would be less than the emissions for construction of approximately 20 miles of new road to develop the Burntlog Route under other action alternatives.

This alternative would require an extra two years (three vs five) for construction of the upgrades to the Johnson Creek Route and the SGP. As a result, operations would start in year 6 instead of year 4 and the highest impact years for emissions would be LOM Years 8 and 12 (as compared to 6 and 10 for the 2021 MMP).

7.2.3.2 Operations

The Johnson Creek Route would be used to access the SGP. The length of this route is approximately 1.5 miles shorter than the Burntlog Route, so that the overall tailpipe emissions for vehicles accessing the SGP would be slightly less for this alternative. The location of ambient air pollutant concentrations due to vehicle traffic would differ, with such effects being located along the Johnson Creek Route.

Providing public access through the SGP reduces the miles of new motorized trails open to all vehicles in the Meadow Creek IRA, and this is expected to reduce net air quality effects due to vehicles traversing the SGP area.

Several air pollution design features proposed by Perpetua are common to both action alternatives and are described in **Section 2.4** and **7.3**. Emission control devices and designs would be put in place to abate emissions of particulate matter, Hg, and criteria pollutant emissions from internal-combustion engines the same as the 2021 MMP. Operational and reclamation air emission impacts for this alternative would therefore be the same as the 2021 MMP.

The facilities would be designed, constructed, and operated with appropriate air pollution controls to comply with applicable regulations and any air quality permits issued by IDEQ. The PTC would include stipulations for control of airborne dust from vehicle traffic along the Johnson Creek Route that are based on applicable state and federal regulations, and that are consistent with best available control technology for new surface mining and processing operations. Key examples of these controls are described for the emission inventory under the 2021 MMP, in **Section 7.2.2.1**.

7.3 Mitigation and Monitoring

A number of emission controls and monitoring actions have been proposed by Perpetua in compliance with government requirements. These are described below:

Perpetua would develop a fugitive dust control plan (FDCP) in accordance with IDEQ permit requirements. The FDCP will address the following:

- Procedures followed by Perpetua employees to control and minimize fugitive dust emissions.
- Trigger levels will be set that require corrective action.
- Actions to bring fugitive dust emissions within acceptable ranges.
- Steps to demonstrate that appropriate corrective procedures are followed.
- Procedures to verify that Perpetua is controlling avoidable fugitive dust emissions.

PET-0982

REC 2702

Additionally, the IDEQ permit would include the following control measures proposed by Perpetua for HAP and mercury emissions:

- Mining – chemical dust suppressant/water application on haul roads, reasonable controls, FDCP
- Rock dumps and storage piles - reasonable controls, FDCP
- Tailings and maintenance pond activities – chemical suppressant, reasonable control, FDCP
- Ore processing – water sprays, moisture carryover, enclosures, reasonable controls, FDCP
- Ore concentration and refining tanks – chemical suppressant
- Autoclave – venturi scrubber, vent gas cleaning tower, carbon filter
- Electrowinning cells and pregnant solution tank – carbon fiber
- Mercury retort – carbon filter
- Melting furnace – baghouse, carbon filter
- Carbon kiln – wet scrubber, carbon filter
- Limestone ball mill – baghouse
- Parallel flow regenerative shaft lime kiln – baghouse
- Lime mill crusher – baghouse
- Lime shaker – wet scrubber
- Storage silos – bin vents
- Aggregate and concrete production – water sprays, moisture carryover, reasonable controls, FDCP
- Fuel Combustion – clean fuel (ultra-low sulfur diesel)
- Emergency engines – EPA Tier IV standard compliant
- Gasoline storage – lids or gasketed seal, submerged filling
- Diesel storage – lids

Fugitive mercury emissions would be reduced with the following measures:

- Mining – Chemical dust suppressant/water application on haul roads, reasonable controls, FDCP.
- Rock dumps and storage piles - reasonable controls, FDCP.
- Tailings and maintenance pond activities – chemical treatment, reasonable control, FDCP
- Ore processing – water sprays, moisture carryover, enclosures, reasonable controls, FDCP

- Aggregate and concrete production – water sprays, moisture carryover, reasonable controls, FDCP

IDEQ permitting is limiting emissions in the following manner:

- "Low-arsenic" quartzite (90 ppm arsenic or less) development rock to be applied for capping haul roads excluding those with the various pits and rock storage facilities.
- Drill rigs would include a dust control system with a minimum efficiency of 90 percent.

In addition to the government requirements for emission controls and monitoring, Perpetua has also proposed additional environmental design measures that would reduce air emissions; these are:

- All off-highway diesel engines would be EPA Tier IV or better.
- Perpetua would encourage employees to use company provided shuttle buses as transport to the SGLF from towns along SH 55.
- Busing and/or vanpooling would be provided for Perpetua and contractor employees. The associated parking area would accommodate approximately 300 vehicles. To the degree practicable, Perpetua would mandate the use of busing and vans for employee and contractor transportation to the SGP and the worker housing facility.

Mitigation measures required by the Forest Service would represent reasonable and effective means to reduce the impacts identified in the previous section or to reduce uncertainty regarding the forecasting of impacts into the future. These mitigation measures are in addition to the prominent regulatory and Forest Plan requirements and project design features (**Section 2.4**) accounted for in the preceding impact analysis.

Mitigation measures may be added, revised, or refined based on public comment, agency comment, or continued discussions with Perpetua regarding this specialist report or subsequent analysis under NEPA. The adopted mitigation measures will be finalized in the Final EIS.

7.4 Cumulative Effects

7.4.1 Past, Present, and Reasonably Foreseeable Activities Relevant to Cumulative Effects Analysis

Past, present, and reasonably foreseeable future actions include activities, developments, or events that have the potential to change the physical, social, economic, and/or biological nature of a specified area. With respect to air quality, activities directly associated with the SGP and other reasonably foreseeable future actions having air pollutant emissions at a level that cause overlap with SGP-related effects in time and location, would result in cumulative impacts. The air quality cumulative effects analysis considers the potential contributions of actions that could occur in the relatively large analysis area. The cumulative effects study area for air quality is generally the same as the larger far-field region.

7.4.2 No Action Alternative

For the No Action Alternative, the nature and extent of cumulative effects is represented by the current air quality conditions in the analysis area. Ambient air data for CO, NO_2, SO_2, and on-site data for PM_{10} and $PM_{2.5}$ are available to serve as quantitative indicators for the impacts from current non-SGP sources on air

quality (refer to **Section 6.1**, Existing Conditions). These background ambient air measurements offer the best indication of cumulative effects due to current emissions sources, absent the SGP. The monitored baseline values used for the air quality impact assessment were obtained at locations that are more developed than the SGP area. By comparison, the cumulative effects in the analysis area due to the current activities and air emission sources would be minor.

The federal agencies entered into an ASAOC with Midas Gold (now Perpetua) in January 2021 for the cleanup of certain legacy mining wastes in the SGP area. The work would involve excavating the wastes out of certain portions of Meadow Creek and East Fork South Fork Salmon River and then relocating those wastes to more suitable locations on site. This work is scheduled for the construction seasons of 2022 through 2024 and would involve excavation and hauling equipment as well as other vehicles for personnel and fuel/supplies transportation on the current access roads to the area. This would produce dust and tailpipe emissions that would likely precede the major construction activities of the action alternatives and so would not be cumulative to the air emissions from those activities.

7.4.3 2021 MMP

For the far-field air quality impact analysis, a suitable far-field modeling domain was defined as an area 420 km by 420 km in extent, centered on the SGP, as shown in **Figure 1-3**. This area encompasses the closest Class I areas and Class II wilderness areas that are most likely to have impacts. The four Class I areas for which far-field modeling results were reported are SAWT, SELW, HECA, and CRMO.

Cumulative effects analysis for air quality considers the geographic range and timeframe of impacts from past, current, and foreseeable activities. In general, the air quality effects from past projects do not generate cumulative effects due to the transient nature of air quality conditions. The release of pollutants in the past in a region, would not contribute to measured conditions in that region afterward. Transport from far more distant urban regions, even overseas, may contribute to local air conditions (e.g., ozone) but are not in the scope of a cumulative effects analysis. Therefore, past operations by Perpetua in the SGP area, such as exploratory drilling, monitoring wells, and roadway construction and maintenance, are not contributors to air quality cumulative effects. Similarly, past activities in the cumulative analysis area, such as prior roadway and infrastructure construction projects, and timber and underbrush harvesting, would not have effects that overlap in time with the SGP emissions, and therefore would not contribute to air quality cumulative effects.

The ambient air data for CO, NO_2, SO_2, and on-site data for PM_{10} and $PM_{2.5}$ indicate the existing impacts from off-site sources on air quality near the SGP area was reviewed for this analysis (refer to **Section 3.3.4**). These background ambient air measurements offer the best indication of cumulative effects due to current emissions sources. Although some background measurements of ozone in the Boise urban area are above the NAAQS, the ozone baseline value for this assessment recommended by the IDEQ is compliant with the NAAQS. The monitored baseline values used for the SGP air quality impact assessment were obtained at locations that are more developed than the SGP area. By comparison, the cumulative effects in the analysis area due to current activities and air emission sources would be minor.

There are no other permitted sources of HAP emissions in the vicinity of the SGP area. One source, the Tamarack Mill, LLC is 75 miles from the SGP, and has reported minor source level emissions to IDEQ. The HAP emission inventory in the vicinity of the SGP area is unknown; however, given the absence of large HAP emission sources near the SGP area, it can be assumed that the baseline HAP cumulative effects are low.

Several reasonably foreseeable activities in the cumulative effects analysis region that were considered regarding cumulative air quality effects are listed in **Tables 7-29** and **7-30**. The nature of the air emissions and contributions to potential cumulative effects are described for each project. Activities that are anticipated to have overlapping impacts with the SGP related to air quality include wildfires and Big Creek fuels reduction.

Table 7-29 Reasonably Foreseeable Activities Considered Regarding Cumulative Air Quality Effects for Specific Planning Projects

Project Type	Project Names/Description	Nature of Air Emissions and Contribution to Cumulative Effects
Roadway Development and Maintenance	Big Creek Road Plan of Operations Project EA Morgan Ridge Exploration Project – Access Road Plan Such projects authorize the use of and/or improvement of roads to conduct exploration and development of locatable mineral claims.	Dispersed short-term local emissions of road dust and vehicle tailpipe emissions. Negligible long-term cumulative air quality effects in combination with the SGP.
Exploratory Drilling for Mineral Resources	Morgan Ridge Exploratory Drilling Plan of Operations EA Project involves exploratory drilling for locatable minerals from remote drill pads approximately 10 miles north of the SGP. Project is reportedly on hold.	Local emissions from drilling equipment (e.g., compressor engines), road dust, and tailpipe emissions. The magnitude of emissions is not expected to be of sufficient magnitude to have overlapping pollutant concentration effects at this distance from the SGP.
Forest Maintenance and Fire Risk Reduction	Big Creek fuels reduction project approx. 10 miles north of SGP South Fork Restoration and Access Management Plan EA, 25 miles southwest of SGP Projects to reduce wildfire risk and fire severity/intensity on NFS lands and private property using commercial timber harvest, understory treatment, and prescribed burning.	Local emissions from portable generator equipment (e.g., compressor engines, road dust, and tailpipe emissions. Particulate emissions from lumbering activities and hauling. The Big Creek project may be of sufficient magnitude to have overlapping PM concentration effects at this distance from the SGP. The South Fork project is of sufficient distance that it would have negligible cumulative air quality effects.

Table 7-30 Reasonably Foreseeable Activities Considered Regarding Cumulative Air Quality Effects for Ongoing Projects and Foreseeable Emissions Sources

Project Type	Project Names/Description	Nature of Air Emissions and Contribution to Cumulative Effects
Construction Projects	Creek remediation/restoration (ASAOC) Trail construction and maintenance Bridge and culvert replacement projects, generally located more than 10 miles north of the SGP area Hydroelectric projects: small residential projects for power	Short-term emissions during construction with no long- term emission impacts that would likely overlap with impacts related to the SGP.

Project Type	Project Names/Description	Nature of Air Emissions and Contribution to Cumulative Effects
	generation Road maintenance	
Natural Emission Events	Wildland fires Past fires with the headwaters of the East Fork SFSR and Sugar Creek include Indian Creek Point (12,204 acres); Tamarack (2,348 acres); Bishop Creek (2,610 acres); Cascade Complex (299,930 acres); Thunder City (13,263 acres), and Buck Fire (19,474 acres). In the fall of 2021, the Krassel Ranger District conducted prescribed burns to areas east of Yellow Pine (Bald Hill project area) and along the SFSR (Four Mile project areas).	Areas devoid of trees and vegetation may have potentially large, short-term air quality effects, due to increased windblown dust.
Mining Activities	Ongoing mining activities on patented land. Mineral exploration and mining have occurred in several locations around the SGP area. Exploration activities area ongoing for potential future mining development.	Local emissions from drilling equipment (e.g., compressor engines), road dust, and tailpipe emissions. Known mine operations are small in size (50 tpd or less) or are inactive. Locations of foreseeable projects with low emissions are at sufficient distances from the SGP to not contribute overlapping effects.
Recreation and tourism	Recreation and Tourist activities: • Sport hunting, fishing, trapping • Snowmobile trails • Fugitive dust and tailpipe emissions from traffic on unpaved roads • Boating and river recreation • Camping, hiking, backpacking • Outfitter/Guide Operations • Tourist Services – Big Creek Lodge • Off-highway vehicle use • Tourist Services – e.g., Big Creek Lodge	Collectively air emissions from vehicles on unpaved roads and trails, boats, and stationary fuel combustion sources. Depending on the proximity of these activities to the SGP area, transient cumulative effects may occur.

7.4.4 Johnson Creek Route Alternative

Although the magnitude and location of SGP air emission sources are different for the action alternatives, the differences are not large enough to significantly change off-site air quality impacts. Consequently, the potential for cumulative air quality effects described above for the 2021 MMP would also apply to the Johnson Creek Route Alternative. The extent and magnitude of potential cumulative air quality effects due to foreseeable projects in the analysis area would be the same.

7.5 Short-term Uses and Long-term Productivity

The CEQ guidelines require an evaluation of environmental sustainability considering the relationship between short-term uses of the environment and the maintenance and enhancement of long-term productivity (40 CFR 1502.16). This section provides a brief overview of the short-term effects of the SGP versus the maintenance and enhancement of potential long-term productivity of the environmental resources in the SGP area. Short-term refers to the analysis period for the SGP (the 20-year life of the mine). Long-term refers to an indefinite period after mine closure.

7.5.1 No Action Alternative

For the No Action Alternative, the impacts to the air quality resource would be roughly the same as current conditions. There would not affect short-term use or long-term productivity of the location with respect to air quality.

7.5.2 2021 MMP

For the 2021 MMP, operation of the mining and production facilities and associated use of transport vehicles would have continual short-term emissions of air pollutants for the duration of the SGP. These short-term emissions and related air quality impacts have been described in **Section 7.2.2**.

There are no anticipated long-term effects related to air quality in the SGP area, after the reclamation of the site. Once the SGP activities cease, air emissions and related effects would no longer occur.

7.5.3 Johnson Creek Route Alternative

The short-term uses of the air resource and effects on long-term productivity for the Johnson Creek Alternative would essentially be the same as the 2021 MMP.

7.6 Irreversible and Irretrievable Commitments of Resources

The CEQ guidelines require an evaluation of "any irreversible or irretrievable commitments of resources which would be involved in the proposal should it be implemented" (40 CFR 1502.16).

7.6.1 No Action Alternative

Under the No Action Alternative, the SGP would not be undertaken. Consequently, there would be no change in the current status of air resources in the SGP area, except for the temporary effects of implementing the ASAOC, and irretrievable or irreversible commitments of public resources with respect to air quality would not occur.

7.6.2 2021 MMP

There are no irreversible commitments for air quality resources under the 2021 MMP. The pollution resulting from 2021 MMP air emissions would occur over the construction through reclamation phases and then stop. Concentrations of pollutants in the analysis area would rapidly decrease to the ambient conditions then existing in the area. This short-term impact to the air resource would constitute an irretrievable commitment of that resource.

7.6.3 Johnson Creek Route Alternative

The irreversible and irretrievable commitment of the air resources under the Johnson Creek Route Alternative would essentially be the same as the 2021 MMP.

7.7 Summary

The air quality analysis conducted for the SGP examined impacts on defined geographic regions that relate to different types of modeling processes. First, a "near field" region surrounding the SGP was examined using air dispersion models to quantify pollutant concentrations and related impacts. For the SGP, preliminary modeling confirmed that a 10-km domain size was adequate to characterize worst-case near-field air quality impacts. Air quality effects would decrease at distances beyond the modeled 10-km range.

Second, a much larger "far-field" region was defined that encompassed more-distant Class I areas, wilderness areas, and tribal lands. In these areas, specialized air quality modeling tools were applied to evaluate the combined effects of dispersion, deposition, and chemical transformations in the atmosphere. The models assessed SGP source contributions to regional haze, nitrogen deposition, and sulfur deposition.

Table 7-30 provides a summary comparison of air quality impacts for each alternative, based on the issue and indicators defined for the air quality resource.

7.7.1 Extent of Pollutant Concentrations and Deposition

Dispersion modeling based on a representative mine operating scenario and the year with highest estimated aggregated air emissions, demonstrated that pollutant concentrations at the Operations Area Boundary would not exceed the NAAQS. This conclusion applies for both action alternatives. Deposition of Hg, and nitrogen and sulfur species were predicted to be less than SILs. A supplemental HAPs modeling analysis was also completed for all sources and compliance with the state AAC/AACCs was maintained.

The differences in SGP emission sources for the Johnson Creek Route Alternative are essentially the same as the 2021 MMP. Under the No Action Alternative, the SGP would not be constructed, so the air quality in the area would essentially remain the same as the existing baseline conditions with the exception of temporary emissions from implementing the ASAOC.

7.7.2 Type and Volume of Air Pollutants Emitted

To characterize the highest anticipated annual emission levels for purposes of conservative air quality impact analysis, a complete emission inventory was compiled for each year from construction through LOM Year 18. The year of peak mine throughput, LOM Year 6, was found to have the highest aggregate pollutant emissions, including haze precursors, airborne dust, and HAPs.

7.7.3 Criteria Air Pollutant Ambient Concentrations Outside the Operations Area Boundary

Dispersion modeling based on the 2021 MMP inventory demonstrated that impacts would not exceed NAAQS outside the operations area boundary. A supplemental HAPs analysis for all potential emission sources and each mine year was analyzed and demonstrated compliance with both the carcinogenic and non-carcinogenic acceptable concentrations. The Johnson Creek Route Alternative do not entail emission source differences of a permanent nature (e.g., roadway construction emissions) to result in long-term

criteria pollutant impacts that differ from the 2021 MMP findings, respectively. Close-in concentrations of pollutants from vehicle exhaust and airborne dust would be distributed differently for other action alternative since some sources and roadways would be in different locations. Under the No Action Alternative, the off-site concentrations of criteria pollutants would remain unchanged from the existing baseline conditions.

7.7.4 Comparison of Modeled Concentrations to Class I and Class II Increments

Both near-field and far-field modeling demonstrated that the Class I and Class II increments would not be exceeded outside the Operations Area Boundary. Although evaluation of incremental air quality impacts is not applicable to minor sources, such as the SGP, this provided an indicator of relative SGP impacts under the 2021 MMP. The far-field air quality impacts resulting from the Johnson Creek Route Alternative would not differ from the findings for the 2021 MMP. For the No Action Alternative, the off-site concentrations of criteria pollutants would remain unchanged from the existing baseline conditions.

7.7.5 HAP Emissions and Hg Deposition

Emissions of HAPs, including mercury, were quantified for the worst case LOM Year as outlined in the Supplemental HAP Air Quality Analysis Addendum – ModPro2 (Air Sciences 2021b). Additionally, HCN, sulfuric acid, Hg, and organic HAPs from fuel combustion, were found to be well below federal major source thresholds. Near-field deposition analysis for Hg indicated that even the maximum predicted deposition rates would be less than significance thresholds.

7.7.6 Deposition Impacts for Nitrogen and Sulfur Compounds at Class I areas and Specified Class II Wilderness Areas

Predicted deposition impacts, in grams pollutant per hectare per year, were obtained from far-field modeling for the 2021 MMP peak year emissions. The modeled results were compared to the DAT an indicator of significance (NPS 2011). The DAT for N and S in the Class I area are listed as 5 g/ha-yr. For the three modeled years of 2015 through 2017, the maximum predicted annual deposition rates were below the DAT in each Class I and Class II area evaluated.

7.7.7 Near-field Plume Blight and Far-Field Regional Haze Impacts

The Level 2 screening analysis addressed an observer at the FCRNRW and demonstrated that the aggregated emissions from the 2021 MMP would have the potential to cause visible plumes at that wilderness area. The VISCREEN updates included adding non-point sources and mobile equipment, increased background visual range to 270 kilometers, adding large-diameter PM emissions and nighttime hours (Appendix C of Air Sciences 2021a). The revised 2020 VISCREEN model predicts that 0.02 percent (1 hour) of the annual daytime hours and 2.9 percent (107 hours) of the annual nighttime hours may experience a visible plume within the FCRNRW area.

For analysis of regional haze impacts, maximum 24-hour SGP source emissions of SO_2, NO_X, SO_4, and fine and coarse PM were modeled. The Class I and Class II wilderness area visibility analysis results show the modeled 98th percentile highest daily change in light extinction parameters, and therefore the change in atmospheric visibility, would be less than the 5 percent change in light extinction that is considered the significance criteria for Class I areas (FLAG 2010). Consequently, the level of regional haze impact in the Class I and Class II areas evaluated was predicted to be minor.

REC 2710

Table 7-31 Comparison of Air Quality Impacts by Alternative

Issue	Indicator	Baseline Conditions	No Action Alternative	2021 MMP	Johnson Creek Alternative
The SGP may affect air quality characteristics and resources	Geographical extent of pollutant concentrations and deposition.	No SGP air emissions to affect existing conditions.	Same as Baseline Conditions.	SGP air quality impacts would be less than NAAQS because emissions and under deposition significance levels. This would be considered minor to moderate and localized/regional.	Same as 2021 MMP.
The SGP may affect air quality characteristics and resources	Type and volume of air pollutants emitted, including haze precursors, airborne dust, and HAPs.	No SGP air emissions to affect existing conditions.	Same as Baseline Conditions.	Emission inventories for construction through LOM Year 18 indicated that the peak year for aggregated pollutant emissions would be LOM Year 10, also the peak year for mine throughput. The overall impact is minor to moderate and localized.	Same as 2021 MMP, except those changes in emissions location due to use of Johnson Creek Route (i.e., different haul routes)
The SGP may affect air quality characteristics and resources	Criteria air pollutant ambient concentrations outside the Operations Area Boundary anywhere the public is allowed unrestricted access.	Current air quality in the SGP area is good, and in attainment with air quality standards.	Same as Baseline Conditions.	SGP air quality impacts would be less than NAAQS because and under deposition significance levels. Expected impacts are minor to moderate, but mostly localized as the highest concentrations are very near the boundary of SGP.	Same as 2021 MMP, except that the locations of off- site concentrations may differ due use of Johnson Creek Route rather than Burntlog Route.
The SGP may affect air quality characteristics and resources	Comparison of modeled concentrations to Class I and Class II increments.	Current air quality in the SGP area is good, and in attainment with air quality standards.	Same as Baseline Conditions.	SGP air quality impacts would be less than the Class I and Class II increments. The overall impacts are minor to Class I and Class II areas and regional in nature.	Same as 2021 MMP, except that the magnitude and locations of off-site concentrations may differ due use of Johnson Creek Route rather than Burntlog route.

Issue	Indicator	Baseline Conditions	No Action Alternative	2021 MMP	Johnson Creek Alternative
The SGP may affect air quality characteristics and resources	HAPs (including Hg emissions and Hg deposition.	Background concentrations and deposition occurs due to transport from distant industrial and urban sources.	Same as Baseline Conditions.	Emissions HAPs, HCN, and Hg estimated for peak mine production year. Deposition of Hg limited in extent and well below health-based thresholds. HAP emission impacts are less than state AAC/AACCs	Same as 2021 MMP.
The SGP may affect air quality characteristics and resources	Deposition impacts from nitrogen and sulfur compounds at Class I areas and specified Class II wilderness areas.	Existing deposition rates occur due to transport from distant industrial and urban sources.	Same as Baseline Conditions.	Modeling of N and S deposition in areas of concern show that deposition rates are below acceptable levels for Class I areas. The overall deposition impacts are minor to Class I and Class II areas and regional in nature.	Same as 2021 MMP.
The SGP may affect air quality characteristics and resources	Near-field plume blight and far- field regional haze impacts in protected areas.	No SGP sources to create visible near-field plumes. Existing regional haze occurs due to transport from distant industrial and urban sources.	Same as Baseline Conditions.	SGP sources may cause visible plumes at the closest Class II wilderness area (FCRNRW) for a small fraction of daylight hours. Far-field modeling of regional haze shows contribution from SGP sources would be below federal significance level. The impacts to visibility is negligible as illustrated by the VISCREEN modeling.	Same as 2021 MMP.

Tank Indentification and Physical Characteristics

Identification

User Identification:	2,500 gallon gasoline tank
City:	Boise
State:	Idaho
Company:	Midas Gold
Type of Tank:	Horizontal Tank
Description:	Midas Gold Landmark facility gasoline tank

Tank Dimensions

Shell Length (ft):	15.00
Diameter (ft):	6.00
Volume (gallons):	2,500.00
Turnovers:	52.00
Net Throughput(gal/yr):	130,000.00
Is Tank Heated (y/n):	N
Is Tank Underground (y/n):	N

Paint Characteristics

Shell Color/Shade:	White/White
Shell Condition	Good

Breather Vent Settings

Vacuum Settings (psig):	-0.03
Pressure Settings (psig)	0.03

Mining Year 10

Open Pit Drilling

Activity Information

Operating schedule	355 day/yr	*(M3 2014)*	
Total drill holes per year	30,313 hole/yr	*(Perpetua 2021a)*	

Annual LOM-10 rates		Material blasted			Drilling[1]	
YPI	Yellow Pine Pit	1,147,269	ton/yr	*(Perpetua 2021a)*	1,175	hole/yr
HFI	Hangar Flats Pit	0	ton/yr	*(Perpetua 2021a)*		hole/yr
WE	West End Pit	28,466,535	ton/yr	*(Perpetua 2021a)*	29,139	hole/yr
BT_	Bradley Tailings	0	ton/yr	*(Perpetua 2021a)*	0	hole/yr
	Total	29,613,804	ton/yr		30,314	hole/yr

(1) *Total drill holes per year scaled based on material blasted; rounded up to the nearest whole number*

Emission Factors

TSP (PM)	1.3 lb/hole	*AP-42, Tab. 11.9-4, 7/98 (overburden)*

PM Scaling Factors

PM	1	
PM10	0.52	*AP-42, Tab. 11.9-1, 7/98 (blasting, overburden)*
PM2.5	0.03	*AP-42, Tab. 11.9-1, 7/98 (blasting, overburden)*

Emission Controls

Dust collector

Control efficiency: 90% *(CDC 2012), up to 99% control*

Stockpile Surface Wind Erosion Event Emission Calculations - Notes

(1) u10 = wind speed at 10 meters reference height, m/s

(2) u10+ = fastest-mile wind speed, m/s
Based on hourly to fastest-mile wind speed conversion factor of 1.2 *(EPA 1994)*

(3) Pile: u* = friction velocity, m/s = (us/ur) × 0.1 × u10+ *AP-42, Sec. 13.2.5, Eqs. 6 & 7, 11/06*

Area ID	A	B	C
(us/ur)	0.9	0.6	0.2

AP-42, Page 13.2.5-10, 11/06

Flat surface:
u* = friction velocity, m/s = 0.053 × u10+ *AP-42, Sec. 13.2.5, Eq. 4, 11/06*

(4) Hours elapsed since previous wind erosion event

(5) Erodible surface area = hours elapsed since previous erosion event × hourly erodible surface area (acre) × surface regime area fraction Surface regime area fractions:

Area ID	A	B	C
% Surface	0.12	0.48	0.4

AP-42, Page 13.2.5-10, 11/06

(6) Erosion potential, g/m^2, = P = 58(u* - ut*)^2 + 25(u* - ut*); P = 0 for u* ≤ ut*
where, ut* = threshold friction velocity = 1.02 m/s *AP-42, Page 13.2.5-5 (overburden), 11/06*
P converted to lb/acre by multiplying with: 0.002205 lb/g and 4,046.86 m^2/acre
Solving u* = (us/ur) × 0.1 × u10+ for u10, when u* = ut* = 1.02 m/s and u10+ = u* × 1.2
yields the following minimum wind speeds to disturb the each stockpile surface regime:

ID-A	9.44 m/s
ID-B	14.17 m/s
ID-C	42.50 m/s

The threshold wind speed to disturbe flat surfaces is 1.02/0.053/1.2
Flat surface 16.04 m/s
The maximum hourly wind speed in the onsite data is 10.4 m/s, which is less than the threshold wind speeds to cause a disturbance of stockpile regimes ID-B and ID-C, and flat surfaces.

(7) PM emissions, lb = P (lb/acre) × erodible surface area (acre)

(8) Total PM emissions, lb = PM (ID-A), lb + PM (ID-B), lb + PM(ID-C), lb

(9) Total PM10 emissions, lb = total PM emissions, lb × PM10 scaling factors of 0.5 *AP-42, Page 13.2.5-3, 11/06*

(10) Total PM2.5 emissions, lb = total PM emissions, lb × PM2.5 scaling factors of 0.075 *AP-42, Page 13.2.5-3, 11/06*

BH	10	m	BH - Bench Height (m) ≥D/15
N	100		N - Number of Holes in a Blast
D	0.15	m	D - Hole Diameter (mm)
B	4.9	m	B - Drilled Burden (m) =(25 to 40) x D
S	5.6	m	S - Drilled Spacing (m) =1.15 x B
L	10	m	L - Hole Length
V	27,330		
Vb	70.7		
V/Vb	386.6	400	

Enclosure Control Efficiency Calculation

Emission factor equation	$E = 0.0032k(U/5)^{1.3}/(M/2)^{1.4}$				*AP-42, Sec. 13.2.4, Eq. 1, 11/06*	
U = Mean wind speed	5.167 mph		2.31 m/s		*(Midas Gold 2017f), Fig. 4-3 (2014 onsite meteorological data)*	
U = Mean wind speed	1.3 mph				*Lowest wind speed for Eq. 1, AP-42, Sec. 13.2.4, Eq. 1, 11/06*	
M = Moisture content	2.5 %					
	PM	PM10	PM2.5			
k = Particle size multiplier	0.74	0.35	0.053		*AP-42, Sec. 13.2.4, Pg. 4, 11/06*	
E = Emission factor	0.00181	0.00086	0.00013	lb/ton	U =	5.167
E = Emission factor	0.00030	0.00014	0.00002	lb/ton	U =	1.300
Control Efficiency	83.4%	83.4%	83.4%

40 CFR 63 Subpart 7E MERCURY SOURCES

Mercury Emissions

Description	Subpart 7E Hg Emissions ton/yr	Oper. hr/yr	% of Subpart 7E for Controlled Systems* %	Controlled Hg Emissions* lb/hr	lb/yr	ton/yr
Autoclave **	0.107	8,760	10.0%	0.002	21.34	0.011
Refinery Sources (Kiln, EW, Retort, Furnace)	0.008	1,248	20.0%	0.003	3.36	0.002
Total 7439-97-6	0.115			0.005	24.70	0.012

**Based on Similar Source Hg Reporting Levels provided below*

***Expected actual emissions from Autoclave:* 0.0105 g/hr 2.3E-05 lb/hr 0.20 lb/yr *(M3 2019)*

Subpart 7E Limit - Ore Pretreatment Processes *(CFR 2018b)*

$$\frac{84\ \text{lb}}{\sout{\text{MMton}}} \times \frac{2{,}540{,}400\ \sout{\text{ton}}}{\text{yr}} \times \frac{\sout{\text{MMton}}}{1.0\text{E+6}\ \sout{\text{ton}}} = \frac{213.39\ \text{lb}}{\text{yr}}$$

Subpart 7E Limit - Carbon Processes with Mercury Retorts

$$\frac{0.8\ \text{lb}}{\sout{\text{ton}}} \times \frac{21\ \sout{\text{ton}}}{\text{yr}} = \frac{16.8\ \text{lb}}{\text{yr}}$$

Similar Source Hg Reporting Levels

Goldstrike Autoclaves 2 & 3 (2015 & 2016 Hg Reports) *(NDEP 2015a) (NDEP 2016)*

$$\frac{28.79\ \text{lb}}{\text{yr}} \times \frac{\text{yr}}{3.13\ \text{MMton}} = \frac{9.18\ \text{lb}}{\text{MMton}} \times \frac{\text{MMton}}{84\ \text{lb}} = 10.9\%$$

Twin Creeks Autoclaves 1 & 2 (2015 & 2016 Hg Reports) *(NDEP 2015a) (NDEP 2016)*

$$\frac{1.01\ \text{lb}}{\text{yr}} \times \frac{\text{yr}}{7.63\ \text{MMton}} = \frac{0.13\ \text{lb}}{\text{MMton}} \times \frac{\text{MMton}}{84\ \text{lb}} = 0.2\%$$

Goldstrike Refinery (2015 & 2016 Hg Reports) *(NDEP 2015a) (NDEP 2016)*

$$\frac{28.79\ \text{lb}}{\text{yr}} \times \frac{\text{yr}}{251.00\ \text{ton}} = \frac{0.11\ \text{lb}}{\text{MMton}} \times \frac{\text{MMton}}{0.8\ \text{lb}} = 14.3\%$$

Twin Creeks Refinery (2015 & 2016 Hg Reports) *(NDEP 2015a) (NDEP 2016)*

$$\frac{31.27\ \text{lb}}{\text{yr}} \times \frac{\text{yr}}{142.77\ \text{ton}} = \frac{0.22\ \text{lb}}{\text{MMton}} \times \frac{\text{MMton}}{0.8\ \text{lb}} = 27.4\%$$

APPENDIX C REVIEW AND RATIONALE FOR SELECTED AIR EMISSION FACTORS

Review and Rationale for Selected Air Emission Factors

Stibnite Gold Project

In the report *Air Quality Analysis*, prepared by Air Sciences Incorporated for Midas Gold Idaho, Inc. (Air Sciences 2018) and in the modeling report provided to support the Permit to Construct application to IDEQ (Air Sciences 2020) a variety of published air emission factors were used to quantify pollutant emissions from the Project sources. This discussion will review the selection of emission factors, as tabulated in Tables 4 through 9 in *Air Quality Analysis*, which are excerpted from that report and provided in **Appendix A**.

The estimation of air pollutant emissions for the action alternatives considered a number of factors to derive an inventory to support the analysis of impacts:

- Construction and operation methods (e.g., earthmoving, material loading, open-pit mining, gold extraction processes);
- Design criteria (e.g., equipment type and size, hauling distances);
- Emission abatement techniques (e.g., watering, baghouse, carbon filter);
- Material characteristics (e.g., moisture content, silt content, density); and
- Site characteristics (e.g., wind, precipitation).

Activity-specific (e.g., drilling, blasting, material crushing and conveying, refining, and other ancillary sources) emissions were estimated based on the maximum activity rates during each life-of-mine year, coupled with applicable emission estimation techniques. Maximum emissions were calculated on a short-term (hourly and daily) and a long-term (annual) basis for ore processing, mining operations, and construction activities. The full inventory of emissions for Alternative 1 and Alternative 2 (lime kiln operation) are provided in Appendices A and B, respectively, in the report Air Quality Analysis prepared for the Project (Air Sciences Inc. 2018), and reproduced in this document as **Appendix A**. The alternative emission inventory used for the IDEQ air permit application (Air Sciences 2020) is provided in **Appendix B**.

Emission Factor Use and Uncertainty

An emission factor is usually a well-supported, representative value that reasonably relates the quantity of a pollutant released from some activity or process to a quantitative measure of the intensity or rate of the activity. Examples of the measure of activity rate are acres disturbed, tons processed, gallons of fuel combusted, or thermal content of fuel utilized. The units of the corresponding emission factor would be the weight of pollutant released per unit of activity (e.g., pounds CO/1000-gallon fuel combusted, pounds PM per acre of soil disturbed). If the activity rate is quantified for a specific period of time, then the emission rate per that unit of time can be calculated:

$$E = A \times EF \times (1 - ER/100)$$

where:

E = emission rate (e.g., weight pollutant emitted per unit of time)

A = activity rate (e.g., a quantity of a particular activity per unit of time)

EF = emission factor (e.g., weight pollutant released per unit of activity)

ER = overall emission reduction efficiency (a percent of emission abated) for a control device or mitigation measure.

The estimation of the activity rates "A" for a future operation is subject to uncertainty for several reasons. It is not possible to predict with certitude the specific level of an activity, e.g., fuel combusted, area disturbed, or tons of material processed, for an operation during the early planning stages. As construction and operational parameters are more closely defined during detail design and actual construction, the activity rate estimates would be more certain. For pre-construction licensing and permitting, the values of "A" are selected to conservatively high-biased, to avoid under-estimating of emissions and impacts.

In general, emission factors are representative of a broad average of emissions data available for a specific source category. So, a single emission factor encompasses data from many actual operations that cover a relatively large range of actual emission rates per unit of activity. One should consider the AP-42 emission factors as representing an average of the range of measured or calculated emission rates. Approximately half of the sources in this population would have emission factors higher than the published average, and the remainder would have lower factors (EPA 2003).

In EPA Document AP-42, the level of uncertainty in a given factor is indicated by an "emission factor rating" with values ranging from "A" for best accuracy, and "E" for greater uncertainty. To illustrate the level of confidence in judging emission estimates, it can be noted that nearly all the emission factor values in Section 11.19.2 in Document AP-42, which is relied upon for many Project sources, have emission factor ratings of "D" or "E" (EPA 2003). To compensate for this uncertainty, the accepted practice is to over-estimate the activity rates for a given operation to avoid under-reporting the final estimates. It is also noteworthy the guidance from the State of Nevada, which is the home of numerous surface gold mines, supports the use of factors from this AP-42 section for surface mining operations (NDEP 2017).

Rationale for Emission Factor Selections Used for the Project

Mining operations, such as those described for the Stibnite Gold Project (the Project) involve a large number of emission source categories characterized by the type of process, material processed, and equipment used. For the Project air pollutant emission sources, activity-specific emission factors and techniques provided in industry-standard technical documents. The remainder of this section provides the rationale for emission factor selection, organized by the tables reproduced in this Appendix. These factors were used for the emission inventory and air impact modeling study prepared for the Project. While alternative emission factor choices are available in the literature, the discussion below describes the

reasoning why the selected factors were used. Most emission factor selections followed guidance from the Nevada Division of Environmental Protection (NDEP 2017).

Table 4. Process Source EF from AP-42.

Material Transfer, Crushing, Screening, AP-42 Table 11.19.2-2: For these operations involving transfer and processing of gold or and waste rock, the emission factors in Table 11.19.2-2 are based on data from processes and materials with close physical similarity to the Project. These factors have ratings of C or D, which indicates moderate uncertainty in using these values for a specific process source. As described in Section 11.19.2:

> Major rock types processed by the crushed stone industry include limestone, granite, dolomite, traprock, sandstone, quartz, and quartzite. Minor types include calcareous marl, marble, shell, and slate. Rock and crushed stone products generally are loosened by drilling and blasting and then are loaded by power shovel or front-end loader into large haul trucks that transport the material to the processing operations. Techniques used for extraction vary with the nature and location of the deposit. Processing operations may include crushing, screening, size classification, material handling and storage operations.

Ball Mill, AP-42 Table 11.19.2-4: The ball mill for the project will be handling minerals of the same nature as that used to derive the emission factors in Table 11.19.2-4. This is a broadly representative value for this type of source. Based on the references cited in AP-42, this factor was derived by the EPA using data obtained from the Pulverized Mineral Division of the National Stone, Sand, and Gravel Association.

Lime Kiln Crushing and Transfer, AP-42 Table 11.17-4: One alternative that will be addressed in the EIS is the implementation of an on-site limestone recovery and lime kiln operation. For this alternative, the emission factors cited in Air Quality Analysis are specifically for the lime production process, using limestone as the raw materials, which would differ from the run of mine ore and waste rock otherwise used in the Project.

Lime/Cement/Shotcrete Silo Storage, Aggregate Bin, Central Mixer, AP-42 Table 11.12-2: The material involved in these steps for the Project most closely resemble the physical materials and processes of the concrete batching industry. The size distribution and moisture content would be comparable to the raw materials used for blending concrete. The silos, transfer equipment, and the cement mixer (stationary or mobile) would be essentially identical to the industry sources in this AP-42 section.

Prill Silo Loading/Unloading, AP-42 Table 8.3-2: This operation refers to the silo loading and unloading of ammonium nitrate "prill", which is a solid form of the chemical produced for blending of ANFO explosive. This matches the actual material and physical handling operations for prill that are describe in this section of AP-42:

> Ammonium nitrate is marketed in several forms, depending upon its use. . . .Solid ammonium nitrate may be produced in the form of prills, grains, granules, or crystals. Prills can be produced in either high or low density form, depending on the concentration of the melt. High density prills, granules,

and crystals are used as fertilizer, grains are used solely in explosives, and low density prills can be used as either.

Propane-fired Heaters and Boilers, AP-42 Table 1.5-1: This table provides the accepted factors for external combustion equipment using liquefied petroleum gas (LPG), which is the commercial form of propane that would be used by the process sources. Although this table and the individual average values are based on a substantial data set, the emission factors have a rating of "E". This is the ranking with most uncertainty, due to the wide variation in the emissions data, fuel characteristics, and combustion conditions for the equipment in this source category.

Table 5. Process Source EF from Similar Source Test Data or Permit Limits

In this table, the selected emission factors are derived from similar gold ore refining and related processes in Nevada. There are numerous gold mines and processing facilities in Nevada, and these are regulated by the Nevada Division of Environmental Protection (NDEP) that demonstrates compliance with permit conditions through reference method testing. The physical similarity of the listed processes at gold mines in Nevada to those planned for the Project, and the level of data quality underlying these emission rates, supports the use of the Nevada mine emission rate data for these sources that are specific to gold ore processing. The processes and materials processed (low-moisture, gold-bearing ores) for the sources described in the NDEP information are closely resemble these same point sources that would be included in the Project. The individual steps in refining are well-established by industrial practice, and do not differ significantly between facilities.

The primary consideration for acceptance of an emission factor or emission rate data for a given source is whether the source characteristics underlying the selected factor are more representative of the activity than for other alternative emission factors that could be adopted. There is limited literature on published emission factors for the gold ore refining and concentrate bagging processes listed in Table 5, and those published factors represent operations that are not specific to gold extraction, or bagging of powdered metal concentrates. In such cases, emission factors or rates can be developed from alternative information, that has been accepted by another state agency, and that more closely aligns with the processes of interest. This can include stack test results and other engineering analyses provided by air quality agencies that support permit compliance, as is the case for the NDEP factors listed in Table 5 (NDEP 2012; NDEP 2015).

The sources listed in Table 5 are process point sources. For these specific sources, the emission characteristics rely on fuel combustion, nature of the material being bagged, and the physical treatment of the material involved (e.g., ore heating in the autoclave, stripping of carbon by heating in a kiln, melting of precipitated gold sludge in a furnace). The processes and materials processed (low-moisture, gold-bearing ores) for the northern Nevada sources described in the NDEP information are comparable to these same point sources included in the Project. Gold mines in Nevada are regulated by NDEP, so the supporting emission information is also viewed as technically credible.

For several processes that are specific to gold ore processing, Midas Gold elected to use NDEP information for gold refining emission rates, rather than EPA Document AP-42. However, at the time of this report it is not confirmed by IDEQ that NDEP emission factors will be acceptable for permitting of

the Project. The IDEQ will review and have final approval of the use of these Nevada gold refining process factors as part of the air permit development for the Project. However, the physical similarity of the listed processes at gold mines in Nevada to those for the Plan supports the use by Midas Gold of the Nevada emission factors for these sources that are specific to gold ore refining.

Table 6. EF Used to Calculate Mining Activity Emissions

Drilling, AP-42, Table 11.9-4, Blasting (PM), Dozing and Grading, AP-42 Table 11.9-1: This section of AP-42 addresses surface coal mining sources. However, in AP-42 this is the sole industry for which emission factors for drilling, blasting, bulldozing and surface grading are provided for a extractive mining facility, versus a more generic construction environment. The Project inventory follows accepted practice in using these mining emission factors for the general operations that involve surface overburden and waste rock, which it has in common with surface coal mining.

Blasting (CO), AP-42 Table 13.3-1: There is limited published information on the nature of pollutant emissions due to the ANFO as a blasting agent. The references for this table in AP-42 are dated 1974, and 1976, when measurement techniques were not as sophisticated or accurate as later analytical instruments. The factor rankings are "D" which infers relatively high uncertainty. Normal practice is to use the values in this AP-42 table as a default, unless more recent and accurate information is available.

Blasting (NO_X) CSIRO 2008, and (SO_2) material balance: More recent data than that in AP-42 was obtained for NO_X emissions due to blasting at surface mines, and was preferred for NO_X for this source (CSIRO 2008). A material balance for SO_2 uses the actual sulfur content of the blasting agent for the Project, which is preferable to an industry-wide average value.

Truck Hauling, Water Trucking, Vehicle Travel on Burntlog Route and Warm Lake Route, EF Equations in AP-42 Section 13.2.2: These equations are the accepted correlations for a wide variety of vehicle travel on unpaved ground, for road travel, construction, and mining operations. The selection of parameters for the correlation 1a (silt, and mean vehicle weight) were vetted by the agencies during initial development of this Project inventory.

Truck Loading, Unloading and Wet Drilling, AP-42 Table 11.19.2-2. See the discussion of the AP-42 table in under Table 4, above. These calculations also use the ratio of $PM_{2.5}$ to PM_{10} that is used to characterize emission from "batch drop" of bulk materials, which are correlated to the prevailing wind speed and material moisture.

Helicopter, AP-42, Volume II, Table II-1-3-7: This is the set of engine tailpipe emission factors that are published by EPA that are specific to this category of aviation engine.

Table 7. MOVES 2014a EF Used to Calculate On-Road Vehicle Tailpipe Emissions

The MOVES program 2014a version is the most recent tool for the estimation of on-road vehicle tailpipe emissions. The key parameter is the selection of vehicle categories and weight classes for use of the model. The categories used in this case match well with the roster of vehicles planned for the Project (EPA 2015).

Table 8. EF Used to Calculate Construction Activity Emissions

Dozing, Compacting, Grading, Table 11.9-1, Scraper Unloading, AP-42 Table 11.9-4: Refer to the discussion of these AP-42 tables under Table 6, above.

Scraper in Travel, Topsoil Removal, Overall General Construction, AP-42 Table 13.2.3-1: For construction operations that are not directly associated with mining, such as scraper travel, topsoil handling, and generic site grading, the emission factors in Section 13.2.3 are normally used. These types of operations are characterized by a need to estimate site-wide construction emissions that encompass the typical range of diverse activities, without regard to the actual plans of any individual construction project. For these reasons, this section offers accepted methods by which site-specific emissions may be estimated.

Material Loading, Material Dumping, AP-42 Section 11.19.2-2: Refer to the discussion of this AP-42 table under Table 4, above. For these construction operations at the Project, the material handled is of the same nature as that involved in crushed stone extraction and handling operations.

Table 9. Control Techniques and Efficiencies in Emission Calculations

For this table, it should be noted that with two exceptions, the emission factors that are identified in the preceeding tables include the effect of controls in the published factors. The categories of unpaved road and underground belt material transfers have control efficiencies that are calculated using correlations in AP-42, Section 13.2. The parameters used in these correlations and the resulting efficiency values have been vetted by the reviewing agencies.

Section 1

Introduction

1.1 Purpose

This Transportation Management Plan (TMP) is a facilities management component plan (Appendix FM-4) of the Stibnite Gold Project (SGP) Environmental Monitoring and Management Program (EMMP; Brown and Caldwell 2021). The purpose of the EMMP is to address environmental monitoring and management requirements in a comprehensive, systematic, planned, and documented manner. This TMP documents the methods (design features, material management, and environmental protection measures [EPMs]) for the SGP to comply with regulatory requirements and manage responsibilities for worker, public, and environmental safety standards of federal and state agencies and Perpetua Resources Idaho, Inc. (Perpetua Resources), formerly Midas Gold Idaho, Inc. (Midas Gold). This Plan will inform standard operating procedures to be incorporated into the design, construction, operation, and maintenance of the SGP transportation system.

Upon United States Forest Service (USFS) signature of the Record of Decision (ROD), Perpetua Resources will review any additional or modified requirements to the TMP and submit a revised TMP to incorporate the modifications and additions.

Additionally, as Perpetua Resources proceeds with the SGP and implements the design features, EPMs, and monitoring, the TMP will be revised if measures are determined to be overly restrictive or not functioning as intended. Similarly, environmental conditions described herein may change to a degree that warrants revising the TMP to address the changes.

1.2 Background

The SGP is a proposed open pit mine in the mountains of central Idaho that needs to provide safe access for the mine site and off-site support facilities. The SGP is located in eastern Valley County, 92 air miles and 144 road miles northeast of Boise, Idaho, 44 air miles northeast of Cascade, Idaho, and 10 air miles east of Yellow Pine, Idaho (Figure 1-1). The construction, operation, reclamation, and closure phases of the SGP would take place over approximately 20 to 25 years, followed by post-closure monitoring and maintenance. Perpetua Resources considers it a critical aspect of the SGP to be able to provide safe, reliable transportation to and from the SGP site for employees, suppliers, and contractors while maintaining safe public access to National Forest System (NFS) lands, area residences, and recreational areas.

Use of access routes are for (1) primary mine access: the transportation of mine employees, equipment, and supplies to and from the mine site during SGP construction through closure; (2) USFS and other agency administrative access for land management and project inspections; and (3) continued public access to NFS land. Most access roads described herein would be used for all three types of access.

The SGP is currently undergoing environmental impact analysis under the National Environmental Policy Act. Following initial analysis in the SGP Draft Environmental Impact Statement (DEIS; USFS 2020), Perpetua Resources submitted improvements to the DEIS Alternative 2 to the USFS in October 2021 (Perpetua Resources' Refined Proposed Action – ModPRO2; Perpetua Resources 2021).

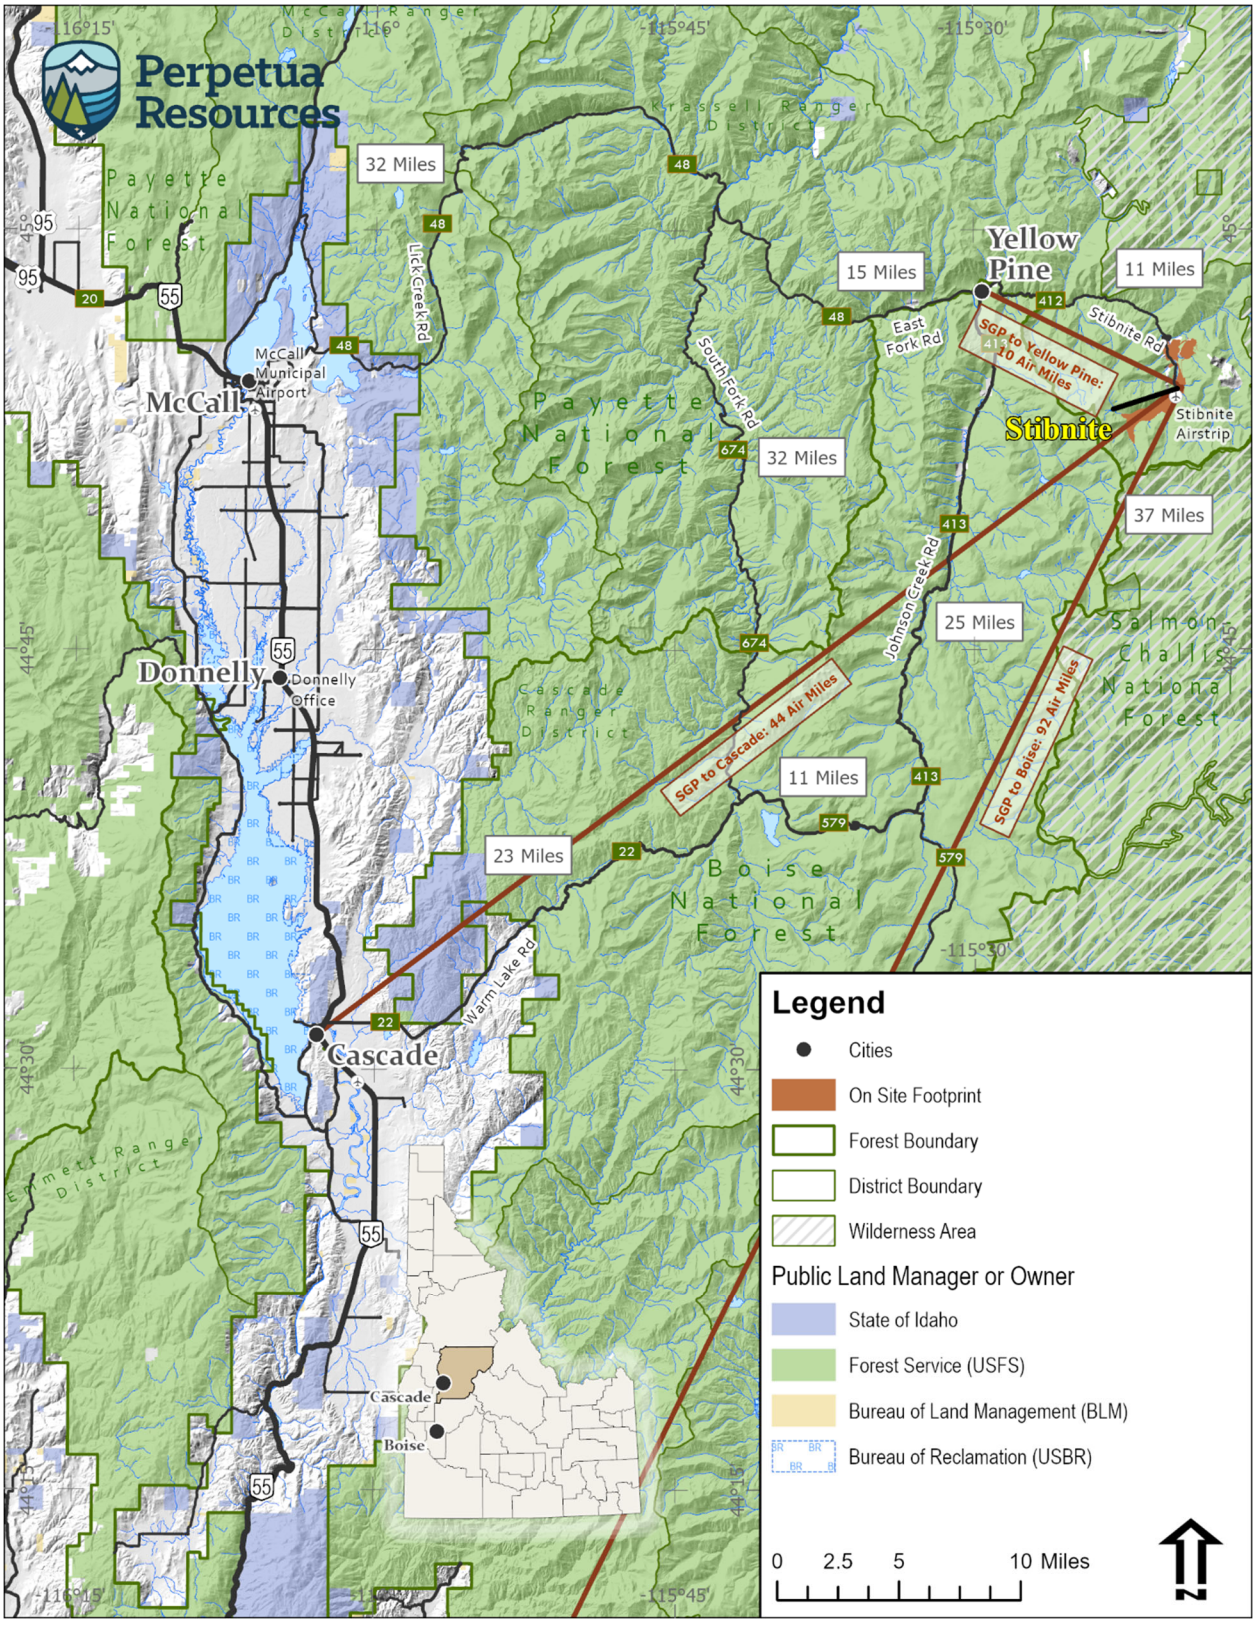

Figure 1-1. Vicinity Map

Primary mine access and public access routes carried forward for further evaluation in the forthcoming Supplemental DEIS (SDEIS) will include the refined version of DEIS Alternative 2 (ModPRO2; Perpetua Resources 2021) and a similarly refined DEIS Alternative 4 (Johnson Creek Route[1] Alternative for ModPRO2). While access differs for each alternative, the ModPRO2 mine plan and all included environmental protection measures and design features are applicable to both alternatives. Specific measures will be confirmed for the selected alternative after a ROD is signed by the USFS. This TMP will be revised to address the alternative selected at that time.

The USFS submitted requests for additional information (RFAI) in February 2021 (RFAI-120) and January 2022 (RFAI-131) to ensure that this TMP provides appropriate information to address public comments on the DEIS. Items requested to be addressed in the TMP are:

- Handling of cyanide
- Handling of antimony concentrate
- Expanding the geographic scope and updated data on spill risk analysis
- Addressing apparent inconsistencies or errors in the relevant sections of the DEIS
- Solid waste handling
- Safety measures to take during hazardous road conditions
- Locations of spill response materials
- Spill response capabilities of local communities
- Providing more information on potential risks related to transportation of hazardous materials
- Providing a description of the proposed cyanide packaging and shipping process
- Describing contingency plans for spills (including diesel spills) in the Project area or along access routes
- Describe contingency plans for wildfire in the Project area and access routes

Information on these topics is included in this Plan.

1.3 Transportation Plan Components

Documents that contain information pertinent to the TMP are listed below and are referenced throughout this TMP. Several of these documents include specific information on transportation system design features or EPMs.

Stibnite Gold Project: Seasonal Public Access – Warm Lake Road and Burntlog Route (Midas Gold 2020a): This document was submitted to the USFS on May 27, 2020. It includes a discussion on expanded public wintertime access on Warm Lake Road east of Warm Lake Lodge due to Perpetua Resources year-round Project access requirements for the life of the mine. Options for appropriate measures to ensure safe public use of the roadway are proposed.

SGP Access Management Plan (Midas Gold 2020b): This document was submitted to the Idaho Department of Environmental Quality (IDEQ) on April 15, 2020, to respond to comments on Perpetua Resources SGP Air Permit to Construct (PTC) Application. Adequate demonstration of appropriate access control for the through-site public access alternative was requested to support ambient air quality modeling parameters included in the permit application.

[1] The Yellow Pine Route is the mine access route assessed in the SGP DEIS (USFS 2020) as Alternative 4. Here, and in forthcoming documents, the Yellow Pine Route is renamed as the Johnson Creek Route. The terms are synonymous and refer to the Project access route that includes Johnson Creek Road (CR-10-413) and Stibnite Road (CR-50-412).

Stibnite Gold Access Roads Snow Avalanche Hazard Assessment for Access Roads (Dynamic Avalanche Consulting, LTD 2021): This document was prepared to support this TMP and is included as Attachment A of this report. It provides additional baseline information regarding identified avalanche slide/chute locations and includes proposed monitoring and mitigation for avalanche occurrences discussed in this TMP.

Perpetua Resources Emergency Response Plans and Emergency Standard Operating Procedures: These documents are referenced in Section 3 of this TMP and include important information regarding best practices and standard procedures to ensure the health and safety of employees, contractors, and the public, and to protect the environment. These are living documents that reflect Perpetua Resources current state of operations and will be updated accordingly as the Project progresses.

1.4 Regulatory and Forest Planning Framework

Perpetua Resources prioritizes the health and safety of people, the protection of the environment, and environmental sustainability. This TMP is prepared in accordance with the Core Values and Guiding Conservation Principles presented in the SGP Plan of Restoration and Operations (PRO; Midas Gold 2016). Transportation routes will be designed to provide safe, reliable roadways that promote health and safety and reduce environmental impacts. Plans for public transportation routes consider that any modifications to access to the National Forest must be offset by options that are likewise (and above all) safe to travel upon, reliable, and reasonably comparable to current levels of access.

As the SGP will be located on federal land and county roads, and is regulated by federal, state, and county regulations, this plan demonstrates how Perpetua Resources will comply with these regulations as they apply to the transportation portion of the SGP. Primary regulations are described below.

1.4.1 Environmental Regulations

Federal and state environmental regulations are applicable to the TMP to address the effects of transporting people, materials, equipment, and waste products to and away from the SGP site. The EMMP notes relevant environmental regulations that apply to transportation management and describes briefly how they are addressed in Section 3 of this Plan:

Endangered Species Act (United States Fish and Wildlife Service and National Oceanic and Atmospheric Administration): Endangered Species Act Section 7 consultation will cover potential impacts of vehicle/wildlife collisions and spills that could impact fisheries and wetlands.

Dredge and Fill in Waters of the United States (United States Army Corps of Engineers and Environmental Protection Agency): Waters of the United States that are subject to regulation under Section 404 of the Clean Water Act could be impacted by transportation during mining operations and post-closure restoration at the SGP.

National Oil and Hazardous Substances Pollution Contingency Plan (United States Environmental Protection Agency): National Oil and Hazardous Substances Pollution Contingency Plan defines the federal agency actions to responding to spills of oil or hazardous substances. This requires notification of any discharge, spill, or release, of a reportable quantity of a hazardous substance to the National Response Center through a toll-free telephone number. The National Response Center acts as the central clearinghouse for all pollution incident reporting.

Emergency Planning and Community Right-to-Know Act (Environmental Protection Agency): Section 312 of the Emergency Planning and Community Right-to-Know Act (EPCRA) contains requirements

for notifying emergency responders and emergency planning committees about the presence and use of hazardous and toxic chemicals at facilities. The EPCRA provisions help increase the public's knowledge and access to information on chemicals at individual facilities, their uses, and releases into the environment.

Hazard Communication (Occupational Safety and Health Administration [OSHA]): This act classifies the potential hazards of chemicals and communicates information concerning hazards and appropriate protective measures to employees. This includes development and implementation of employee training programs regarding hazards of chemicals and protective measures.

Hazardous Waste Operations and Emergency Response (HAZWOPER; OSHA): OSHA's HAZWOPER standards (in general industry, 29 Code of Federal Regulations [CFR] 1910.120; emergency response [§1910.38]; fire prevention plans [§1910.39]; and construction [§1926.65]) established health and safety requirements for employers engaged in these operations, as well as responses to emergencies involving releases of hazardous substances. HAZWOPER requires that employers follow specific work policies, practices, and procedures to protect their workers potentially exposed to hazardous substances.

Federal Mine Safety and Health Act of 1977 (Mine Act) as amended by the MINER Act of 2006. (Mine Safety and Health Administration [MSHA]): MSHA is responsible for enforcing the Mine Act, including the federal mine safety and health regulations outlined in 30 CFR, Subchapter K, Part 56 and 57 - Safety and Health Standards for Surface/Underground Metal and Non-Metal Mines. The purpose of these standards is the protection of life, the promotion of health and safety, and the prevention of accidents. They include requirements for new employee training and providing access to emergency response services.

1.4.2 Federal, State, and County Planning Framework

The SGP and associated transportation infrastructure occur in large part on NFS lands on the Payette National Forest (PNF) and the Boise National Forest (BNF). Therefore, the SGP must meet the requirements for a plan of operations for approval by the USFS for operations under regulations at 36 CFR 228 Subpart A, as well as the requirements for a plan of operations for approval by the Idaho Department of Lands (IDL) under state regulations and Idaho state code. The SGP DEIS (USFS 2020) describes applicable laws, regulations, policies, and plans for providing access across NFS lands for locatable mineral operations. Other applicable transportation management entities include the IDL and Valley County. Federal, state, and county planning documents relevant to this TMP are described below and are addressed by the design features, materials handling, and EPMs provided in Section 3.

United States Department of Agriculture Forest Service: 36 CFR 228.12 – Access:

- …Proposals for construction, improvement, or use of such access as part of a plan of operations shall include…location of the access route, design standards, means of transportation, and other conditions reasonably necessary to protect the environment and forest surface resources, including measures to protect scenic values and to ensure against erosion and water or air pollution.

United States Department of Agriculture Forest Service: 36 CFR 212 – Travel Management: Directives related to travel management on NFS lands include:

- §212.8 Permission to cross lands and easements owned by the United States and administered by the Forest Service.
- §212.9 Principles for sharing use of roads.
- (a) Road improvement. Use of a road for commercial hauling…will be conditioned upon improvement or supplemental construction of the road to safety and economically serve the

contemplated use, unless the Chief determines that the safety and economy of the established and foreseeable use by the United States, its users and cooperators will not be impaired by the use for which application is being made…

Mine Safety and Health Administration Department of Labor: 30 CFR Chapter 1 Subchapter A: MSHA health and safety regulations specific to transportation management are generally restricted to mine site operations. However, best practices included in the MSHA regulations that may be applicable to the transportation system include:

- §56.4330 Firefighting, evacuation, and rescue procedures.
- (a) Mine operators shall establish emergency firefighting, evacuation, and rescue procedures. These procedures shall be coordinated in advance with available firefighting organizations.
- (b) Fire alarm procedures or systems shall be established to promptly warn every person who could be endangered by a fire.
- (c) Fire alarm systems shall be maintained in operable condition.
- §56.9313 Roadway maintenance - Water, debris, or spilled material on roadways which creates hazards to the operation of mobile equipment shall be removed.
- §56.9315 Dust control - Dust shall be controlled at muck piles, material transfer points, crushers, and on haulage roads where hazards to persons would be created as a result of impaired visibility.
- §56.11001 Safe access - Safe means of access shall be provided and maintained to all working places.
- §56.18013 Emergency communications system - A suitable communication system shall be provided at the mine to obtain assistance in the event of an emergency.

Forest Roads and Trails Act:

- 7703.24.4: Intermittent-service roads may provide access for USFS administration of NFS lands or for motor vehicles authorized by contract, permit, or under other written authorization. These roads should continue to be managed, maintained, and operated consistent with the applicable land management plan and applicable road management objectives.

Payette National Forest Land and Resource Management Plan (Payette Forest Plan; USFS 2003) goals and objectives:

- FRG001 - Intermittent-service roads may provide access for USFS administration of NFS lands or for motor vehicles authorized by contract, permit, or under other written authorization. These roads should continue to be managed, maintained, and operated consistent with the applicable land management plan and applicable road management objectives.
- FROB05 – Coordinate transportation systems, management, and decommissioning with other federal, state, and county agencies, tribal governments, permittees, contractors, cost-share cooperators, and the public to develop a shared transportation system serving the needs of all parties to the extent possible.
- FRST02 – To accommodate floods, including associated bedload and debris, new culverts, preplacement culverts, and other stream crossings shall be designed to accommodate a 100-year flood recurrence interval unless site-specific analysis using calculated risk tools, or another method determines a more appropriate recurrence interval.
- FRST04 – Roads shall be constructed to a standard appropriate to their intended use, considering safety and concerns for resource degradation.

- FRST05 – Mitigate handling of road waste material (e.g., slough, rocks) to avoid or minimize delivery of waste material to streams that would result in degradation of soil, water, riparian, and aquatic resources.

Boise National Forest Land and Resource Management Plan (Boise Forest Plan; USFS 2010):

- FRG001 - Provide and maintain a safe, efficient forest transportation system that meets resource management and access needs, while mitigating degrading resource effects.
- FROB05 – Coordinate transportation systems, management, and decommissioning with other federal, state, and county agencies, tribal governments, permittees, contractors, cost-share cooperators, and the public to develop a shared transportation system serving the needs of all parties to the extent possible.
- FRST02 – To accommodate floods, including associated bedload and debris, new culverts, preplacement culverts, and other stream crossings shall be designed to accommodate a 100-year flood recurrence interval unless site-specific analysis using calculated risk tools, or another method determines a more appropriate recurrence interval.
- FRST04 – Road shall be constructed to a standard appropriate to their intended use, considering safety and concerns for resource degradation.
- FRST05 – Mitigate handling of road waste material (e.g., slough, rocks) to avoid or minimize delivery of waste material to streams that would result in degradation of soil, water, riparian, and aquatic resources.

Forest Service Handbook 7709.56 Road Preconstruction Handbook Chapter 40 – Design: This document provides guidance for the selection of design elements and standards required to meet design criteria and resource management prescriptions as set forth in the road management objectives.

United States Department of Transportation – Has jurisdiction over hazardous materials (including explosives) while they are in transit, whether by rail, water, motor carrier, air, or other conventional means. The United States Department of Transportation (USDOT) regulates the transportation of hazardous materials from the Hazardous Materials Transportation Act,49 United States Code 5101 et seq., including shipper and carrier responsibilities, communications training requirements, packaging, and emergency response.

Valley County Master Transportation Plan (Holladay Engineering Company 2008): The Valley County Master Transportation Plan includes recommendations for the maintenance of gravel roads (pp 69, 70).

- The debris and excess vegetation like grass and weeds should be removed from the bottom of ditches and culverts at the beginning of every fall season.
- The ditches should be graded by removing excess silt and sand sediments and reestablishing longitudinal and side slopes at the beginning of every spring and fall seasons.
- Road cross slope and shoulder slopes should be inspected and graded as required and at a minimum of the beginning of spring and fall seasons.
- Repair and/or upgrade culverts depending on storm water demand and existing culvert capacity each fall season.

Section 2

Transportation System

Existing access routes into the Stibnite area, the access route during construction (Johnson Creek Route), and SGP and public access routes proposed during the life of the SGP for the ModPRO2 (modified DEIS Alternative 2; Burntlog Route) and modified DEIS Alternative 4 (Johnson Creek Route) are discussed below.

2.1 Existing Conditions

Existing access to SGP from McCall and Cascade is primarily via paved roads that lead to unpaved county and NFS roads. Three existing primary routes are illustrated in Figure 2-1.

- Lick Creek Route: Stibnite can be accessed from McCall during non-winter conditions by traveling east on the Lick Creek portion of McCall-Stibnite Road (CR 50-412; Lick Creek Road) for approximately 37 miles to the East Fork South Fork portion of McCall-Stibnite Road (CR 50-412; East Fork Road), then approximately 16 miles to the village of Yellow Pine, and approximately 14 miles east on Stibnite Road. Lick Creek Road is closed during the winter because of a high avalanche potential; however, East Fork Road and Stibnite Road are plowed from South Fork Salmon River Road (forest road [FR] 50674) to Yellow Pine by Valley County and from Yellow Pine to the mine site by Perpetua Resources to access their private land inholdings in the area.
- Johnson Creek Route: During non-winter conditions Stibnite can be accessed from Cascade by traveling northeast from State Highway 55 on Warm Lake Road (CR 10-579) for approximately 34 miles to Landmark, then north on Johnson Creek Road (CR 10-413) for approximately 25 miles to the village of Yellow Pine, and approximately 14 miles east on Stibnite Road (CR 50-412). During the winter, Valley County plows approximately 10 miles of Johnson Creek Road from Yellow Pine to Wapiti Meadow Ranch and grooms the remaining 17 miles of Johnson Creek Road from Wapiti Meadow Ranch to Warm Lake Road (CR 10-579) at Landmark for over- snow vehicle (OSV) use. Valley County does not plow Warm Lake Road from Warm Lake to Landmark. This section is a designated groomed OSV route.
- South Fork Salmon River Route: Stibnite may be accessed year-round from Cascade by traveling northeast from State Highway 55 approximately 24 miles northeast on Warm Lake Road (CR 10-579) to the intersection with South Fork Salmon River Road (FR 474), then north on South Fork Salmon River Road (FR 474 to FR 50674) for approximately 30 miles to McCall-Stibnite Road (CR 50-412), and approximately 30 miles east on McCall-Stibnite Road (i.e., East Fork Road and Stibnite Road). Perpetua Resources (under agreement with Valley County) plows along Stibnite Road. This route currently provides the only access to the mine site during winter months.

The Lick Creek Route and South Fork Salmon River Route were evaluated for suitability as part of the mine transportation network and were dismissed from further consideration.

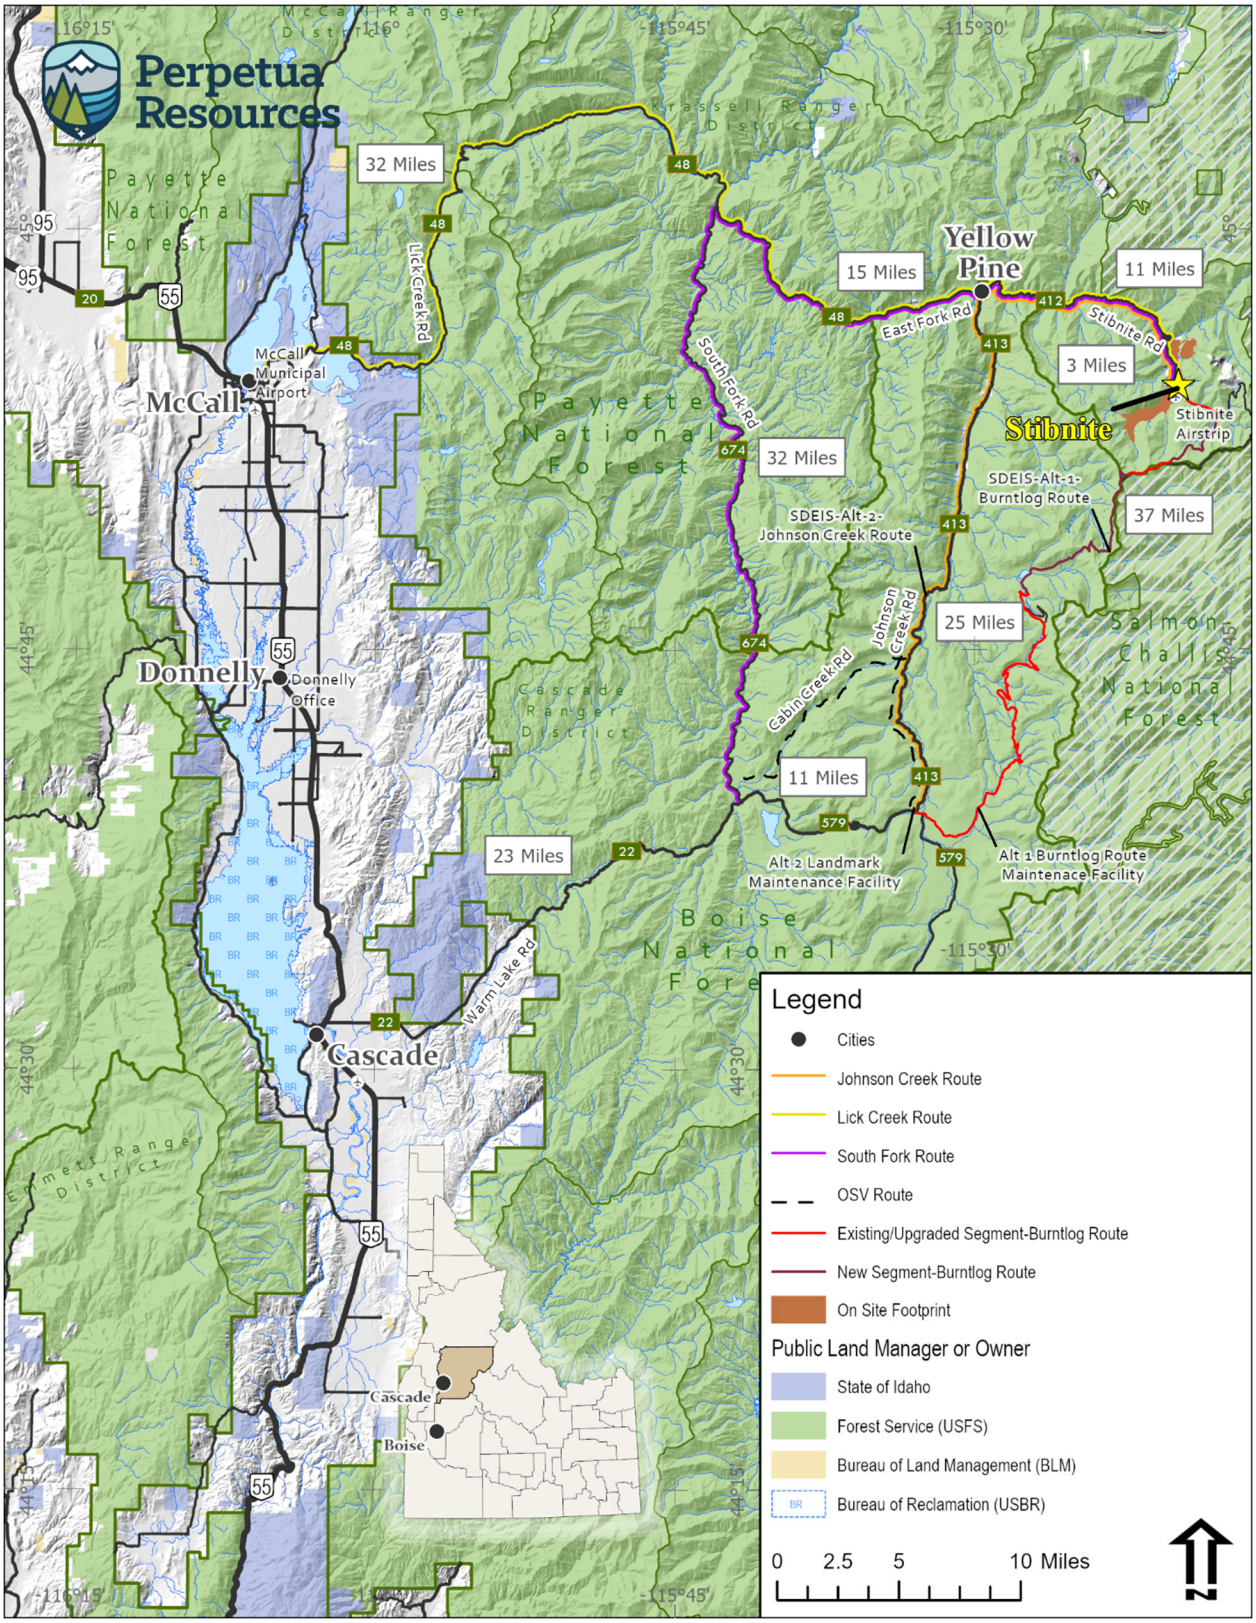

Figure 2-1. SGP Transportation System – Current Conditions

2.2 Access Routes

SGP access routes for the ModPRO2 (Burntlog Route) and modified DEIS Alternative 4 (Johnson Creek Route) will be carried forward for further environmental impact analysis in the SGP SDEIS. Current and proposed conditions for the roads comprising these two alternatives are described in this section. Alternative access routes are illustrated on Figure 2-2.

2.2.1 Warm Lake Road (Cascade to Landmark)

Current Conditions: Warm Lake Road (CR 10-579) is a two-lane (one lane each direction), asphalt-paved roadway with lane markings. The route starts in Cascade, Idaho at an intersection with Idaho State Highway 55 and continues eastward for approximately 34 miles, ending at Johnson Creek Road (CR 10-413) at Landmark. Warm Lake Road is under the jurisdiction of Valley County (USFS 2020; Table 3.16-1). Currently, Valley County does not maintain Warm Lake Road in winter beyond Warm Lake Lodge. With adequate snowpack, an eight-mile segment of the Warm Lake Road east of Warm Lake Lodge is used as an OSV route, allowing access into Landmark and points beyond. Warm Lake Road is used to access recreational sites and residences and has the highest existing use among roads considered in this TMP (1,174 average annual daily traffic [AADT]; USFS 2020: Table 3.16-2).

Proposed Use: SGP will need year-round passenger and delivery truck access from the onset of construction through the life of the mine. Warm Lake Road is suitable for this use in its current condition and would be a necessary road segment for both the ModPRO2 (Burntlog Route) Alternative (DEIS Alternative 2) and the Johnson Creek Route Alternative (DEIS Alternative 4). During SGP construction, operations, and reclamation/closure phases (approximately 23 years), Perpetua Resources will sign a road use agreement with Valley County to conduct wintertime maintenance on the full length of Warm Lake Road from State Highway 55 to Landmark to ensure safe, year-round access to the sole route of ingress/egress to the SGP for all mine support traffic. This would include snow removal and road sanding, as appropriate, to maintain a safe driving surface. Commitments for wintertime maintenance of Warm Lake Road would be documented in a Road Maintenance Agreement with Valley County. Anticipated road use between the Stibnite Gold Logistics Facility (SGLF) and the SGP will be similar to that which is described for SGP DEIS Alternative 2 (USFS 2020); it is expected to peak at 65 AADT during the construction phase of the SGP and reduce to 50 AADT during the operations phase.

Perpetua Resources wintertime maintenance and use of Warm Lake Road would result in two changes to current traffic conditions:

a. Warm Lake Road east of Warm Lake Lodge will not be available as a recreational OSV route from construction through reclamation of the SGP (approximately 20 to 25 years). To replace this recreational use, a dedicated alternative OSV route would be established from the Warm Lake area to Landmark via the Cabin Creek/Trout Creek drainages and adjacent to Johnson Creek Road. Establishing this replacement OSV route would minimize the interactions between SGP traffic and recreational traffic in the winter. The proposed OSV route is illustrated in Figure 2-1.
b. Expanded wintertime public vehicle access on Warm Lake Road east of Warm Lake Lodge would commingle SGP and public travel and thus would be a public health and safety concern. Perpetua Resources proposed several alternatives to address this concern in a memorandum submitted on May 27, 2020 (Midas Gold 2020a). The alternatives include: (1) no seasonal access restriction: broad distribution and availability of public information to deter winter condition travel past the point of current access, (2) administrative seasonal access restriction: static and electronic signage and automated timed stoplights at the point

of public access control, or (3) engineered seasonal access restriction: a physical blockage (lift-gate) near Warm Lake lodge consisting of a manual, electronic or remote-monitored gate. Procedures for managing winter public access on Warm Lake Road east of Warm Lake lodge during the life of the SGP will be determined through consultation with Valley County and the USFS.

2.2.2 Burntlog Route (ModPRO2)

Current Conditions: The Burntlog Route in its entirety does not exist (Figure 2-1); it is proposed as the primary mine access route to the SGP under the ModPRO2 Alternative. The roads that would be connected to create the Burntlog Route (Burntlog Road [FR-447], Meadow Creek Lookout Road [FR 51290], and Thunder Mountain Road [FR 440]) are USFS local roads that connect terminal facilities (e.g., trailheads) with collector roads, arterial roads, or public highways and usually serve a single purpose and receive intermittent use (USFS 2020; Sec. 3.16.3.4). Traffic volume data for Burntlog Road and Thunder Mountain Road indicate AADT of 27 and 11, respectively (USFS 2020; Table 3.16-2).

Proposed Use: Under the ModPRO2, the Burntlog Route would be the designated SGP access route (Figure 2-2). The Burntlog Route would connect the eastern end of Warm Lake Road (at Landmark) to the site (to the northeast) via the existing Burntlog Road (FR 447), Meadow Creek Lookout Road (FR 51290), Thunder Mountain Road (FR 50375) and approximately 15 miles of new road constructed to connect the three. Anticipated road use due to access activities would peak during the SGP construction phase at 65 AADT and would be 50 AADT during the operations phase of the SGP (USFS 2020).

The Burntlog Route would be a two-lane, all-weather, gravel-surfaced road. The full length of the Burntlog Route - including improvements on existing portions would be required to meet all applicable USFS design criteria as well as criteria for semi-trailers (WB-50) and oversize deliveries of large equipment (WB-67) (Parametrix 2018c). Perpetua Resources would conduct all wintertime maintenance of the Burntlog Route for the full duration of its existence (approximately 23 years).

2.2.3 Johnson Creek Route

Current Conditions: The Johnson Creek Route refers to an existing route currently used to access SGP (see Section 2.2). The Johnson Creek Route originates at Landmark at the intersection of Warm Lake Road and Johnson Creek Road and extends north on Johnson Creek Road (CR 10-413) for approximately 25 miles to Yellow Pine. From there, the Stibnite Road (CR 50-412) continues eastward to Stibnite and passes through the site and consists of approximately 14 miles of variable width (one-lane to two-lane), native-surfaced (dirt) roadway (Figure 2-2). Stibnite Road connects to Thunder Mountain Road on the southeastern portion of the Stibnite site and currently provides public access through the site. Johnson Creek Road (CR 10-413), and Stibnite Road (CR 50-412) are considered county collector roads per the Idaho Transportation Department (ITD) functional classification, which generally move traffic from local roads to the arterials or other points of interest. Traffic volume data for Johnson Creek Road and Stibnite Road indicate AADT of 57 and 39, respectively (USFS 2020; Table 3.16-2).

Portions of Johnson Creek Road (from Wapiti Meadows southward) are currently used as a groomed OSV trail during winter and use of the Johnson Creek Route by mine-related construction traffic would conflict with this existing groomed OSV trail. Thus, while the Johnson Creek Route is used as a construction access route, a temporary 15-foot-wide groomed OSV trail adjacent to Johnson Creek Road between the proposed Cabin Creek Groomed OSV Route and Landmark would be constructed (see Public Access below).

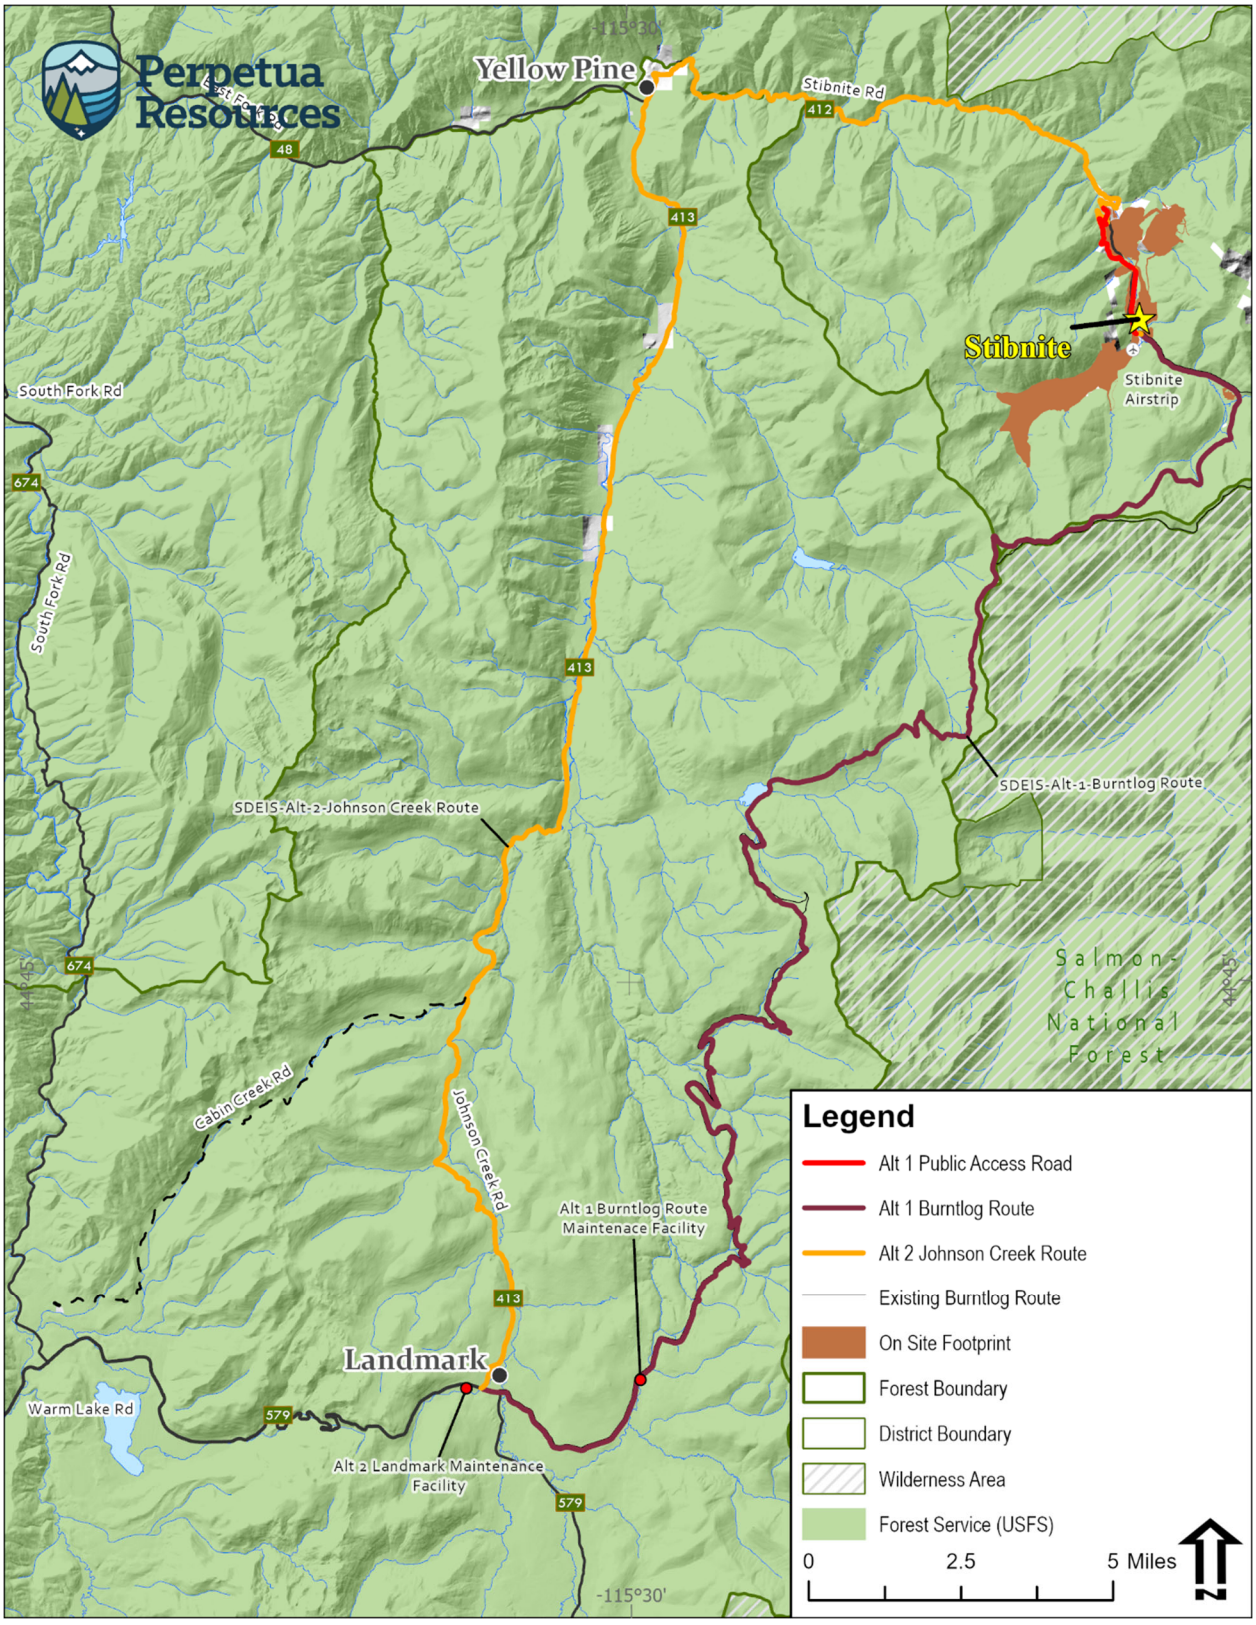

Figure 2-2. SGP Transportation System - Alternative Routes

2.2.3.1 Johnson Creek Route – Construction Phase (ModPRO2)

Proposed Use: During the first two years of the three-year construction phase of the SGP for the ModPRO2, mine-related traffic would access the mine site from State Highway 55, north of the city of Cascade, via Warm Lake Road (CR 10-579), then Johnson Creek Road (CR 10-413) to Yellow Pine, and from Yellow Pine to the mine site via the Stibnite Road segment of the McCall – Stibnite Road (CR 50-412). The USFS submitted RFAI-60 on October 28, 2017, to request additional information on any upgrades to the Johnson Creek Route that would be required for its use during the construction phase of the SGP. The response, submitted on January 4, 2018, notes that minor surface improvements (e.g., ditch and culvert repair, adding gravel, winter snow removal, and summer dust suppression) would occur on the Johnson Creek Route to reduce sediment runoff and dust generation. There would be no road alignment modification or widening of the existing roads for ModPRO2. Traffic volume data for the Johnson Creek Route during the ModPRO2 construction phase would be 65 AADT (USFS 2020).

For the ModPRO2 Alternative, once construction of the Burntlog Route has been completed, the Johnson Creek Route would no longer be used by mine-related traffic. While the Johnson Creek Route is in use, Perpetua Resources would coordinate with Valley County on the use and maintenance of the route for year-round access in accordance with Valley County's public road easement stipulations.

2.2.3.2 Johnson Creek Route – Construction and Operations Phase (Alternative 4)

Proposed Use: The Johnson Creek Route would be mixed SGP access/public access route under DEIS Alternative 4 and would be the only route of ingress/egress into the SGP. The full length of the Johnson Creek Route - particularly the Stibnite Road segment - would require significant improvements to serve as the primary access route and would be required to meet design criteria for WB-50 and WB-67 vehicles (semi-trailers and oversize deliveries of large equipment; Parametrix 2018c). Also, the Johnson Creek Route Alternative (DEIS Alternative 4) would increase the amount of interaction between the public and SGP traffic during construction and throughout the life of the mine. Improvements to Stibnite Road would require drilling and blasting rock overhangs, installing retaining walls, widening and straightening, drainage improvements (e.g., ditching, culvert repair), gravel surfacing and paving approximately one mile of road through Yellow Pine. Anticipated additional traffic on the Johnson Creek Route during SGP construction would be 65 AADT (USFS 2020) and 50 AADT during the operations phase of the SGP (USFS 2020). During the construction, operations, and reclamation/closure phases of the SGP (approximately 23 years), Perpetua Resources would establish a Road Maintenance Agreement with Valley County to conduct all wintertime road maintenance on Johnson Creek Road and Stibnite Road.

2.3 Public Access

Current conditions: Public access to Stibnite and surrounding area is primarily via paved roads that lead to unpaved county and NFS roads. The three existing primary routes to access the Stibnite area are described in the SGP DEIS (USFS 2020) and in Section 2.1 of this document and are illustrated in Figure 2-1. Proposed public access routes described below are included in Figure 2-3.

2.3.1 Burntlog Route (ModPRO2)

The Burntlog Route is the proposed SGP access route for the SGP ModPRO2 Alternative. During the construction of the ModPRO2 through-site public access road (described below), the Burntlog Route would serve as an alternative public access route to Meadow Creek Lookout Road (FR 51290).

2.3.2 OSV Route (Cabin/Trout Creek and Johnson Creek; Both Alternatives)

Due to year-round access to the mine site along Warm Lake Road (for both the ModPRO2 Alternative and DEIS Alternative 4) for the life of the SGP, an existing, approximately 8-mile groomed OSV trail from Warm Lake to Landmark would be closed. To replace this recreational use, a dedicated alternative OSV route would be established from the Warm Lake area to Landmark via the Cabin Creek/Trout Creek drainages. The groomed OSV trail would be approximately 10.4 miles in length on the existing road and would include an approximately 2-acre parking area west of South Fork Road, and a new 1.5-mile groomer access trail from the USFS Warm Lake Project Camp on Paradise Valley Road (FR 488) where the groomer would be stored. From Trout Creek to Landmark, an approximately 7-mile temporary groomed OSV trail would be maintained on NFS lands adjacent to the west side of Johnson Creek Road (CR 10-413). Portions of the temporary groomed OSV trail would be established using a snowplow wing attachment requiring some vegetation and tree removal to allow for safe snowplowing. The precise location of this trail is not yet determined, and in areas where topography and vegetation prevent using the wing attachment to establish the groomed OSV trail, sections would merge with Johnson Creek. Figure 2-1 and Figure 2-2 show the Cabin Creek/Trout Creek/Johnson Creek Road groomed OSV trail from Warm Lake Lodge to Landmark.

2.3.3 Stibnite Road – Through Site Public Access

Current Conditions: Stibnite Road (CR 50-412) extends from Yellow Pine to Stibnite and passes through the site connecting with Thunder Mountain Road on the southeastern portion of the Stibnite site. Stibnite Road provides public access and consists of approximately 14 miles of variable width one-lane to two-lane), native-surfaced (dirt) roadway (Figure 2-1). Stibnite Road is considered a county collector road per ITD functional classification, generally moving traffic from local roads to the arterials or other points of interest. Traffic volume data for Stibnite Road indicates an AADT of 39 (USFS 2020; Table 3.16-2).

Proposed Use (ModPRO2): Public access through the site for both Alternatives would realign Stibnite Road through the site to provide seasonal (non-winter), controlled, through-site access that is safe, provides travel-time comparable to current conditions, and is consistent with the USFS travel management plan.

For the ModPRO2, a through-site public access road would be constructed to replace the current access through the SGP site on Stibnite Road (FR 50375) during mine operations. During construction, public access through the SGP site on Stibnite Road would be restricted for one year or more while a new 4-mile long, 12-foot-wide gravel road is constructed to provide public access from Stibnite Road (FR 50412) to Thunder Mountain Road (FR 50375) (Figure 2-3). The public access road would be constructed on a widened bench in the Yellow Pine pit. South of the Yellow Pine pit, this road would pass under the haul road and continue southward, parallel to the mine haul road on a partially revegetated portion of a former haul road.

Southwest of the ore processing area, the public access road would connect with Thunder Mountain Road and continue toward the Worker Housing Facility, exiting the Project site to the southeast. Public access would be separated from other mine site roads by berms, security fencing, and an underpass to allow the public road to pass beneath the mine haul road. The underpass would be in the vicinity of Fiddle Creek. The public access road would not be plowed in the winter (current county maintenance standards) and signs would inform the public of seasonal and temporary closures.

Proposed Use (Johnson Creek Route Alternative): Through-site public access would be provided by shared public use of the primary mine access road for the Johnson Creek Route Alternative (Figure 2-3). Due to the design criteria for the mine access road to accommodate larger vehicles, the orientation of this route would differ from the ModPRO2, the road would be wider, would include

additional switchbacks, and would be constructed so that road gradients do not exceed 10 percent. South of the Yellow Pine pit, this road would diverge from the combined mine access/public access route and follow an alignment similar to the ModPRO2 through-site public access road. It would pass under the haul road and continue southward, and southwest of the ore processing area would connect with Thunder Mountain Road and continue toward the Worker Housing Facility, exiting the Project site to the southeast. This portion of the public access road (south of the Yellow Pine pit) would not be plowed in the winter (current county maintenance standards) and would not be accessible to the public.

Proposed Use (Both Alternatives): The through-site public access would be seasonal, similar to current conditions. During operations, public access through the mine site would be provided during the snow-free season to all vehicle types. Vehicles passing through the mine site would be required to check-in with mine personnel at the north or south mine site entry points to receive a safety briefing and to check-out with mine site personnel upon exiting the mine site. For safety purposes, no stopping or deviating from the public access road would be allowed. Mine site access would be restricted during road construction and maintenance, blasting, high wall scaling, mining in the immediate area of the road, and similar operations. During mine reclamation and closure, the portion of Stibnite Road (FR 50375) passing through the site will be relocated and reestablished east of the East Fork of the South Fork of the Salmon River (EFSFSR) to minimize waterway crossings, but otherwise will be in an alignment similar to its current configuration. The relocated Stibnite Road will provide permanent public access through the reclaimed site and will also provide mine site access for post closure monitoring and maintenance.

2.4 Mine Haul Roads

With the exception of a portion of the mine access/public access road west of the Yellow Pine pit (Johnson Creek Route Alternative) mine haul roads and access roads/trails on the mine site would not be accessible to the public. Haul roads would be used to transport ore, development rock, and reclamation materials from mining or storage areas to the ore processing facility or tailings storage facility (TSF) Buttress, or to transport vehicles to the mobile equipment maintenance shop. Personnel would primarily use haul roads for access to the reclamation and construction areas, pits, TSF, TSF Buttress, ore processing facility, water treatment plant, and maintenance areas. A typical haul road running surface would be approximately 87 feet wide. The haul roads would be built and maintained for year-round access and would be surfaced with gravel aggregate sourced from on-site development rock or aggregate borrow sources. Road maintenance activities would be conducted to manage fugitive dust emissions in accordance with the IDEQ Air PTC, and to maintain stormwater management features per the site multi-sector general permit Stormwater Pollution Prevention Plan (SWPPP; Aquionix, Inc. 2021). Perpetua Resources would maintain internal service and access roads and trail systems designed specifically for smaller vehicles and foot traffic to facilitate access to certain sites and facilities for safety and maintenance. These sites include water quality monitoring sites, well sites, radio communications tower, perimeter of the TSF, and various monitoring sites.

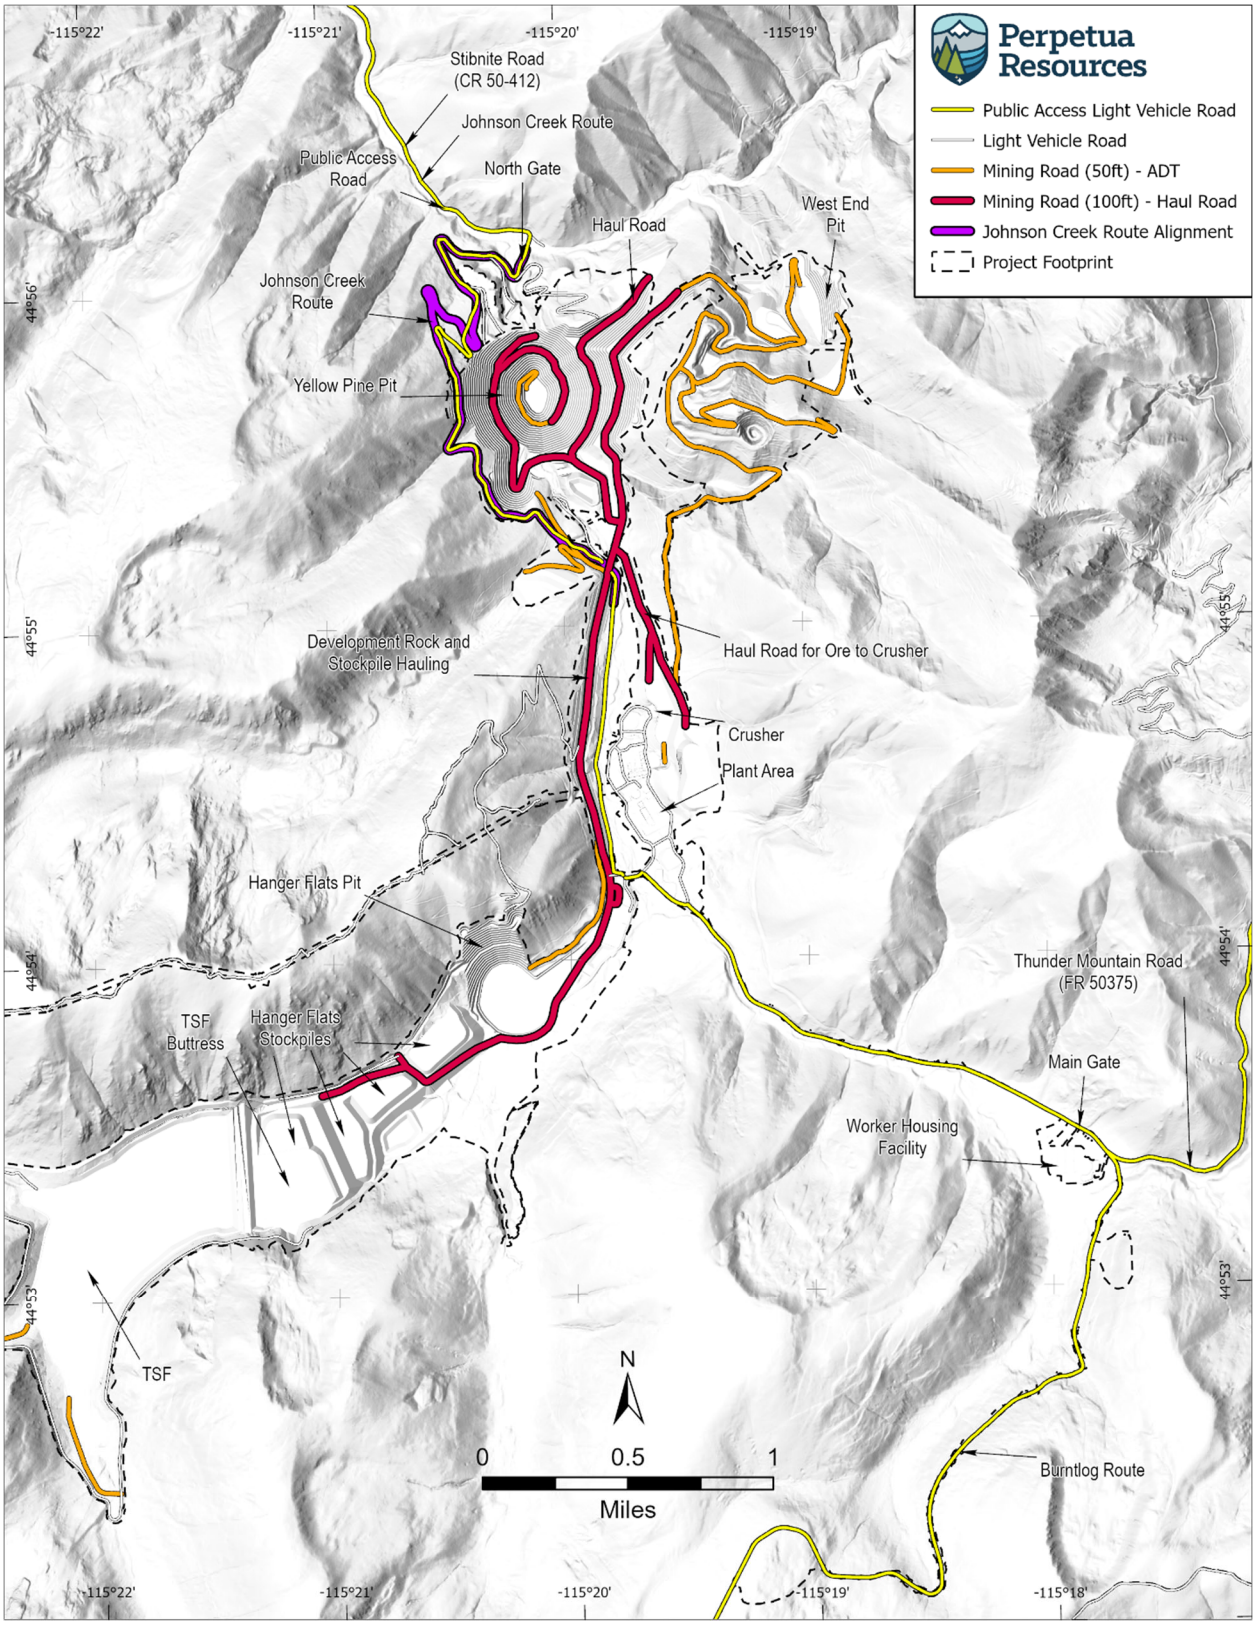

Figure 2-3. Mine Haul Roads and Facilities

Section 3

Design Features, Materials Handling, and Environmental Protection Measures

This section lists transportation design features, hazardous materials handling and spill response procedures, and EPMs to provide for public health and safety and protect environmental quality.

3.1 Design Features

The SGP includes several design features incorporated into the mine plan that are meant to minimize or avoid transportation related risks. These include road construction design standards to reduce sedimentation and dust impacts, road design features and maintenance protocols to address geologic hazards, road construction material choices to avoid surface water impacts, bridge restrictions and load hauling rules to increase safety, and a dedicated facility for road maintenance.

3.1.1 Road Construction Design Standards

Design standards for the access road are addressed in a Feasibility Design Memorandum (Parametrix 2018a) provided in response to RFAI-79 and in a Feasibility Study Access Road Design report (Parametrix 2018c). Applicable excerpts detail appropriate design standards relative to proposed road use and included provisions for oversized equipment that would be delivered to the SGP (e.g., the pressure oxidation autoclave).

- Road design, construction, and operation/maintenance will consider all practicable methods to avoid and minimize potential impacts to waters of the United States (Dredge and Fill in waters of the United States).
- Guidelines and standards for designing NFS Roads as published in the USFS handbook (FSH) 7709.56 (published in 2010 with partial amendments in 2011 and 2014) were used as the primary basis for the design criteria. The FSH incorporates design standards for two lane service roads from American Association of State Highway and Transportation Officials (AASHTO's) Guidelines for Geometric Design of Very Low-Volume Roads (average daily traffic [ADT] less than 400).
- Valley County has adopted the 'Greenbook' AASHTO standards. AASHTO's Guidelines of Very Low-Volume Local Roads (ADT less than 400) provides a functional classification for Rural Resource Recovery Roads specifically for logging and mining operations.
- The debris and excess vegetation like grass and weeds should be removed from the bottom of ditches and culverts at the beginning of every fall season.
- The ditches should be graded by removing excess silt and sand sediments and reestablishing longitudinal and side slopes at the beginning of every spring and fall seasons.
- Road cross slope and shoulder slopes should be inspected and graded as required and at a minimum of the beginning of spring and fall seasons.

- Repair and/or upgrade culverts depending on storm water demand and existing culvert capacity each fall season.
- A summary of key design standards (Parametrix 2018c):
  - ADT: 70 vehicles.
  - Level of Service: Criteria 'I', Rural Resource Recovery Road.
  - Design Speed: 20-miles per hour (mph) posted (designed to 25-mph where possible and reduced to 15-mph where needed).
  - Design Vehicle & Loading: WB-50 (intermediate sized tractor-trailer) with AASHTO HL-93 loading.
  - Critical design vehicle (only occurring in special situations with appropriate traffic control) is a lowboy trailer with mining equipment (similar to WB-67). Additional loading requirements may be placed on structures for the autoclave and other equipment.
  - Number of Lanes & Road Width (including shoulders and recovery zone): 2 lanes (with the ability to reduce to 1 if needed under special circumstances); 21-feet wide (14-feet for single lane).
  - Bridge Width: 24-feet minimum (14-feet for single lane).
  - Bridge Span: Clear span 120 percent of bankfull width; bankfull defined as a peak flow event that occurs on average once every 1.5 years (Q1.5).
  - Surfacing: Gravel, with asphalt 100-feet each side of bridges.
  - Cross-slope & Direction: 3 percent to 5 percent, insloped typical on steep areas (more than 5 percent grade), crowned or outsloped on flatter areas may be considered.
  - Minimum Radii: 50-foot (policy), 85-foot (15 mph), 160-foot (20 mph), 245-foot (25 mph).
  - Curve Widening: 11-foot on 50-foot radius, and 5-foot on 100-foot radius.
  - Stopping Sight Distance (SSD): 157-foot (30 mph), (232-foot worst case, 15 mph downgradient in snow).
  - Sight Distance: Exceed the SSD.
  - Horizontal Clear Zone: 0 to 4-feet.
  - Vertical Grade: 10 percent max, 0.5 percent min, and 5 percent at switch backs (extending 100 feet).
  - Vertical Curves (Sag and Crest), Minimum K and Length: 15 crest, 26 sag (75-foot length).
- Mitigate handling of road waste material (e.g., slough, rocks) to avoid or minimize delivery of waste material to streams that would result in degradation of soil, water, riparian, and aquatic resources.

Additional road design features to reduce environmental impacts from sedimentation, provide appropriate drainage and reduce fugitive dust are included in Section 3.3 – Environmental Protection Measures.

3.1.2 Geologic Hazards

Geologic hazards in the vicinity of the Yellow Pine and Burntlog access routes are discussed in the SGP DEIS (USFS 2020: Section 3.2.3.7.2). Identified geologic hazards on the Burntlog and Johnson Creek Routes are illustrated in Figure 3-1. Although the geologic hazards for the alternative access routes differ based on the location of the roadway, measures were incorporated into preliminary road construction design to address geologic hazards and reduce their potential impacts on roadways:

- Elevation out of the drainages, less avalanche chutes: A memorandum submitted to the USFS in July 2019 (RFAI-83c) documented the destructive nature of avalanches in the Stibnite Road corridor. The location of Stibnite Road - in the bottom of the EFSFSR drainage – places it in the runout zone of avalanches in the area. The design of the Burntlog Route specifically targeted road placement higher up in the drainages to reduce potential damage from intersecting avalanche chutes. This design feature has the important added benefit of reducing the risk to human health and safety of a catastrophic avalanche.
- Retaining walls and layback design; The potential for rockfall and landslides to incur into roadways is addressed by (1) road placement relative to identified areas of potential slope instability and (2) road design, i.e., appropriate cut/fill slope, laybacks, and retention structures to deter mass movement. The response to RFAI-83 and supporting technical memorandum (Parametrix 2018b) note that appropriate design considerations for the Stibnite Road portion of the Johnson Creek Route to mitigate for geotechnical hazards would include drilling and blasting of rock overhangs along 3 miles of roadway to achieve an appropriate layback slope, retaining walls along 7 miles of roadway and concrete barriers along nearly 5 miles of roadway to mitigate for adjacent steep topography. Similar required design features for the Burntlog Route are less robust as it occurs higher in the drainage in alluvium and regolith with virtually no overhanging rock and thus less upslope geotechnical load. Preliminary design for the Burntlog Route includes approximately 5 miles of retaining wall (RFAI-83a). General cut/fill slope recommendations (Parametrix 2018c) for various surface materials include:
  - Cut Slopes - Colluvium/Non-Glacial Soils
  - 1.5 horizontal to 1 vertical (H:V), 10-foot vertical slope preferred (20-foot maximum) with a minimum 3-foot-wide catchment ditch. Utilize mechanically stabilized earth walls downslope of the road if needed
  - 2H:1V is the preferred slope
- Glacial Till
  - 1H:1V, 20-foot vertical maximum slopes with a minimum 5-foot-wide catchment ditch
  - 1.5H:1V preferred slopes with a 3-foot-wide catchment ditch
- Rock
  - 0.5H:1V slope with a minimum 5-foot-wide catchment ditch
- Fill Slopes - All Conditions
  - 1.5H:1V maximum slope
  - 2H:1V preferred if geometry allows. This slope angle is more suitable for applying erosion protection and maintaining vegetation and requires less maintenance
- Maintenance: The Feasibility Study Access Road Design memorandum (Parametrix 2018c) notes that all slide areas adjacent to the roadway will require periodic cleanup of debris, including inspection and cleaning of adjacent culverts.

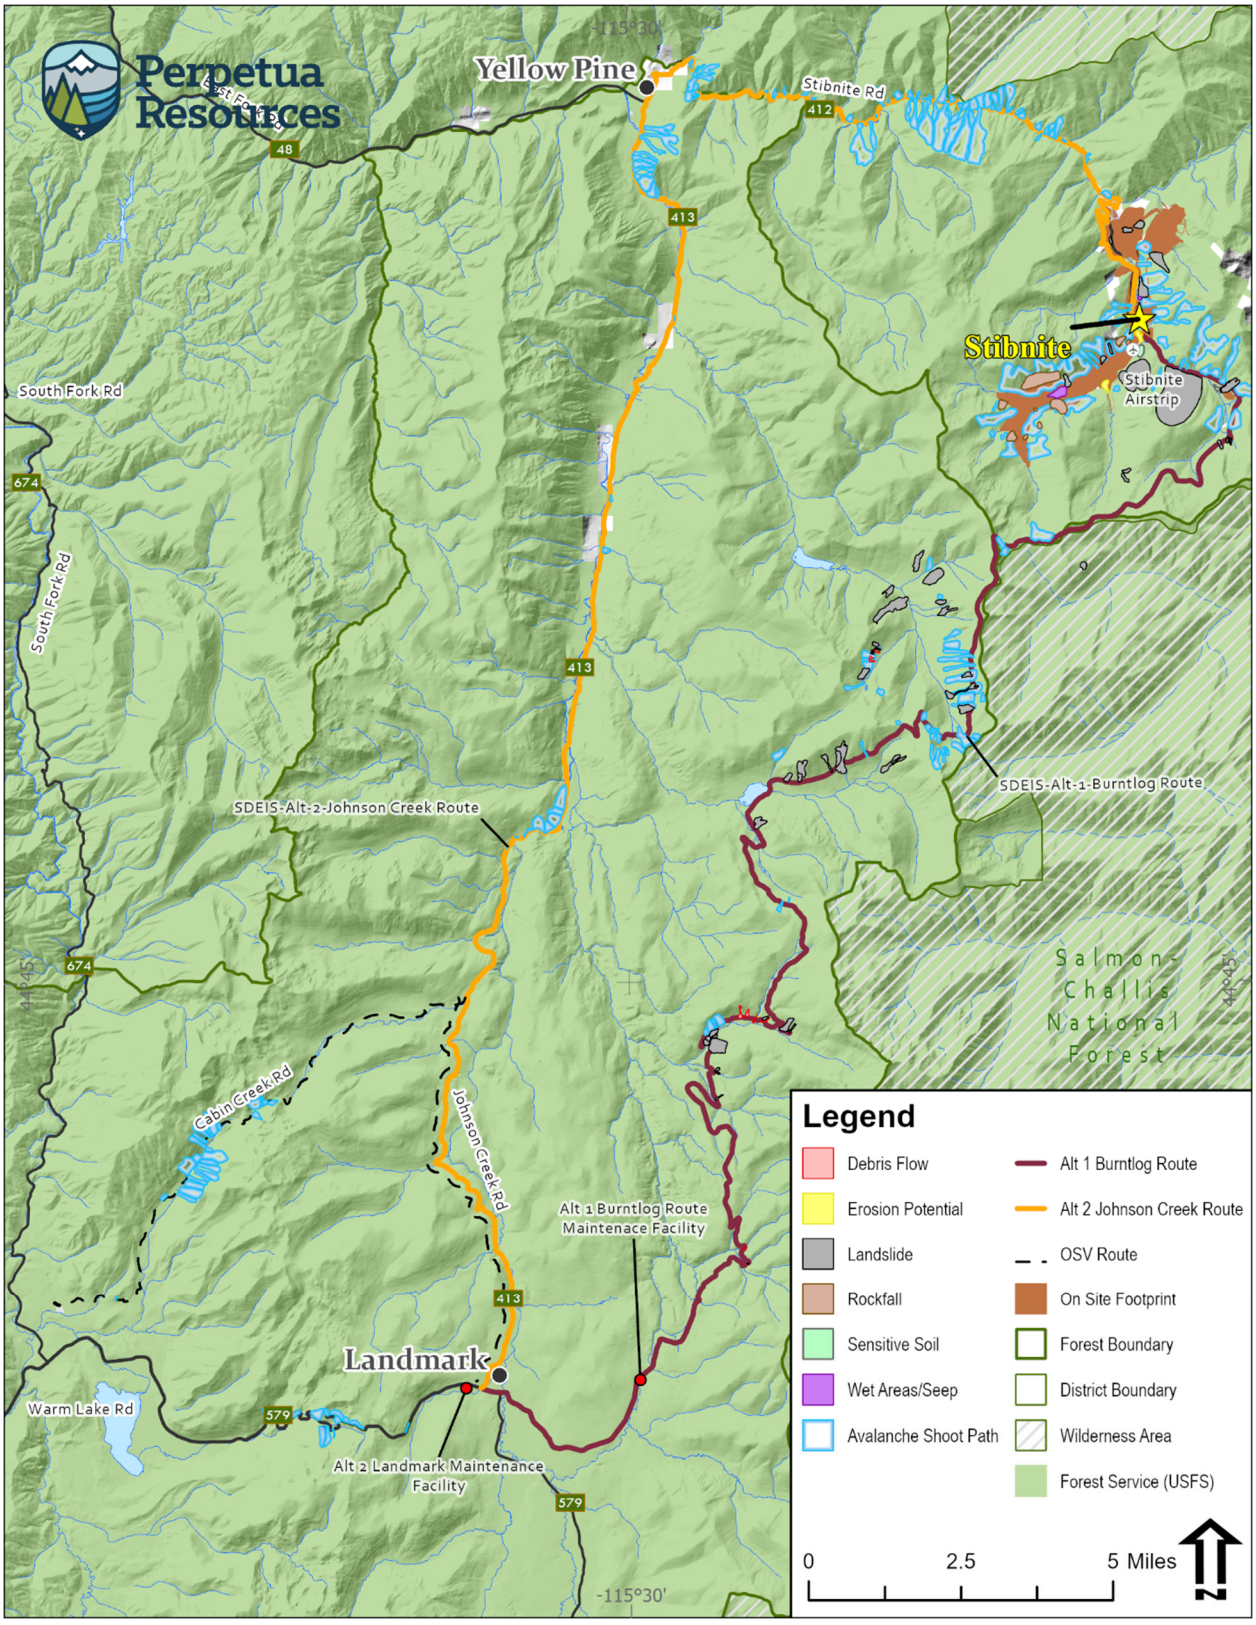

Figure 3-1. Geologic Hazards and Avalanche Chutes

3.1.3 Road Construction Materials

Road construction material for either of the mine access routes will come from borrow sources that are located along the access route. Borrow site material quality assessment and construction material specifications are included in documentation supporting the Feasibility Study Access Road Design memorandum (Parametrix 2018c), which recommends targeting USFS standard specifications for aggregate quality.

Road construction materials for haul roads on the SGP will be sourced from quartzite development rock from the West End mine pit that demonstrates relatively low arsenic concentrations compared to other available development rock. An evaluation of estimated haul road runoff water quality based on the use of this material was prepared in response to RFAI-115 (SRK Consulting, Inc. [SRK] 2021). It concluded that runoff from haul road surfaces would not exceed any of the strictest applicable water quality criteria. Modeling of haul road fugitive dust is addressed in Appendix A of the ModPRO2 Air Quality Analysis Addendum (Air Sciences, 2021).

3.1.4 Bridge Restrictions

Gross vehicle, axle, and wheel loads shall not exceed the following limits on bridges:

a. For typical State of Idaho highway-legal vehicles, maximum gross vehicle, axle, and wheel loads shall not exceed posted load limits or those established by the State of Idaho or the USFS.
b. All vehicles that do not meet the conditions of (a) will be required to obtain written approval (given by the Forest Engineer on a case-by-case basis) prior to crossing the bridge.

Detailed analysis for bridge loading was conducted for the Burntlog Route only; however, a similar approach to bridge loading analysis would be applied to the Johnson Creek Route. Per USFS standards, bridges on NFS roads are to be designed to handle AASHTO HL-93 loading. The SGP Feasibility Study Access Road Design (Parametrix 2018c) notes that there are five existing bridges (four timber and one three-sided concrete box) along Burntlog Road. Due to the anticipated loading that these structures would experience with the mine development and operations, each of the four timber bridges would need to be replaced. A total of six new bridges (four to replace the existing timber bridges) would be needed for the ModPRO2 (Burntlog Route) alignment. There will likely be several special transports to deliver large equipment to the site. To accommodate this additional loading, steel beams would provide temporary support, pending approval by the Forest Engineer.

3.1.5 Long Load/Over-width Load Hauling

All SGP, contractor, and vendor vehicles will be required to comply with the rules for long load/over-width load hauling on the permitted roads. Pilot vehicles would be required for long load/over-width load hauling and for the transport of various materials on permitted roads. Perpetua Resources would include these rules in the safety training for all employees.

3.1.6 Road Maintenance

The Landmark Maintenance Facility proposed in the PRO and included in Alternative 4 would be located near the intersection of the Warm Lake and Johnson Creek Roads (Figure 2-1. The ModPRO2 proposes the Maintenance Facility be located approximately 4 miles northeast of Landmark on the Burntlog Route, within a proposed borrow area. Both alternative locations for the Maintenance Facility are located on federal land administered by the BNF and would include:

- Covered stockpiles of coarse sand and gravel for winter sanding activities
- Housing for road maintenance crews during periods of heavy snow removal needs and other winter maintenance activities

- Communications equipment including a tower
- Equipment such as sanding/snowplowing trucks, snow blowers, road graders, and support equipment
- A fuel storage area with secondary containment for maintenance equipment
- Facilities to support snowmobile trail grooming and grooming equipment storage if needed
- Handling of road waste material (e.g., slough, rocks) to avoid or minimize delivery of waste material to streams that would result in degradation of soil, water, riparian, and aquatic resources

3.2 Hazardous Materials Handling and Spill Management

This section addresses potential risks related to transportation of hazardous materials (including explosives) and emergency spill response (in compliance with Idaho Water Quality Standards, National Oil and Hazardous Substances Pollution Contingency Plan, OSHA Hazardous Communication, HAZWOPER).

- Personnel who transport, handle, or use mine processing reagents, fuel, or other materials that have the potential to be released and impact surface water and groundwater quality will receive appropriate training in best management practices, spill response procedures, and reporting requirements.
- Personnel who transport, handle, or use mine processing reagents, fuel, or other hazardous or toxic materials will receive appropriate training in best management practices, personal protective equipment, emergency response procedures, and reporting requirements.
- Information on hazardous and toxic chemicals transported to the SGP and used in mining operations is included in the PRO (Midas Gold 2016); additional information will be recorded in publicly available documents (EPCRA, HAZWOPER).

3.2.1 Cyanide Transport and Handling

The PRO (Section 12.3.6) indicates that all SGP onsite and offsite facilities, and contractor equipment and materials handling facilities will be designed and operated to meet the International Cyanide Management Institute (ICMI) Cyanide Management Code (ICMC). The Principles and Standards of Practice of the ICMC requires adherence to Principles and Standards of Practice with regard to cyanide production, purchasing, transport, and handling, including:

- Purchase cyanide from certified manufacturers employing appropriate practices and procedures to limit exposure of their workforce to cyanide and to prevent releases of cyanide to the environment.
- Require that cyanide is safely managed through the entire transportation and delivery process from the production facility to the mine by use of certified transport with clear lines of responsibility for safety, security, release prevention, training, and emergency response.
- Design and construct unloading, storage, and mixing facilities consistent with sound, accepted engineering practices and quality control and quality assurance procedures, spill prevention and spill containment measures.
- Operate unloading, storage, and mixing facilities using inspections, preventive maintenance, and contingency plans to prevent or contain releases and control and respond to worker exposures.

In accordance with these ICMC principles, Perpetua Resources will incorporate the following EPMs:

- The anticipated supplier of cyanide for the SGP is Cyanco, a founding member and signatory of the ICMC. All of Cyanco's facilities are ICMC certified.

- Solid form, dry sodium cyanide briquettes would be transported in an International Organization for Standardization (ISO) container, which eliminates the risk of fluid leaks or spills during transportation. Any release of the solid form could be easily recovered. ISO containers are heavy-duty steel containers that are air and water-tight and ruggedly designed to withstand rollovers and other accidents.
- The ISO containers remain sealed at all times because dry solid sodium cyanide is extracted by circulating water through the container to dissolve the briquettes, then directly to the reagent circuit. There is no risk of spills during unloading or transfer steps since there are none.
- Cyanide unloading facility will be constructed and operated consistent with the ICMC standards for primary and secondary containment.
- The ISO containers are returned to the supplier for reuse, so there is no container disposal.
- Cyanide trucks will be escorted by pilot vehicles and be subject to other protocols, as described in the PRO Section 12.2.

3.2.2 Mercury Handling

The capture and handling of mercury in the ore processing circuit is described by SRK (2019); a memorandum provided with RFAI-104.

- Mercury will follow gold and silver through carbon stripping and electrowinning. It will be separated from the precious metals in the retort process, where it is volatilized with heat from the electrowinning sludge. The retort gas will then be passed through a chilled condenser, where mercury will be converted to its liquid metallic state and then securely stored prior to shipment to a Resource Conservation and Recovery Act certified hazardous waste disposal facility.

3.2.3 Antimony Concentrate Transportation and Handling

Additional clarification on antimony concentrate handling was requested in RFAI-131 (January 2022); applicable information from the RFAI-131 response is incorporated here.

The SGP ore processing circuit will produce an antimony concentrate that would contain approximately 55 to 60 percent antimony by weight. The remaining 40 to 45 percent of the concentrate would be predominantly sulfur (as sulfide in the stibnite) and common rock, with trace amounts of gold, silver, and mercury. The concentrate would be filtered then transferred by a screw feeder to a feed hopper on the bagging machine. The feed hopper would load antimony concentrate into 2-ton sealed supersacks constructed of woven polypropylene. Filled supersacks would be sampled, sealed, and placed with a forklift on the concrete floor of the antimony loadout facility prior to being loaded into a steel, wooden-floored shipping container for transport. Shipping containers would be closed and affixed with a numbered metal shipping seal.

The shipping containers would utilize either the Burntlog Route or Johnson Creek Route to Landmark before traveling along Warm Lake Road to the intersection with State Highway 55 (Figure 2-1. From there the concentrate would be trucked via State Highway 55 to a commercial truck, train, barge, or ship loading facility depending upon the final destination.

Approximately one to two shipping containers with a typical payload of 20 to 27 tons would be hauled off site each day. Perpetua Resources would assume ownership of the antimony concentrate until it arrives at its final destination.

Best practices for handing and transporting antimony concentrate would include:

- Shipping containers would be inspected upon arrival at the SGP and prior to loading. Any unsealed, damaged, or punctured containers would be tagged, segregated, and handled in accordance with the nature and degree of the specific situation.

- Shipping container leaks would be investigated to identify the cause of leakage, the location of the damage that caused the leakage, and trigger spill response in accordance with the Spill Prevention, Control, and Countermeasures (SPCC) Plan to address the effects of leakage from the point of damage to the point of discovery.
- Supersacks would be loaded into shipping containers using a forklift with hooked lifting racks. Using the lifting straps keeps the forks or hooks above the bag and reduces the chances of puncture and spillage.
- Filled and unused supersacks would be inspected at the beginning of each shift for tears, punctures, open spouts, or leakage and replaced as necessary.
- Spilled antimony concentrate would be cleaned up in a manner that does not disperse dust and returned to the antimony concentration/filtering process.

3.2.4 Solid Waste Handling

Solid waste handling will be conducted as described in the ModPRO2 Section 3.12 (Perpetua Resources 2021):

- No petroleum-contaminated soil landfarm nor solid waste landfill will be constructed or maintained at the Project site; these waste materials will be transported off-site for disposal.
- Used petroleum products would be stored on site in approved containers then transported off site for recycling or disposal in an approved facility.
- All waste materials will be recycled to the extent practicable or disposed of in accordance with regulations. Wastes anticipated to be generated at the mine site include fluorescent bulbs, batteries, empty aerosol containers, and hazardous wastes, which would be managed in accordance with the regulatory standards.
- Legacy waste materials may be encountered during construction and operations. These materials would be characterized to determine whether to reprocess, reuse, or dispose of off-site.
- Sanitary waste facilities would be present at the mine site and off-site facilities and would be constructed and operated in accordance with Valley County, IDEQ, and Idaho Department of Health and Human Services standards.
- A large-scale on-site composting facility is not anticipated due to the lack of space in the Project area. Small scale composting of organic materials generated at the worker housing facility may be incorporated within the centralized growth media stockpile in the Fiddle Valley. Any larger composting facilities necessary to support growth media quality or quantity improvements would be located off-site.
- Material that meets the classification of a “hazardous waste” will be collected and stored, per the Waste Management Plan at specially designed and operated secured satellite collection sites and a main storage site prior to shipment to a Resource Conservation and Recovery Act certified hazardous waste disposal facility.
- All municipal waste and construction and demolition waste generated at the SGP will be hauled off-site for disposal. Concrete foundations would be broken and buried in the TSF Buttress or pit backfill prior to installation of a geomembrane barrier cover.

3.2.5 Material Transportation Safety Measures

Operation will entail the use of petroleum fuels, chemicals, and hazardous materials in order to mine and process ore and conduct related activities. Anticipated quantities and delivery frequency of materials, supplies, and reagents are summarized in the PRO (Table 12-4). Perpetua Resources’ standard operating procedures for fuel transportation are presented in a Fuel Transportation Plan

(Environmental Standard Operating Procedure [ESOP]-44); a similar hazardous materials transportation plan is in development to address the transport of chemical reagents and supplies that will be required during the operation of the SGP.

Appropriate measures will be taken to protect worker health and safety and protect the environment when transporting chemicals and hazardous materials to prevent spills, fires, or explosions and to protect the existing biological and hydrologic resources of the area during construction, operation, reclamation, and closure.

All transport drivers will be required to have spill response, safety, and resource awareness training. In this program, drivers will be informed of the Idaho State Emergency Medical Service, first hazardous materials responder actions, and the importance of anadromous fisheries that must be protected. In addition, each driver will participate in a SGP safe-driver training course. The course will cover the operating procedures as well as discuss causes of accidents and how to minimize risks. Chemical use volumes would be reported under the United States Environmental Protection Agency Toxic Release Inventory program, as applicable and required by Section 313 of the EPCRA.

Several of the materials that would be transported to SGP require safe handling and transport procedures. Hazardous chemicals will be transported to the mine site in (USDOT)-certified containers and by USDOT-registered transporters, who will comply with applicable USDOT, OSHA, and MSHA regulations. Transportation vehicles will meet the standards of USDOT requirements and carry required markings, labels, and placards.

The following safety measures would be implemented to reduce the risk of accidents:

- Schedules will be developed for planned dates and times for transport of materials. The schedules will be communicated with staff and drivers so that timing of material transport is known, and arrangements can be made to minimize possible hazards.
- Fuel hauling will be done with single chassis units.
- Transportation of fuel and materials will be done during daylight hours.
- Spill response equipment are located along portions of the access route and in in the Perpetua Resources Spill Response trailer (Figure 3-2).
- Prior to material hauls, areas of “flat water” along the route will be communicated to appropriate hazardous materials response personnel to identify areas of potential booming in waterways adjacent to the route. These areas are identified for the Johnson Creek Route (Figure 3-2) and will be established along the Burntlog Route in revised versions of the SPCC Plan.
- Documented annual inspections of commercial transport vehicles are required by 49 CFR 396.17-23. Inspections will be conducted by a qualified USDOT inspector. Commercial transport vehicles will also be inspected by the drivers prior to transport. Transport companies are required to document DOT annual inspections and vehicle inspections. In addition, daily inspection of transport vehicles will occur as required by MSHA requirements.
- Material transporters to the site:
  - Will be required to check in at the SGLF. Safety inspections of all transport vehicles will be conducted by Perpetua Resources personnel prior to transportation of fuel and materials.
  - Will be required to provide documentation of successfully completed training in responding in the event of spills or other releases of transported materials and will have spill cleanup kits on the vehicle at all times.
  - Will be familiarized with the transportation route prior to transportation of fuel, hazardous materials, and operational supplies.

- Pilot vehicles will be used to escort shipments of fuel, chemicals, reagents, or antimony concentrate from the site. The pilot vehicles will have radio contact with the site and the transport vehicle. Pilot and emergency response vehicles would carry appropriate spill containment and first aid equipment.
- The pilot vehicle will advise oncoming traffic to park until the convoy passes and will regulate the speed of the transporting vehicle so that it does not exceed posted speed limits and safety conditions inherent to the road.
- Road signs will be placed at both the start and end of the route while a convoy is operating, indicating to the public that a fuel convoy is in progress and to use caution.
- Communications with Perpetua Resources management by using the SPOT™ GPS Messenger, (or similar GPS vehicle tracking equipment) – signal on the road/still traveling (custom message) at least hourly, and signal checking-in/OK upon reaching the Stibnite camp and upon safely returning to Cascade.

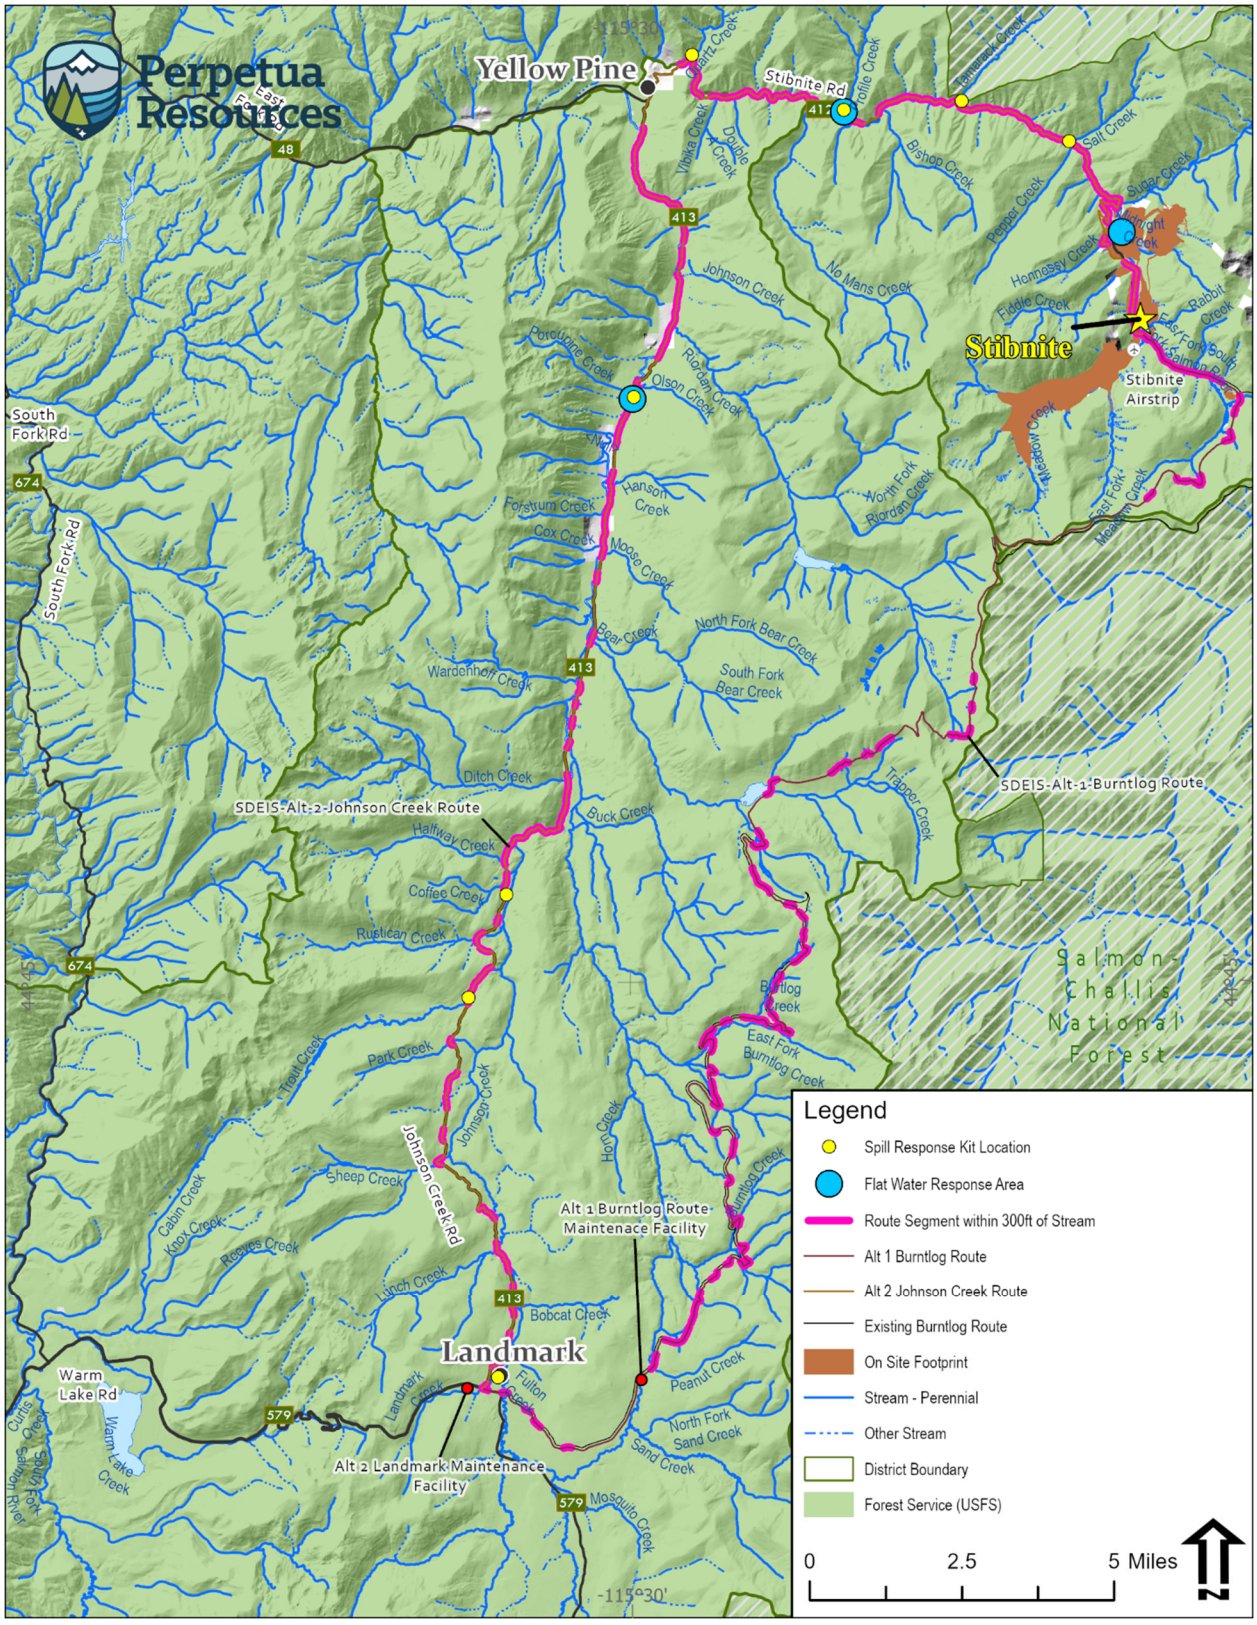

Figure 3-2. Spill Response Kit Locations and Access Route Segments Near Streams

3.2.6 Spill Prevention, Control, and Countermeasures Plan

A SPCC Plan will be maintained for material transportation, transfer, and storage operations as required by 40 CFR 112 regulations. Perpetua Resources maintains an SPCC Plan for current fuel storage at the SGP to support site exploration and current site maintenance activities. Anticipated quantities of materials stored at the SGP are included in the ModPRO2 document (Midas Gold, 2020). The SPCC Plan will be updated to reflect the approved Environmental Impact Statement alternative and will address site-specific spill prevention measures, fuel haul guidelines, fuel unloading procedures, inspections, secondary containment of all onsite fuel storage tanks, and staff training.

- The SGP SPCC Plan (most current revision, February 2019) includes measures to avoid inadvertent release of hazardous materials into the environment, particularly streams and rivers and describes response and remediation measures to minimize effects of an inadvertent release. Spill response kit locations on the Yellow Pine access route are indicated on Figure 3-2; similarly spaced spill response kits would be placed along the Burntlog Route during its construction and when it is in operation.
- Per the requirements of 40 CFR 112, the SPCC plan meets the applicable requirements for drainage, bulk storage tanks, tank car and truck loading and unloading, transfer operations (intra-facility piping), inspections and records, security, and training. Additionally, the facility must fully implement the SPCC Plan and train personnel in the execution of the SPCC Plan.
- The SPCC Plan will be updated and revised to address spill response through all phases of mine life from construction through post-closure (or as required to maintain compliance with 40 CFR 112).
- Secondary containment will be maintained for all chemicals and reagents to be used, including any oil storage areas (unleaded gasoline, diesel fuel), the autoclave facility, and the leaching circuit).

3.2.7 Emergency Response Plans and Procedures

In the event of spills, Perpetua Resources will respond with spill response measures described in the SGP Emergency Response Program (OHS-008) Spill Plan (OHSF-008K). This document includes supporting Emergency Response Plans that provide information specific to incident response actions including:

- Emergency Call List and Contact Matrix (OHSF-008-A): Communication protocols for internal (Perpetua Resources) contacts for emergency notification and call matrices per incident type (e.g., spill, flood, fire, avalanche, etc.) for appropriate federal, state, and county agency reporting.
- Protection Systems and Response Equipment (OHSF-008-D): Identifies the locations of emergency response equipment and includes an inventory of available emergency response equipment at each location.
- Spill Plan (OHS-008 K): Provides emergency response protocols for employees and contractors in the event of spills. Includes directives for minor and major spill response, emergency contacts, reporting requirements for fuel spills/hazardous materials spills, contact numbers for environmental response contractor (Specialty Environmental Services), muster points, and emergency medical services contact information (i.e., LifeFlight and Cascade Ambulance).
- Related plans include:
  - Critical Operations List (OHSR-008-C)
  - Evacuation Plan (OHSF-008-G)
  - HAZWOPER Program (OHSF-008-N)

  - Waste Determinations SOP (ESOP-021)
  - Herbicide Spill Response SOP (ESOP-024)
- For major spills, areas of "flat water" in adjacent waterways will be identified prior to material hauls in the event that booms need to be placed to capture major spills. [These areas are identified for the Johnson Creek Route (Figure 3-1) and will be established along the Burntlog Route in revised versions of the SPCC Plan].

3.3 Environmental Protection Measures

3.3.1 Public Use Safety

Interaction with the public is an important transportation safety consideration. Current operations at the Stibnite site include interaction between the public and Stibnite maintenance staff. Future SGP operations will increase the amount of traffic in the area. Numerous considerations are incorporated into the proposed SGP and subsequent alternatives (including ModPRO2 Alternative and DEIS Alternative 4) to ensure the safety of public users of Forest System roads:

- Employee traffic into and out of the SGP site will be reduced by providing worker housing and mass transit to/from SGP. Perpetua Resources would maintain a parking and assembly area as part at the SGLF. The parking area would accommodate approximately 300 light vehicles and mandatory employee and contractor busing would provide transportation for workers to the site.
- The Burntlog Route was proposed as the primary access route to reduce the interaction of SGP and public traffic. The Johnson Creek Route would require significant measures during construction and operations to ensure continued safe roadway access. In particular, during construction of the Stibnite Road portion of the Johnson Creek Route which requires extensive drilling and blasting to widen the route, provisions for continued public access would increase the overall construction phase by at least two years (four years in total) due to limited daily construction periods that allow for intervals of public access.
- DEIS Alternative 2 and the Modified Alternative 2 (ModPRO2) would include on-site lime production to reduce anticipated operational AADT by more than 25 percent (68 AADT in the PRO to 50 AADT in DEIS Alternative 2 and ModPRO2),
- Public access through the SGP site during operations would be separated from the SGP haul roads and monitored to ensure timely passage of vehicles through the site. Protocols for through-site public access are discussed in Section 2.3 of this document and detailed in the SGP Access Management Plan (Midas Gold 2020b).
- Increased wintertime access on Warm Lake Road east of Warm Lake Lodge would increase the potential for interaction between SGP public traffic. Appropriate alternative measures to promote safe public travel up Warm Lake Road to Warm Lake Summit are discussed in Section 2.2.1 of this document and included in Seasonal Public Access: Warm Lake Road and Burntlog Route (Midas Gold 2020b).
- The SGLF, and a nearby site on private property, would host radio and microwave repeater equipment to provide telephone, internet, and radio communications for the facility and SGP traffic. Additional radio repeater locations will be needed to facilitate full coverage along the Burntlog Route.
- All access routes would have signed speed limits and appropriate traffic control devices. Posted speed limits are those that are sign-posted along the road and are enforceable by law. The posted speed limits will be consistent with County and/or USFS guidelines. Work zone speed limits would be as specified in the traffic control plan, which is used to help facilitate safe and efficient movement of traffic through a work zone. Factors that influence work zone speed limits

can include: the posted speed limit when the work zone is not present, location of the work zone and workers in relation to traffic, type of traffic control (e.g., cones, barrels, concrete barriers), and the complexity of the work zone (e.g., lane shifts, narrowed lanes).

- Traffic controls convey important information about the road conditions, potential hazards, and other obstacles. They are markers, signs, and signal devices used to inform, guide, and control traffic, including pedestrians, motor vehicle drivers, and bicyclists. These devices are usually placed adjacent to, over, or along the roads and other public areas that require traffic control. The Federal Highway Administration Manual on Uniform Traffic Control Devices (Federal Highway Administration, 2009) will be used to determine appropriate traffic controls on the access routes.
- Signs warning motorized and nonmotorized road users of hazardous conditions or the presence of large trucks and equipment would be placed following the recommendations in the Manual on Uniform Traffic Control Devices.
- Planned responses to vehicle collisions are described in the SGP Emergency Response Program Vehicle Incident Plan (OHSF-008-L).

3.3.2 Avalanche

Road design features that address the potential for road damage from avalanches are discussed in Section 3.1 of this document. Avalanches also have important health and safety implications and can impact the environment. This is illustrated in RFAI-83c, which documents avalanche occurrences in 2014 and 2019, along the Stibnite Road portion of the Johnson Creek Route and again most recently in 2021. One avalanche in 2019 obliterated approximately ½ mile of the Stibnite Road delivering the included road material into the stream as well as entrained sediment (and hundreds of trees). Reducing the potential for avalanche/roadway interaction can be accomplished by (1) appropriate design of the access road alignment that avoids placement in the bottom of avalanche chutes, (2) continual monitoring of avalanche occurrences and appropriately updating the avalanche database to inform road users, and (3) mitigating catastrophic avalanches by inducing smaller, less destructive events.

Recent, updated assessments of identified avalanche chutes on the Burntlog and Yellow Pine Project access routes have been prepared (Dynamic 2021) and will be provided in draft form as Attachment A of this TMP submittal. Figure 3-1 illustrates avalanche chutes referenced in the report.

Perpetua Resources used these data to develop EPMs for avalanches. These measures are listed below and may be modified after monitoring and reassessment as described in the Dynamics (2021) report, after consultation with the USFS:

- Map locations where small-sized avalanches frequently occur and include these locations in safety plans to inform drivers of areas of potential risk.
- Periodically update the mapping before the next snow season if wildfire or any other large scale vegetation modification alter the size or frequency following the methods described in the Snow Avalanche Hazard Assessment for Access Roads (Dynamic 2021). Current known locations are shown on Figure 3-1.
- Review all paths with summer and winter imagery, review topographic contours and slope classes.
- Construct catchment areas for smaller avalanche paths on slopes on the west side of the Warm Lake Summit.

- Frequently remove snow from catchment areas/ditches or design ditches to hold most of the snow for the winter with "Jersey" barriers to increase the depth. The appropriate size of the ditch could be evaluated on a site-specific basis, which is a function of the length and incline of the slope above and the depth of the snow in a design (e.g., 10-year) winter.
- Implement an avalanche hazard management program for larger avalanches with return periods of 1 to 10 years. This could include avalanche control and/or road closure.
- Post permanent warning signage in avalanche-prone areas of critical avalanche size[2].
- Monitor avalanche parameters and take appropriate actions:
  - Daily region-scale assessments
  - Daily weather observations, including snowpack and avalanche observations
  - Notify SGP staff when conditions are highly unstable
  - Close roads during periods of elevated hazard or blocked roadways.
  - Control avalanche initiation with explosives using helicopters, case charging, Avalauncher, hand charging, or remote control.

3.3.3 Landslides, Debris Flows, and Rock Fall

Landslides and debris flows are types of mass earth movements and are shown on Figure 3-1. They are initiated by periods of heavy precipitation that saturates slopes, decreasing the internal stability of unconsolidated materials (soil, alluvium) while increasing their mass. Freeze/thaw cycles of the nearby ground and soils may result in materials falling from the roadside onto the access routes, potentially blocking the route and striking vehicles. Road cuts at the base of these features can increase their likelihood by reducing the amount of material effectively buttressing the slope. More volumetric slope failures can result in large slumps that completely obliterate sections of roadway. The Riordan Creek Valley segment of the Burntlog Route crosses areas of active landslides (Figure 3-1). They may also be seismically induced.

Rock fall occurs from rock spalling from steep, rocky overhangs and creates debris on the roadways in steep sections of the access routes. This is particularly notable along sections of Stibnite Road, and there is potential for rockfall on the Black Lake and Riordan Creek Valley segments of the Burntlog Route. Rock falls are caused by diurnal freeze/thaw cycles typical of spring weather conditions. Potential impacts from rock falls include roadway blockage and/or damage, and there is also a significant human health and safety concern due to the potential to strike vehicles. EPMs such as rock bolts, netting, and signage will be installed along segments susceptible to rock falls. Responsibility for removal of rock debris from the roadways will be detailed in the maintenance agreement with Valley County.

As noted in Section 3.1 above, appropriate design features and construction considerations would be made to minimize the exacerbation of geologic hazards.

- Avoid known occurrences of slope failures to the degree practicable,
- Incorporate appropriate cut slopes and stabilizing features (e.g., retaining walls, soil nails) into road design to reduce the potential for slope failure.
- Road layback design to prevent the formation of steep overhangs and prevent spalling.
- Consider rock bolt and netting and catch benches would also be considered in these areas.

[2] At least, could bury and destroy a car, damage a truck, destroy a wood frame house, or break a few trees, typically 10,000 tons or more and 3,000 feet long with 2,000 pounds/square foot of pressure (Dynamic Avalanche Consulting 2021)

- A Road Maintenance Agreement between Perpetua Resources and Valley County would be developed defining the procedure and protocols for removing material debris from the access route.
- Dewatering or other stabilizing structural features as control measures.
- Where necessary, realign the roadway.

3.3.4 Roadway Washouts/Culvert Design

Adequately handling water along the roadway is imperative to maintain the roadway in good condition. Periods of heavy precipitation that saturate the roadway and surrounding roadside increase the risk of the roadway surfaces and base courses to be washed out, making the access routes unpassable. This is best addressed in appropriate road design and associated culvert sizing and maintaining culverts to perform as designed.

- Ditches would be installed on the in-sloped edge of the road, which would collect water from the gravel surfacing as well as the hillside above the road.
- For the proposed Burntlog Route, an 18-inch-deep V-shaped ditch with 1.5H:1V slopes would be used along the roadway, as is typical of most gravel roads in mountainous areas.
- Culverts providing drainage for non-fish bearing streams would take into account the estimated drainage basin area and would be sized to accommodate a recommended peak 25-year design flow at each culvert location (Parametrix 2018c). (Culvert sizing for fish-bearing streams is discussed later in this Section.)
- Additional relief culverts would be placed at intervals depending upon the uphill drainage basin size and road profiles.
- The drainage system (roadside ditches and culverts) would require a reasonable amount of maintenance and inspection to ensure the system is working properly. Debris and sediment would be removed on an annual basis, in addition to any emergency situations that may arise. To maintain culvert efficiency, Perpetua Resources would monitor the roadways and clear debris from culvert inlets and outlets during and after significant storm events.
- The planned Maintenance Agreement with Valley County would include procedures and protocols for rerouting traffic, providing temporary signage for the road closure, and any repairs required for the access roadways to return to functional operation.
- Washouts will be addressed by variable message signage and rerouting traffic until the damaged segment can be repaired.
- New culverts, replacement culverts, and other stream crossings shall be designed to accommodate a 100-year flood recurrence interval unless site-specific analysis using calculated risk tools, or another method determines a more appropriate recurrence interval.

3.3.5 Safety Measures During Hazardous Road Conditions

Consistent with recommendations included in the Feasibility Study Road Design Report (Parametrix 2018c), the following measures will address hazardous road conditions.

- Appropriate signage would be placed along SGP and public access roads to guide travelers along the roadway at night or during inclement weather.
- In areas of steep terrain and side slopes, delineators would be placed at the edge of the road to visually distinguish in shadows and snow cover.
- Delineators would be high enough to remain effective during the winter season due to the snow depth.

- Repairs to roadway signs and delineators each summer to address damage from winter maintenance activities.
- If a major storm event, wildfire, or other condition arises that represents a significant hazard and is determined to represent a health and safety risk to travel on the mine access road, delivery vehicles would be detained at the SGLF, the mine site, or notified at their point of origin to delay their delivery. Once safe travel conditions resume, Perpetua Resources would consolidate and coordinate accumulated vehicles to safely complete their delivery routes. This would temporarily increase daily traffic rates; however, it would not impact overall AADT for construction, operations, or reclamation/closure phases of the SGP.

3.3.6 Public Access During Construction

For the ModPRO2 Alternative, during the Burntlog Route construction phase (2 years), safe public access would be maintained by:

- Mine-related traffic would access the mine site from State Highway 55, north of the city of Cascade, via Warm Lake Road (CR 10-579), then Johnson Creek Road (CR 10-413) to Yellow Pine, and from Yellow Pine to the mine site via the Stibnite Road segment of the McCall – Stibnite Road (CR 50-412) (Figure 2-1).
- During the construction phase, minor surface improvements (e.g., ditch and culvert repair, adding gravel, winter snow removal, and summer dust suppression) would occur on the Johnson Creek Route to reduce sediment runoff and dust generation.
- There would be no road alignment modification or widening of the existing roads. Public access during this construction phase would include periodic lane restrictions and appropriate signage to notify travelers of construction activities.

Estimates of changes in public access are based on a preliminary construction schedule for the Johnson Creek Route as part of a revised (Johnson Creek Route) Access Road Feasibility Design memorandum (Parametrix 2019). Construction of the Johnson Creek Route is estimated to require two more years to complete than the Burntlog Route; a total of four years. Upgrades on the Johnson Creek Road portion of the Johnson Creek Route would require one full year with no public access. During the same season, the road around the mine operations would also be constructed, which starts south of Sugar Creek and ends at the Worker Housing Facility. In this manner, both segments would be closed to public access for one year; however, this approach would facilitate partial public access in subsequent years during the construction of the Stibnite Road segment of the Johnson Creek Route. The remaining three years of the construction period would be used to complete upgrades and widening of Stibnite Road; an effort which would be complicated by providing continued periodic public access through the construction area. Parametrix (2019) notes: “With the tight terrain and amount of rock blasting anticipated, daily full-road closures would be expected. It was assumed that the Stibnite Road would have to re-open for public use each night (after 4 PM), thus reducing production rates and construction efficiencies.”

- In summary, public access under the Johnson Creek Route Alternative during the first year of construction would completely restrict public access on Johnson Creek Road for one year. Public access to Yellow Pine during this time would be on the South Fork Road.
- Public access to points beyond Yellow Pine would be partially restricted for the next three years of construction. Public access to Yellow Pine via Johnson Creek Road would be re-established during this time.

3.3.6.1 Through Site Public Access Road Construction

The ModPRO2 (modified DEIS Alternative 2) and DEIS Alternative 4 each include a through-site public access route that would replace the current access through the SGP site on Stibnite Road (FR 50375) during mine operations. Through-site public access routes for both Alternatives are described in Section 2.3.3.

For the ModPRO2, the through-site public access road would be a designated roadway separate from the mine haul road network and would be constructed on a widened bench within the Yellow Pine pit. South of the Yellow Pine pit, this road would parallel a mine haul road and use a partially revegetated portion of the former Bradley mine haul road. This road would be approximately 4 miles. The public access road would be constructed concurrent with the removal of development rock from Yellow Pine pit.

- During construction, current public access through the SGP site on Stibnite Road would be restricted for one year or more while a new through-site public access road is constructed.
- A new 12-foot-wide gravel road would be constructed to provide public access from Stibnite Road (FR 50412) to Thunder Mountain Road (FR 50375) through the mine site Figure 2-2 and Figure 2-3.

For DEIS Alternative 4, the through-site public access road would be a shared roadway with mine access traffic to the area south of the Yellow Pine Pit. The shared access road would have a slightly different alignment to meet the mine access road design criteria (lower maximum grade, wider running width, greater curve radius, etc.). As noted in Section 3.3.6, the through-site public access road would be constructed in the first year of construction. For the next three years, access to the through-site public access road would be subject to daily restrictions (estimated 10 A.M. to 4 P.M. daily) to allow for construction upgrades to Stibnite Road.

3.3.6.2 Recreational Access for OSVs

Due to year-round access to the mine site along Warm Lake Road (for both the ModPRO2 Alternative and DEIS Alternative 4) for the life of the SGP:

- The existing, approximately 8-mile groomed OSV trail from Warm Lake to Landmark would be closed.
- To replace this recreational use, at the onset of the construction phase (including minor upgrades to Johnson Creek Road) a dedicated alternative OSV route would be established from the Warm Lake area to Landmark via the Cabin Creek/Trout Creek drainages.
- The groomed OSV trail would be approximately 10.4 miles in length on the existing road and would include an approximately 2-acre parking area west of South Fork Road, and a new 1.5-mile groomer access trail from the USFS Warm Lake Project Camp on Paradise Valley Road (FR 488) where the groomer would be stored. An approximate 0.1-mile segment would be groomed from the intersection of Paradise Valley Road (FR 488) and FR 488A to Warm Lake Road.
- From Trout Creek to Landmark, an approximately 7-mile temporary groomed OSV trail would be maintained on NFS lands adjacent to the west side of Johnson Creek Road (CR 10-413).
- Portions of the temporary groomed OSV trail would be established using a snowplow wing attachment requiring some vegetation and tree removal to allow for safe snowplowing.
- The precise location of this trail is not yet determined, and in areas where topography and vegetation prevent using the wing attachment to establish the groomed OSV trail, sections would merge with Johnson Creek.
- A 0.3-mile trail would be maintained south of Warm Lake Road and would connect Johnson Creek Road to the Landmark-Stanley Road (FR 579).

Figure 2-2 shows the Cabin Creek/Trout Creek/Johnson Creek Road groomed OSV trail from Warm Lake lodge to Landmark.

3.3.7 Wildfire

- The SGP transportation system would maintain emergency road access as required by the Forest Roads and Trails Act, and the BNF and PNF Land and Resource Management Plans goal FRG001). Perpetua Resources Fire and Explosion Emergency Response Plan (OHSF-008-H) includes Wildfire response measures address employee, contractor, and public health and safety. Additionally, an Emergency Response Plan that incorporates fire/wildfire response will be developed per the requirements of the Cyanidation Permit (Idaho Administrative Procedures Act 58.01.13).
- The Fire and Explosion Emergency Response Plan addresses fire/explosions and spills (including flammable liquids). Plans detail evacuation directives, designated muster points, and shelter-in-place procedures. These existing plans will be incorporated into a comprehensive Emergency Response Plan that will detail best practices for all manner of emergency response through all phases of mine life from construction through post-closure.
- A fire emergency response and evacuation plan will be developed and maintained as part of Perpetua Resources' overall safety aspects to comply with both company and MSHA requirements (Section 1.4.1).
- The potable water tank(s) at the ore processing facility will include a capacity for firefighting needs. In case of a fire, water from these tanks can be gravity fed to a series of fire hydrants at the ore processing facility and truck shop complexes and at the employee housing facility.
- Fire extinguishers and fire hoses will be installed and maintained at strategic locations, such as the ore processing facility, shop, offices, and employee housing facility. Site water trucks, portable tanks, and pumping apparatus may be used by Perpetua Resources for firefighting purposes. The mobile equipment and apparatus would also be available for wildland firefighting, if requested by the appropriate authorities.

3.3.8 Response to Traffic Accidents

Reponses to vehicle accidents are addressed by Perpetua Resources Vehicle Incident Emergency Response Plan (OHSF-008-L). Included are best practices for responding to accidents by or between mine employees and contractors, including situational safety assessment, reporting protocols, information to be collected/shared, and in the case of injuries, notifying emergency health care services as appropriate.

- Perpetua Resources contractors, suppliers, and/or staff: Perpetua Resources Emergency Response staff, as well as local law enforcement would be contacted and dispatched to the accident location to address any blockage to the access route and reopening the route to travel.
- Environmental hazardous materials: For vehicle accidents involving other potential hazardous materials spills (e.g., gasoline, oil, vehicle fluids, etc.), Perpetua Resources Emergency Response staff would be dispatched to the accident location to address any hazardous materials spills and local law enforcement would be contacted to control traffic until the route can reopen to travel.
- Local law enforcement to be contacted and dispatched to the accident location to address any blockage to the access route and reopening the route to travel.

For incidents that involve the public.

- Where possible, Perpetua Resources will assist local people in the event of an incident.
- Perpetua Resources employees may obtain consent (or implicit consent) and render first aid to any person who may be injured, if safe to do so, in accordance with the Personal Injury Emergency Response Plan (OHSF-008-I).

3.3.9 Air Quality

Perpetua Resources provided a response to RFAI-118 on March 31, 2021, providing information on fugitive dust control (environmental protection) measures that would be implemented as part of the Fugitive Dust Control Plan (FDCP); this is a forthcoming document that is an IDEQ requirement for the Air PTC. The EPMs would target maintaining a control efficiency of 90 percent on the on-site haul roads.

The FDCP would address the following:

- Procedures followed by Perpetua Resources employees to control and minimize fugitive dust emissions, including speed limits, application of dust suppressants (e.g., water, chemical dust suppressants).
- Trigger levels (identified by monitoring to be determined in the forthcoming Air PTC) requiring corrective actions.
- Actions to bring fugitive dust emissions within acceptable ranges.
- Visual monitoring and reporting that demonstrates that appropriate corrective procedures are followed.

General EPMs to ensure that fugitive dust generation is minimized would include:

- All suppliers, vendors, and employees maintain posted speed limits on the access routes.
- Application of binding agent (e.g., magnesium chloride, lignin sulfonate, etc.) or road wetting on SGP and public access roads would be applied as needed.

3.3.10 Water Quality and Aquatic Habitats

The SWPPP (Aquionix, Inc. 2021) includes measures (including best management practices) to protect waterways from pollution and sedimentation during construction. In summary (see the SWPPP for details) measures address:

- General best management practices for earth disturbed activities and construction guidelines
- Timing of construction
- Staging area
- Preservation of existing vegetation
- Clearing limits
- Stabilization of construction entrance and exit
- Erosion prevention from temporary roads
- Good Housekeeping
- Dust control
- Cover for materials and equipment
- Stockpile management
- SPCC
- Vehicle and equipment washing and maintenance
- Waste management
- Sanitary and septic waste management
- Slope Protection and Stabilization
- Mulching
- Hydromulching
- Geotextile
- Matting
- Soil binders
- Topsoil seeding
- Planting slope roughening

- Gradient terracing
- Channel Protection
- Temporary channel liners
- Riprap slope and outlet protection
- Inlet protection
- Check dams
- Temporary stream crossings
- Sediment Collection and Runoff Diversion
- Biofilter bags
- Fiber rolls
- Silt fence
- Vegetative buffer strip
- Sediment trap (basin) portable sediment tank
- Temporary swale
- Earth dike
- Perimeter dike/swale
- Temporary berms

All vendor contracts will include requirements for adhering to posted speed limits, drivers trained in spill response, and spill kits on all vehicles transporting hazardous materials. In the event of spills, Perpetua Resources will respond with spill response measures described in the SGP Emergency Response Program Spill Plan (OHS-008-K).

3.3.11 Culvert Design and Fish Passage

Road crossings of fish bearing streams will be designed such that structures allow fish passage. FSH guidelines for fish-bearing streams include structures that span 120 percent of the channel's bankfull width and pass the peak 100-year design storm. The USFS generally considers the bankfull discharge to occur on average every 1 to 3 years (USFS 2014). The bankfull width determination will be completed in the field during final design; however, the 1.5-year design storm or a localized drainage area regression equation was generally used for initial calculations included in the Feasibility Study Road Design Report (Parametrix 2018c).

The existing box culvert on the EFSFSR just downstream of the confluence with Meadow Creek at the Stibnite Road (CR-412) crossing is believed to be a full or partial barrier to upstream movement by salmonids. Improvements to fish passage will be made along the Burntlog Route by replacing collapsed, undersized, or otherwise degraded or poorly designed culverts. Perpetua Resources will complete this work using the USFS Stream Simulation approach (USFS 2008).

- The SWPPP (Aquionix, Inc. 2021) discussed in Section 3.3.10.1, measures in Public Safety Section 3.3.1, road engineering with surface drainage, roadside ditching, road-cut stabilization, and road surface maintenance would be implemented to maintain water quality and aquatic habitats.
- Road surfaces would be stabilized and managed to minimize transport of sediment, dust, and other materials, especially near watercourses. Crushed rock would be placed on access roads as needed to provide a durable surface and limit sediment transport into nearby streams. Erodible (i.e., non-rock cut) slopes along roads would be mulched, hydro-seeded, or covered with rock or coarse gravel to minimize the potential for sediment mobilization.
- During winter road maintenance, snow would be removed from the Burntlog Route, haul roads, and the temporary construction access Johnson Creek Route.
  - Avoiding disposal of snow in riparian areas, wetlands, or areas where snowmelt might cause road damage or erosion during spring melt.
- Care will also be taken to avoid disposing of collected snow, which may contain sand or gravel, into nearby streams and rivers.
- Perpetua Resources would use coarse sand (with less than 20 percent fines) for winter sanding of the main access road and haul roads in combination with a fine to medium gravel as needed, (approximately 1/4 - 5/8-inch sizing).

- New roads constructed for the SGP on NFS lands will be closed and reclaimed once they are no longer needed to support construction, operations, closure, or reclamation activities.

3.3.12 Wildlife

- Measures to reduce the amount of mine traffic listed in Section 3.3.1 would similarly reduce the potential for wildlife/vehicle collisions.
- Appropriate speed limits and other measures will target minimizing vehicle and wildlife interactions. Personnel will be trained in the documentation and reporting of wildlife mortality incidents to reduce future occurrences (see RFAI-29) (Endangered Species Act).
- Signage of known crossing and wildlife usage areas along access and haul road corridors and all active facility areas. Sign locations are to be determined, but signs would include the road name and mile markers where these corridors are known to exist. Known wildlife areas near roads would be referenced in the training materials along with visible signage in these locations.
- Refer to the EMMP Wildlife Monitoring and Management Plan (Appendix RM-3) for the procedure and protocols for removing animals that have been struck. Coordination with Idaho Department of Fish and Game would be made for carcass removal.

Figure 3-2 shows the road segments within 300 feet of streams with anadromous fish. For Alternative 2, the operational traffic would not use Johnson Creek Road or Stibnite Road thus reducing the length of the route within 300 feet to less than 10 percent. Alternative 4 would have over 50 percent of the route within 300 feet of a stream during operations. ESOP-004 includes procedures for spill response to protect water quality.

REPLY MEMORANDUM IN SUPPORT OF INTERVENOR-RESPONDENT PERPETUA'S MOTION FOR SUMMARY JUDGMENT

TABLE OF CONTENTS

TABLE OF AUTHORITIES III

KEY TO TERMS AND ABBREVIATIONS V

INTRODUCTION 1

DEQ'S PERMIT RECORD AND EVIDENCE RELIED ON 2

STANDARD OF REVIEW 3

I. The Board must decide, as a matter of law, whether Petitioners proved DEQ's action was arbitrary and capricious, an abuse of discretion, or contrary to law. 3

II. The Board may defer to DEQ's technical expertise and special skill 4

REPLY ARGUMENT 5

I. Standing: Petitioners failed to demonstrate, as is their burden, that they are persons "aggrieved" by an action or inaction of DEQ. 5

II. Ambient air boundary (Claims 11 and 12): DEQ followed EPA guidance and exercised discretion to exclude the Stibnite Access Route from the Project's ambient air boundary. 5

III. Fugitive dust emissions (Claims 1, 2, 5, and 8): DEQ did not act arbitrarily and capriciously or violate the Idaho Air Rules in determining that fugitive dust emissions from the Project's roads will comply with the PM_{10} NAAQS and arsenic AACC. 9

A. DEQ reasonably determined that 93.3% control efficiency for fugitive dust from haul roads was attainable and enforceable (Claims 2 and 8). 9

1. Petitioners have not shown that DEQ's use of the 93.3% control efficiency was unsupported or unreasonable. 9

2. Petitioners fail to prove that the Final Permit lacks enforceable conditions to ensure 93.3% control efficiency when DEQ imposed technical limits, daily monitoring, and other substantive conditions. 11

B. Petitioners fail to show that DEQ is required to impose conditions restricting vehicle miles traveled and truck weights when DEQ imposed surrogate production limits and other requirements (Claims 1 and 8). 14

C. Petitioners did not prove that DEQ's use of 120 days of precipitation data to estimate fugitive dust emissions was arbitrary and capricious (Claims 5 and 8) 17

IV. Work Plans (Claim 3): the Final Permit requires Perpetua to develop work plans for DEQ approval and does not violate the CAA or the Idaho Air Rules. 18

V. Ambient air monitoring (Claim 13): DEQ did not violate the law by issuing a preconstruction permit that omitted ambient air monitoring. 21

VI. Arsenic T-RACT (Claims 6 and 7): because chemical dust suppressant and water are already established as reasonably available control technologies, DEQ was not required to conduct a technological or economic feasibility analysis. 22

VII. Arsenic averaging (Claim 9): DEQ reasonably exercised its discretion in evaluating the health risks from arsenic..... 25

CONCLUSION..... 27

T-RACT	Toxic air pollutant reasonably available control technology

Intervenor-Respondent Perpetua Resources Idaho, Inc. ("Perpetua") submits this reply brief in support of its motion for summary judgment.

INTRODUCTION

The Stibnite Gold Project (the "Project") is a pioneering approach to mining precious and critical minerals. Not only will it afford Valley County and resident Idahoans with economic benefits, the Project will restore a contaminated mine site that has long since been abandoned by the federal government. In 2021, Perpetua entered into a voluntary administrative settlement agreement with the United States Environmental Protection Agency ("EPA") and the United States Forest Service ("USFS"), committing millions of dollars to pre-permitting cleanup.

The Idaho Department of Environmental Quality's ("DEQ") issuance of Permit to Construct No. 2019.0047 (the "Final Permit") is the first of many permits needed to construct and operate the Project. Perpetua welcomes these regulatory reviews and commits to compliance with the many legal obligations imposed to protect public health and the environment. Following more than three years of scrutiny and review by DEQ and members of the public, including Petitioners Nez Perce Tribe, Idaho Conservation League, and Save the South Fork Salmon ("Petitioners"), Perpetua seeks affirmation of the validity of the Final Permit.

In their response brief, there is much that Petitioners conveniently ignore about the Final Permit and the exhaustive process DEQ and Perpetua navigated to get to this point. Petitioners ignore that DEQ thoroughly assessed future fugitive dust emissions from fourteen maximum emission operating scenarios. They ignore that an effective permit must conservatively address the expected mining activities and afford operational flexibility to the permittee. They ignore that an effective permit must protect the National Ambient Air Quality Standards ("NAAQS") through practically enforceable permit conditions that are consistent with DEQ programs, practices, and policies.

Overall, they ignore the expertise reflected in DEQ's careful, deliberative, thorough, and conservative three-year process to develop the Final Permit, including four requests for supplemental information and air quality analyses from Perpetua, three extended public review and comment opportunities, two public informational meetings, and three draft permits. Petitioners ignore DEQ's discretion to impose "any reasonable conditions upon an approval." IDAPA 58.01.01.211.01. And Petitioners ignore the dense record supporting DEQ's decisions following years of review and analyses, including significant attention to Petitioners' numerous and repetitive critiques.

In the end, Petitioners have not shown, as is their burden, that DEQ's decision making violated the law, was arbitrary and capricious, or was an abuse of discretion. Each of Petitioners' challenges to the Final Permit were considered and rejected (several times over the years) by DEQ based on reasoned, rational, and lawful choices. Perpetua respectfully asks the Board of Environmental Quality ("Board") to grant Perpetua and DEQ's motions for summary judgment and dismiss Petitioners' Amended Petition.

DEQ'S PERMIT RECORD AND EVIDENCE RELIED ON

For this reply brief, Perpetua continues to rely on documents from DEQ's permit file supporting the Final Permit (cited as "PET [bates #]" and "PRI [bates #]"). As part of their response, Petitioners submitted three documents that are not in DEQ's permit file but produced in discovery. Those documents are also cited as "PET [bates #]." Perpetua also relies on the Declaration of Kevin Lewis ("Lewis Decl.") submitted with this brief and the Declarations of Kevin Schilling ("Schilling Decl."), Mike Simon ("Simon Decl."), and Tiffany Floyd ("Floyd Decl.") submitted by DEQ in support of its motion for summary judgment.

STANDARD OF REVIEW

I. The Board must decide, as a matter of law, whether Petitioners proved DEQ's action was arbitrary and capricious, an abuse of discretion, or contrary to law.

It is worth repeating the standards applicable to the Board's review of the Amended Petition. First, Petitioners must prove the allegations of the Amended Petition by a preponderance of the evidence. *See* IDAPA 58.01.23.062. Second, Petitioners must prove that DEQ's issuance of the Final Permit violated the law, was arbitrary and capricious, or was an abuse of discretion. *See* Idaho Code § 67-5279(3). Third, the Board must affirm DEQ's action unless Petitioners show their substantial rights were prejudiced. *See* Idaho Code § 67-5279(4). Fourth, the Board must decide as a matter of law whether Petitioners met their burden of proof and are entitled to the relief they seek when there are no genuine disputes of material fact, as is the case here. *See* IDAPA 58.01.23.162.02, .410; I.R.C.P. 56.

Petitioners do not dispute the legal standards outlined above, except for the requirement to show prejudice to a substantial right. *See* Pet. Response Br. at 13 n.2.[1] They argue this requirement only applies to judicial review, not the Board's contested case review. Petitioners, however, initiated review under the standards of the Administrative Procedures Act and specifically Idaho Code § 67-5279, *see* Amended Petition at ¶¶ 4, 7, 35, 52, 61, 69, 72, and cannot pick and choose which parts of those standards they must satisfy.

[1] We refer to Petitioners' Opening Summary Judgment Brief (submitted Apr. 14, 2023) as "Pet. Opening Br." and Petitioners' Response to DEQ and Perpetua's Motion for Summary Judgment and Reply in Support of Petitioners' Motion for Summary Judgment (submitted June 9, 2023) as "Pet. Response Br." Perpetua's Memorandum in Support of Motion for Summary Judgment and in Opposition to Petitioners' Motion for Summary Judgment (submitted May 12, 2023) is referred to as "Perpetua Opening Br."

II. The Board may defer to DEQ's technical expertise and special skill.

In fulfilling its role as reviewer of the Amended Petition, the Board can defer to DEQ's expertise under both the Administrative Procedure Act and the Board's contested case rules. Applicable law is clear that the Board may defer to DEQ's technical expertise and special skill in evaluating its preconstruction permitting decisions. *See* Idaho Code § 67-5251(5); IDAPA 04.11.01.600; *see also J.R. Simplot Co. v. Idaho State Tax Comm'n*, 120 Idaho 849, 859, 820 P.2d 1206, 1216 (1991) ("[T]he expertise of an agency is often useful in technical areas of the law where the risk of failing to understand all of the implications of a decision are great.").

Deference is particularly appropriate here. DEQ is granted primary authority to determine specific, source-by-source emission limitations in air quality permitting. *See* Idaho Code § 39-115 (granting DEQ the authority to issue pollution source permits); *see also* Floyd Decl. at ¶ 7. As the United States Supreme Court recognized in *Train v. NRDC*, 421 U.S. 60, 79 (1975), "so long as the ultimate effect of a State's choice of emission limitations is compliance with the [NAAQS], the State is at liberty to adopt whatever mix of emission limitations it deems best suited to its particular situation."

In their response brief, Petitioners agree "that states have broad discretion to develop permit conditions." Pet. Response Br. at 34. But while admitting that DEQ has discretion to develop permit conditions, Petitioners ignore the discretion manifest in the many decisions DEQ made as part of the Final Permit. In other words, while Petitioners accept the idea of agency discretion, they then reject DEQ's use of that discretion to choose which conditions to impose or how to implement them in the Final Permit. That is illogical and absurd.

Petitioners also suggest (in their conclusion) that DEQ used its expertise as a substitute for evidence in the record. *See* Pet. Response Br. at 46 (citing *Laurino v. Bd. of Pro. Discipline of Idaho State Bd. of Med.*, 137 Idaho 596, 602 (2002)). Yet other than lobbing a disparaging

grenade at DEQ in their conclusion, Petitioners did not point to any aspect of the Final Permit that proves DEQ relied solely on its expertise. Indeed, as will be explained, DEQ carefully weighed and evaluated Perpetua's application and made professional and technical judgments that are rational, justified by the record, supported by substantial evidence, and entitled to deference.

REPLY ARGUMENT

I. Standing: Petitioners failed to demonstrate, as is their burden, that they are persons "aggrieved" by an action or inaction of DEQ.

In opposition to Petitioners' motion for summary judgment, Perpetua joined in DEQ's argument that none of the Petitioners demonstrated legal standing, as is each Petitioner's burden. *See* Perpetua Opening Br. at 13-14. Petitioners provided absolutely no evidence to show they were aggrieved persons under Idaho Code § 39-107(5) and IDAPA 58.01.23.005.01. *Id*. For the first time, in their response, Petitioners submitted declarations purporting to show that each of them has legal standing. Those evidentiary submissions do not show the Petitioners will suffer an injury that is causally connected to the challenged DEQ action, nor do Petitioners show any real and actual injury. The Board must dismiss the Petition for this reason alone.

II. Ambient air boundary (Claims 11 and 12): DEQ followed EPA guidance and exercised discretion to exclude the Stibnite Access Route from the Project's ambient air boundary.

DEQ conformed to EPA guidance and exercised reasonable discretion in excluding the Stibnite Access Route from the Project's ambient air boundary. While Petitioners raise several questions in their response brief and may have different opinions on how DEQ should have established the ambient air boundary, Petitioners fail to meet their burden to show that DEQ's decision is arbitrary, capricious, or an abuse of discretion. As demonstrated by the underlying

record and EPA guidance, DEQ's decision to exclude the Stibnite Access Route from the ambient air boundary is rational and reasonable and supported by substantial evidence.

Petitioners present two primary misunderstandings in their response brief: (1) Perpetua is unable to control access on the Stibnite Access Route and (2) the individuals traveling on the road cannot be considered "guests of the mine." Pet. Response Br. at 15-16. For the following reasons, both opinions are unavailing and should be rejected.[2]

With respect to control, Perpetua controls access to the Stibnite Access Route consistent with EPA's updated 2019 guidance defining ambient air (the "2019 Guidance"). *See* PET 772. That analysis is thoroughly addressed in earlier submittals by Respondents. *See* Perpetua Opening Br. at 23-28; Schilling Decl. at 7-8. Yet Petitioners challenge Perpetua's control over the route by misrepresenting statements made in an USFS Air Quality Specialist Report (the "USFS Report"), PET 885, and a memorandum developed for USFS by Stantec Consulting Services, PET 838. According to Petitioners, "the mine plan that is in front of the U.S. Forest Service for review and approval *requires* that 'public access through the site would be provided by' the new Route." Pet. Response Br. at 15 (emphasis added). This reading of the USFS Report and Stantec memorandum is fundamentally wrong and misleading.

[2] In addition to their two primary viewpoints, Petitioners inaccurately predict that the Stibnite Access Route "will be polluted with undisclosed and unregulated amounts of PM_{10} and arsenic, and other criteria, toxic, or hazardous air pollutants as the health-based limits established under the CAA and the Idaho Air Rules will not apply." *See* Pet. Response Br. at 13. This statement is misleading and wrong. Activities and emissions throughout the Project, including on the Stibnite Access Route, will be highly regulated by the Final Permit to control the fully disclosed and thoroughly analyzed estimated emissions of regulated air pollutants. Excluding the route from the ambient air boundary means that compliance with the NAAQS and ambient TAPs concentrations is demonstrated at other locations representing the operational perimeter of the Project. For TAPs, this approach is consistent with IDAPA 58.101.210.03. For NAAQS, this approach follows EPA guidance. *See* Schilling Decl. at 7-8.

As the record demonstrates, Perpetua volunteered to construct the Stibnite Access Route for limited connectivity to Thunder Mountain Road and points beyond. PET 529. Perpetua is not legally obligated to construct the Stibnite Access Route and has sole and complete control over construction, operation, and use of the road, including complete closure of the road when necessary for safety or operational reasons. PET 310-311, 570. It follows, and should be clear, that the USFS Report and the Stantec memorandum merely report what Perpetua volunteered to do and will do once the mine plan is approved. *See* PET 838-839, 917-918, 964.

The USFS Report states that access through the Project will be provided by constructing a new route around the Yellow Pine pit and below the mine haul road to link Stibnite Road to Thunder Mountain Road. PET 957. The report does not require the Stibnite Access Route and does not treat the route as an ambient air boundary. *See* PET 917-918. In fact, the Stantec memorandum concludes that the route is exempt from the ambient air boundary:

> After review of all pertinent information associated with other cooperating agencies, it is Stantec's understanding that the public access road can be justifiably excluded from ambient air consideration. The State agency responsible for issued air permits has excluded the road because of restriction measures put in place consistent with their rules and requirements in the permit. Also, EPA Region X has accepted DEQ's conclusions.

PET 839. Thus Petitioners' argument that Perpetua does not have the legal or practical ability to preclude public access is disingenuous, as they ignore the record and fail to cite any authority to support its position. *See* Pet. Response Br. at 15-16.

Conversely, the record and the Final Permit illuminate the many ways the general public is legally and physically precluded from accessing the Stibnite Access Route. *See* Perpetua Opening Br. at 20-21. Under Condition 2.7, only authorized vehicles and individuals can enter the route, and Perpetua must maintain, control, and monitor access points. PET 10. Conforming to these controls allows only "guests" to transgress the Project area. *Id*. Perpetua must develop an

Access Management Plan ("AMP") such that "[o]nly registered guests of the facility will be allowed access to or though the facility." *Id.*; *see also* Schilling Decl. at 8.

Petitioners claim that those accessing the Stibnite Access Route cannot be considered "guests of the mine," Pet. Response Br. at 16-17, but they ignore DEQ's record and reasoned analyses. Petitioners' argument on the semantics of a "guest" is unpersuasive. Based on Condition 2.7 and Perpetua's physical and non-physical barriers to entry, only registered vehicles and their passengers will be permitted entry onto the Stibnite Access Route. PET 10. Vehicles will be supervised, cannot stop, and must check out at the egress point. *See id*. The elaborate measures at both entry and egress locations, plus supervision of vehicles requiring continuous movement without stopping along the route, reinforce Perpetua's control of the route, in contrast to a county road or other thoroughfare that is uninhibitedly open to the general public. The measures required by the Final Permit preclude access by the general public and support DEQ's well-reasoned decision to exclude the Stibnite Access Route from the ambient air boundary.

Petitioners also argue that Perpetua's reliance on *REDOIL v. U.S. EPA*, 716 F.3d 1155, 1165 (9th Cir. 2013), is misplaced since the fact patterns are not identical. Pet. Response Br. at 14 n.5. Perpetua, however, did not and does not contend that the cases are identical. Rather, Perpetua cited *REDOIL* because it is relevant authority on agency discretion to determine the ambient air boundary. Perpetua Opening Br. at 18-19, 21. The case stands for the notions that safety zones and control measures influence ambient air boundary analyses, and deference is allowed for agency decisions. *See id*.

Perpetua demonstrated that it has legal and practical ability to exclude the general public from the Stibnite Access Route consistent with EPA's 2019 Guidance. DEQ concluded after thorough deliberation and consultations with EPA Region 10 that the Stibnite Access Route was

properly excluded from the ambient air boundary. *See* PRI 10, 156; Schilling Decl. at 8 & Ex. A. The Board should uphold DEQ's well-supported and documented determination.

III. Fugitive dust emissions (Claims 1, 2, 5, and 8): DEQ did not act arbitrarily and capriciously or violate the Idaho Air Rules in determining that fugitive dust emissions from the Project's roads will comply with the PM_{10} NAAQS and arsenic AACC.

Petitioners insist that DEQ's conclusions regarding fugitive dust emissions from unpaved roads are arbitrary and capricious and violate the Rules for the Control of Air Pollution in Idaho, IDAPA 58.01.01, *et seq*. (the "Idaho Air Rules"). After exhaustive review (much of it in response to Petitioners' public comments), DEQ concluded that these emissions will neither cause nor contribute to violations of the PM_{10} NAAQS and the acceptable ambient concentration for a carcinogen ("AACC"). DEQ also concluded that a 93.3% control efficiency for fugitive dust from the haul roads was appropriate. Petitioners disagree with DEQ's assessment and prefer that it use a lower control efficiency. DEQ imposed enforceable permit limits and conditions to ensure the 93.3% control efficiency is achieved to reduce emissions. Petitioners disagree with that work too and would add more permit limits and conditions to control operations. Petitioners' objections are simply a difference of opinion. Petitioners have not shown that DEQ's choices were unreasonable, unsupported, irrational or unlawful.

A. DEQ reasonably determined that 93.3% control efficiency for fugitive dust from haul roads was attainable and enforceable (Claims 2 and 8).

1. Petitioners have not shown that DEQ's use of the 93.3% control efficiency was unsupported or unreasonable.

Petitioners fail to meet their burden to prove that DEQ's use of the 93.3% control efficiency to predict emissions from the haul roads was unsupported or unreasonable. DEQ reasonably established the 93.3% control efficiency based on a combination of dust suppressant

chemical application (90% control) and watering (33% control).[3] *See* PET 143, 551. Petitioners do not contest these individual control efficiencies, nor do they contest that chemical suppressant and water are commonly used together to control fugitive dust emissions from unpaved roads. *See* Pet. Response Br. at 17-21; *see also generally* PET 90, 551, 558; Simon Decl. at 13. Petitioners repeat the same refrain "that there is no evidence for, and no rationale provided, that supports a finding that Perpetua will be able to achieve 93.3% dust control efficiency by using a *combination* of chemical dust suppressants and water." Pet. Response Br. at 19 (emphasis in original). Petitioners simply ignore DEQ's robust, reasoned, and rational analysis and decision making reflected in the permit record.

For their response, Petitioners rely on a similar argument they made in public comments: of the seven case-specific projects that DEQ identified from the EPA RACT/BACT/LAER Clearinghouse ("RBLC") database, "*none* of them were able to achieve higher than 90% control efficiency" using a combination of chemicals and water. *Id*. (emphasis in original); *see also* PET 557-558. Petitioners' reading of the RBLC database is wrong. They also rely on EPA's comments that the permitting record "does not appear to provide support for" the 93.3% control efficiency. Pet. Response Br. at 20; *see also* PET 556. This reference highlights that both Petitioners and EPA choose to ignore the dense permit record.

The RBLC database provides the *minimum* control efficiency required for 10 major stationary source projects using chemical dust suppressants or a combination of chemical suppressants and watering. *See* PET 546-547. The database does not report the maximum control

[3] DEQ explained in its response to comments that it could have listed the control efficiencies separately for chemical (90% control) and water (33.3% control), but it chose to combine the control efficiency as 93.3% to emphasize the importance of using chemical and water suppressants in combination. PET 557, 558.

efficiency achieved by the projects. *See id*. As the permitting authority familiar with the RBLC database, DEQ concluded the database identified projects—including gold, cement and concrete, steel, and quarry projects—referencing control efficiency of 90% *or greater* for unpaved roads. *Id*. When using chemical suppressants alone, two of the RBLC projects identified a 90% control efficiency and one of the projects a 98% control efficiency. PET 547. DEQ found those and the other projects representative of circumstances presented by Perpetua. PET 546. Petitioners ignore this work by DEQ.

To bolster its analysis, along with its assessment of the RBLC database, DEQ relied on AP-42 examples, which likewise supported a control efficiency over 90% when chemical and water suppressant is used in combination. *Id*. As DEQ noted, test reports referenced in AP-42 13.2.2 show that a chemical suppressant alone can achieve 90% to 99% control efficiency and 98% for magnesium chloride in particular. PET 546-547. Watering alone achieves 75% to 95% control efficiency. *Id*. DEQ also found that fugitive dust from the haul roads was likely to be controlled at levels greater than 93.3% during wintertime conditions when the site receives an average snow depth of 21-68 inches and 6 inches of average precipitation. PET 558-559.

Ultimately DEQ chose to rely on empirical data gleaned from the RBLC database and AP-42 rather than rely on Petitioners' opinions and unsupported critiques of DEQ's professional analyses. *See* PET 551, 558, 620. Petitioners lack any evidence that DEQ's decisions were arbitrary and capricious or unsupported by the record.

2. Petitioners fail to prove that the Final Permit lacks enforceable conditions to ensure 93.3% control efficiency when DEQ imposed technical limits, daily monitoring, and other substantive conditions.

Petitioners make much of DEQ's recognition that meeting the 93.3% control efficiency for fugitive dust from the haul roads "requires conscientious efforts, vigilant inspection and monitoring, and a comprehensive FDCP." Pet. Response Br. at 18-19 (citing PET 90, 328).

Petitioners contend the Final Permit only "requires Perpetua to generally control dust by using chemical dust suppressants and water" and that the Final Permit lacks legally or practically enforceable permit limits and conditions to ensure the control efficiency is met. *Id*. at 21. But as Perpetua explained in its opening brief, Petitioners simply want different conditions from those imposed by DEQ. *See* Perpetua Opening Br. at 23-30. Petitioners seek to substitute their choices for DEQ's. Yet Petitioners cannot prove that the conditions imposed in the Final Permit are arbitrary and capricious or violate the Idaho Air Rules.

Petitioners blatantly misrepresent Perpetua's argument in support of the adequacy of the Final Permit. As told by Petitioners, "Perpetua argues that there is no 'legal authority' that requires DEQ to include legally and practically enforceable permit conditions." Pet. Response Br. at 21 (citing Perpetua Opening Br. at 23-24). Perpetua said no such thing. Perpetua took issue with Petitioners' unsupported contention that DEQ must include the specific conditions demanded by Petitioners on the type, quantity, application rate, and frequency of using dust suppressants. As Perpetua pointed out, Petitioners "cite to no legal authority that DEQ was required to include those conditions" to satisfy the requirements of Section 211. Perpetua Opening Br. at 23-24. That was true then, and it is true now.

Petitioners maintain the same opinions and preferences for enforceable permit conditions that they expressed throughout the permit process, without citing any requirement under the Idaho Air Rules that DEQ must impose the specific conditions on the specific activities that Petitioners prefer. Moreover, Petitioners ask the Board to view each condition in isolation for adequacy, without considering how the Final Permit's numerous conditions operate together to require and verify compliance with the 93.3% fugitive dust control efficiency. DEQ determined that the totality of conditions imposed in the Final Permit, including monitoring, recordkeeping,

and reporting, are practically enforceable and sufficient to achieve compliance. *See* PET 558-559.

For emphasis consider: Conditions 1.2 establishes the 93.3% fugitive dust control efficiency, PET 3; Condition 3.5 establishes mine production limits through daily and annual hauling and excavating limits, PET 19; and Condition 3.13 establishes maximum silt content of 4% for capping haul roads and the contents for the Haul Road Capping Plan ("HRCP"), PET 19-20. Conditions 2.2, 2.4, 2.5, and 2.6 then provide enforceable conditions for achieving 93.3% haul road dust control by the proper application of dust suppressant chemicals and watering. Condition 2.2 requires monitoring and recordkeeping of fugitive dust control methods twice a day; Condition 2.4 requires daily facility-wide inspections, recordkeeping, and immediate corrective action if fugitive dust is not controlled; Condition 2.5 requires fugitive dust control measures at all times to ensure no more than 10% opacity and immediate corrective action if the limit is not met; and Condition 2.6 requires a Fugitive Dust Control Plan ("FDCP"). PET 8-9. In total, DEQ imposed a robust and extensive set of conditions to control fugitive dust.

Those conditions also refute Petitioners' opinions and complaints that DEQ did not include actual monitoring and recordkeeping requirements to ensure compliance. *See generally* Pet. Response Br. at 22-23. As for monitoring, Condition 2.4 again establishes a daily monitoring time interval. PET 8. As for recordkeeping, chemical suppressant and water applications must be recorded every 12 hours under Condition 2.2, dust complaints must be recorded under Condition 2.3, and all inspections and corrective actions must be recorded under Condition 2.4. PET 9. Condition 3.13 requires haul road inspections and silt content sampling. PET 20. Moreover, Condition 7.10 establishes detailed recordkeeping requirements for

monitoring records, and Condition 7.11 requires documentation and reporting of excess opacity emissions. PET 40-41.

Petitioners' repeated observation that the Fugitive Dust Control Plan ("FDCP") and its contents are "unknown" is also easily refuted. *See generally* Pet. Response Br. at 23. In Condition 2.6, DEQ provides detailed instructions for the contents of the FDCP, including: maximum speed limits for haul trucks; the application of chemical suppressant and water to haul roads; the maintenance of roads; criteria to determine frequency, type, and application rates of dust suppressant consistent with manufacturer's instructions and recommendations; trained and EPA certified inspectors; and yearly evaluation of those requirements and practices. PET 9-10. These elements of the FDCP required by Condition 2.6 provide Petitioners ample knowledge on the contents of the FDCP.

Despite express limits and extensive conditions requiring "conscientious efforts, vigilant inspection and monitoring, and a comprehensive FDCP," Petitioners just disagree with the conditions DEQ chose. Petitioners ask the Board to ignore DEQ's expertise and experience and substitute Petitioners' choices for DEQ's. No matter how many times Petitioners express their opinions, they fail to prove that DEQ acted unlawfully, unreasonably or irrationally in exercising discretion to impose limits and conditions that together ensure the legal and practical enforceability of the 93.3% control efficiency. Claims 2 and 8 must be dismissed.

B. Petitioners fail to show that DEQ is required to impose conditions restricting vehicle miles traveled and truck weights when DEQ imposed surrogate production limits and other requirements (Claims 1 and 8).

Petitioners are also wrong that the Final Permit is unenforceable because it does not include limits on vehicle miles traveled, truck weights, and speed limits. Pet. Response Br. at 24-26. Petitioners finally admit there are no requirements under the Idaho Air Rules to include those parameters as enforceable permit limits, yet they still contend DEQ acted arbitrarily and

capriciously by not considering or including them and by using production limits instead. *Id*. Petitioners ignore the support in the record for the use of production limits to constrain vehicles miles traveled, truck weights, and speed limits. *Id*.

As already explained in Perpetua's opening brief, DEQ disagreed with Petitioners' assessment and exercised discretion to develop the Final Permit as issued. Nothing about DEQ's decision to limit production, as one of many controls on fugitive dust emissions, was unreasonable or irrational. The record reflects that DEQ considered all emissions inputs and variables, both minor and critical, and established enforceable permit conditions to control fugitive dust. *See* Perpetua Opening Br. at 27-30.

Over the three years and in response to repeated comments from Petitioners on this topic, DEQ estimated fugitive dust emissions from the haul roads using 14 maximum emission scenarios, evaluating the silt content of the road, vehicle miles traveled, and the average weight of the haul truck fleet. PET 797-798, 800; Simon Decl. at 9; Lewis Decl. at ¶¶ 4, 8-9. DEQ also modeled numerous mining scenarios, each using a maximum production rate of 180,000 tons per day, which was repeated for 365 days per year, to define conservative, upper-bound emissions cases for the Project. PET 275-276, 551; *see also* Lewis Decl. at ¶¶ 8-10. Actual production will not be 180,000 tons per day, 365 days per year, but approximately 116,964 tons per day. PET 65.

DEQ relied on Perpetua's mining knowledge and business objectives to optimize operations, as reflected in the emissions estimates and project descriptions presented in the application for the Project. For example, Perpetua intends to use the largest trucks possible based on safety, operational, and cost considerations. Using large trucks requires less labor and less fuel and results in less dust emissions. This operational input is utilized to estimate emissions for the application but is not an operational detail that would be within DEQ's scope to dictate in the

Final Permit. DEQ's role is to review the Project as defined by Perpetua, not to direct Perpetua in the design or operating details, like dictating truck size. *See* Lewis Dec. ¶¶ 9-12.

Ultimately, as discussed above, DEQ chose three variables to be the most effective and practically enforceable permit conditions: 93.3% control efficiency, a haul road silt content limit, and daily production limits for hauling and excavation. *See* PET 3, 19-20, 551-552; Lewis Decl. at ¶¶ 11-12. DEQ explained the importance of those variables to emissions estimates and ensuring compliance with the PM_{10} NAAQS. PET 551-552, 557, 567, 572. DEQ also reasoned that enforceable emissions limits are not commonly included for fugitive sources; production rates limits are used for process rate-limiting sources; production rate limits "serve as surrogate emissions limits for PM, PM_{10}, $PM_{2.5}$, HAP and TAP from fugitive sources"; variables for vehicle speed limit, type, and miles traveled are not typically included in a permit, but can be found in Perpetua's application materials; and enhanced monitoring of silt content and production levels would verify estimated vehicle miles traveled. PET 557, 562, 574, 578-579, 611; *see also* Lewis Decl. at ¶ 11.

Finally, Petitioners argue that "the actual permit limitation found in Permit condition 3.5 does not have any associated monitoring or recordkeeping requirements to ensure compliance." Pet. Response Br. at 26. Perpetua has already shown that is not true. *See* Perpetua Opening Br. at 32-34. Condition 3.16 requires daily and monthly monitoring to ensure compliance with the production limits, PET 20, and Condition 7.10 requires those records be retained for at least five years, PET 40. Further, Condition 3.16 requires that the devices and methodologies used to measure production be identified in the Operations and Maintenance Manual ("O&M Manual"). PET 20. And just like the FDCP, the Final Permit mandates detailed requirements for the

contents of the O&M Manual. PET 13 (Condition 2.20 requiring a regular schedule for operation, inspection, maintenance, and repair of devices).

In sum, Petitioners fail to show that the Final Permit lacks practically enforceable monitoring requirements to ensure compliance. The Board must dismiss Claims 1 and 8.

C. Petitioners did not prove that DEQ's use of 120 days of precipitation data to estimate fugitive dust emissions was arbitrary and capricious (Claims 5 and 8).

Petitioners also continue to take issue with DEQ's choice of 120 days of precipitation per year (rain and snow) to estimate fugitive dust emissions from the Project's access road. Recall that this value is provided in AP-42. *See* PET 146. Petitioners contend that DEQ failed to consider "true site conditions when the data is available," yet they fail to cite any legal requirement that the agency do so. *See* Pet. Response Br. at 27. Moreover, they fail to cite what local data DEQ should have used or show how the data used by DEQ underestimated fugitive dust emissions from the access road. *See id*.

Petitioners again ignore DEQ's reasoned decision to use the 120 days per year value. DEQ considered local precipitation data collected by Perpetua in 2014, which showed 155 days of precipitation.[4] Schilling Decl. at 13. DEQ also considered data (showing 113 days of precipitation per year) from a weather station that is over 40 kilometers from the Project. DEQ found neither dataset appropriate and choose the 120 days per year value from AP-42. DEQ also noted that the weather station data nearly matched AP-42, which was far more conservative than the site specific 2014 data. *Id*. Petitioners fail to explain how DEQ's choice was unreasonable or irrational, based on clearly erroneous findings, or prejudices their substantial rights.

[4] Perpetua and DEQ differ on the number of days of precipitation in 2014: Perpetua calculated 168 days, and DEQ calculated 155 days. *See* Perpetua Opening Br. at 31; Schilling Decl. at 13. Regardless, the available local data shows far more days of precipitation than AP-42's default 120 days per year.

Petitioners simply prefer a different precipitation input. Claims 5 and 8 must be dismissed because Petitioners fail to demonstrate, as is their burden, that DEQ's decision making was arbitrary and capricious.

IV. Work Plans (Claim 3): the Final Permit requires Perpetua to develop work plans for DEQ approval and does not violate the CAA or the Idaho Air Rules.

DEQ lawfully required future development of the AMP, FDCP, HRCP, and O&M Manual in the Final Permit. Petitioners' argument that the Final Permit is "incomplete" ignores the evidence in the permit record, ignores DEQ's well established practice, and is legally unfounded. Petitioners cite Section 202.01 of the Idaho Air Rules and argue the work plans at issue were required "plans" to be submitted as part of Perpetua's permit application and to be circulated for public comment. Pet. Response Br. at 28. There is no textual support that the AMP, FDCP, HRCP, and O&M Manual are "plans" as that term is used in Section 202.01. Petitioners fail to present any argument to support their interpretation of the word. DEQ's interpretation of its rules, plus its authority to determine an application complete and to request additional information that DEQ needs to make the determinations required, like whether the Project will cause or contribute to a violation of the NAAQS per Section 202, are entitled to deference. Section 202.03. Notably, none of DEQ's incompleteness letters to Perpetua requested that the work plans be included in the permit application.

Petitioners contend that DEQ failed to develop important permit conditions for work plans, but DEQ included permit conditions prescribing great specificity for Perpetua's work plans. PET 9-10 (Condition 2.6 (FDCP) and Condition 2.7 (AMP)), 12-14 (Condition 2.20 (O&M Manual)), 19-20 (Condition 3.13 (HRCP)). DEQ requires that the work plans "ensure compliance" with pertinent requirements. *See*, *e.g.*, PET 009 (Condition 2.6: "The Permittee shall develop and maintain a FDCP to ensure compliance with fugitive dust requirements (Permit

Conditions 2.1-2.5) and also fugitive dust best management practices…in accordance with IDAPA 58.01.01.799.").

Petitioners ignore the explicit permit conditions prescribing the contents of the work plans. *See*, *e.g.*, PET 012-014 (Condition 2.20 detailing nine specific items to be included in the O&M Manual). The Final Permit requires Perpetua to develop and submit for DEQ approval at least 30 days prior to startup a FDCP, O&M Manual, AMP, and HRCP. PET 9-10 (Condition 2.6 (FDCP) and Condition 2.7 (AMP)), 12-14 (Condition 2.20 (O&M Manual)), 19-20 (Condition 3.13 (HRCP)). The Final Permit details the minimum and substantive requirements that Perpetua must account for in the work plans. *Id*. Once approved, the work plans and manuals are incorporated into the permit and are enforceable. *Id*.

DEQ confirmed that requiring work plans after issuance of the Final Permit and prior to startup for DEQ review and approval complies with the Idaho Air Rules, its discretion therein, and agency practice:

> DEQ contends the requirement to review and approve each Plan and Manual after the permit is issued and prior to facility startup is sufficient, reasonable, and appropriate to ensure compliance with applicable requirements…[;] DEQ uses its authority to require a permittee to develop and submit for DEQ approval Plans and Manuals in accordance with IDAPA 58.01.01.211.01.[5]

Simon Decl. at 9. DEQ explains that this is standard protocol, because more information becomes available after the permit application is approved and prior to startup, such as actual equipment purchased and installed, and the operational activities implemented after construction is completed. *Id*. at 10.

[5] Petitioners state that "DEQ does not even argue that the work plans comply with the Air Rules," but Simon's Declaration speaks directly to this point. *Compare* Pet. Response Br. at 29 *with* Simon Decl. at 9.

Contrary to Petitioners' accusations, DEQ is not "shielding" work plans from public review. DEQ placed the specific requirements for content of the work plans in plain sight within the Final Permit and DEQ intends to publish the approved work plans on the agency website. DEQ is not required to review and approve work plans during the preconstruction permit review process, nor is public review appropriate for the specific operational choices implemented by the permittee in those plans.

Petitioners fail to point to any legal obligation in the Idaho Air Rules, or the Clean Air Act ("CAA") more generally, that requires AMPs, FDCPs, HRCPs, or O&M Manuals be circulated for public comment and review. Petitioners attempt to shift the burden to Perpetua and DEQ when it states "Perpetua does not point to any Air Rule or CAA cases" related to excluding work plans during CAA permitting processes. Pet. Response Br. at 32. This is Petitioners' burden. And there are no Idaho Air Rules or CAA cases for either party to cite because the Idaho Air Rules and CAA do not require these documents in the application nor in the public review process.

Petitioners rely on Clean Water Act ("CWA") cases ignoring the distinct statutory requirements of the CWA. The cases cited are distinguishable and inapposite because they (1) relate to an entirely different federal law and permitting scheme and (2) address information that is expressly required by the CWA to be provided to the public. In *Environmental Defense Center, Inc. v. U.S. EPA*, the Ninth Circuit held Notices of Intent needed to be made available to the public due to the express requirements of the CWA. 344 F.3d 832, 858 (9th Cir. 2003). Similarly, in *Waterkeeper Alliance, Inc. v. U.S. EPA*, the Second Circuit held nutrient management plans are requisite effluent limitations and must be made available to the public by the express terms of the CWA. 399 F.3d 486, 492 (2d Cir. 2005). Petitioners' citation to

Waterkeeper Alliance underscores that the reason the Second Circuit held the nutrient management plans are required to be made publicly available is because these plans constitute effluent limitations and, even if they did not, "'site specific nutrient management practices'" are explicitly listed in EPA's Preamble to the Rule as necessary. *Id*. at 504 (citation omitted).

Petitioners try to extrapolate that because the Ninth Circuit and Second Circuit upheld express requirements of the CWA that address what needs to be made publicly available, the Board here must offer Perpetua's work plans for public comment, too. Pet. Response Br. at 33. This argument has no merit because neither the CAA nor Idaho Air Rules require the Board to do so. Rather, the Idaho Air Rules and relevant CAA jurisprudence provide that DEQ has broad discretion in development of permit conditions. *Train*, 421 U.S. at 79; IDAPA 58.01.01.211.01.

Petitioners agree that "states have broad discretion to develop permit conditions." Pet. Response Br. at 34 but reject DEQ's manifestations of that discretion. That Petitioners would like something different or something more detailed is inapt. DEQ's approach to the work plans complies with the Idaho Air Rules, its discretion, and its practice. The Board should accordingly reject Petitioners' Claim 3.

V. Ambient air monitoring (Claim 13): DEQ did not violate the law by issuing a preconstruction permit that omitted ambient air monitoring.

Petitioners acknowledge that DEQ has discretion to require ambient air monitoring. Pet. Response Br. at 34-35. Petitioners present no new arguments on this point, nor do they explain how DEQ erred in a manner that would be reversible. *See id*. Instead, based on their difference of opinion about the effectiveness of the conditions of the Final Permit, Petitioners argue that DEQ should have required ambient air monitoring. Petitioners point to their standing declarations to suggest that since people will be infrequently accessing areas around the Project, DEQ must protect these individuals by requiring ambient air monitoring. Petitioners fail to differentiate the

Project, the Final Permit, or these infrequent visitors from any other permit issued by DEQ that does not require ambient air monitoring.

As explained by both Kevin Schilling and Mike Simon, requiring an ambient air monitor for a remote facility that is not located near relatively permanent sensitive receptors (like a school) is not consistent with DEQ's practice. Simon Decl. at 10-11; Schilling Decl. at 19. Further, as Kevin Schilling explained, a monitor does not ensure compliance with the NAAQS because it only reflects an isolated location. Schilling Decl. at 19. Here, DEQ followed its practice, applied its expertise and judgment, established enforceable permit conditions to ensure compliance with the Air Rules, and determined that no ambient air monitor was necessary or appropriate in these circumstances. Petitioners have not identified a reversible error or even a legal theory of reversible error, instead, Petitioners just do not like DEQ's decision. Therefore, The Board should accordingly reject Petitioners' Claim 13.

VI. Arsenic T-RACT (Claims 6 and 7): because chemical dust suppressant and water are already established as reasonably available control technologies, DEQ was not required to conduct a technological or economic feasibility analysis.

Petitioners criticize DEQ for failing to analyze the economic feasibility and environmental impacts of Perpetua's use of chemical dust suppressants and frequent watering. Pet. Response Br. at 36-40. Petitioners ignore the totality of the applicable rules and focus narrowly on IDAPA 58.01.01.210.14(c) and (d). Petitioners' argument also ignores DEQ's toxic air pollutant reasonably available control technology ("T-RACT") selection process and the common knowledge of the control technologies that were selected.

As explained in Perpetua's opening brief, the control technologies selected as T-RACT are both well recognized by DEQ and EPA and are even required by the Air Rules. Perpetua Opening Br. at 41-42. Reading the Air Rules as Petitioners do would require DEQ and each applicant to repeatedly evaluate accepted and non-controversial control technologies such as

basic filters, bag houses, and commonly applied dust suppressants. Take watering and chemical dust suppressant, which are required by IDAPA 58.01.01.651.01 and .02 for fugitive dust control – no economic or technological feasibility analysis is required by these rules. But, under Petitioners' reading of the Air Rules, any applicant that designates watering or chemical suppressant as T-RACT must evaluate the economic and technological feasibility of these methods. This is truly an absurd result.

Instead of the absurd result urged by Petitioners, DEQ's approach to implementing T-RACT is efficient and recognizes the effects and impacts of commonly utilized methods of emissions control, especially those methods prescribed by DEQ in its own rules. DEQ identifies the most effective control technology that is feasible and reasonably available—which is what the Idaho Air Rules require. IDAPA 58.01.01.210.14. As explained in Mike Simon's declaration, Idaho's T-RACT rules were developed to follow the same process as the selection of Best Available Control Technology ("BACT") for major new sources. Simon Decl. at 11. The process of selecting control technology under both T-RACT and BACT follows a five-step approach:

1) Identify all available control options;
2) Eliminate technically infeasible options;
3) Rank remaining control technologies;
4) Consider the energy, environmental and economic impacts;
5) Select the most effective control technology not eliminated in Step 4.

Id. at 11-12.[6]

Perpetua followed this process in its T-RACT analyses to confirm selection of the methods required for fugitive dust control. PET 544. First, Perpetua queried EPA's RBLC

[6] *See also* John Calcagni, Director, Air Quality Management Division, *Transmittal of Background Statement on "Top-Down" Best Available Control Technology (BACT)*, U.S. Environmental Protection Agency (June 13, 1989), https://www.epa.gov/sites/default/files/2015-07/documents/topdawn.pdf.

database to identify all possible control technologies and identified those potential control technologies in its T-RACT analyses. PET 546. Perpetua then provided DEQ with information regarding which technologies were not technologically feasible and why. PET 544, 547. After determining certain control technologies were not feasible (wet drilling and paving haul roads), Perpetua then selected *all* of the remaining identified control technologies as T-RACT. Perpetua also included capping the haul roads with low-arsenic development rock as an additional T-RACT work practice. PET 548.

Petitioners' argument that DEQ erred by failing to thoroughly analyze the environmental and economic feasibility of well-recognized control technologies ignores the common knowledge of these methods reflected in DEQ's rules, and ignores the process that DEQ uses to select T-RACT.

Under the process utilized by DEQ, the applicant and DEQ are only required to analyze the technological and economic feasibility of a control technology if the applicant asserts that it is not reasonably available. Perpetua and DEQ agreed that paving haul roads and wet drilling were not technologically feasible based on the process and operating parameters of the Project. PET 70; PET 544, 547. Perpetua then selected all of the remaining control technologies as T-RACT, thus DEQ was never called on to evaluate whether the remaining control technologies were economically or technologically feasible because both DEQ and Perpetua recognized that they were reasonably available.

DEQ's approach in the Final Permit was entirely consistent with the Air Rules. Nowhere do the Air Rules require that DEQ conduct a technological and economic feasibility analysis of each proposed control technology. *See* IDAPA 58.01.01.210.14.b. Instead, and consistent with DEQ's approach, described above, Section 210.14.c and .d set forth factors that DEQ and the

applicant are to consider on a case-by-case basis to determine that an identified control technology is not "reasonably available." This is an entirely reasonable and consistent interpretation of the Air Rules, and as such is entitled to deference. *See Idaho Power Co. v. Idaho PUC*, 155 Idaho 780, 791 n.2, 316 P.3d 1278, 1289 n.2 (2013) (Jones, J. concurring) ("As a general rule, courts defer to an agency's interpretation of its own regulations unless the interpretation is 'plainly erroneous or inconsistent with the regulation.'" (quoting *Auer v. Robbins*, 519 U.S. 452, 461 (1997)). Therefore, the Board should accordingly dismiss Petitioners' Claims 6 and 7.

VII. Arsenic averaging (Claim 9): DEQ reasonably exercised its discretion in evaluating the health risks from arsenic.

Petitioners disagree with DEQ's approach for evaluating whether arsenic emissions will injure or unreasonably affect human or animal life or vegetation, as required by the Idaho Air Rules. But they cannot decide on a legal theory, much less demonstrate how DEQ's decision warrants reversal. In their opening brief, Petitioners argued that DEQ's arsenic analysis "violates the Air Rules" by allowing arsenic emissions to exceed the AACC. Pet. Opening Br. at 36-37. In their response brief, Petitioners abandon this position and argue that "DEQ's determination that the Project's arsenic emissions demonstrates preconstruction compliance with the Air Rules Section 210.12 is unreasonable, arbitrary and capricious, and unsupported by the record." Pet. Response Br. at 45. Both of Petitioners' legal theories ignore the record and reveal Petitioners' lack of understanding of the complex analyses conducted by DEQ.

As documented in the record and described in DEQ's TAPs Modeling Review Attachment, PET 331, DEQ thoroughly evaluated Perpetua's modeling and analyses of arsenic emissions. *See* Perpetua Opening Br. at 48-49. DEQ considered the conservative aspects of the TAPs compliance framework, which likely overstated the estimated TAPs emissions impacts

from the Project. PET 333. Further, DEQ evaluated the potential lifetime exposure of a receptor to carcinogenic TAPs, which was appropriate because carcinogenic impacts are of concern from a long-term exposure basis. PET 332. No other aspect of emissions from the Project received more discussion by both Perpetua and DEQ (or more criticism from Petitioners during the many public comments) than TAPs emissions, and specifically arsenic emissions. *See* PET 331-354; PET 596-609; PRI 581-806; PRI 807-811.

DEQ's exhaustive analyses were entirely reasonable considering the health risks posed by arsenic and the purpose of the TAPs requirements in the Air Rules. As explained in Perpetua's opening brief, arsenic is a carcinogen, and the Air Rules establish limits for arsenic emissions based on a lifetime – 70 year – exposure.[7] Perpetua Opening Br. at 47-48.

Kevin Schilling explains that the air permitting process was established primarily to regulate well-defined sources that have consistent emissions through time. Schilling Decl. at 8. Assessing emissions from fugitive sources at a dynamic mine site is significantly more difficult due to the dynamic nature of the mining activity and emissions generating activities. *Id.* DEQ's approach, of evaluating worst-case emissions over a five-year averaging period and accounting for the lifetime operations of the Project, more accurately reflected the variability inherent in fugitive emissions from the Project and was consistent with the intent of the Air Rules. *Id.* at 12.

DEQ's analyses were also consistent with the text of the Air Rules. Under the Air Rules for sources using T-RACT, DEQ compared the source's approved T-RACT ambient

[7] Petitioners suggest that the definition of Toxic Air Pollutant Carcinogenic Increments which describes the basis for the values established in the AACCs is no longer operative. However, the version of the Air Rules containing the definition was still in effect when DEQ issued the Permit, and is therefore still applicable for purposes of reviewing the Permit. *See Hoppe v. Nichols*, 100 Idaho 133, 137, 594 P.2d 643, 647 (1979). This definition was not removed as a material change in the Air Rules, but was instead part of a regulatory cleanup. Schilling Decl. at 11.

concentration at the point of compliance to the amount of TAP that would contribute to an ambient air cancer risk probability of less than one in one hundred thousand. IDAPA 58.01.01.210.12.c. The "T-RACT ambient concentration of the source . . . is estimated by using refined modeling and the T-RACT emission rate." IDAPA 58.01.01.210.03.g. Notably, nothing in the rules requires emissions to be evaluated on an annual basis. DEQ used refined modeling to account for operational variability of the Project to fully account for arsenic exposure at the point of compliance from emissions from the Project. PET 344-345; Schilling Decl. at 11-12. DEQ then analyzed the cancer risk of the arsenic emissions by comparing the lifetime exposure at the point of compliance on an annual basis against the 1 in 100,000 cancer risk provided in the T-RACT adjusted AACC and found that the arsenic emissions would be below the acceptable risk level and the AACC. PET 348.

DEQ thoroughly analyzed the lifetime cancer risk posed by arsenic emissions from the Project and satisfied itself that Perpetua complied with IDAPA 58.01.01.203.03. DEQ used the methods provided in Section 210. DEQ thoroughly explained and documented its analysis and arrived at its decision with reason supported by the record. This is the work required to lawfully issue the Final Permit. The Air Rules afford DEQ discretion to select an analytical pathway to account for carcinogenic TAPs emissions from highly variable fugitive sources. DEQ used its discretion to interpret its own rules to account for the inherent variability of fugitive emissions and the finite operational life of the Project. DEQ's approach and interpretation of the Air Rules is well reasoned and supported and therefore should be upheld. *Idaho Power Co.*, 155 Idaho at 791 n.2. The Board should accordingly dismiss Petitioners' Claim 9.

CONCLUSION

Petitioners devalue and misrepresent DEQ's three-year review process that included four requests for additional information to supplement the permit application, three extended public

comment opportunities to solicit feedback from the public and other stakeholders, two informational meetings requested by the public, and three iterations of draft permits. This unprecedented review process allowed Petitioners an extensive opportunity to participate in the shaping of the Final Permit. DEQ thoroughly and diligently addressed Petitioners' concerns throughout the prolonged review period. While Petitioners accept of the idea of agency discretion, Petitioners reject DEQ's manifestations of that discretion, and ask the Board to substitute Petitioners' preferences for DEQ's deliberative work in the substantive record for the Final Permit. Evidence in the voluminous record and declarations from DEQ personnel confirm and document that the agency's decision-making and choices complied with applicable law, were not arbitrary and capricious, and were entirely consistent with the discretion afforded DEQ by state and federal law. The Final Permit must be affirmed by the Board.

The Board should deny Petitioners' motion for summary judgment and instead grant Perpetua's motion for summary judgment as a matter of law.

BEFORE THE OFFICE OF ADMINISTRATIVE HEARINGS
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047	Case Docket No. 0101-22-01
NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON, Petitioners, v. IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent, and PERPETUA RESOURCES IDAHO, INC., Intervenor-Respondent.	**DECLARATION OF KEVIN LEWIS IN SUPPORT OF INTERVENOR-RESPONDENT PERPETUA'S REPLY IN SUPPORT OF MOTION FOR SUMMARY JUDGMENT**

I, KEVIN LEWIS, declare as follows:

1. My name is Kevin Lewis. I am currently a Principal Air Quality Engineer at Air Sciences, Inc. (Air Sciences). I have prepared this declaration in support of Intervenor-

Respondent Perpetua Resources Idaho, Inc.'s ("Perpetua") reply in support of motion for summary judgment in the matter of Air Quality Permit to Construct P-2019.0047.

2. I have been an employee of Air Sciences since 1993, an owner since 1996, and the President of the company from 2011 through 2021. I have over 32 years of air quality experience: 2 years with the Wisconsin Department of Natural Resources writing air quality permits for toxic air pollutants and conducting compliance inspections and 30 years with Air Sciences performing air quality analysis for air permits in over 25 states. My work at Air Sciences has primarily consisted of air permitting for the gold mining industry. I received a Bachelor of Science (BS) degree in Chemical Engineering from the University of Wisconsin, Madison in 1990.

3. During my tenure at Air Sciences, I have developed the air quality analyses for hundreds of air permits, permit renewals, and permit modifications; provided technical support to the state agencies during their technical review, permit drafting, and public comment stages of air permitting; and helped my clients comply with their air permits. In this time, I have never experienced a permit review process that was as long and as thorough as the one conducted by the Air Division of the State of Idaho Department of Environmental Quality (DEQ) for the Perpetua gold mining project (Project).

4. The initial application review process for this project included six meetings and five rounds of application revisions (January 28, 2019, through June 24, 2020). The DEQ air quality review and final permit issuance included the development of two supplemental toxic air pollutant analysis reports, three public comment periods (all extended by an additional 30 days) with responses to public comments, two public meetings, three draft permits and technical review documents, and one final permit and technical review document (June 25, 2020 through

June 17, 2022). This total timeline was over three years, not counting the time for the ongoing contested case appeal.

5. In my 32 years of experience, I have never seen an air permitting process conducted with this level of review and scrutiny. The Perpetua Project is classified as a non-major stationary source. In my 30 years of working on gold mining air permits in multiple states, I have seen these air permits typically issued within three to nine months for non-major sources and a year for major stationary sources.

6. The over three-year timeline for the Perpetua Project is unprecedented and was primarily driven by DEQ going to great lengths to address concerns raised by the public, and to ensure and document that the Perpetua Project would meet all air quality standards. Additional time and consideration were also dedicated by DEQ to craft a set of comprehensive air permit conditions that limited operations and air emissions in a verifiable and enforceable manner.

7. In my experience, the permit conditions for the Perpetua Project are more onerous than those in other gold mining permits I have reviewed for both non-major and major stationary sources.

8. DEQ's analyses and determination of compliance considered 14 maximum-emission operating scenarios and included layers of conservatism to ensure compliance with the NAAQS with a margin of safety. DEQ performed these analyses using conservative inputs for key variables, such as production, haul road miles, and control efficiency.

9. Variables relevant to haul road emissions considered by DEQ included:

   a. Mining Production (180,000 tons per day, resulting in a maximum of 16,415 miles/day of haul truck travel for operating scenario W3);

b. Emissions Factor (3.55 lb/mi) that reflects relevant conditions that can impact haul road emissions, such as surface moisture, precipitation, wind speed, truck weight, silt concentration (4%), other parameters; and

c. Haul Road Control Efficiency (90% for chemical, 33% for water, and 93.3% combined).

10. Estimated emissions using these inputs demonstrated compliance using an inherently conservative ambient air quality model. DEQ's highest modeled impacts for the Project were 82% of the PM_{10} NAAQS.

11. Air quality permits will often include conditions only for the key variables (or key variable surrogates) used in conservative air quality analyses. It is not necessary to establish permit limits for all variables. The Final Permit imposes enforceable limitations on three key variables: Mining Production (180,000 tons/day), Haul Road Control Efficiency (93.3%) and Silt Content (4%).

12. These three key variables in the Final Permit are practically enforceable through monitoring, recordkeeping and required work plans, Fugitive Dust Control Plan and Haul Road Capping Plan. Compliance with these enforceable conditions ensure emissions do not exceed estimated air quality results.

I declare under penalty of perjury pursuant to the laws of the State of Idaho that the foregoing is true and correct.

DATED: June 23, 2023.

BEFORE THE OFFICE OF ADMINISTRATIVE HEARINGS
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047 NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON, Petitioners, v. IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent, and PERPETUA RESOURCES IDAHO, INC., Intervenor-Respondent.	Case Docket No. 0101-22-01 **INTERVENOR-RESPONDENT PERPETUA'S MOTION TO STRIKE**

INTRODUCTION AND REQUESTED RELIEF

Intervenor-Respondent Perpetua Resources Idaho, Inc. ("Perpetua"), through undersigned counsel, moves to strike paragraphs 15 and 16 of the Declaration of Jonathan Oppenheimer, and related exhibits attached thereto. Mr. Oppenheimer's Declaration was filed on June 9, 2023, in support of Petitioners' Response to Respondent DEQ's Cross-Motion for Summary Judgment and Intervenor Perpetua's Motion for Summary Judgment and Petitioners' Reply in Support of Petitioners' Motion for Summary Judgment.

Paragraphs 15 and 16 of Mr. Oppenheimer's declaration offer opinion testimony regarding the health effects of particulate matter and arsenic. His opinions are not rationally based on his perception and are improper expert opinion testimony and therefore must be stricken from the record. Further, the studies included as exhibits to Mr. Oppenheimer's declaration were not produced in discovery, are not authenticated, and are the subject of improper expert opinion testimony. The exhibits must also be stricken from the record. Perpetua makes this motion based on the grounds and authority set forth below.

ARGUMENT

I. The Contested Case Rules require declarations to be based on personal knowledge and that expert testimony be disclosed and qualified.

Under the Contested Case Rules, the Board of Environmental Quality's (the "Board") consideration of motions for summary judgment are governed by the Idaho Rules of Civil Procedure ("I.R.C.P."). IDAPA 58.01.23.162.02. I.R.C.P. 56(c)(4) requires that "an affidavit used to support or oppose a motion must be made on personal knowledge, set out facts that would be admissible in evidence, and show that the affiant or declarant is competent testify on the matters stated."

Further, the Contested Case Rules incorporate the Idaho Rules of Administrative Procedure of the Attorney General. *See* IDAPA 58.01.123.03. The Attorney General Rules allow the admission of evidence "if it is of a type commonly relied upon by prudent persons in the conduct of their affairs," IDAPA 04.11.01.600, and also set forth requirements for the disclosure of expert testimony, IDAPA 04.11.01.530, .355. The Board requires that experts be qualified and that their testimony be consistent with their knowledge, skill, and training. *Freeman v. IDEQ*, Docket No. 0101-11-04, at 11 (Apr. 11, 2012); *Ford v. Idaho Department of Health and Welfare*, Docket No. 0102-98-16, at 4 (June 16, 1999) (finding that expert needed to be qualified to render expert opinion). To qualify as an expert witness, there must be "some demonstration that the witness has acquired, through some type of training, education or experience, the necessary expertise and knowledge to render the proffered opinion." *State v. Pearce*, 146 Idaho 241, 246, 192 P.3d 1065, 1070 (2008).

II. Mr. Oppenheimer is not qualified as an expert and the scientific studies on which he bases his testimony were not timely disclosed.

In his declaration, Mr. Oppenheimer makes conclusions about scientific matters and purports to support them by reference to recent scientific studies. With no attempt to qualify his expert testimony or authenticate the evidence provided, Mr. Oppenheimer states:

> 15. …. Any amount of additional particulate matter (PM) makes air less healthy to breathe. Recent studies on the nature of PM concentrations and their health effects back up previous studies and provide support for a no-threshold relationship between PM exposure and several respiratory and cardiovascular effects, and mortality, meaning any concentration of PM can have negative health effects. These health risks from increased particulates are even more significant for people like me, with asthma or other respiratory ailments.
>
> 16. I am also concerned about arsenic air pollution from the Project. Inhalation of arsenic-bearing dusts have been definitively linked to increased systemic uptake, as well as carcinogenic and non-carcinogenic health outcomes.

Oppenheimer Decl., ¶¶ 15, 16 (citations omitted). Both paragraphs are supported by footnotes, which cite to and incorporate the scientific studies.

Mr. Oppenheimer offers no evidence to demonstrate that he has the necessary expertise and knowledge to render the opinions proffered in his declaration. Further, he does not purport that his opinions are rationally based on his perception, and indeed they are not. Again, they are based on the scientific studies. Unauthenticated testimony submitted by a declarant that has failed to qualify as an expert is not of the type "commonly relied upon by prudent persons." IDAPA 04.11.01.600. Accordingly, the Board should strike paragraphs 15 and 16 from Mr. Oppenheimer's declaration and the associated exhibits.

Beyond the failure of Mr. Oppenheimer to qualify as an expert, the studies attached to his declaration must be struck for two independent reasons. First, these studies were not disclosed by Petitioners during the discovery process and must therefore be excluded. *Zylstra v. State*, 157 Idaho 457, 467, 337 P.3d 616, 626 (2014) (holding that expert testimony provided after the deadline for discovery established in the scheduling order should be stricken). The deadline for discovery was February 14, 2023. Scheduling Order at 2 (Jan. 19, 2023). The studies Mr. Oppenheimer refers to were not disclosed until long after this deadline.

Second, Mr. Oppenheimer does not purport to have personal knowledge of the methods used to arrive at the conclusions expressed in these studies, nor of the studies themselves. The opinions offered in the studies are those of experts, which Mr. Oppenheimer is not qualified to rely or testify on. Not only is Mr. Oppenheimer unqualified, but Perpetua is prejudiced by these late disclosed studies as it has not had the ability to counter them with competent evidence without also running afoul of the Scheduling Order entered in this case.

////

////

CONCLUSION

For the foregoing reasons, Perpetua respectfully requests that the Board strike paragraphs 15 and 16 from Mr. Oppenheimer's declaration and the associated exhibits.

DATED: June 23, 2023.

Based upon a stipulation among the Parties, the Scheduling Order of January 19, 2023 states that, "[t]he Parties will coordinate with the hearing officer a date for the hearing on the motion(s) for summary judgment on the next status conference held in this matter." Petitioners filed a Motion for Summary Judgment on April 14, 2023. DEQ and Perpetua Resources filed summary judgment motions on May 12, 2023. Briefing on all of the summary judgment motions concluded on June 23, 2023. On that same day, Perpetua Resources also filed a motion to strike certain portions of the Declaration of Jonathan Oppenheimer.

Based on the foregoing, NOTICE IS HEREBY GIVEN that the hearing officer and Parties

will hold a status and scheduling conference on Tuesday, July 11, 2023, at 2:00 p.m. mountain time, via Zoom, in order to schedule a hearing on the pending motions. The Zoom credentials have been distributed to counsel for the Parties electronically and are attached hereto.

Dated this 7th day of July, 2023.

Attorneys for Petitioners

BEFORE THE OFFICE OF ADMINISTRATIVE HEARINGS
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047	Agency Case No. 0101-2201 OAH Case No. 23-245-01
NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON, *Petitioners,* *v.* IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY, *Respondent,* and PERPETUA RESOURCES IDAHO, INC. *Intervenor-Respondent*.	**OPPOSITION TO PERPETUA'S MOTION TO STRIKE OPPENHEIMER DECLARATION**

INTRODUCTION

Petitioners hereby oppose the Motion to Strike filed by Perpetua on June 26, 2023. Perpetua moved to strike two paragraphs in the Declaration of Jonathan Oppenheimer ("Oppenheimer Declaration") and two studies cited in those paragraphs. The Oppenheimer Declaration was submitted to show Petitioner Idaho Conservation League ("ICL") has standing to bring this contested case in response to DEQ's and Perpetua's arguments that ICL lacked standing. As set forth below, the Hearing Officer can consider the Oppenheimer Declaration in its entirety, including the studies submitted with it, for the purpose of standing and should, thus, deny Perpetua's Motion to Strike.

BACKGROUND

In its response/opening brief on cross motions for summary judgment, DEQ contested Petitioners' standing. *See* DEQ Resp. Br. at 5–12. DEQ argued that Petitioners lack standing because they did not show that they would suffer any personal injuries, that those injuries were causally linked to DEQ's issuance of the permit to construct ("PTC"), and that a favorable decision would redress such injuries. *See id.* In its response/opening brief, Perpetua joined DEQ's standing argument. Perpetua Resp. Br. at 13–14. With their reply/response brief, Petitioners submitted seven standing declarations, including the Oppenheimer Declaration, to establish each Petitioner's organizational standing. *See* Pet'rs' Reply Br. at 2–5.

As stated in his declaration, Mr. Oppenheimer has worked at ICL since 2002, and has been an ICL member for even longer. Oppenheimer Decl. ¶ 2. Every summer, for more than a decade, Mr. Oppenheimer has visited and recreated in and near the East Fork of the South Fork Salmon River ("SFSR"). *Id.* ¶¶ 9–11. The East Fork SFSR is "special" to Mr. Oppenheimer and his family, and they "look forward to returning every year and enjoying the fresh air, public

lands, clean waters, and environment" there. *Id.* ¶ 12. This summer, Mr. Oppenheimer plans to camp at the Old East Fork Campground and to stay at the Johnson Creek Guard Station, about which he says: "I look forward to exploring the area with my family, fishing in Johnson Creek and the East Fork SFSR, and visiting the Stibnite area." *Id.* ¶¶ 12–13.

Expressing his concerns and beliefs about the health risks from breathing increased levels of particulate matter and arsenic, especially for an asthmatic like himself, Oppenheimer states:

> 15. I am concerned about the air pollution the proposed gold mine would emit and the adverse health effects to my family and me. I have suffered from allergy and exercise induced asthma since I was a child. I regularly use an albuterol inhaler to manage my asthma. Any amount of additional particulate matter (PM) makes air less healthy to breathe. Recent studies on the nature of PM concentrations and their health effects back up previous studies and provide support for a no-threshold relationship between PM exposure and several respiratory and cardiovascular health effects.[1] These health risks from increased particulates are even more significant for people like me, with asthma or other respiratory ailments.[2]
>
> 16. I am also concerned about arsenic air pollution from the Project. Inhalation of arsenic-bearing dusts have been definitively linked to increased systemic uptake, as well as carcinogenic and non-carcinogenic health outcomes.[3]

[1] *See* Exhibit A (attached and excerpted), U.S. EPA. Integrated Science Assessment (ISA) for Particulate Matter (Final Report, Dec 2019). U.S. Environmental Protection Agency, Washington, DC, EPA/600/R-19/188, 2019 (available at https://cfpub.epa.gov/ncea/isa/recordisplay.cfm?deid=347534).
[2] *See id.*, p. 1-1.
[3] *See* Exhibit B (attached), Martin, R.; Dowling, K.; Pearce, D.; Sillitoe, J.; Florentine, S. Health Effects Associated with Inhalation of Airborne Arsenic Arising from Mining Operations. Geosciences 2014, 4, 128-175 (available at https://doi.org/10.3390/geosciences4030128).

Oppenheimer Decl. ¶¶ 15–16.

In its Motion to Strike, Perpetua asks the Hearing Officer to strike paragraphs 15 and 16, arguing that they are "improper expert opinion testimony." Perpetua Mot. to Strike at 2. Perpetua also asks the Hearing Officer to strike Exhibits A and B, arguing they were not produced during discovery, were not authenticated, and are improper expert opinion testimony. *Id.*

ARGUMENT

The Oppenheimer Declaration was submitted for the purpose of establishing Petitioner ICL's standing in response to DEQ and Perpetua's arguments that ICL lacked standing and was not submitted for the merits. As such, the Hearing Officer can consider the Oppenheimer Declaration in its entirety, including the studies submitted therewith, for the purpose of evaluating ICL's standing.

"Th[e Idaho Supreme] Court has adopted the federal justiciability standard. When deciding whether a party has standing, [the Idaho Supreme Court has] looked to decisions of the United States Supreme Court for guidance." *Radford v. Van Orden*, 168 Idaho 287, 299 (2021) (quotation and citations omitted). For an organization like ICL to have standing, it must show, among other factors, that for one of its members: (1) the member must suffer an "injury in fact" that is "(a) concrete and particularized and (b) actual or imminent, not conjectural or hypothetical;" (2) the injury must be "fairly traceable to the challenged action;" and (3) it must be "likely, as opposed to merely speculative, that the injury will be redressed by a favorable decision." *Friends of the Earth v. Laidlaw Env't Servs. (TOC)*, 528 U.S. 167, 180–81 (2000).

To demonstrate injury in fact, the declarant must demonstrate that they have "reasonable concerns about the effects of" the challenged action on their "interests." *Friends of the Earth*, 528 U.S. at 183–84. At the summary judgment stage, the plaintiff "must set forth by affidavit or other evidence specific facts, which for purposes of the summary judgment motion will be taken to be true." *Lujan v. Defenders of Wildlife*, 504 U.S. 555, 561 (1992). Like the U.S. Supreme Court, the Idaho Supreme Court and the Board of Environmental Quality consider affidavits and other evidence, like the Oppenheimer Declaration for the purpose of evaluating standing. *See*, *e.g.*, *Boundary Backpackers v. Boundary Cnty.*, 128 Idaho 371, 375 (1996) (reviewing

organization member affidavits to evaluate standing); *In re Section 401 Water Quality Certification for Relicensing of the C.J. Strike Hydroelectric Facility*, Docket No. 0102-01-6, at *14 (Nov. 2002) (same).

The Idaho Supreme Court has found that a plaintiff failed to establish standing when she "failed to provide any testimony or other evidence that she suffered an injury in fact." *Haight v. Idaho Dep't of Transp.*, 163 Idaho 383, 392 (2018). Similarly, the Board of Environmental Quality has explained that in response to a motion for summary judgment on the issue of standing: "Petitioners had to submit affidavits or other evidence showing through specific facts that individual or organizational petitioners would be directly affected" by the challenged action. *Solomon v. IDEQ*, Docket No. 0101-03-01, at *5 (Dec. 2003).

"The doctrine of standing focuses on the party seeking relief and not on the issues the party wishes to have adjudicated." *Miles v. Idaho Power Co.*, 116 Idaho 635, 641 (1989). Courts "assume the truth of evidence proffered by plaintiffs" for the purpose of establishing standing. *Bonnichsen v. U.S. Dep't of Army*, 969 F. Supp. 628, 633 (D. Or. 1997). "The issue of standing, [however], should not be confused with the merits of the underlying action." *Id.* at 637, n.5.

Federal courts have denied motions to strike standing declarations, even if they are extra-record evidence or contain opinion statements. For example, in *Center for Biological Diversity v. U.S. EPA*, 90 F. Supp. 3d 1177 (W.D. Wash. 2015) the court denied a motion to strike, even though the declaration was not part of the administrative record before the court and even though it was filed with a summary judgment reply brief. *Id.* at 1192 n.11. The court concluded that the declaration was properly "submitted for the limited purpose of satisfying Article III standing requirements," and found the declaration was timely submitted since it was submitted after standing was contested and when the other side would still have an opportunity to respond. *Id.*

Similarly, in *Oregon Natural Desert Ass'n v. Rasmussen*, 451 F. Supp. 2d 1202 (D. Oregon 2006), the court denied a motion to strike, even though the declarant's stated "concerns regarding specific wilderness issues . . . do not qualify him as an expert." *Id.* at 1209. The court considered the declaration "in its entirety only for the purpose of establishing [plaintiff]'s standing." *Id.*

Here, in response to DEQ's and Perepetua's cross motions for summary judgment, which raised the issue of standing, Petitioners responded by submitting "affidavits," including the Oppenheimer Declaration, and "other evidence," namely the PM and arsenic studies included as exhibits to the Oppenheimer Declaration. The Oppenheimer Declaration and its exhibits set forth specific facts and demonstrate Mr. Oppenheimer's "reasonable concerns," as required to establish standing.

The two paragraphs Perpetua moves to strike include Mr. Oppenheimer's reasonable concerns about the risk he and his family face from breathing air with increased concentrations of PM and arsenic in and near the proposed mine site. Again, in paragraph 15, Oppenheimer states: "I am concerned about the air pollution the proposed gold mine would emit and the adverse health effects to my family and me. I have suffered from allergy and exercise induced asthma since I was a child. . . . Any amount of additional particulate matter (PM) makes air less healthy to breathe. . . ." In paragraph 16, he states: "I am also concerned about arsenic air pollution from the Project. Inhalation of arsenic-bearing dusts have been definitively linked to increased systemic uptake, as well as carcinogenic and non-carcinogenic health outcomes." These paragraphs can be considered by the Hearing Officer for purposes of standing.

Perpetua also seeks to strike the two studies cited by Oppenheimer in paragraphs 15 and 16 and included as exhibits to his declaration. These studies substantiate the concerns and beliefs Mr. Oppenheimer states in his declaration, that any PM or arsenic air pollution caused by DEQ's

approval of the Stibnite Gold Project could harm his physical well being. The 2019 EPA study, "Integrated Science Assessment for Particulate Matter," includes a number of "overall conclusions" that substantiate Oppenheimer's reasonable concerns about the health risks associated with PM exposure (even short-term PM exposure, and especially for someone who suffers from asthma like Mr. Oppenheimer), including the following EPA conclusions:

> Many populations (e.g., healthy, diseased, etc.) and lifestages (e.g., children, older adults, etc.) have been shown to be at risk of a health effect in response to short- or long-term PM exposure, particularly PM2.5. However, of the populations and lifestages examined, current scientific evidence indicates that only some populations may be at *disproportionately increased risk* of a PM2.5-related health effect, including . . . people with pre-existing cardiovascular and respiratory diseases. . . .

Exhibit A to Oppenheimer Decl., at 1-1. The 2014 study in *Goesciences*, "Health Effects Associated with Inhalation of Airborne Arsenic Arising from Mining Operations," substantiates Oppenheimer's reasonable concerns about the health risks associated with inhaling arsenic-laden PM caused by the Stibnite Gold Project. *See* Exhibit B to Oppenheimer Decl.

In summary, in response to DEQ's and Perpetua's summary judgment filings raising the issue of standing, Petitioners were required to and properly did submit declarations and other evidence—including the Oppenheimer Declaration and the two studies included with it—setting forth specific facts showing Mr. Oppenheimer's reasonable concerns about the ways the Stibnite Gold Project (as approved by DEQ) harms his interests. The Hearing Officer can consider this evidence for the purpose of evaluating Petitioners' standing.

CONCLUSION

For the reasons set forth above, Petitioners respectfully request that the Hearing Officer deny Perpetua's Motion to Strike.

Dated this 7th day of July, 2023.

Respectfully submitted,

BEFORE THE OFFICE OF ADMINISTRATIVE HEARINGS
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047	Agency Case No. 0101-22-01
	OAH Case No. 23-245-01
NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON Petitioners, v. IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent, and PERPETUA RESOURCES IDAHO, INC., Intervenor.	**PETITIONERS' MOTION TO STRIKE DECLARATION OF KEVIN LEWIS AND BRIEF IN SUPPORT**

MOTION TO STRIKE LEWIS DECLARATION

Pursuant to IDAPA 58.01.23.162.01 and 4.11.01.260, Petitioners Nez Perce Tribe, Idaho Conservation League, and Save the South Fork Salmon ("Petitioners") move to strike the Declaration of Kevin Lewis ("Lewis Declaration") and all portions of Respondent-Intervenor Perpetua Resources Idaho's ("Perpetua") briefs that rely on the declaration.

Mr. Lewis's declaration was filed on June 23, 2023, in support of the Reply Memorandum in Support of Intervenor-Respondent Perpetua's Motion for Summary Judgment ("Perpetua's Reply"). The Lewis Declaration should be stricken because it was improperly filed well after discovery had closed in the case. In the alternative, if the Lewis Declaration is not stricken from the record, Petitioners request that the Hearing Officer allow Petitioners to file a sur-reply responding specifically to the allegations in the Lewis Declaration and relied on by Perpetua in its Reply.

BRIEF IN SUPPORT

The January 9, 2023 Scheduling Order entered in this case ordered that each party provide "any additional documentary evidence they deem relevant to these proceedings by February 14, 2023." That time passed months ago. Yet Perpetua attempts to introduce further evidence by submitting the Lewis Declaration in support of its cross motion for summary judgment, well beyond the end of the discovery period and after Petitioners filed their final brief on summary judgment.

The Lewis Declaration makes several assertions regarding the air permit review process in this case, but also makes several unsupported assertions comparing this permit to the declarant's other experiences in permitting gold mines. *See* Lewis Decl. ¶¶ 4–7. The Lewis Declaration also makes factual assertions regarding the record that has been submitted in this

case. *See id.* ¶¶ 8–10. Additionally, the Lewis Declaration impermissibly attempts to provide legal conclusions on the legal sufficiency of DEQ's review which extend beyond what is permissible. *See* Lewis Decl. ¶¶ 8–12. Regardless of whether Mr. Lewis's declaration is offered as a fact or expert witness, to the extent that Mr. Lewis reaches specific conclusions that DEQ acted in compliance with applicable legal duties are impermissible.

At this stage of the proceedings, Petitioners do not have the opportunity to depose Mr. Lewis because discovery has closed. Petitioners also do not have the opportunity to respond to the assertions Perpetua has made in its brief in reliance on the Lewis Declaration because no further briefing is authorized under the Scheduling Order. Petitioners are thus prejudiced by Perpetua's late disclosure of this "witness" and by Perpetua's reliance on his declaration in Perpetua's Reply. The Hearing Officer should thus strike from the record the Lewis Declaration and the portions of Perpetua's Reply that rely on it.

CONCLUSION

For the reasons set forth above, Petitioners respectfully request that the Hearing Officer strike the Lewis Declaration and portions of Perpeteua's Reply that rely on the Lewis Declaration for support, or in the alternative allow Petitioners to file a sur-reply limited to responding to the assertions Perpetua relies on in the Lewis Declaration.

BEFORE THE BOARD OF ENVIRONMENTAL QUALITY
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047	
NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON, Petitioners, v. DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent, and PERPETUA RESOURCES IDAHO, INC., Intervenor.	BEQ Case No. 0101-22-01 OAH Case No. 23-245-01 ORDER AND NOTICE FROM STATUS AND SCHEDULING CONFERENCE

On July 11, 2023, a status and scheduling conference was held virtually via Zoom. Bryan Hurlbutt appeared for Petitioners Nez Perce Tribe and Idaho Conservation League, and Julia Thrower appeared for Petitioner Save the South Fork Salmon. John Shackelford, Deputy Attorney General, appeared for Respondent. W. Christopher Pooser, Krista McIntyre, and Wade Foster appeared for Intervenor.

Based on the discussions and agreements at the conference, it is hereby ordered that:

Pursuant to BEQ Rule of Procedure 162.02, Intervenor may file a reply brief in support of its pending Motion to Strike no later than Friday, July 14, 2023; and

Pursuant to BEQ Rule of Procedure 162.02, Petitioners may file a reply brief in support of their pending Motion to Strike no later than seven (7) days after Intervenor's filing of its response to Petitioners' Motion.

In addition, notice is hereby given that oral argument on the pending motions for summary judgment will take place beginning at 9:30 a.m. on Thursday, September 21, 2023, in the 2nd Floor courtroom of the Borah Building, 304 N. 8th Street, Boise, Idaho 83702.

Dated this 12th day of July, 2023.

Dylan Lawrence
Hearing Officer

BEFORE THE BOARD OF ENVIRONMENTAL QUALITY
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047 _____ NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON, Petitioners, v. IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent, and PERPETUA RESOURCES IDAHO, INC., Intervenor-Respondent.	Case Docket No. 0101-22-01 **INTERVENOR-RESPONDENT'S REPLY IN SUPPORT OF MOTION TO STRIKE OPPENHEIMER DECLARATION**

Perpetua Resources Idaho, Inc. ("Perpetua") submits this reply in support of its motion to strike paragraphs 15 and 16 of the Declaration of Jonathan Oppenheimer, and related exhibits attached thereto. Petitioners essentially argue that because these unauthenticated scientific studies are offered solely for purposes of standing, the rules of evidence do not apply. Not so.

Petitioners cannot evade the requirements of the Contested Case Rules and Idaho Rule of Evidence ("I.R.E.") 702 to backdoor undisclosed scientific studies under the guise of making a limited standing argument. However, if the Board does allow this evidence, it should only be for the very limited purpose of standing.

ARGUMENT

A. Oppenheimer's Declaration includes highly technical scientific studies that require expert testimony to be admitted.

Petitioners essentially argue that, since Mr. Oppenheimer offers expert testimony and undisclosed studies only in support of the Idaho Conservation League's ("ICL") standing, the Board is free to ignore the rules of evidence. Nothing in the Contested Case Rules or the Idaho Rules of Evidence exempt expert testimony offered solely to prove a petitioner's standing from Rule 702. *Boundary Backpackers v. Boundary County*, 128 Idaho 371, 375, 913 P.2d 1141, 1145 (1996) (holding that plaintiff had standing where declarant qualified as expert and expert testimony demonstrated injury was not speculative); *see In re ConAgra Foods, Inc.*, 302 F.R.D. 537, 549 (C.D. Cal. 2014) (granting motion to strike expert declaration offered in part to support plaintiff's standing).

The cases cited by Petitioners do not provide support for admitting unverified scientific studies under the guise of establishing standing.

In *Center for Biological Diversity v. U.S. EPA*, the U.S. Environmental Protection Agency moved to strike a declaration of Dr. Burke Hales, Professor of Oregon Ecology and Biogeochemistry at Oregon State University, which offered expert testimony regarding ocean acidification solely for the purpose of establishing plaintiff's standing. 90 F. Supp. 3d 1177, 1191, 1192 n.11 (W.D. Wash. 2015). In that case, no one objected to admission of the studies cited by Dr. Hales to support plaintiff's standing because they were already in the administrative

record under review.[1] *Id.* at 1191. And no one questioned Dr. Hales' expert qualifications. *Id.* at 1192 n.11. EPA moved to strike the declaration because it was filed with the plaintiff's reply brief. The court denied EPA's motion to strike, finding that consideration of the expert declaration was appropriate solely for establishing standing. Unlike *Center for Biological Diversity*, here, Mr. Oppenheimer is not an expert qualified to testify about the studies cited in his declaration. Further, as discussed below, these studies *are not part of the record* and were not disclosed as documentary evidence in discovery.

In *Oregon Natural Desert Ass'n v. Rasmussen*, the court refused to strike portions of the declaration where the declarant offered his opinion of the adverse impacts of overgrazing on public lands. 451 F. Supp. 2d 1202, 1209 (D. Or. 2006). Mr. Oppenheimer offers an opinion on the adverse impacts to him and his family from the Stibnite Gold Project. Oppenheimer Decl. ¶ 15. Oppenheimer goes well beyond the declaration in *Rasmussen*, however, and attempts to introduce two scientific studies, without establishing his qualifications as an expert witness under I.R.E. 702.

Under I.R.E. 702, Oppenheimer is not qualified to opine on the studies attached to his declaration. Oppenheimer does not suggest that he developed his concerns about arsenic only after reading the studies attached to his declaration, nor does he offer any first-hand personal knowledge related to the effects of arsenic or particulate matter. To the extent Oppenheimer purports to interpret studies that were not previously disclosed nor within the declarant's verified expertise, those portions of his declaration must be struck, along with the attached studies.

[1] Under the Administrative Procedure Act, the Court is to review agency action based on "the whole record [before the agency] or those parts of it cited by a party." 5 U.S.C. § 706. In *Center for Biological Diversity*, none of the parties challenged plaintiff's ability to rely on documents contained in the administrative record to support its standing.

B. The studies cited by Oppenheimer were not disclosed in discovery.

Petitioners do not address their failure to disclose the studies attached to Oppenheimer's declaration as documentary evidence prior to the discovery cutoff in this matter, as required by the Scheduling Order (dated Jan. 19, 2023). The Scheduling Order established a February 14, 2023 discovery deadline for "any additional documentary evidence [the parties] deem relevant to these proceedings." Under Idaho law, a court is well within its discretion to strike documentary evidence attached to a declaration, especially a purported expert declaration, that were not disclosed in discovery. *Hilliard v. Murphy Land Co.*, 158 Idaho 737, 740, 351 P.3d 1195, 1198 (2015). For this reason alone, the studies attached to the Oppenheimer Declaration should be struck.

C. If admitted, the evidence must be limited to the narrow issue of Idaho Conservation League's standing.

As Petitioners explain in their brief, even when declarations are admitted for the purpose of demonstrating standing, "the issue of standing … should not be confused with the merits of the underlying action." Petitioners' Memorandum in Opposition at 4 (citing *Bonnichsen v. U.S. Dep't of Army*, 969 F. Supp. 628, 637 n.5 (D. Or. 1997)). Accordingly, to the extent the Board does not strike paragraphs 15 and 16 of the Oppenheimer Declaration and studies cited therein, Perpetua requests that the Board only consider these statements for the purpose of determining whether Petitioners have standing.

CONCLUSION

For the foregoing reasons, Perpetua respectfully requests that the Board grant the motion to strike paragraphs 15 and 16 from Oppenheimer's declaration and the associated exhibits. Alternatively, if the Board denies the motion to strike, Perpetua respectfully requests that the testimony be admitted for the limited purpose of standing.

DATED: July 14, 2023.

BEFORE THE BOARD OF ENVIRONMENTAL QUALITY
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047 _____ NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON, Petitioners, v. IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent, and PERPETUA RESOURCES IDAHO, INC., Intervenor-Respondent.	Case Docket No. 0101-22-01 **INTERVENOR-RESPONDENT'S OPPOSITION TO PETITIONERS' MOTION TO STRIKE DECLARATION OF KEVIN LEWIS**

Perpetua Resources Idaho, Inc. ("Perpetua") submits this opposition to Petitioners' Motion to Strike Declaration of Kevin Lewis ("Lewis Decl."). Petitioners seek to strike paragraphs 4 through 12 of Mr. Lewis' declaration on the grounds that (1) it is new evidence improperly filed after the close of discovery, and (2) it includes improper legal conclusions.

Alternatively, Petitioners seek permission to file a surreply to respond to the allegations in Mr. Lewis' declaration and relied on by Perpetua in its Reply Memorandum submitted June 23, 2023. The hearing officer should deny the motion to strike and request to file a surreply. As explained below, Mr. Lewis' declaration simply reiterates what is already in the record and thoroughly addressed by the parties in their briefs and raises no new evidence or argument.[1]

I. ARGUMENT

A. Mr. Lewis' declaration is not subject to the February 14, 2023 deadline for documentary evidence and, in any event, contains no new evidence or argument.

Petitioners contend Mr. Lewis' declaration should be struck because it was submitted after the February 14, 2023 fact discovery deadline established by the Scheduling Order (dated Jan. 19, 2023). That deadline relates solely to "any additional documentary evidence [the parties] deem relevant to these proceedings" and did not require the disclosure of witnesses. Mr. Lewis' declaration is not documentary evidence. Moreover, a party may support its reply in support of a motion for summary judgment with an additional declaration. *See, e.g., Hauser v. Idaho Dep't of Health & Welfare*, No. CV-03-04943, 2004 WL 1854250, at *7 n.8 (Idaho Dist. May 21, 2004) (unpublished). Only when the declaration makes "wholly new arguments in support of [the] motion" does the court have the "discretion to disregard the arguments" and grant a motion to strike. *See Franklin Bldg. Supply Co. v. Hymas*, 157 Idaho 632, 640, 339 P.3d 357, 365 (2014).

Mr. Lewis' declaration does not include any new evidence or new arguments. In fact, it is no different than, and is entirely consistent with, the declarations of Kevin Schilling (the "Schilling Decl."), Mike Simon (the "Simon Decl."), and Tiffany Floyd (the "Floyd Decl.") submitted by the Idaho Department of Environmental Quality ("DEQ") in support of its motion

[1] If the Lewis Declaration is stuck it should be because it is redundant, as it provides no materially new information. However, Petitioners did not move to strike the declaration for that reason.

for summary judgment. DEQ submitted the declarations after the February 14, 2023 deadline, yet Petitioners did not seek to strike them—presumably because they are not "documentary evidence" and simply explain or expand on concepts in the documentary evidence disclosed by DEQ, Perpetua, and Petitioners. Mr. Lewis' declaration is no different.

Consider each of the paragraphs Petitioners seek to strike.

Lewis Decl. ¶ 4 – "The initial application review process for this project included six meetings and five rounds of application revisions (January 28, 2019, through June 24, 2020). The DEQ air quality review and final permit issuance included the development of two supplemental toxic air pollutant analysis reports, three public comment periods (all extended by an additional 30 days) with responses to public comments, two public meetings, three draft permits and technical review documents, and one final permit and technical review document (June 25, 2020 through June 17, 2022). This total timeline was over three years, not counting the time for the ongoing contested case appeal."

This same information is documented in the Statement of Basis, PET 52-54, 93, as well as in the Simon Decl. at 3-4 and Floyd Decl. at ¶¶ 9-16. It was also addressed in Perpetua's Opening Brief (at p. 3), DEQ's Opening Brief (at p. 4), and Petitioners' Response Brief (at pp. 31-32).

Lewis Decl. ¶ 5 – "In my 32 years of experience, I have never seen an air permitting process conducted with this level of review and scrutiny. The Perpetua Project is classified as a non-major stationary source. In my 30 years of working on gold mining air permits in multiple states, I have seen these air permits typically issued within three to nine months for non-major sources and a year for major stationary sources."

This same information is documented in the Statement of Basis, PET 60, 72, Simon Decl. at 3-4, and Floyd Decl. at ¶¶ 9, 18-19. These statements are also addressed in Perpetua's Opening Brief (at pp. 1, 2, 25-26).

Lewis Decl. ¶ 6 – "The over three-year timeline for the Perpetua Project is unprecedented and was primarily driven by DEQ going to great lengths to address concerns raised by the public, and to ensure and document that the Perpetua Project would meet all air quality standards. Additional time and consideration were also dedicated by DEQ to craft a set of comprehensive air permit conditions that limited operations and air emissions in a verifiable and enforceable manner."

This same information is documented in the Simon Decl. at 3-4 and Floyd Decl. at ¶¶ 10-20. And, it was addressed in Perpetua's Opening Brief (at pp. 3, 22-32), and Petitioner's Response Brief (at pp. 17-27).

Lewis Decl. ¶ 7 – "In my experience, the permit conditions for the Perpetua Project are more onerous than those in other gold mining permits I have reviewed for both non-major and major stationary sources."

Perpetua did not rely on this paragraph in its Reply Memorandum and does not object to the Board disregarding it in deciding the motions for summary judgment. Notwithstanding, this is simply a factual observation based on Mr. Lewis' personal experience and does not rely on any documentary evidence that was not disclosed.

Lewis Decl. ¶ 8 – "DEQ's analyses and determination of compliance considered 14 maximum-emission operating scenarios and included layers of conservatism to ensure compliance with the NAAQS with a margin of safety. DEQ performed these analyses using conservative inputs for key variables, such as production, haul road miles, and control efficiency."

This same information is included in the Statement of Basis, PET 64-65, and Appendix B to the Statement of Basis (Ambient Air Quality Impact Analyses Review Memorandum), PET 261-265, 276, 284, 297, 313. DEQ's conservative approach is further documented in the Schilling Decl. at p. 10; the Statement of Basis, PET 62, 65; Response to Comments, PET 551, 555, 557, 561-562, 567-568, 572, 574, 578-579, 585-586, 609, 628, 630; and addressed in both Perpetua's Opening Brief (at pp. 4, 8) and Petitioners' Response Brief (at pp. 23-24).

Lewis Decl. ¶ 9 – "Variables relevant to haul road emissions considered by DEQ included:

a. Mining Production (180,000 tons per day, resulting in a maximum of 16,415 miles/day of haul truck travel for operating scenario W3);
b. Emissions Factor (3.55 lb/mi) that reflects relevant conditions that can impact haul road emissions, such as surface moisture, precipitation, wind speed, truck weight, silt concentration (4%), other parameters; and
c. Haul Road Control Efficiency (90% for chemical, 33% for water, and 93.3% combined)."

This same information is included in the Simon Decl. at 6, 9; Appendix B to the Statement of Basis, PET 320-321; and addressed in Perpetua's Opening Brief (at pp. 22-23, 28-29) and Petitioners' Response Brief (at pp. 17-19, 25, 39). Moreover, this paragraph simply restates facts in the record; it offers no legal conclusion as to the meaning of these facts.

Lewis Decl. ¶ 10 – "Estimated emissions using these inputs demonstrated compliance using an inherently conservative ambient air quality model. DEQ's highest modeled impacts for the Project were 82% of the PM10 NAAQS."

This same information is documented in the Schilling Decl. at 17-18; Appendix B of the Statement of Basis, PET 265; TAP Addendum Modeling Review, PET 351; and addressed in Perpetua's Opening Brief (at pp. 4-5).

Lewis Decl. ¶ 11 – "Air quality permits will often include conditions only for the key variables (or key variable surrogates) used in conservative air quality analyses. It is not necessary to establish permit limits for all variables. The Final Permit imposes enforceable limitations on three key variables: Mining Production (180,000 tons/day), Haul Road Control Efficiency (93.3%) and Silt Content (4%)."

This same information is documented in the Statement of Basis, PET 65; DEQ's Response to Comments, PET 557, 562, 574, 578-579, 611; and addressed in Perpetua's Opening Brief (at pp. 22-23, 28-29); and Petitioner's Response Brief (at pp. 17-19, 25, 39). Additionally, this paragraph offers a factual observation based on Mr. Lewis' considerable experience based on the contents of the Final Permit. It does not contain a a legal conclusion.

Lewis Decl. ¶ 12 – "These three key variables in the Final Permit are practically enforceable through monitoring, recordkeeping and required work plans, Fugitive Dust Control Plan and Haul Road Capping Plan. Compliance with these enforceable conditions ensure emissions do not exceed estimated air quality results."

To the extent Mr. Lewis offers a legal conclusion, this paragraph is consistent with the Simon Decl. at 8-9 and DEQ's Response to Comments, PET 551-552, 557, 567, 572, 578-579, 611. Further, this statement has been thoroughly addressed in Perpetua's Opening Brief (at pp. 22-26, 41-45) and Petitioners' Response Brief (at pp. 18, 23, 27-34).

Thus, as shown above, Mr. Lewis' declaration does not include any "wholly new arguments." His declaration only restates information already in the record and addressed by the parties in their briefing. Moreover, no new facts were alleged in the declaration. Mr. Lewis' statements support arguments that had been made in Perpetua's and DEQ's motions for summary judgment. Petitioners' claim that there was no opportunity to respond to these assertions is entirely without merit. Petitioners have had ample opportunity to respond to all facts reasserted by Mr. Lewis, and in fact did, because this declaration only confirms the arguments made in support of Perpetua's and DEQ's motions for summary judgment.

B. Mr. Lewis' declaration contains factual assertions, not legal conclusions.

An affidavit will be adequately supported if it is based on "personal knowledge . . . [and] set[s] out facts that would be admissible in evidence." I.R.C.P. 56(e). Thus, while an affidavit will not be acceptable if merely conclusory, it must be accepted if it sets forth facts based on personal knowledge. *State v. Shama Res. Ltd. P'ship*, 127 Idaho 267, 271, 899 P.2d 977, 981 (1995).

As shown above, in his declaration, Mr. Lewis makes factual assertions that are based on personal knowledge. Indeed, the foundation for such personal knowledge is outlined in the declaration itself, where he addresses his close involvement with the development of the Final Permit. Lewis Decl. ¶¶ 1-3. Mr. Lewis does not make any legal conclusions in the declaration, but merely recounts facts based on his personal knowledge and the contents of the Final Permit. Petitioners argue that the declaration attempts to provide legal conclusions but offer no explanation or reasoning for this claim. Mr. Lewis' statements are merely assertions of fact based on his personal knowledge. Accordingly, the motion to strike this declaration has no legal basis and should be denied.

C. Petitioners have failed to show that there are new arguments for which a surreply is warranted.

Additionally, Petitioners' request for a surreply is improper and unsupported. The Idaho Rules of Civil Procedure do not allow a surreply as a matter of right. I.R.C.P. 56. The court has discretion to allow supplemental briefing in the form of a surreply. *Oregon Mut. Ins. Co. v. Seattle Collision Ctr. Inc.*, No. 09-36105, 2010 WL 4629066 (9th Cir. Nov. 16, 2010). However, surreplies are "'highly disfavored,'" *Green Technology Lighting Corp. v. Insure Idaho, LLC*, No. 1:17-CV-00432-DCN, 2023 WL 2744121, at *15 (D. Idaho Mar. 31, 2023) (citation omitted), and the court should only grant a request for a surreply in "extraordinary circumstances." *Id*. Raising new issues or evidence in a reply brief may constitute extraordinary circumstances. *Id.* But, as explained above, Mr. Lewis' declaration does not include any new arguments. Therefore, there is no new information to which Petitioners need to reply.

II. CONCLUSION

For the foregoing reasons, the Board should deny Petitioners' motion to strike and alternative request for surreply.

DATED: July 14, 2023.

Attorney for Save the South Fork Salmon

BEFORE THE OFFICE OF ADMINISTRATIVE HEARINGS
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047	Agency Case No. 0101-22-01
	OAH Case No. 23-245-01
NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON *Petitioners*, v. IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY, *Respondent*, and PERPETUA RESOURCES IDAHO, INC., *Intervenor-Respondent*.	**PETITIONERS' REPLY IN SUPPORT OF MOTION TO STRIKE DECLARATION OF KEVIN LEWIS**

Petitioners Nez Perce Tribe, Idaho Conservation League, and Save the South Fork Salmon file this Reply in Support of Motion to Strike Declaration of Kevin Lewis. The Lewis Declaration was filed by Intervenor-Respondent Perpetua Resources Idaho, Inc. ("Perpetua") with its reply brief in support of its cross motion for summary judgment, *after* the close of the limited discovery agreed to by all parties, and *after* the deadline by which Petitioners were required to file their final brief on summary judgment. Petitioners, thus, ask the Hearing Officer to strike the Lewis Declaration, or alternatively, allow Petitioners to file a sur-reply to respond to the points for which Perpetua relied on the Lewis Declaration. Each of the points Perpetua makes in its opposition to the Motion to Strike can be rejected.

First, Perpetua argues that the Lewis Declaration did not run afoul of the Scheduling Order's February 14, 2023 deadline for disclosing "documentary" evidence, because the Lewis Declaration is not documentary evidence. Perpetua is correct that the Lewis Declaration is not documentary evidence; it is witness testimony. However, this does not excuse Perpetua from failing to disclose Mr. Lewis as a witness and filing his declaration at the last possible moment. The Scheduling Order does not include any deadline for disclosing witnesses and for discovery of such experts, because the parties agreed there was no need for witnesses, expert or otherwise. Instead of conferring with the parties to discuss Perpetua's change of mind regarding witness testimony, Perpetua simply submitted the Lewis Declaration at the last minute, without agreement from the parties or approval from the Hearing Officer, and without any opportunity for Petitioners to conduct discovery of the witness or to respond.

The Lewis Declaration should thus be stricken as not complying with the Scheduling Order. Alternatively, Petitioners should be allowed to file a sur-reply, which is a modest request, given that Petitioners could seek to conduct discovery related to Mr. Lewis's statements.

Next, Perpetua argues that because Petitioners did not move to strike declarations submitted by DEQ, this somehow gives Perpetua the right to file an improper declaration. Like the Lewis Declaration, the DEQ declarations were also submitted improperly, as they too were submitted beyond the close of discovery and are improper witness testimony that was not authorized under the agreed to discovery plan and schedule. Petitioners, however, made the decision not to move to strike DEQ's declarations, in part because the DEQ declarations were submitted with DEQ's opening summary judgment brief and Petitioners, therefore, had the opportunity to respond in their summary judgment reply brief. By contrast, Perpetua submitted the Lewis Declaration later, after Petitioners filed their summary judgment reply brief and when (absent being granted leave to file a sur-reply) Petitioners would have no opportunity to respond.

Finally, Perpetua makes the curious argument that the Lewis Declaration should not be stricken because it "raises no new evidence or argument." Perpetua Opp., p. 2. Perpetua is wrong. For example, Lewis discusses his history of working on other gold mining air permits in multiple states and makes statements regarding his opinion of what "typical" timeframes are. Lewis. Decl. ¶ 5. Lewis also opines that DEQ went "to great lengths" in issuing the permit. *Id.* ¶ 6. Lewis also asserts that in his "experience," the permit conditions are "more onerous" than for other gold mine permits. *Id.* at 7. He also offers improper legal opinions that the permit limits are "verifiable and enforceable," are "practically enforceable," and complying with them will "ensure emissions do not exceed air quality results." *Id.* at ¶¶ 7 & 12. Mr. Lewis's background, the other gold mining projects he refers to, and his opinions about the permit at issue here are new evidence and argument, which Perpetua introduced after the close of discovery and at the very end of summary judgment briefing, without giving Petitioner any opportunity to take discovery of the witness and to otherwise respond to his declaration.

Moreover, if Perpetua is correct that the Lewis Declaration provides no new evidence or argument (as it repeatedly asserts in its opposition), then this is further grounds for striking the Declaration. "Evidence is relevant if: (a) it has any tendency to make a fact more or less probable than it would be without the evidence; and (b) the fact is of consequence to determining the action." Idaho Rule of Evidence (I.R.E.) 401. "Irrelevant evidence is not admissible." I.R.E. 402. Thus, accepting Perpetua's argument that the Lewis Declaration adds nothing to the facts or arguments in this case, it is irrelevant and inadmissible and should be stricken.

CONCLUSION

For the reasons set forth above, Petitioners respectfully request that the Hearing Officer grant Petitioners Motion to Strike Lewis Declaration or grant leave to file a limited sur-reply.

Dated this 20th day of July, 2023.

Respectfully submitted,

/s/ Bryan Hurlbutt

BEFORE THE BOARD OF ENVIRONMENTAL QUALITY
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047	
NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON, Petitioners, v.	BEQ Case No. 0101-22-01 OAH Case No. 23-245-01 ORDER ON PEREPETUA'S MOTION TO STRIKE
DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent, and PERPETUA RESOURCES IDAHO, INC., Intervenor.	

I. PROCEDURAL BACKGROUND

Pursuant to the stipulated Scheduling Order of January 19, 2023, all three sets of parties have filed and fully briefed motions for summary judgment. The Petitioners filed their summary judgment motion and supporting materials on April 14; Perpetua Resources and DEQ filed their responses to that motion and their own motions and supporting materials on May 12; the Petitioners filed their response to the Perpetua and DEQ motions and reply in support of their own motion on June 9; and Perpetua filed a reply brief in support of its own motion on June 23. Petitioners' June 9 filing included several declarations from witnesses. There were eight declarations total, seven of

which were geared primarily towards establishing standing. For the Nez Perce Tribe, the declarants were Joseph Oatman and Emmit Taylor, Jr. For the Idaho Conservation League (ICL), the declarants were Allison Fowle, Asa Menlove, and Jonathan Oppenheimer. For Save the South Fork Salmon, the declarants were Drew Hollenback and Zak Sears. The ninth declaration was a declaration of counsel authenticating documents from the record.

Simultaneously with its summary judgment reply brief, Perpetua Resources filed a motion to strike a portion of the Oppenheimer Declaration. In particular, Perpetua requests the striking of Paragraphs 15 and 16 of that declaration and the two related exhibits. Paragraph 15 reads:[1]

> [(a)] I am concerned about the air pollution the proposed gold mine would emit and the adverse health effects to my family and me. [(b)] I have suffered from allergy and exercise induced asthma since I was a child. [(c)] I regularly use an albuterol inhaler to manage my asthma. [(d)] Any amount of additional particulate matter (PM) makes air less healthy to breathe. [(e)] Recent studies on the nature of PM concentrations and their health effects back up previous studies and provide support for a no-threshold relationship between PM exposure and several respiratory and cardiovascular effects, and mortality, meaning any concentration of PM can have negative health effects.[1] [(f)] These health risks from increased particulates are even more significant for people like me, with asthma or other respiratory ailments.[2]

The footnotes at the end of Paragraphs 15(e) and (f) both refer to Exhibit A of the Declaration, an 88-page EPA report titled "Integrated Science Assessment for Particulate Matter" (December 2019). The second footnote refers specifically to page 1-1 of that report. Paragraph 16 then reads:

> [(a)] I am also concerned about arsenic air pollution from the Project. [(b)] Inhalation of arsenic-bearing dusts have been definitively linked to increased systemic uptake, as well as carcinogenic and non-carcinogenic health outcomes.[3]

The footnote at the end of Paragraph 16(b) refers to Exhibit B of the Declaration, a 48-page article from a 2014 issue of the journal *Geosciences*, titled "Health Effects Associated with Inhalation of Airborne Arsenic Arising from Mining Operations." No pinpoint cites were provided.

---

[1] Subparagraph labels have been inserted within Paragraphs 15 and 16 for ease of reference.

II. RELEVANT STANDARDS

There are multiple sets of standards relevant to Perpetua's motion and the Oppenheimer Declaration. First, because the Oppenheimer Declaration was filed in connection with Petitioners' summary judgment response, the standards governing motions for summary judgment are relevant. Motions for summary judgment filed in administrative proceedings before the BEQ are governed by the Idaho Rules of Civil Procedure. *In the Matter of Simmons Sanitation*, Findings of Fact, Conclusions of Law, and Preliminary Order on Motion for Summary Judgment of 9/23/05, at p. 3 (BEQ Dkt. No. 0106-05-01). Those rules provide in relevant part:

> An affidavit used to support or oppose a motion must be made on personal knowledge, set out facts that would be admissible in evidence, and show that the affiant or declarant is competent to testify on the matters stated. Sworn or certified copies of all papers or parts of papers referred to in an affidavit must be attached to or served with the affidavit.

IDA.R.CIV.PROC. 56(c)(4); *see also Freeman v. Idaho Dept. of Env. Quality*, Final Order of 4/11/12 at p. 11 (BEQ Dkt. No. 0101-11-04) (applying Rule 56 standards to conclude an affidavit was admissible as expert testimony).

Second, on matters of admissibility of evidence, BEQ Procedural Rule 003.13 adopts AG Procedural Rule 600, which states:

> Evidence should be taken by the agency to assist the parties' development of the record, not excluded to frustrate that development. The presiding officer at hearing is not bound by the Idaho Rules of Evidence. No informality in any proceeding or in the manner of taking testimony invalidates any order. The presiding officer, with or without objection, may exclude evidence that is irrelevant, unduly repetitious, inadmissible on constitutional or statutory grounds, or on the basis of any evidentiary privilege provided by statute or recognized in the courts of Idaho. All other evidence may be admitted if it is of a type commonly relied upon by prudent persons in the conduct of their affairs. The agency's experience, technical competence and specialized knowledge may be used in evaluation of evidence.

Third, even if the BEQ is not strictly bound by the Idaho Rules of Evidence, those rules do

---

throughout this Order.

provide helpful guidance and standards in evaluating technical evidence that may require expert witness testimony. Idaho Rule of Evidence 702 states:

> A witness who is qualified as an expert by knowledge, skill, experience, training, or education may testify in the form of an opinion or otherwise if the expert's scientific, technical, or other specialized knowledge will help the trier of fact to understand the evidence or to determine a fact in issue.

Finally, the decision on a motion to strike is within the discretion of the court (in judicial proceedings) or agency (in administrative proceedings). *See generally Shea v. Kevic Corp*., 328 P.3d 520, 524, 156 Idaho 540, 544 (Idaho 2014). "A trial court does not abuse its discretion if it (1) correctly perceives the issue as discretionary, (2) acts within the bounds of discretion and applies the correct legal standards, and (3) reaches the decision through an exercise of reason." *Id*.

III. LEGAL ANALYSIS

Perpetua articulates a few different bases to strike Paragraphs 15 and 16 of the Oppenheimer Declaration and the related exhibits. First, Perpetua argues that Mr. Oppenheimer's testimony is not properly qualified as expert witness testimony. Also, as to the two exhibits, Perpetua argues they should be stricken both because they were not disclosed in discovery, and because Mr. Oppenheimer "does not purport to have personal knowledge of the methods used to arrive at the conclusions expressed in these studies, nor of the studies themselves."

The Petitioners respond that Paragraphs 15 and 16 help to establish ICL's standing in this matter. Petitioners describe the Oppenheimer Declaration as one of seven "standing declarations" it filed on June 9. (*See* Petitioners' Resp. Br. of 7/7/23, pp. 1, 4.)

Paragraph 15(a)-(c) and 16(a) simply discuss Mr. Oppenheimer's personal experience, condition, and concerns, which are rationally related to concern over the issuance of an air quality permit. There is no basis to strike these four subparagraphs. As to Paragraph 15(a)-(c) and 16(a), Perpetua's motion is denied.

The remainder of Paragraphs 15 and 16 are affirmative, mostly definitive statements regarding the effects of emissions on human health. These statements are inherently of a technical nature and require the witness to be qualified as an expert. The Oppenheimer Declaration does not purport to establish Mr. Oppenheimer as an expert witness on air emissions or human health. Moreover, these statements do not attempt to explain how they relate to the actual legal and regulatory standards that govern the disposition of this matter. In other words, even if Mr. Oppenheimer were qualified to make these statements, they do not "help the trier of fact to understand the evidence or to determine a fact in issue" under Idaho Rule of Evidence 702.

However, the Petitioners rely on the Oppenheimer Declaration for the limited purpose of helping to establish ICL's standing. When otherwise inadmissible evidence may still be relevant to the standing issue, it is appropriate for the decision-maker to refrain from striking the offending evidence but clarify the scope of its relevance and consideration. *See generally Oregon Natural Desesrt Ass'n v. Rasmussen*, 451 F.Supp.2d 1202, 1208-1209 (D.Ore. 2006).

Overall, Paragraphs 15(d)-(f) and 16(b) and the two related exhibits are rationally related to establishing Mr. Oppenheimer's concern over the air permit issued to Perpetua Resources and, therefore, ICL's standing in this matter. Therefore, Perpetua's motion to strike those subparagraphs is denied. However, because those subparagraphs do not satisfy the requirements of Idaho Rule of Evidence 702, the Hearing Officer will limit consideration of them to the standing issue. The Hearing Officer will not consult the Oppenheimer Declaration or either of the two exhibits in evaluating any alleged errors on the part of DEQ in issuing the permit to Perpetua Resources.

As to Perpetua's argument that the two exhibits should be stricken because they were not disclosed in discovery, DEQ and Perpetua moved for summary judgment on the standing issue on May 12, 2023—well after the February 14, 2023 discovery deadline. While the Petitioners have an

ongoing duty to supplement their discovery responses, *see generally* IDA.R.CIV.PROC. 26(e), the Hearing Officer does not find the length of time from May 12 to June 9 to be inordinately long, particularly given that Petitioners were under a deadline to prepare and file summary judgment response and reply materials during that same timeframe. In any event, because the Hearing Officer will not rely on the exhibits in evaluating whether DEQ has committed any substantive errors in issuing the air permit to Perpetua, there is limited prejudice to Perpetua arising from their late disclosure, which is outweighed by the Petitioners' interests in responding to Perpetua's standing arguments.

IV. CONCLUSION

Based on the foregoing, the Hearing Officer denies Perpetua's motion to strike Paragraphs 15 and 16 of the Oppenheimer Declaration, but will consider the declaration and its exhibits in their entirety only for the limited purpose of evaluating ICL's standing to bring this action.

Dated this 31st day of July, 2023.

BEFORE THE BOARD OF ENVIRONMENTAL QUALITY
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047	
NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON, Petitioners, v.	BEQ Case No. 0101-22-01 OAH Case No. 23-245-01 ORDER ON PETITIONERS' MOTION TO STRIKE
DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent, and PERPETUA RESOURCES IDAHO, INC., Intervenor.	

I. PROCEDURAL BACKGROUND

Pursuant to the stipulated Scheduling Order of January 19, 2023, all three sets of parties have filed and fully briefed motions for summary judgment. The Petitioners filed their summary judgment motion and supporting materials on April 14; Perpetua Resources and DEQ filed their responses to that motion and their own motions and supporting materials on May 12; the Petitioners filed their response to the Perpetua and DEQ motions and reply in support of their own motion on June 9; and Perpetua filed a reply brief in support of its own motion on June 23, along with a declaration of Kevin Lewis, an air quality engineer at Air Sciences, Inc. In general, the Lewis

Declaration discusses DEQ's efforts in evaluating Perpetua's permit application and issuing the permit. According to Lewis, the process was conducted with an unprecedented "level of review and scrutiny" and the permit conditions are "more onerous than those in other gold mining permits" he has reviewed. (Lewis Decl., ¶¶ 5-7.)

The Petitioners filed a motion to strike the Lewis Declaration on July 7, arguing primarily that it should be stricken because discovery has closed. In addition, in the event the Lewis Declaration is not stricken, the Petitioners have requested an opportunity to file a sur-reply brief to respond to it substantively.

II. LEGAL ANALYSIS

The Lewis Declaration should be stricken, though on a somewhat different basis than that articulated by the Petitioners. Motions for summary judgment filed in administrative proceedings before the BEQ are governed by the Idaho Rules of Civil Procedure. *In the Matter of Simmons Sanitation*, Findings of Fact, Conclusions of Law, and Preliminary Order on Motion for Summary Judgment of 9/23/05, at p. 3 (BEQ Dkt. No. 0106-05-01). Those rules provide:

> The motion [for summary judgment], ***supporting documents and brief*** must be served at least 28 days before the date of the hearing. If the adverse party wishes to oppose summary judgment, the party must serve an answering brief. The ***answering brief and any opposing documents*** must be served at least 14 days before the date of the hearing. Any ***reply brief*** of the moving party must be served at least 7 days before the date of the hearing.
>
> ***
>
> The court may alter or shorten the time periods and requirements of this rule for ***good cause shown***….

IDA.R.CIV.PROC. 56(b)(2), (3) (emphasis added).

Similarly, the rule governing motions other than summary judgment motions contemplates the filing of affidavits to support motions and responses, but not reply briefs. *See* IDA.R.CIV.PROC. 7(b)(3)(A)-(C). The text of these rules provides a clear indication that a summary

judgment movant must specifically request leave and establish "good cause shown" to file an affidavit (or declaration) in support of a reply brief. While the Scheduling Order in this matter alters the standard deadlines under Rule 56, it does not otherwise authorize the filing of affidavits or declarations out of sequence with that established by the Rule. (*See* Order of 1/19/23.)

Generally speaking, the decision on a motion to strike is within the discretion of the court (in judicial proceedings) or agency (in administrative proceedings). *See generally Shea v. Kevic Corp*., 328 P.3d 520, 524, 156 Idaho 540, 544 (Idaho 2014). However, the Idaho Supreme Court has held that ***not*** striking the Lewis Declaration under these circumstances would be an abuse of the Board's discretion:

> Before analyzing whether the depositions and affidavits on file in this case present any issues of material fact, we must first address the correctness of the district judge's decision to consider the Jensen affidavit. As mentioned previously, RR & T served Sun Valley with a copy of this affidavit no more than three days before the hearing on the motion and did not actually file the affidavit until the day before the hearing. Nonetheless, the district judge denied Sun Valley's motion to strike the affidavit ruling that I.R.C.P. 56(e) allows a court to permit a party to supplement or oppose an affidavit by further affidavit and that Sun Valley failed to show any resulting prejudice.
>
> Rule 56(c) requires the moving party to serve the motion along with supporting brief and affidavits not less than twenty-eight days before the hearing. I.R.C.P. 56(c). The purpose is to give the opposing party an adequate and fair opportunity to support its case. The rule requires the adverse party, if it chooses, to respond with an opposing brief and affidavits no less than fourteen days prior to the hearing. *Id*. Again, the purpose is to give the moving party an adequate opportunity to respond. Finally, if the moving party chooses to reply, the rule permits the service of a reply brief no fewer than seven days before the hearing. *Id*. While the above language is mandatory, the trial court may shorten the time periods for good cause shown. *Id*.
>
> ***
>
> Rule 56(e) does give the trial court discretion to allow a party to oppose or supplement an affidavit by further affidavits, however, ***the time limitations set forth in Rule 56(c) still apply unless the court shortens the time for good cause shown***.
>
> ***
>
> With the Jensen affidavit in hand, the district judge granted RR & T's motion for

> partial summary judgment noting that Sun Valley failed to contradict assertions made in the affidavit.
>
> ***
>
> Because there was no showing of good cause for failing to comply with the time limits by RR & T, and clearly Sun Valley was at a disadvantage in responding to the summary judgment motion, ***the district judge abused his discretion in considering Jensen's affidavit***. Therefore, we will not consider Jensen's statements in our review of RR & T's motion for partial summary judgment.

Sun Valley Potatoes, Inc. v. Rosholt, Robertson & Tucker, 981 P.2d 236, 240-241, 133 Idaho 1 (Idaho 1999) (emphasis added).

Admittedly, the circumstances in *Sun Valley Potatoes* were much more extreme than they are here. In that case, the offending affidavit was served on the other party three days prior to the summary judgment hearing and was filed with the court the day before the hearing. *Id*. at 240. Here, the summary judgment hearing has been scheduled for September 21, 2023—nearly three months after the Lewis Declaration was filed.

Regardless, the basic mechanics of Rule 56 still apply: In order for a summary judgment movant to file an affidavit or declaration after the deadlines established by rule (or as amended by a scheduling order), it must establish "good cause" for doing so. Neither Perpetua's summary judgment reply brief that accompanied the Lewis Declaration nor its opposition to the Petitioners' motion to strike reference the "good cause" standard or otherwise attempt to explain why it could not have filed the declaration earlier.

This would be difficult in any event. The briefing deadlines established by the Scheduling Order are generous. Moreover, Perpetua itself agreed that the Petitioners would file their summary judgment motion nearly a full month before Perpetua's motion. (Order of 1/19/23, at p. 2.) Effectively, Perpetua had a preview of the Petitioners' arguments that Rule 56 does not normally provide. Why Perpetua would have needed more than two months from the time Petitioners filed

their summary judgment motion on April 14 to file the Lewis Declaration on June 23 is not apparent.

III. CONCLUSION

Based on the foregoing, the Petitioners' motion to strike the June 23 declaration of Kevin Lewis is granted. The Hearing Officer will not consider that declaration in ruling on the pending motions for summary judgment. Petitioners' request for leave to file a sur-reply brief is now moot.

Dated this 31st day of July, 2023.

CONTRACT HEARING OFFICER'S REQUEST FOR WAIVER

PURSUANT TO IDAHO CODE § 67-5283(1)(d)

I, Dylan Lawrence, hereby request a waiver of prohibited conduct pursuant to Idaho Code §§ 67-5283(1)(d) as follows (***please select each applicable item***):

☑ **Engaging in the practice of law outside of the Hearing Officer's role with the Office of Administrative Hearings**. The following also specifically applies to my practice:

- ☐ I currently or previously have represented the State of Idaho, its agencies, and/or its personnel;
- ☑ I am or have been adverse to the State of Idaho, its agencies, and/or its personnel; or
- ☐ None of the above apply to me.

☐ **Holding, or being a candidate for, any federal state, county, municipal, district, or elective office**. Please identify the office:

_____

☐ **Serving as the agent, representative, officer, political treasurer, or employee, whether for profit or otherwise, of any political party, political committee, or candidate, whether as defined in either Chapter 1, Title 34, or Chapter 66, Title 67, Idaho Code, or otherwise.** Please identify the position:

_____

☐ **Holding any other public or private-sector position, whether for profit or otherwise, except for volunteer positions that are not inconsistent with their duties as a Hearing Officer.** Please insert specifics below:

_____

☐ **Any other provision of the Code of Conduct.** Explain:

_____

Additional information may be requested by the Chief Administrative Hearing Officer or their designee. Following review of all submitted information, you will be informed in writing if your request for waiver is granted or denied.

THIS FORM MUST BE SUBMITTED EACH TIME YOU NEED TO REQUEST NEW/ADDITIONAL GROUNDS FOR WAIVER

Current Formal Judicial/Administrative Proceedings Involving State Agencies as Adverse Parties

State of Idaho v. BLH Enterprises, et al. (Bear Lake County; Case No. CV04-22-0168): I am co-counsel of record for defendants in a case filed by IDL for activities at Bear Lake below the ordinary high water mark. The judicial proceedings are currently dormant while the defendants prepare and file a permit application. It is likely that resolution of the permit application will require a hearing under the Lake Protection Act that, as of Jan. 1, 2023, would be conducted by a representative of OAH.

In the Matter of Application for Permit No. 63-34753 in the Name of Idaho Water Resource Board: This involves the water right application filed by IWRB that is associated with the proposed raise of Anderson Ranch Dam. I represent Elmore County, who has filed a protest in opposition to the application.

In the Matter of Applications for Permits for the Diversion and Use of Surface and Ground Water Within the Snake River Basin: This involves a recent moratorium issued by IDWR on water right applications on the Snake River between King Hill and Swan Falls Dam. I represent Elmore County, who has filed a petition opposing the moratorium.

In the Matter of Application for Permit No. 63-35061 in the Name of Heritage Ranch, LLC: I represent the applicant for a new water right in the Parma area that has been protested by IDFG.

In the matter of: United Oil of Magic Valley, Inc., LUST Consent Order 4-160052: I have been asked to review the terms of a proposed Consent Order on behalf of the regulated entity. This would involve direct interaction with one of the DAGs assigned to DEQ.

Other Ongoing, Less Formal Contacts with State Agencies

My client in the BLH Enterprises case described above has communicated with DEQ regarding related boat fueling practices. Thus far, I have not been directly involved in such discussions, but future contacts are reasonably forseeable. I understand BLH Enterprises recently provided a copy of a letter I drafted on this issue to representatives of DEQ, the Idaho Department of Lands, and the Idaho Department of Insurance.

I have clients who have been pursuing funding from DEQ for water projects. I have been involved in some discussions with DEQ staff related to that effort.

My practice focuses on water rights, so I am nearly always involved in multiple matters and communications with IDWR and IWRB. For example, I typically have multiple clients with water right applications or protests pending with IDWR, and am in regular communication with IWRB and IDWR staff on a variety of topics and matters.

Past Matters

DEQ/BEQ: I have been directly adverse to DEQ in two air quality permit matters and in a handful of matters involving releases and management of hazardous waste.

Others: I have been directly adverse to IDWR, IWRB, IDFG, IDL, and ABC in dozens of past matters (mostly IDWR and IWRB).

BEFORE THE BOARD OF ENVIRONMENTAL QUALITY
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047 _____ NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON, Petitioners, v. IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent, and PERPETUA RESOURCES IDAHO, INC., Intervenor-Respondent.	Case Docket No. 0101-22-01 **JOINT MOTION *IN LIMINE* TO EXCLUDE COMMUNICATIONS FROM U.S. EPA SENT AFTER PERMIT WAS ISSUED**

The Idaho Department of Environmental Quality (the "Department") and Perpetua Resources Idaho, Inc. ("Perpetua") respectfully move to exclude recent comments from the U.S. Environmental Protection Agency ("EPA") to the Department that were communicated after the

Final Permit to Construct was issued and briefing on the Parties' motions for summary judgment was concluded.

I. INTRODUCTION

The Regional Administrator of EPA Region 10 corresponded with the Director of the Department in a letter dated August 10, 2023 (the "EPA Letter") regarding the Permit to Construct issued to Perpetua on June 17, 2022 (the "Permit"). The Permit is currently the subject of this contested case proceeding, and scheduled for a summary judgment hearing September 21, 2023.

No party has attempted to introduce the EPA Letter, however it has been shared by an unknown party or parties with the press. An article regarding the letter appeared on August 28, 2023, and included comments from at least one Petitioner in this proceeding. The letter itself, together with Petitioner's comments to the press, are outside the record and do not fairly characterize either the EPA Letter nor the facts at issue in this proceeding. Both the EPA Letter and the press reports occasioned by its release should be ignored and it is for that reason that the Department and Perpetua are filing this motion.

The Department and Perpetua move to exclude the EPA Letter and the press reports regarding the EPA Letter to ensure that this proceeding is not tainted by claims made by non-parties, including EPA, or by parties commenting on this case. Specifically, (1) EPA is not a party to this contested case proceeding; (2) the EPA Letter was sent over a year after the Permit was issued; (3) the EPA Letter was not relied upon by the Department in determining whether to issue the Permit or in determining what conditions to include in the Permit; and (4) the EPA Letter was sent months after briefing concluded on the Parties' cross-motions for summary judgment. The pending administrative review of the Department's action in this contested case

proceeding is subject to Idaho law and the Board of Environmental Quality's (the "Board") contested case rules, and the Board's review of the Permit is not impacted by comments from EPA.

II. LEGAL STANDARD

"A motion in limine is a procedural mechanism to limit in advance testimony or evidence in a particular area." *Hana Fin., Inc. v. Hana Bank*, 735 F.3d 1158, 1162 n. 4 (9th Cir. 2013) (quoting *United States v. Heller*, 551 F.3d 1108, 1111 (9th Cir. 2009)). There is no express authority for motions in limine in either the Idaho Rules of Civil Procedure or the Idaho Rules of Evidence. Nevertheless, these motions are well recognized in practice and by case law. *See, e.g., Noel v. City of Rigby*, 166 Idaho 575, 587 (2020); *Ohler v. United States*, 529 U.S. 753, 758. The purpose of a motion in limine is to "exclude prejudicial evidence before the evidence is actually offered." *Luce v. United States*, 469 U.S. 38, 40 (1984).

III. ARGUMENT

The EPA Letter must be excluded because it is not part of the record before the Board and was not considered by the Department in issuing the Permit. Additionally, the EPA Letter was sent to the Department after briefing on the cross-motions for summary judgment was completed. Finally, the EPA Letter contains impermissible hearsay.

A. The EPA Letter was not considered by the Department in issuing the Permit and is not part of the Record.

Petitioners challenge the Department's Permit under the Idaho Administrative Procedure Act ("APA") standard for judicial review of adjudicative agency actions. *See* First Amended Petition ¶¶ 4, 7, 35, 52, 61, 69, 72.[1] It is well established under the APA, and not disputed here

[1] *See also* Petitioner's Opening Summary Judgment Brief ("Opening Br.") at 13; Perpetua's Memorandum in Support of Motion for Summary Judgment and in Opposition to

by the Parties, that in determining whether the Department erred as a matter of law, the role of the Board is to review the permitting record before the Department at the time it took the action of issuing the Permit. *See* Opening Br. at 13; Perpetua Br. at 10; *Floyd v. Bd. of Ada Cty. Comm'rs*, 164 Idaho 659, 663, 667 (2019).

The EPA Letter was transmitted to the Department over a year after the Permit was issued. EPA previously submitted multiple comments on the Permit that the Department appropriately responded to. The EPA Letter was not before the Department when it issued the Permit and has no bearing on whether the Department's action, based on the permitting record before it, was supported by substantial evidence or was arbitrary, capricious, or an abuse of discretion. *See* Idaho Code § 67-5279(3). The EPA Letter is therefore not part of the record upon which review of the Department's action is based, and accordingly, the EPA Letter should be excluded.

B. The EPA Letter was sent after briefing on the motions for summary judgment was complete and was not addressed by the parties.

Briefing on the pending cross-motions for summary judgment was completed on June 23, 2023. The EPA Letter was dated August 10, 2023. The EPA Letter should be excluded because it was sent after briefing concluded. *See* I.R.C.P. 26(e)(3) ("The court may exclude … evidence not disclosed" as required by the Idaho Rules of Civil Procedure).

C. The EPA Letter contains inadmissible hearsay.

"Hearsay" is a statement that "the declarant does not make while testifying at the current trial or hearing; and a party offers in evidence to prove the truth of the matter asserted in the

---

Petitioner's Motion for Summary Judgment ("Perpetua Mem.") 9-10; DEQ Response to Petitioner's Motion for Summary Judgment and Brief in Support of Cross Motion for Summary Judgment ("DEQ Br.") at 12-13.

statement." I.R.E. 801(c). "Hearsay is not admissible" unless it meets one of the enumerated exceptions in the Idaho Rules of Evidence. I.R.E. 802.

EPA is not a party to this contested case proceeding, nor have any of the Parties offered direct testimony from the EPA Regional Administrator in this contested case proceeding. To the extent that the EPA Letter, or press reports about it, might be offered for the truth of the matters asserted in the EPA Letter, it should be excluded as hearsay. The statements in the EPA Letter offer further critiques of the Permit and do not meet any of the enumerated exceptions on Rule 803 or Rule 804 of the Idaho Rules of Evidence.

Finally, because EPA is not a party to this contested case proceeding, the Department and Perpetua were not able to test the validity of EPA's assertions in their summary judgment briefing, nor will they be able to test these assertions through cross-examination at any eventual hearing. *State v. Harris*, 141 Idaho 721, 726, 117 P.3d 135, 140 (Ct. App. 2005) (explaining that the purpose of the hearsay rule "is to assure that testimony presenting assertions can be tested by cross-examination of the person making the assertion"). Accordingly, the EPA Letter must be excluded.

IV. CONCLUSION

For the foregoing reasons, the Board should exclude the EPA and any press reports about the Letter and not consider either in deciding this contested case proceeding.

BEFORE THE BOARD OF ENVIRONMENTAL QUALITY
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047 _____ NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON, Petitioners, v. IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent, and PERPETUA RESOURCES IDAHO, INC., Intervenor-Respondent.	Case Docket No. 0101-22-01 **JOINT MOTION TO SHORTEN TIME AND FOR EXPEDITED CONSIDERATION**

The Idaho Department of Environmental Quality (the "Department") and Perpetua Resources Idaho, Inc. ("Perpetua") respectfully move to shorten time for Petitioners to respond to the Joint Motion *in Limine*, filed on August 28, 2023, and move for expedited consideration of

the Joint Motion *in Limine* such that it may be decided before the summary judgment hearing scheduled for September 21, 2023.

I. INTRODUCTION

The Parties' cross motions for summary judgment are scheduled to be heard on September 21, 2023.[1] On August 28, 2023, the Department and Perpetua filed a joint motion in limine to exclude correspondence sent to the Department by the U.S. Environmental Protection Agency after the Permit was finalized. Under the Board of Environmental Quality's contested case rules, the Hearing Officer has authority to shorten time for consideration of pre-hearing motions. *See* IDAPA 58.01.23. Due to the rapidly approaching summary judgment hearing, and the need to adequately prepare for the hearing, the Department and Perpetua respectfully request that the Hearing Officer shorten time for Petitioners to respond to the Joint Motion *in Limine* and also to expedite consideration of the motion. The Department and Perpetua also request the opportunity to file a reply in support of the Joint Motion *in Limine*.

II. ARGUMENT

Pursuant to IDAPA 58.01.23.162, the Hearing Officer has authority to manage the process for consideration of a pre-hearing motion, including the time for parties to respond to the motion. Typically, the responding party has 14 days to respond to a pre-hearing motion. *Id.* This would make Petitioners' response due on September 11, which is 10 days from the summary judgment hearing. To allow the Parties adequate time to prepare for the hearing, the Department and Perpetua respectfully request that the Hearing Officer shorten time for Petitioners to file their

[1] During the Status Conference held on July 11, 2023, the Hearing Officer indicated that he would provide a list of questions to focus the issues to be addressed at the hearing. Expedited briefing of and a decision on the Motion *in Limine* and early submission of the Hearing Officer's questions will allow the parties time to prepare for the summary judgment hearing.

response to the Joint Motion *in Limine* such that it is due no later than September 6. The Department and Perpetua also request that the Hearing Officer expedite consideration of the Joint Motion *in Limine* so that the Parties may have a decision on the motion in time to prepare for the summary judgment hearing.

Pursuant to IDAPA 58.01.23.162.02, the Hearing Officer may allow an opportunity for the movant to file a reply brief. The Department and Perpetua respectfully request the opportunity to file a reply brief in support of the Joint Motion *in Limine*. The Department and Perpetua will file its reply brief the day after Petitioners file their response brief.

III. CONCLUSION

For the foregoing reasons, the Department and Perpetua respectfully request that the Hearing Officer shorten time for Petitioners to respond to the Joint Motion *in Limine* and expedite consideration of the motion. The Department and Perpetua also request that the Hearing Officer allow a reply in support of the Joint Motion *in Limine*.

Attorney for Save the South Fork Salmon

BEFORE THE OFFICE OF ADMINISTRATIVE HEARINGS
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047	Agency Case No. 0101-22-01
	OAH Case No. 23-245-01
NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON Petitioners, v. IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent, and PERPETUA RESOURCES IDAHO, INC., Intervenor.	**PETITIONERS' MOTION TO STAY THE CASE AND BRIEF IN SUPPORT**

MOTION TO STAY

Petitioners Nez Perce Tribe, Idaho Conservation League, and Save the South Fork Salmon ("Petitioners") hereby move to stay this contested case, including postponing the summary judgment hearing scheduled for September 21, 2023, and setting a status conference in October to discuss the status of the contested case.

Petitioners' stay request is based on the letter dated August 10, 2023, from EPA Regional Administrator Casey Sixkiller to Idaho Department of Environmental Quality ("DEQ") Director Jess Byrne (the "EPA Letter"),[1] raising concerns with the Permit to Construct for the Stibnite Gold Project (the "PTC"), which is the subject of this contested case. The EPA Letter is attached as Exhibit A. The EPA Letter requests an in-person meeting aimed at a timely resolution of EPA's concerns, such as by issuing a revised PTC. Some of the concerns raised in the EPA Letter are substantially similar to the claims that Petitioners' have raised in this case. A stay is necessary to give EPA and DEQ time to meet and potentially resolve EPA's concerns, which could dispose of this contested case and/or narrow the issues, saving the Parties' and the Hearing Officer's time and resources. Petitioners' counsel reached out to counsel for DEQ and Perpetua, and they oppose a stay.

BRIEF IN SUPPORT OF MOTION TO STAY

The Hearing Officer has broad discretion to manage this contested case, including by staying these proceedings. *See* IDAPA 04.11.01.

[1] The EPA Letter is the subject of DEQ's and Perpetua's pending Joint Motion in Limine. Petitioners are filing a Motion to Supplement, and a Response to the Motion in Limine, regarding the propriety of considering the EPA Letter on the merits. Here, the EPA Letter is submitted for the purpose of supporting this Motion to Stay.

I. THE EPA LETTER

In the EPA Letter, Regional Administrator Sixkiller requested a personal and in-person meeting with DEQ Director Byrne, including with appropriate members of the agency's permit and legal teams, within 30 days, "[g]iven the seriousness of the concerns raised by the EPA and the need to reach a timely resolution." EPA Letter at 1. It is Petitioners' understanding that such a meeting has not yet occurred, but that DEQ and EPA do plan to meet, including possibly a site visit, to discuss these matters.

The EPA Letter states that EPA has three primary concerns with the Permit:

> The Agency has three primary concerns with the Department's Permit: (1) the Permit's emission limits are not adequate to limit the Stibnite Gold Project's potential to emit below the Prevention of Significant Deterioration permitting threshold; thus, construction of the Stibnite Gold Project would constitute construction of a major stationary source without a Prevention of Significant Deterioration permit, (2) the Permit's emission limits are not adequate to protect the particulate matter National Ambient Air Quality Standard, and (3) the Department's delineation between the Stibnite Gold Project boundary and the ambient air—where the National Ambient Air Quality Standards apply—is not adequately supported. Details of the Agency's evaluation of the final permit are enclosed for your review.

EPA Letter at 1. The EPA Letter also states that EPA "believes that the deficiencies in the Permit outlined in the enclosure and articulated in prior comments can be rectified through issuance of a revised permit to construct with adequate and enforceable conditions." *Id.*

II. GRANTING A LIMITED STAY WILL SAVE RESOURCES AND WILL NOT PREJUDICE ANY PARTY

By granting the requested stay, DEQ will have time to meet with EPA to try to resolve EPA's concerns with the PTC, which could resolve this contested case or significantly narrow the issues. Two of the three primary concerns EPA has with the PTC (inadequate limits to comply with particulate NAAQS and inadequate support for setting the ambient air boundary) are the same as or substantially overlap with the issues Petitioners' have pursued in this contested case.

See Pet'rs' Br. in Supp. of Mot. Summ. J. Should EPA and DEQ resolve these concerns by going through the process of revising the PTC, as EPA has requested, this could address some or all of the issues Petitioners raised in this contested case.

A stay will not prejudice the other parties. If EPA and DEQ are not able to reach a timely resolution, or if such resolution does not dispose of Petitioners' contested case, the contested case can resume and proceed to a decision on summary judgment.

DEQ will not be prejudiced by a stay. DEQ is a state agency created by the Idaho Environmental Health and Protection Act. Idaho Code § 39-101. DEQ's stated mission is: "To protect human health and the quality of Idaho's air, land, and water." Webpage, About Us, https://www.deq.idaho.gov/about-us/. DEQ works in partnership with the EPA to implement the Clean Air Act, 42 U.S.C. § 7401 *et seq.*, and the Idaho Air Rules, IDAPA 58.01.01, as the "CAA is a joint venture, one that makes the States and the Federal Government partners in the struggle against air pollution." *In re Volkswagen*, 959 F.3d 1201, 1214 (9th Cir. 2020). It is in DEQ's interest to issue a lawful and valid PTC that protects health and the environment and is supported by its federal partner agency EPA. Even if no resolution is reached, it is still in DEQ's interest to at least meet with EPA with time to try to timely address EPA's concerns.

Perpetua will not be prejudiced by a temporary stay either. Because Petitioners have not sought to stay the PTC, the PTC is currently in effect. *See* IDAPA 58.01.23.061. Thus, the pendency of this contested case does not preclude Perpetua from commencing construction. Moreover, before Perpetua can commence construction and operation of the Stibnite Gold Project, it needs numerous additional state and federal approvals. Other than the PTC issued by DEQ, most (if not all) of these other approvals have not yet been granted. Thus, temporarily

staying this matter for a short time will not prejudice Perpetua, but it could save the parties and the Hearing Officer substantial time and resources.

For the foregoing reasons, Petitioners' request that the Hearing Officer grant this motion for stay, vacate the September 21, 2023 hearing date, and set a date for a status conference in October or as allowed by the Hearing Officer's and the parties' schedules.

Dated this 1st day of September 2023.

Respectfully submitted,

s/ Julia Thrower

Exhibit A

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
REGION 10
1200 Sixth Avenue, Suite 155
Seattle, WA 98101

OFFICE OF THE REGIONAL ADMINISTRATOR

August 10 2023

Mr. Jess Byrne
Director
Idaho Department of Environmental Quality
1410 North Hilton Street
Boise, Idaho 83706

Dear Mr. Byrne,

The purpose of this letter is to request an in-person meeting, either in Seattle or Boise, to follow-up on our recent discussion regarding concerns with Idaho Department of Environmental Quality's air quality Permit to Construct issued to Perpetua Resources Idaho, Inc. on June 17, 2022. The Permit authorizes Perpetua Resources Idaho, Inc. to construct a gold, silver and antimony mine, referred to as the Stibnite Gold Project. The Agency previously provided comments on draft permits to the Department raising numerous issues. The Agency has reviewed the final Permit, statement of basis and the Department's response to comments and continues to be concerned that construction and operation of the Stibnite Gold Project under the terms set out in the Department's Permit would not comply with the Clean Air Act. As we discussed, the Agency does not oppose the Stibnite Gold Project, generally. The Agency's interest is ensuring that the Stibnite Gold Project is properly permitted and complies with the Clean Air Act to ensure the protection of human health and the environment.

The Agency has three primary concerns with the Department's Permit: (1) the Permit's emission limits are not adequate to limit the Stibnite Gold Project's potential to emit below the Prevention of Significant Deterioration permitting threshold; thus, construction of the Stibnite Gold Project would constitute construction of a major stationary source without a Prevention of Significant Deterioration permit, (2) the Permit's emission limits are not adequate to protect the particulate matter National Ambient Air Quality Standard, and (3) the Department's delineation between the Stibnite Gold Project boundary and the ambient air—where the National Ambient Air Quality Standards apply—is not adequately supported. Details of the Agency's evaluation of the final permit are enclosed for your review.

The Agency believes that the deficiencies in the Permit outlined in the enclosure and articulated in prior comments can be rectified through issuance of a revised permit to construct with adequate and enforceable conditions that limit the Stibnite Gold Project's potential to emit and ensure compliance with the National Ambient Air Quality Standards. I invite the Department to discuss these concerns with the Agency and collaborate with the Agency on an appropriate path forward.

Given the seriousness of the concerns raised by the EPA and the need to reach a timely resolution, I would like to schedule the meeting in the next 30 days, with your and my personal involvement, along with appropriate members of our permit and legal teams.

If you are supportive of such a meeting, please have your scheduler contact my Executive Assistant, Michelle Fraser, at (206) 553-4629 or fraser.michelle@epa.gov. Thank you for your attention to this matter.

Sincerely,

CASEY SIXKILLER

ENVIRONMENTAL PROTECTION AGENCY
EVALUATION OF AIR QUALITY PERMIT TO CONSTRUCT
Perpetua Resources Idaho, Inc.
Permit Number P-2019-0047
Issued: June 17, 2022

PRIOR ENVIRONMENTAL PROTECTION AGENCY (EPA) COMMENTS ON DRAFT PERMITS

Perpetua Resources Idaho, Inc. (PRI) submitted an application for a permit to construct (PTC) the Stibnite Gold Project (SGP) to Idaho Department of Environmental Quality (IDEQ) on August 20, 2019. Prior to issuance of the final PTC, IDEQ developed and offered for public comment three draft PTCs. EPA submitted two formal comment letters dated March 19, 2021, and March 16, 2022, on two of the prior permit drafts dated February 18, 2021, and January 13, 2022, respectively. In these comments, EPA raised numerous concerns with the adequacy of the draft PTCs to limit the SGP's potential to emit (PTE) to below major stationary source levels and to ensure the SGP does not cause or contribute to a violation of the National Ambient Air Quality Standards (NAAQS). IDEQ issued the Final Permit, Statement of Basis (SOB), and Response to Comments (RTC) on June 17, 2022.

STATUTORY AND REGULATORY REQUIREMENTS

Major stationary sources in Idaho are required to obtain a prevention of significant deterioration permit (PSD) prior to commencing construction.[1] Similarly, major stationary sources in Idaho must obtain a Tier I operating permit.[2] For purposes of the PSD permitting requirement, a source meets the definition of major stationary source if it has a PTE of 250 tons per year or more of a regulated NSR pollutant or 100 tons per year or more of a regulated air pollutant if the source is of the type specifically listed in the regulations (e.g., lime plants).[3] For the purposes of the requirement to obtain a Tier I operating permit, a source meets the definition of major stationary source if the source has a PTE of 100 tons per year or more of any regulated air pollutant, 10 tons per year or more of any hazardous air pollutant (HAP), or 25 tons per year of any combination of HAPs.[4] Particulate matter and particulate matter with an aerodynamic diameter of less than or equal to 10 micrometers are regulated air pollutants.[5]

A state-issued permit condition can legally restrict a source's PTE if it meets two criteria: 1) the condition is legally enforceable by the state air pollution control agency; and 2) it is enforceable as a practical matter.[6]

---

[1] IDAPA 58.01.01.205; 40 CFR 52.670(c).
[2] In Idaho, major sources under Title V of the CAA and 40 CFR part 70 are referred to as Tier I Sources. IDAPA 58.01.01.300-397.
[3] IDAPA 58.01.01.201 and 205.01 and 40 CFR 52.21(b); 40 CFR 52.670(c).
[4] IDAPA 58.01.01.006; 58.01.01.008; 58.01.01.107; 40 CFR 70.2.
[5] IDAPA 58.01.01.006; 40 CFR 52.670(c).
[6] Terrell E. Hunt and John S. Seitz, "Limiting Potential to Emit in New Source Permitting" (June 13, 1989) ("Hunt Memo") at 2; John Seitz and Robert Van Heuvelen, "Release of Interim Policy on Federal Enforceability of Limitations on Potential to Emit" (Jan. 22, 1996) at 3.

In general, practical enforceability for a source-specific permit term means that the provision must specify: (1) a technically accurate limitation and the portions of the source subject to the limitation; (2) the time period for the limitation (hourly, daily, monthly, annually); and (3) the method to determine compliance including appropriate monitoring, record keeping and reporting.[7]

Emission factors used to derive a PTE limit must be technically accurate.[8] In general, emissions factors published in EPA's *AP-42 Compilation of Air Pollutant Emission Factors* (AP-42) are based on averages and are not intended for establishing source-specific limits.[9] EPA recommends using emissions factors in AP-42 only when source specific emissions factors are not available and selecting conservatively higher emissions factors.[10] EPA assigns each emissions factor in AP-42 a rating from A to E, with A being the best.[11] According to AP-42, "Factors based on many observations, or on more widely accepted test procedures, are assigned higher rankings. Conversely, a factor based on a single observation of questionable quality, or one extrapolated from another factor from a similar process, would probably be rated much lower."[12]

Emission factors also include numerous operating assumptions and variables regarding the source.[13] Accordingly, the permit should contain conditions to ensure the operating assumptions and variables underlying the emission factor accurately reflect site-specific conditions and are enforceable.[14]

When permits require add-on controls operated at a specified efficiency level, permit writers should include, so that the operating efficiency condition is enforceable as a practical matter, those operating parameters and assumptions which the permitting agency depended upon to determine that the control equipment would have a given efficiency.[15]

[12] *Id.* at 8.

[13] Peabody Western Coal, 12 E.A.D. at 39 n.40.

[14] Hunt Memo at 7-8; See also Peabody Western Coal, 12 E.A.D. at 38 n.38; Yuhuang Order at 19, 28.

[15] Hunt Memo at 7, 20-21; see also Cash Creek General LLC, Title V Petition Response Order, No. IV-2010-4 (June 22, 2012) at 17, 26 (granting in part because the permittee's claims of 90% control efficiency of PM emissions from storage piles and associated roadways was unsubstantiated and the permit lacked any requirements governing frequency of wet suppression, atmospheric or operations conditions under which wet suppression should applied the time of day that wet or chemical suppression should be applied, or the amount that should be applied).

When permits contain emissions, production or operational limits, they should also have monitoring, recordkeeping, and reporting (MRR) requirements that allow a permitting agency to verify a source's compliance with its limits.[16] The permit should provide for the collecting, maintaining, and reporting of information necessary to determine emissions of each pollutant as well as compliance with operating parameters.[17] The permit must include conditions that clearly specify the monitoring requirements and how the permittee must demonstrate compliance via the monitoring requirements.[18]

With respect to National Ambient Air Quality Standards (NAAQS) compliance, in accordance with IDAPA 58.01.01.203.02: "No permit to construct shall be granted for a new or modified source unless the application shows to the satisfaction of the Department all of the following: NAAQS. The stationary source or modification would not cause or significantly contribute to a violation of any ambient air quality standard." See also 40 CFR 52.670(c). Similarly, new major stationary sources in attainment or unclassifiable areas are subject to IDAPA 58.01.01.205, which is an approved part of Idaho's State Implementation Plan.[19] In order to satisfy the requirements of CAA Section 110(a)(2)(J), IDAPA 58.01.01.205 incorporates by reference several sections of 40 CFR 52.21, including 40 CFR 52.21(k). The regulation at 40 CFR 52.21(k) and CAA Section 165(a)(3) require that, "The owner or operator of the proposed source or modification shall demonstrate that allowable emission increases from the proposed source or modification, in conjunction with all other applicable emissions increases or reductions (including secondary emissions), would not cause or contribute to air pollution in violation of: Any national ambient air quality standard in any air quality control region; or Any applicable maximum allowable increase over the baseline concentration in any area."

EVALUATION OF FINAL PERMIT

1. The production limits in the PTC do not restrict the SGP's PTE to below major stationary source permitting thresholds under the prevention of significant deterioration (PSD) or Title V programs.

a. Underestimation of Emissions from Ore Processing Emission Units

In its prior comment letters, EPA advised DEQ that the emission factors relied upon in the draft permits were not representative of emissions. For instance, EPA's March 16, 2022 comment letter stated: "Some of the PTE limitations may not be technically accurate because they are not based on emission factors that are representative of the emission sources. For example, AP-42 Section 11.24 Metallic Minerals Processing emission factors applies to the processing of hard ores including gold. However, the application uses AP-42 emissions factors from Section 11.19.2 Crushed Stone Processing that is applicable to non-metallic mineral processing. The permitting record does not provide a reasoned explanation as to why emission factors from Section 11.24 were selected over those from Section 11.19.2."[20]

---

[16] Hunt Memo at 17; In re Shell Offshore, Inc. 15 E.A.D. at 551.
[17] 84 Fed. Reg. 36,304, 36,320.
[18] Yuhuang Order at 21.
[19] 40 CFR 52.670(c).
[20] March 16, 2022, EPA Comment 5

DEQ's Response to Comment did not provide any additional information or rationale for decision making. Instead, DEQ stated, "Representativeness of these parameters was discussed with and reconfirmed by PRI at various points during review and the estimates of emissions and underlying assumptions were supported to the satisfaction of DEQ."[21]

Even if a permitting authority was unable to find more accurate emission factors than AP-42, the introduction to Section 11.19 states, "The construction aggregate industry covers a range of subclassifications of the nonmetallic minerals industry (see Section 11.24, Metallic Minerals Processing, for information on that similar activity)." IDEQ did not follow the listed instructions to see Section 11.24 for Metallic Minerals Processing.

IDEQ did not state that it performed any analysis of other emission information. IDEQ did not state that it sought out emission factor information of higher quality than AP-42, as required by IDEQ Guidance[22] (Guidance) which states, "When estimating emissions, emissions data that *best* reflects emissions from a stationary source must be used" (emphasis added). DEQ did not make a determination that the emission factor chosen meets the Guidance. Similarly, the Guidance states "The rating of the AP-42 factor must be considered…" However, IDEQ did not state how it considered the rating of the factor chosen or if IDEQ considered other factors with higher ratings. For reference, AP-42 Section 11.24 has a rating of "C" for primary crushing emission factor. AP-42 Section 11.19 has no emission factor for primary crushing, but states that tertiary crushing can be used for primary and secondary crushing and the rating for tertiary crushing is "E", the lowest rating assigned by AP-42. Setting aside the choice of using an emission factor for Non-Metallic Minerals instead of the Metallic Minerals, IDEQ has not evaluated the available emission factors based on the rating, as required by its own Guidance.

EPA's document AP-42 Metallic Mineral Processing Plants – Background Information for Proposed Standards Volume 2 Appendices (EPA-450/3-81.009b) lists visits and emission testing at various mineral processing and mining operations. Appendix C – Summary of Test Data includes data on nine plants that processed metallic minerals. Table C-1 specifically includes testing at processing equipment at a gold mine with baghouse control. Thus, the metallic mineral processing plants evaluated and tested to form the basis for the emissions factors in AP-42 Section 11.24 are most similar to the metallic mineral processing emission units at the SGP. These background documents clearly indicate that the emissions factors in Section 11.24 are most appropriate for estimating emissions from the SGP.

Multiplying the emission factor found in AP-42 Section 11.24 by the production limitation on the primary crusher (OC7) results in an emission estimate over 90 tons of PM per year for that unit alone. Similarly, if AP-42 Section 11.24 emission factors are multiplied by the production limits for the remaining emission units OC1 through OC13, potential PM emissions from that collection of units *exceeds 800 tons PM per year*. Given the PSD threshold of 250 tons per year and the fact that even Section 11.24 is an average emission factor (and approximately half of all emission units will emit above an average rate), the PTC fails to restrict emissions below major source thresholds.

---

[21] RTC at pp. 3; 23; 25-26.

[22] Guidance available at https://www2.deq.idaho.gov/admin/LEIA/api/document/download/5521.

Based on the above information, IDEQ did not follow DEQ Guidance, did not support the use of the chosen emission factor, and was arbitrary when choosing emission factors for the ore processing emission units. Accordingly, the PTC does not restrict the Facility's PTE below major source thresholds as a legal and practical matter.

b. Underestimation of Emissions from Lime Plant Emission Units

EPA previously commented that IDEQ's emission estimates for the lime production emission units are not technically accurate because they do not appear to be based on emission factors that are representative of the emission sources. For example, EPA commented that AP-42 Section 11.17 Lime Manufacturing emission factors applies to the processing of lime derived from marble. However, IDEQ used AP-42 emissions factors from Section 11.19.2 Crushed Stone Processing. In addition, the limestone excavating emission estimates (Material Load & Unload) appear to use emission factors from Section 11.19.2 Crushed Stone Processing instead of Section 11.9 Western Surface Coal Mining emission factors that are representative and specific to mining excavation activities. The permitting record does not explain why emission factors from AP-42 Section 11.19.2 were selected over those from Sections 11.17 and 11.9. If IDEQ does not have a good technical reason for their selection of emission factors, the most conservative emission factor should be used for emission units.[23]

IDEQ responded to EPA and other commenters that: "As described previously in the Representativeness and Uncertainty of Emissions section, although some degree of uncertainty is present in all emission factors used in estimating emissions, all emission factors were adequately supported and the approach of estimating potential to emit (PTE) at design capacity was considered a conservative approach. Emission factors with control efficiencies built into them were adequately supported by that corresponding control device listed in the permit. Representative emission factors from EPA's AP-42 Section 11.17, 11.19.2 and 11.9 were used to estimate emissions from the lime plant, lime plant support equipment, and marble overburden mining, respectively. The facility's emission inventory includes crushers, screens, and conveyors controlled by water sprays. EPA's AP-42 11.19.2 (08/2004) provides representative emission factors for these specific processes and controls."[24]

Consistent with the evaluation in Section 1.a., above, DEQ failed to apply appropriate emission factors to the lime plant emission units, did not follow IDEQ guidance specific to emission factor use in permits and failed to create an enforceable restriction on the lime plant's potential to emit below major source thresholds (e.g., 100 tons PM per year).

IDEQ's selection of emissions factors for the lime plant and basis therefor suffer from the same deficiencies as the ore processing units evaluated in Section 1.a., above. IDEQ relied upon sections of AP-42 that are not specific to the process units being permitted. For instance, IDEQ relied upon non-metallic mineral processing emission estimates in EPA's AP-42 Section 11.19 instead of evaluating EPA's emission factors for lime manufacturing, Section 11.17. A single example of how important it is to accurately estimate emissions is illustrated by a process unit in

[23] March 16, 2022, EPA Comment 11.
[24] RTC at pp. 27-28.

the Lime Plant, LS3/LS4 (primary Screen/Secondary Crusher). If the emission factor for secondary crushers (0.62 lb/ton) in Section 11.17 is applied to those production units, potential emissions would exceed 100 tons PM per year from those units alone. The same result applies to emission unit LS5 (secondary screen), resulting in an additional 128 tons PM per year. These two simple examples highlight the importance of accurately estimating future emissions from the proposed SGP.

Based on the above and corresponding issues highlighted in Section 1.a., IDEQ did not follow IDEQ Guidance, did not support the use of the chosen emission factor and was arbitrary when choosing emission factors for the lime processing emission units, and did not restrict the lime plant's PTE below major source thresholds.

c. Lack of Emission Limits

IDEQ's permit imposes only production limits for the ore processing units while relying on the unrepresentative emission factors that significantly underestimate emissions. While use of production limits alone to limit PTE may be acceptable in certain circumstances, such as when the limits are derived from conservative emission factors, this is not the case here.

In addition to inadequate production limits derived from unrepresentative emission factors, the Final Permit lacks emissions limits for several emission units, including the ore crushers, screens, and conveyors. This further undermines the enforceability of the synthetic minor limits. EPA advised IDEQ of this problem in its March 19, 2021, letter (Comments 1-4). Despite these comments, the Final Permit does not contain either source-wide emission limits applicable to all emission units or unit-specific limits on the mining and ore processing emission units.[25] As a result, enforcement of the synthetic minor limits is constrained to the inaccurate production limits with no corresponding limitation on the emissions from those units. As discussed above, IDEQ used emission factors that significantly underestimate the emissions from the ore processing units as well as the lime plant units. Based on the analysis above, DEQ's permit does not restrict the SGP's PM PTE to below PSD or Title V major source thresholds as a legal and practical matter.

d. Lack of Sufficient Monitoring, Recordkeeping and Reporting

EPA previously commented that the Draft Permit lacked sufficient monitoring, recordkeeping and reporting (MRR) to ensure the production and emission limits are enforceable as a practical matter.[26] EPA commented that the Final Permit did not include core monitoring, recordkeeping, and reporting (MRR) requirements directly, but rather allowed the permittee to develop these MRR requirements post permit issuance in an Operations and Maintenance Manual (O&M Manual). EPA, as well as many other commenters, raised procedural and substantive concerns with IDEQ's approach to incorporating MRR requirements into the permit. Procedurally, EPA commented that the O&M Manual ought to be developed and available for public comment prior to permit issuance and that any changes to the O&M Manual ought to be reviewed and approved

[25] Includes Drilling Activities, Blasting Activities, Excavating and hauling activities, Rock dumps and hauling activities, Prill Silos #1-2, OC1 through OC13.
[26] March 16, 2022 EPA Comments 6, 7, 12, 13, 22-25

by IDEQ prior to the change. Substantively, EPA commented that the permit condition specifying the minimum requirements for the O&M Manual lacked the necessary specificity to ensure the permit include adequate MRR.

IDEQ's RTC included some responses to EPA's comments. IDEQ revised PTC Condition 2.20 from draft to final to require that the O&M manual be developed 30 days prior to startup of any process equipment. Condition 2.20 also states: "The requirements in the O&M manual shall be incorporated by reference to this permit and shall be enforceable permit conditions." In addition, PTC Condition 2.21 requires: "The O&M manual shall be submitted for approval to DEQ 30 days prior to startup of any ore processing, ore concentration and refining, lime production, or aggregate production emission source regulated by this permit (as identified in Table 1.1) at the address provided (Permit Condition 2.26), and shall remain onsite at all times. Any changes to the O&M manual shall be submitted to DEQ for review, comment, and approval 30 days prior to the change."[27]

These conditions in the Final PTC and Idaho's RTC do not fully address EPA's concerns regarding the development and approval of the O&M Manual. IDEQ did not require the applicant to develop and submit the O&M Manual as part of its application. Accordingly, the O&M Manual will not be subject to public review and comment, even though the Manual will establish enforceable conditions in the permit. In addition, Conditions 2.20 and 2.21 do not mandate IDEQ *approval* prior to startup or a change to the O&M Manual, only that the Permittee submit the O&M Manual to IDEQ for approval. Finally, Condition 2.20 specifies that the O&M Manual shall be incorporated by reference into the permit. However, this condition does not make clear whether only the approved O&M Manual is incorporated by reference or any version of the O&M Manual submitted by the permittee. Moreover, given that the O&M Manual establishes permit conditions that bear on emission and compliance, revisions to the O&M Manual constitute permit revisions that ought to be subject to public review and comment.[28]

Condition 2.20 contains the minimum content requirements for the O&M Manual. In response to commenters questioning the sufficiency of these minimum requirements, IDEQ reasserted that Condition 2.20 contains the minimum requirements for the O&M Manual and that Condition 2.20 requires the permittee to describe various methods, procedures, and schedules to monitor emission units and control equipment.[29] Neither the Final Permit nor IDEQ's RTC adequately address EPA's concerns.

At the outset, these minimum requirements are vague and may not compel specific, enforceable conditions in the ultimate O&M Manual. For many critical monitoring and operational requirements, Condition 2.20 merely requires the permittee to "describe" the procedures and/or schedule. In addition, the requirement to "Describe the schedule and procedures for routine inspection (Permit Condition 2.10), maintenance, repair, and replacement of control equipment" does not specify any particular method (e.g. EPA Test Methods 9, 22) for visual observation of opacity or fugitive emissions. Accordingly, this vague condition will not lead to sufficient MRR in the O&M Manual.

---

[27] RTC at p. 15.
[28] *See* IDAPA 50.01.01.209.04.
[29] RTC at pp. 13-18; 20 (Comments 6, 7, 8, 11, 12, and 15).

In addition to these overarching concerns with Condition 2.20, numerous permit conditions reference the O&M Manual to satisfy MRR requirements. However, as illustrated in Table 1, below, Condition 2.20 does not mandate specific MRR for all of these corresponding production or emission limits.[30]

Table 1: Evaluation of O&M Manual Requirements

Conditions	O&M Manual Requirements	Evaluation
Conditions 3.11-3.12: • The permittee shall install and operate dust collection systems with a minimum control efficiency of 90% on all drilling rigs in accordance with the O&M manual. • The permittee shall install, operate, and maintain water sprays in accordance with the O&M manual (Permit Condition 2.20) to control PM emissions from each ore processing crusher and conveyor.	Condition 2.20 does not contain any specific minimum requirements for water sprays.	The MRR for drill rigs and rock crushing equipment is inadequate. The O&M manual contains no provisions regarding water sprays. While Condition 2.20 does require incorporation of certain manufacturer's guarantees, this requirement is specific to certain control devices: wet scrubber, vent gas cleaning tower, venturi scrubber, carbon filter, baghouse and bin vent filter cartridge control device.
Conditions 3.16-3.20: • The devices and methodologies used to measure weights shall be identified in the O&M Manual.	Condition 2.20 requires the O&M Manual to "Describe each monitoring device and methodology used to measure weight rates of materials to demonstrate compliance with each material throughput limit (Permit Conditions 3.5–3.9, 4.8–4.11, and 5.4–5.8). Procedures for proper installation, calibration, and maintenance shall be included."	This condition lacks specificity with respect to the scale used to determine the weights of materials, particularly daily ore loading conditions in 3.16-3.20. In order for these daily limits to be practically enforceable, the permit must contain monitoring, recordkeeping and reporting of total daily weights of ore. This necessitates use of an accurate scale. Condition 2.20

[30] Conditions 3.11-3.12; 3.16-3.20; 4.13-4.17; Table 4.2, Footnote C; 4.21-4.23; 4.29-4.32; 5.11-5.16; 5.17-5.26.

		does not mandate the use of any particular scale, or that the permittee maintain the scale within a certain percent accuracy. Without these minimum conditions in Condition 2.20, IDEQ has limited grounds to disapprove an O&M Manual that allows for inappropriate or inaccurate scales. See the regulation at 40 CFR 63.11646(a)(8)-(10) for detailed requirements for the measuring and recording of weights. Neither Condition 2.20 nor Conditions 3.16-3.20 contain required calculations for summing daily weights to demonstrate continuous compliance. In its response to comments, IDEQ stated that the permittee will use a weighometer to measure weights.[31] While this may be true, no condition in the permit requires the use of a weighometer.
Conditions 4.13-4.17 • The permittee shall install, operate, and maintain venturi scrubber (VS1), vent gas cleaning tower (ST1), vent gas steam condensation tower (CT1), and carbon filter (CA5) systems in accordance with the O&M manual (Permit	Describe the schedule and procedures for routine inspection (Permit Condition 2.10), maintenance, repair, and replacement of control equipment. • See-no-see visible emissions inspection of each wet scrubber, carbon filter, baghouse, and bin vent shall be	No conditions specify any specific methods for see-no-see inspections, e.g. Method 22 observations. Without referencing the method, the compliance determination is subjective and likely unenforceable.

[31] RTC at p. 15.

Condition 2.20) and consistent with manufacturer's recommendations. • The permittee shall install, operate, and maintain a carbon filter (CA2) in accordance with the O&M manual (Permit Condition 2.20) and consistent with manufacturer's recommendations.	conducted at least once per day. • Describe the schedule and procedures for corrective action that will be taken if visible emissions are present from wet scrubber (WS2, WS3), carbon filter (CA1, CA2, CA3, CA4, CA5), baghouse (BH2, BH3, BH4, BH5), or bin vent filter (LS, LS1, MillS2, ACS1, ACS2, ACS3, ACS4, CS1, CS2) control equipment at any time. Procedures should include how to determine whether filter cartridges are ruptured or are not appropriately secured in place, and how to determine whether the wet scrubber, condenser, and carbon filters are operating properly.	
Table 4.2 Footnote C Pounds per hour, as determined by a test method prescribed by IDAPA 58.01.01.157, EPA reference test method, continuous emission monitoring system (CEMS) data, or DEQ-approved alternative. Condition 4.8 The permittee shall process ore concentrate as the raw	Describe each monitoring device and methodology used to measure weight rates of materials to demonstrate compliance with each material throughput limit (Permit Conditions 3.5–3.9, 4.8–4.11, and 5.4–5.8). Procedures for proper installation, calibration, and maintenance shall be included. Establish operating ranges for control equipment, based on	Condition 2.20 does not contain MRR requirements specific to Venturi Scrubber (VS1) Vent Gas Cleaning Tower (ST1) or Vent Gas Steam Condensation Tower (CT1) used to control emissions from the Autoclave. Condition 2.20 contains a requirement to describe the schedule for taking corrective action if visible emissions are

material in the autoclave, and the maximum input to the autoclave shall not exceed 6,960 T/day. Condition 4.13 The permittee shall install, operate, and maintain venturi scrubber (VS1), vent gas cleaning tower (ST1), vent gas steam condensation tower (CT1), and carbon filter (CA5) systems in accordance with the O&M manual (Permit Condition 2.20) and consistent with manufacturer's recommendations. Conditions 4.21-4.23 • The devices and methodologies used to measure weights shall be identified in the O&M Manual, and the devices shall be installed in accordance with the requirements of NESHAP Subpart EEEEEEE. • The devices and methodologies used to measure weights shall be identified in the O&M Manual. • At least once per shift, the permittee shall monitor and record the circulation flow rate in the venturi scrubber, the circulation flow rate in the vent gas cleaning tower, the	manufacturer specifications and conditions measured during performance testing. • Minimum pressure drop across each wet scrubber, vent gas cleaning tower, and venturi scrubber; • Minimum circulation flow rate for each wet scrubber, vent gas cleaning tower, venturi scrubber; • Maximum inlet gas stream temperature to each carbon filter; • Maximum pressure drop across each carbon filter; • Minimum pressure drop across each baghouse. Describe the schedule and procedures for corrective action that will be taken if visible emissions are present from wet scrubber (WS2, WS3), carbon filter (CA1, CA2, CA3, CA4, CA5), baghouse (BH2, BH3, BH4, BH5), or bin vent filter (LS, LS1, MillS2, ACS1, ACS2, ACS3, ACS4, CS1, CS2) control equipment at any time. Procedures should include how to determine whether filter cartridges are ruptured or are not appropriately secured in place, and how to determine whether the wet scrubber, condenser, and carbon filters are operating properly.	present, but does not mandate any specific corrective actions. NESHAP Subpart EEEEEE contains detailed MRR requirements at 40 CFR 63.11646(a)(8)-(10), including maintenance and calibration requirements. However, Condition 4.21 does not require maintenance or calibration in accordance with NESHAP Subpart EEEEEEE, only installation in accordance with NESHAP Subpart EEEEEEE.

pressure drop across the venturi scrubber, and the pressure drop across the vent gas cleaning tower to ensure compliance with O&M specifications.		
Conditions 5.11-5.16 • The permittee shall install, operate, and maintain water sprays in accordance with the O&M manual (Permit Condition 2.20) to control PM emissions from each portable crushing and screening plant. Water sprays shall operate at all times, except as specified in the O&M manual during winter conditions, when this equipment is operated to ensure compliance with Fugitive Dust requirements (Permit Conditions 2.1–2.6). • The permittee shall install, operate, and maintain a baghouse system (BH4) in accordance with the O&M manual (Permit Condition 2.20) and consistent with manufacturer's recommendations. All emissions from the parallel flow regenerative kiln shall be ducted to the baghouse at all times	Establish operating ranges for control equipment, based on manufacturer specifications and conditions measured during performance testing. Describe the schedule and procedures for routine inspection (Permit Condition 2.10), maintenance, repair, and replacement of control equipment. The replacement dates for each baghouse and bin vent filter cartridge and for each activated carbon filter medium shall be recorded at the time of each replacement. For cartridges, records shall include the manufacturer and model. For carbon filters, records shall include the manufacturer, type, and form of medium added. Records shall also include any changes in supplier and other relevant information Describe the schedule and procedures for corrective action that will be taken if visible emissions are present from wet scrubber (WS2, WS3), carbon filter (CA1,	Condition 2.20 does not contain any specific minimum requirements for water sprays. Thus, the permit lacks sufficient MRR for these conditions.

to ensure compliance with parallel flow regenerative emission limits.	CA2, CA3, CA4, CA5), baghouse (BH2, BH3, BH4, BH5), or bin vent filter (LS, LS1, MillS2, ACS1, ACS2, ACS3, ACS4, CS1, CS2) control equipment at any time. Procedures should include how to determine whether filter cartridges are ruptured or are not appropriately secured in place, and how to determine whether the wet scrubber, condenser, and carbon filters are operating properly.	
Condition 5.3 Emissions from the lime production plant stacks shall not exceed any emission rate limit in the following table . . .	None	The permit does not contain any requirements to calculate emissions to demonstrate ongoing compliance with these emission limits. The permit does not contain any formulas, data reduction methods, or periodic calculation requirements to demonstrate continuous compliance with these emission limits.
Conditions 5.17-5.26 • The devices and methodologies used to measure weights shall be identified in the O&M Manual.	Describe each monitoring device and methodology used to measure weight rates of materials to demonstrate compliance with each material throughput limit (Permit Conditions 3.5–3.9, 4.8–4.11, and 5.4–5.8). Procedures for proper installation, calibration, and maintenance shall be included.	Same evaluation as Conditions 3.16-3.20.

In addition, the Permit does not require testing for the ore processing or lime production emission units to confirm the accuracy of emission factors. As discussed above, IDEQ used inaccurate emission factors to derive production limits for ore processing and lime production emission units. In its RTC, IDEQ acknowledges the uncertainty present in emission factors. However, IDEQ did not require initial or routine testing to confirm the accuracy of the emissions

factors used to establish production and emission limits. Given the low quality of the emissions factors used, such testing is critical to ensuring the adequacy of the synthetic minor limits. However, the Final Permit does not require any testing.

Given the absence of sufficient MRR requirements for the corresponding production limits, emission limits, and control equipment requirements, many of the synthetic minor emission limits are not enforceable as a practical matter.

2. The SGP, as permitted, will cause or contribute to a violation of the PM_{10} NAAQS.

a. Unsubstantiated estimates of fugitive dust control

EPA, as well as several other commenters, questioned the basis for IDEQ's determination that PRI could achieve a 93.3% control efficiency to control fugitive dust from haul roads at the SGP. Specifically, EPA commented that IDEQ did not provide a reasoned analysis demonstrating that the studies showing that 90% control efficiency is achievable using magnesium chloride reflect conditions at the SGP. EPA also commented that IDEQ did not include specific details necessary to support such a demonstration in the permitting record.[32]

In its RTC, IDEQ responded stating that 93.3% is an aggressive level of control and that PRI has committed to undertaking all measures to achieve this level of control. IDEQ further stated that, based on a review of test studies, the 93.3% level of control can be achieved using water and magnesium chloride dust suppressants (citing PRI's application). IDEQ explained that chemical and water dust suppressants are used in combination for the control of dust from haul roads, and that achieving the target combined control efficiency of 93.3% is ultimately important to ensure compliance with applicable standards. According to IDEQ, it is for this reason that the combined control efficiency was listed in the permit in lieu of separate chemical (90% control) and water (33.3%) dust suppressant control efficiencies.[33]

IDEQ's responses do not adequately address EPA's comments. IDEQ did not proffer further evidence that conditions at the SGP are comparable to areas where studies indicating a 90% control efficiency on fugitive dust is achievable. Even so, these studies do not support IDEQ's contention that a control efficiency of *93.3%* is achievable. Ultimately, IDEQ appears to have back-calculated the control efficiency necessary to demonstrate NAAQS compliance, rather than determine a control efficiency that is achievable in practice.[34]

b. Underestimation of Fugitive Dust Emissions

With respect to demonstrating NAAQS compliance, EPA commented that IDEQ's use of a median silt content of 4.0% underestimates fugitive dust emissions from haul roads. EPA commented that the arithmetic average silt content for haul roads based on Perpetua's site-specific data is 4.3%. Use of the 4.3% average value results in about 7% more fugitive dust emissions from the haul roads than estimated using the median value. IDEQ's modeling

[32] March 16, 2022, EPA Comment 19.
[33] RTC at p. 3.
[34] SOB at p. 59; 65-66 (Table 28).

sensitivity study showed values just below the NAAQS, such that an 7% increase in fugitive dust from haul roads would have resulted in 24-hour PM_{10} NAAQS violations.[35]

In response, IDEQ stated the use of site-specific median values for silt content is commonly accepted by DEQ, and the values used in calculations were supported by PRI.[36] This response does not adequately justify why a median value rather than the arithmetic average is more appropriate taking into consideration the site-specific sampling. Given that a small difference in the silt content will result in an exceedance of the NAAQS, IDEQ's insistence on using a median silt content appears arbitrary and unreasonable and indicates that PRI has not demonstrated that the emissions will not cause or contribute toa NAAQS violation. On the contrary, operation of the SGP will likely cause or contribute to a violation of the PM_{10} NAAQS.

c. Lack of Conditions to Ensure Continuous Compliance with PM_{10} NAAQS

EPA, along with several other commenters, commented that the permit lacks conditions sufficient to ensure continuous compliance with the PM_{10} NAAQS. Specifically, EPA raised concerns with the adequacy and practical enforceability of the Fugitive Dust Control Plan (FDCP). Specifically, EPA raised concerns that the permit did not contain specific conditions necessary to ensure continuous compliance with the 93.3% control efficiency, but rather allowed the permittee to develop these conditions as part of an FDCP after permit issuance and allowed the permittee to change the FDCP without IDEQ approval. EPA also commented that the permit lacks conditions necessary to make the 93.3% control efficiency practically enforceable, such as frequency of dust suppression, requirements for when to use chemical dust suppression, amount of dust suppression that must be applied, vehicle weight, vehicle speed, vehicle daily miles traveled, and road silt content.[37] With respect to Condition 2.5 requiring PRI to apply fugitive dust control measures such that visible emissions are below 10% opacity, EPA also commented that permitting record does not support a correlation of the 10% opacity requirement in Condition 2.5 with a 93.3% control efficiency.[38]

In response to these comments, IDEQ updated permit condition 2.8 to require IDEQ approval of the FDCP 30 days prior to startup and after any subsequent changes. IDEQ also responded that the permit contains activity rate limits that serve as surrogate limits for fugitive sources. IDEQ also stated that it typically does not include vehicle speed, type, and miles traveled in permits. IDEQ also asserted that Conditions 2.1-2.6 contain the minimum requirements for the contents of the fugitive dust plan.[39] Finally, IDEQ responded that "An instantaneous 10% opacity limit for vehicle traffic on haul roads is considered a very conservative control trigger level to ensure that an appropriate control measure is taken to reasonably control emissions of fugitive dust (Permit condition 2.5)."[40]

---

[35] March 16, 2022 EPA Comment 20.
[36] RTC at p. 4.
[37] March 16, 2022, EPA Comments 16 – 19
[38] *Id.* at Comment 19.
[39] RTC at p. 9.
[40] *Id.*

These responses do not fully address EPA's comments with respect to the practical enforceability of emission limits necessary for NAAQS compliance. Condition 2.8 does not require that IDEQ approve the FDCP prior to startup, only that the permittee submit the FDCP 30 days prior to startup. Similarly, Condition 2.8 does not clearly require IDEQ approval of FDCP changes prior to the permittee making the changes.

Conditions 2.1 through 2.6 are insufficient to ensure the permittee achieves 93.3% fugitive dust control efficiency on haul roads. First, the permitting record indicates that application of magnesium chloride is necessary to achieve up to 90% control of fugitive dust. However, Conditions 2.1 through 2.6 do not require the permittee to use magnesium chloride for dust suppression. Rather, Condition 2.6 merely requires that the FDCP contain reasonable precautions including: "apply water or suitable dust suppressant (e.g. magnesium chloride, calcium chloride) to disturbed areas, haul roads, equipment staging areas, parking areas, and storage piles during the dry season and at other times as necessary to control fugitive dust." Moreover, magnesium chloride degrades over time. However, the permit does not require the permittee to reapply magnesium chloride at regular intervals.

Similarly, IDEQ assumed a combined control efficiency of water and chemical dust suppression to achieve 93.3%. However, Conditions 2.1 through 2.6 contain no explicit requirements that the permittee use both water and chemical dust suppression in a manner necessary to achieve the 93.3% control efficiency. Magnesium chloride does not perform as a dust suppressant in dry conditions. Therefore, supplemental watering will be necessary. However, the permit does not require supplemental watering to ensure the magnesium chloride performs as a dust suppressant.

With respect to vehicle weight and vehicle miles traveled, compliance with the NAAQS is dependent on vehicle miles traveled staying at or below 7,758 per day.[41] However, the permit contains no such limit. IDEQ also did not make clear how the activity limits, including Condition 2.4 (Blasting Limits) and Condition 3.5 (Daily Hauling and Excavating Limits), would necessarily restrict vehicle miles traveled to at or below 7,758 per day. There are no requirements or restrictions on the manner the permittee uses the haul roads.

Regarding the silt content, the permit does not contain conditions to ensure the silt content on haul roads remains at or below 4%. Condition 3.13 contains the minimum requirements for the Haul Road Capping Plan (HRCP). According to IDEQ, Condition 3.13 limits maximum silt content to 4.0%. This is not accurate. Condition 3.13 states that "The permittee shall use capping material with a maximum of 4.0% silt content." This condition does not require the permittee to maintain the haul road silt content to at or below 4.0%. Nor does the requirement account for mixing of the capping material with the base or wearing of the cap over time. Condition 3.13 also contain no explicit sampling or compliance demonstration methods. Rather, Condition 3.13 allows the permittee to develop a "silt content sampling plan including standard operational procedure for sampling, frequency of sampling, and ASTM (or equivalent) method of analysis for silt content."

Finally, IDEQ's response to EPA's comment on the basis for the 10% opacity limit in Condition 2.5 does not provide additional basis for a correlation between opacity and the 93.3% control.

[41] SOB at Appendix B, p. 65

The permit contains no testing requirements to establish a correlation between fugitive dust control and opacity. Nor does the permit contain any specific method for determining opacity or the frequency or location of opacity observations.

3. Neither the permit record nor permit conditions demonstrate that the entirety of the SGP ought to be excluded from the scope of "ambient air."

"Ambient air" is defined as that portion of the atmosphere, external to buildings, to which the general public has access."[42] General public includes "any person(s) other than those who are permitted access to the property as employees or business invitees of a specific stationary source (including trespassers)."[43] EPA interprets access to encompass two key concerns: legal access and physical or practical access.[44] Legal access concerns whether the general public has the right or permission to enter a specific property. Physical access addresses whether the general public is able to, under actual circumstances, enter a particular parcel of land. In order to preclude physical access to a parcel of land, the source must employ measures, which may include physical barriers, that are effective in precluding access to the land by the general public.[45] Such measures can include video surveillance, monitoring, clear signage, and routine security patrols.[46] Measures can be effective even if there is not 100 percent certainty that they will prevent public access.[47] Measures must be reasonable taking into consideration the nature of the measure used, source location, type and size of source and property to be excluded, and surrounding area.[48]

a. Legal Right to Exclude General Public

As stated above, legal access concerns whether the general public has the right or permission to enter a specific property. IDEQ asserts in the SOB and RTC that PRI has "complete and sole authority to control access to or through the facility, granting access at their discretion to anyone wishing to visit the site or pass through the site."[49] Neither the SOB nor the RTC, however, evaluate PRI's claims. In light of the fact that the SGP encompasses the East Fork South Fork Salmon River and is located within National Forest lands, the permitting record ought to contain a more thorough evaluation of PRI's legal authority and members of the general public's right of access to the SGP area of operations.

b. Measures to Exclude General Public as a Practical Matter

EPA commented that the permit lacks conditions to ensure PRI employs sufficient measures such that the entirety of the SGP is appropriately excluded from the definition of ambient air. Specifically, EPA raised concerns that the general public may be able to access the SGP,

---

[42] IDAPA 58.01.01.006.10; 40 CFR 50.1(e).
[43] "Revised Policy on Exclusions from 'Ambient Air'" Memorandum from Andrew R. Wheeler to Regional Administrators, December 2, 2019, at p. 6.
[44] *Id.* at 5.
[45] *Id.* at 9.
[46] *Id.* at 7.
[47] *Id.* at 8.
[48] *Id.*
[49] RTC at p. 21.

regardless of their legal right to do so.[50] The basis for EPA's comment was that the permit does not contain specific measures the permittee will take to exclude members of the public from the SGP. Rather, the permit allows the permittee to develop an Access Management Plan ostensibly designed to exclude members of the public. In response, IDEQ asserted that Condition 2.7 contains the requirements for the ACP, including adequately informing anyone approaching an access point that travel beyond the established gate involves entering an active mine site as a guest of the permittee and providing verbal and written requirements that must be followed while on the SGP site.[51] The SOB also states that the primary and secondary access points are controlled by adjacent natural features, such as streams and creeks, steep topography, and areas of thick vegetation and undergrowth.[52] In addition, the SOB states that PRI will place boulders across trails and adjacent to the train to prevent vehicle access.[53] Finally, according to the SOB, PRI security personnel will routinely patrol mine facilities and roadways for unauthorized individuals.[54]

IDEQ's responses and statements in the SOB do not adequately address EPA's concerns. As permitted, the general public will likely have physical or practical access to portions of the SGP. The SGP operations area boundary covers 2,372 acres of land within the Payette and Boise National Forests. The SGP is located in Valley County, Idaho. The nearest settlement is the village of Yellow Pine, Idaho, approximately 14 miles by road.[55] The Payette National Forest includes the Frank Church River of No Return Wilderness. The Salmon River runs through the Payette National Forest. The SGP is surrounded by numerous recreation areas in the Payette and Boise National Forests.[56] National Forest roads 374, 440, and 640 provide vehicle access to the site.[57]

Given the scale of the SGP, proximity to recreation opportunities, and multiple access points, the permittee should employ multiple measures to preclude public access. However, condition 2.7 is vague and leaves the permittee considerable latitude on the methods used to exclude members of the general public. While the SOB indicates that placement of boulders on secondary roadways is necessary to prevent access, Condition 2.7 contains no such requirement. Also, Condition 2.7 does not specify a minimum patrol frequency or minimum signage requirements. Nor does Condition 2.7 require the permittee to post or monitor the vast operations boundary to effectively preclude recreators from entering the site. Condition 2.7 only requires the permittee to employ measures to "discourage" access to secondary roadways and trails. This does not meet the standard to effectively exclude members of the general public. Similarly, EPA questions whether the entire boundary surrounding the operations area incorporates natural features that preclude access. Given the numerous recreational opportunities in the surrounding wilderness areas, access by recreators off trail appears possible. Therefore, the Final PTC does not ensure that the

entirety of the SGP is appropriately excluded from the definition of ambient air. This implicates IDEQ's determination that the SGP will not cause or contribute to a violation of the PM_{10} NAAQS.

Attorney for Save the South Fork Salmon

BEFORE THE OFFICE OF ADMINISTRATIVE HEARINGS
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047	Agency Case No. 0101-22-01
	OAH Case No. 23-245-01
NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON Petitioners, v. IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent, and PERPETUA RESOURCES IDAHO, INC., Intervenor.	**PETITIONERS' MOTION TO SUPPLEMENT WITH AUGUST 10, 2023 EPA LETTER AND BRIEF IN SUPPORT**

MOTION TO SUPPLEMENT

Petitioners Nez Perce Tribe, Idaho Conservation League, and Save the South Fork Salmon ("Petitioners") hereby move to supplement the evidence in this case with the August 10, 2023 letter from EPA Regional Administrator Casey Sixkiller to Idaho Department of Environmental Quality ("DEQ") Director Jess Byrne (the "EPA Letter"), which as attached as Exhibit A.[1] The EPA Letter raises multiple concerns the EPA has with the Permit to Construct for the Stibnite Gold Project (the "PTC"). EPA's concerns, and the information EPA provides to back up its concerns, support many of Petitioners' claims and should be considered in this contested case.

BRIEF IN SUPPORT

As set forth below, the applicable rules favor admitting relevant evidence to develop the agency record in a contested case like this one; the EPA Letter supports Petitioners' summary judgment arguments and is thus relevant to the pending cross motions for summary judgment; and granting this motion to supplement is not prejudicial.

ARGUMENT

I. The Rules Favor the Inclusion of Relevant Evidence in a Contested Case

Under the Board of Environmental Quality's Contested Case Rules (IDAPA 58.01.23), a contested case like this one allows for factual development, including through discovery and evidentiary hearings.[2] Even after the Hearing Office makes a decision and issues a recommended

[1] The EPA Letter is the subject of DEQ's and Perpetua's pending Joint Motion in Limine, filed on August 28, 2023. The Joint Motion in Limine also requests that press reports regarding the EPA Letter be excluded from the evidence in this case. Petitioners do not seek to supplement the evidence with any press reports.

[2] DEQ and Perpetua's Joint Motion in Limine attempts to exclude the EPA Letter because it "was not part of the record upon which review of the Department's action is based." Mot. in Limine at 4. IDAPA 58.01.23 does not, however, limit contested case records solely to those documents in possession of the agency. Furthermore, the January 19, 2023 Scheduling Order in this case

or preliminary order, the Board of Environmental Quality "may hold additional hearings or may remand the matter for further evidentiary hearings if further factual development is necessary before issuing a final order." IDAPA 58.01.23.720.02.b. & 730.03.

The Board's Contested Case Rules incorporate many provisions of the Idaho Rules of Administrative Procedure of the Attorney General ("AG Rules"). IDAPA 58.01.23.003. This includes the AG Rules on evidence at IDAPA 04.11.01.600-606. The AG Rules strongly favor the inclusion of relevant evidence and discourage its exclusion:

> Evidence should be taken by the agency to assist the parties' development of the record, not excluded to frustrate that development. The presiding officer at hearing is not bound by the Idaho Rules of Evidence. No informality in any proceeding or in the manner of taking testimony invalidates any order. The presiding officer, with or without objection, may exclude evidence that is irrelevant, unduly repetitious, inadmissible on constitutional or statutory grounds, or on the basis of any evidentiary privilege provided by statute or recognized in the courts of Idaho. All other evidence may be admitted if it is of a type commonly relied upon by prudent persons in the conduct of their affairs.

IDAPA 04.11.01.600.

In addition, a party may supplement prior responses to a discovery request with additional information. *See* I.R.C.P. 26.[3] The January 19, 2023 Scheduling Order in this case states that "[e]ach Party shall serve upon the other Parties any additional documentary evidence they deem relevant to these proceedings by February 14, 2023." As discussed below, the EPA Letter is relevant to the proceedings, but it was not available at the time documentary evidence was due. Nothing in the Board's Contested Case Rules, the AG Rules, the Idaho Rules of Civil

---

allowed both Perpetua and Petitioners to submit "any additional documentary evidence they deem relevant," demonstrating that the record in this case was never limited to those documents in DEQ's possession at the time it approved the PTC. Petitioners will file a response to the Motion in Limine further addressing this issue subsequent to this Motion to Supplement.

[3] Although the EPA Letter does not create a duty to supplement prior discovery responses under I.R.C.P 26(e), nothing in the Idaho Rules of Civil Procedure prohibits a party from doing so.

Procedure, or order's entered in this case prohibit augmentation of the record with new information relevant to the claims at issue.

II. The EPA Letter Is Relevant

In the EPA Letter, Regional Administrator Sixkiller requested a personal and in-person meeting with DEQ Director Byrne, including with appropriate members of the agency's permit and legal teams, within 30 days, "[g]iven the seriousness of the concerns raised by the EPA and the need to reach a timely resolution." The EPA Letter states:

> The Agency has three primary concerns with the Department's Permit: (1) the Permit's emission limits are not adequate to limit the Stibnite Gold Project's potential to emit below the Prevention of Significant Deterioration permitting threshold; thus, construction of the Stibnite Gold Project would constitute construction of a major stationary source without a Prevention of Significant Deterioration permit, (2) the Permit's emission limits are not adequate to protect the particulate matter National Ambient Air Quality Standard, and (3) the Department's delineation between the Stibnite Gold Project boundary and the ambient air—where the National Ambient Air Quality Standards apply—is not adequately supported. Details of the Agency's evaluation of the final permit are enclosed for your review.

EPA Letter at 1.

Two of these three primary concerns raised by EPA—inadequate limits to comply with particulate NAAQS and inadequate support for setting the ambient air boundary)—are the same as or substantially overlap with the issues Petitioners have raised in this contested case. *See* Pet'rs' Br. in Supp. of Mot. Summ. J ("Pet'rs. MSJ").

The enclosure to the EPA Letter ("Enclosure") includes more detailed and up-to-date information about these issues, including sections on the following issues which largely match issues Petitioners raised in their summary judgment brief related to particulate emissions: "Lack of Sufficient Monitoring, Recordkeeping and Reporting," *compare* Enclosure at 6-14 *with* Pet'rs' MSJ at 26-31; "Unsubstantiated Estimates of Fugitive Dust Controls," *compare* Enclosure at 14

with Pet'rs' MSJ at 19-23; "Lack of Conditions to Ensure Compliance with PM10 NAAQS," *compare* Enclosure at 15-17 *with* Pet'rs' MSJ at 23-28. The enclosure also includes more detailed and up-to-date information about EPA concerns with the ambient air boundary, including sections on the: "Legal Right to Exclude General Public" and "Measures to Exclude General Public as a Practical Matter." *Compare* Enclosure at 17-18 *with* Pet'rs' MSJ at 14-19.

EPA had already raised similar concerns during public comment on the PTC. *See* EPA Comment Letter (PET 663). The current EPA Letter, however, provides additional information and states EPA's position that DEQ's final PTC and response to comments did not resolve EPA's concerns. The EPA Letter is thus relevant and is the type of information a "prudent" person would consider here.

III. Admitting the EPA Letter Is Not Prejudicial

Petitioners' request to add the EPA Letter to the record is timely and does not prejudice DEQ or Perpetua. The EPA Letter was not available during the discovery period of January 19 to February 14, 2023, established by the January 19, 2023 Scheduling Order. Thus, Petitioners could not have submitted the EPA Letter while discovery was open. Furthermore, allowing the EPA Letter into evidence does not prejudice DEQ or Perpetua even though summary judgment briefing has concluded on the claims presented in Petition for Review. Again, the EPA Letter confirms that the concerns EPA already raised in its public comments on the draft PTC, and which Petitioners have already raised in this matter, remain concerns to EPA in the final PTC. Considering the EPA Letter does not expand the issues already briefed, an the Parties can readily address the EPA Letter at the hearing on the motions for summary judgment.

CONCLUSION

For the foregoing reasons, the Hearing Officer should augment the record to include the EPA Letter for consideration of the merits of the case.

Dated this 1st day of September 2023.

Respectfully submitted,

Exhibit A

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
REGION 10
1200 Sixth Avenue, Suite 155
Seattle, WA 98101

OFFICE OF THE
REGIONAL
ADMINISTRATOR

August 10 2023

Mr. Jess Byrne
Director
Idaho Department of Environmental Quality
1410 North Hilton Street
Boise, Idaho 83706

Dear Mr. Byrne,

The purpose of this letter is to request an in-person meeting, either in Seattle or Boise, to follow-up on our recent discussion regarding concerns with Idaho Department of Environmental Quality's air quality Permit to Construct issued to Perpetua Resources Idaho, Inc. on June 17, 2022. The Permit authorizes Perpetua Resources Idaho, Inc. to construct a gold, silver and antimony mine, referred to as the Stibnite Gold Project. The Agency previously provided comments on draft permits to the Department raising numerous issues. The Agency has reviewed the final Permit, statement of basis and the Department's response to comments and continues to be concerned that construction and operation of the Stibnite Gold Project under the terms set out in the Department's Permit would not comply with the Clean Air Act. As we discussed, the Agency does not oppose the Stibnite Gold Project, generally. The Agency's interest is ensuring that the Stibnite Gold Project is properly permitted and complies with the Clean Air Act to ensure the protection of human health and the environment.

The Agency has three primary concerns with the Department's Permit: (1) the Permit's emission limits are not adequate to limit the Stibnite Gold Project's potential to emit below the Prevention of Significant Deterioration permitting threshold; thus, construction of the Stibnite Gold Project would constitute construction of a major stationary source without a Prevention of Significant Deterioration permit, (2) the Permit's emission limits are not adequate to protect the particulate matter National Ambient Air Quality Standard, and (3) the Department's delineation between the Stibnite Gold Project boundary and the ambient air—where the National Ambient Air Quality Standards apply—is not adequately supported. Details of the Agency's evaluation of the final permit are enclosed for your review.

The Agency believes that the deficiencies in the Permit outlined in the enclosure and articulated in prior comments can be rectified through issuance of a revised permit to construct with adequate and enforceable conditions that limit the Stibnite Gold Project's potential to emit and ensure compliance with the National Ambient Air Quality Standards. I invite the Department to discuss these concerns with the Agency and collaborate with the Agency on an appropriate path forward.

Given the seriousness of the concerns raised by the EPA and the need to reach a timely resolution, I would like to schedule the meeting in the next 30 days, with your and my personal involvement, along with appropriate members of our permit and legal teams.

If you are supportive of such a meeting, please have your scheduler contact my Executive Assistant, Michelle Fraser, at (206) 553-4629 or fraser.michelle@epa.gov. Thank you for your attention to this matter.

Sincerely,

CASEY SIXKILLER

ENVIRONMENTAL PROTECTION AGENCY
EVALUATION OF AIR QUALITY PERMIT TO CONSTRUCT

Perpetua Resources Idaho, Inc.
Permit Number P-2019-0047
Issued: June 17, 2022

PRIOR ENVIRONMENTAL PROTECTION AGENCY (EPA) COMMENTS ON DRAFT PERMITS

Perpetua Resources Idaho, Inc. (PRI) submitted an application for a permit to construct (PTC) the Stibnite Gold Project (SGP) to Idaho Department of Environmental Quality (IDEQ) on August 20, 2019. Prior to issuance of the final PTC, IDEQ developed and offered for public comment three draft PTCs. EPA submitted two formal comment letters dated March 19, 2021, and March 16, 2022, on two of the prior permit drafts dated February 18, 2021, and January 13, 2022, respectively. In these comments, EPA raised numerous concerns with the adequacy of the draft PTCs to limit the SGP's potential to emit (PTE) to below major stationary source levels and to ensure the SGP does not cause or contribute to a violation of the National Ambient Air Quality Standards (NAAQS). IDEQ issued the Final Permit, Statement of Basis (SOB), and Response to Comments (RTC) on June 17, 2022.

STATUTORY AND REGULATORY REQUIREMENTS

Major stationary sources in Idaho are required to obtain a prevention of significant deterioration permit (PSD) prior to commencing construction.[1] Similarly, major stationary sources in Idaho must obtain a Tier I operating permit.[2] For purposes of the PSD permitting requirement, a source meets the definition of major stationary source if it has a PTE of 250 tons per year or more of a regulated NSR pollutant or 100 tons per year or more of a regulated air pollutant if the source is of the type specifically listed in the regulations (e.g., lime plants).[3] For the purposes of the requirement to obtain a Tier I operating permit, a source meets the definition of major stationary source if the source has a PTE of 100 tons per year or more of any regulated air pollutant, 10 tons per year or more of any hazardous air pollutant (HAP), or 25 tons per year of any combination of HAPs.[4] Particulate matter and particulate matter with an aerodynamic diameter of less than or equal to 10 micrometers are regulated air pollutants.[5]

A state-issued permit condition can legally restrict a source's PTE if it meets two criteria: 1) the condition is legally enforceable by the state air pollution control agency; and 2) it is enforceable as a practical matter.[6]

[1] IDAPA 58.01.01.205; 40 CFR 52.670(c).
[2] In Idaho, major sources under Title V of the CAA and 40 CFR part 70 are referred to as Tier I Sources. IDAPA 58.01.01.300-397.
[3] IDAPA 58.01.01.201 and 205.01 and 40 CFR 52.21(b); 40 CFR 52.670(c).
[4] IDAPA 58.01.01.006; 58.01.01.008; 58.01.01.107; 40 CFR 70.2.
[5] IDAPA 58.01.01.006; 40 CFR 52.670(c).
[6] Terrell E. Hunt and John S. Seitz, "Limiting Potential to Emit in New Source Permitting" (June 13, 1989) ("Hunt Memo") at 2; John Seitz and Robert Van Heuvelen, "Release of Interim Policy on Federal Enforceability of Limitations on Potential to Emit" (Jan. 22, 1996) at 3.

In general, practical enforceability for a source-specific permit term means that the provision must specify: (1) a technically accurate limitation and the portions of the source subject to the limitation; (2) the time period for the limitation (hourly, daily, monthly, annually); and (3) the method to determine compliance including appropriate monitoring, record keeping and reporting.[7]

Emission factors used to derive a PTE limit must be technically accurate.[8] In general, emissions factors published in EPA's *AP-42 Compilation of Air Pollutant Emission Factors* (AP-42) are based on averages and are not intended for establishing source-specific limits.[9] EPA recommends using emissions factors in AP-42 only when source specific emissions factors are not available and selecting conservatively higher emissions factors.[10] EPA assigns each emissions factor in AP-42 a rating from A to E, with A being the best.[11] According to AP-42, "Factors based on many observations, or on more widely accepted test procedures, are assigned higher rankings. Conversely, a factor based on a single observation of questionable quality, or one extrapolated from another factor from a similar process, would probably be rated much lower."[12]

Emission factors also include numerous operating assumptions and variables regarding the source.[13] Accordingly, the permit should contain conditions to ensure the operating assumptions and variables underlying the emission factor accurately reflect site-specific conditions and are enforceable.[14]

When permits require add-on controls operated at a specified efficiency level, permit writers should include, so that the operating efficiency condition is enforceable as a practical matter, those operating parameters and assumptions which the permitting agency depended upon to determine that the control equipment would have a given efficiency.[15]

[12] *Id.* at 8.

[13] Peabody Western Coal, 12 E.A.D. at 39 n.40.

[14] Hunt Memo at 7-8; See also Peabody Western Coal, 12 E.A.D. at 38 n.38; Yuhuang Order at 19, 28.

[15] Hunt Memo at 7, 20-21; see also Cash Creek General LLC, Title V Petition Response Order, No. IV-2010-4 (June 22, 2012) at 17, 26 (granting in part because the permittee's claims of 90% control efficiency of PM emissions from storage piles and associated roadways was unsubstantiated and the permit lacked any requirements governing frequency of wet suppression, atmospheric or operations conditions under which wet suppression should applied the time of day that wet or chemical suppression should be applied, or the amount that should be applied).

When permits contain emissions, production or operational limits, they should also have monitoring, recordkeeping, and reporting (MRR) requirements that allow a permitting agency to verify a source's compliance with its limits.[16] The permit should provide for the collecting, maintaining, and reporting of information necessary to determine emissions of each pollutant as well as compliance with operating parameters.[17] The permit must include conditions that clearly specify the monitoring requirements and how the permittee must demonstrate compliance via the monitoring requirements.[18]

With respect to National Ambient Air Quality Standards (NAAQS) compliance, in accordance with IDAPA 58.01.01.203.02: "No permit to construct shall be granted for a new or modified source unless the application shows to the satisfaction of the Department all of the following: NAAQS. The stationary source or modification would not cause or significantly contribute to a violation of any ambient air quality standard." See also 40 CFR 52.670(c). Similarly, new major stationary sources in attainment or unclassifiable areas are subject to IDAPA 58.01.01.205, which is an approved part of Idaho's State Implementation Plan.[19] In order to satisfy the requirements of CAA Section 110(a)(2)(J), IDAPA 58.01.01.205 incorporates by reference several sections of 40 CFR 52.21, including 40 CFR 52.21(k). The regulation at 40 CFR 52.21(k) and CAA Section 165(a)(3) require that, "The owner or operator of the proposed source or modification shall demonstrate that allowable emission increases from the proposed source or modification, in conjunction with all other applicable emissions increases or reductions (including secondary emissions), would not cause or contribute to air pollution in violation of: Any national ambient air quality standard in any air quality control region; or Any applicable maximum allowable increase over the baseline concentration in any area."

EVALUATION OF FINAL PERMIT

1. The production limits in the PTC do not restrict the SGP's PTE to below major stationary source permitting thresholds under the prevention of significant deterioration (PSD) or Title V programs.

a. Underestimation of Emissions from Ore Processing Emission Units

In its prior comment letters, EPA advised DEQ that the emission factors relied upon in the draft permits were not representative of emissions. For instance, EPA's March 16, 2022 comment letter stated: "Some of the PTE limitations may not be technically accurate because they are not based on emission factors that are representative of the emission sources. For example, AP-42 Section 11.24 Metallic Minerals Processing emission factors applies to the processing of hard ores including gold. However, the application uses AP-42 emissions factors from Section 11.19.2 Crushed Stone Processing that is applicable to non-metallic mineral processing. The permitting record does not provide a reasoned explanation as to why emission factors from Section 11.24 were selected over those from Section 11.19.2."[20]

---

[16] Hunt Memo at 17; In re Shell Offshore, Inc. 15 E.A.D. at 551.
[17] 84 Fed. Reg. 36,304, 36,320.
[18] Yuhuang Order at 21.
[19] 40 CFR 52.670(c).
[20] March 16, 2022, EPA Comment 5

DEQ's Response to Comment did not provide any additional information or rationale for decision making. Instead, DEQ stated, "Representativeness of these parameters was discussed with and reconfirmed by PRI at various points during review and the estimates of emissions and underlying assumptions were supported to the satisfaction of DEQ."[21]

Even if a permitting authority was unable to find more accurate emission factors than AP-42, the introduction to Section 11.19 states, "The construction aggregate industry covers a range of subclassifications of the nonmetallic minerals industry (see Section 11.24, Metallic Minerals Processing, for information on that similar activity)." IDEQ did not follow the listed instructions to see Section 11.24 for Metallic Minerals Processing.

IDEQ did not state that it performed any analysis of other emission information. IDEQ did not state that it sought out emission factor information of higher quality than AP-42, as required by IDEQ Guidance[22] (Guidance) which states, "When estimating emissions, emissions data that *best* reflects emissions from a stationary source must be used" (emphasis added). DEQ did not make a determination that the emission factor chosen meets the Guidance. Similarly, the Guidance states "The rating of the AP-42 factor must be considered…" However, IDEQ did not state how it considered the rating of the factor chosen or if IDEQ considered other factors with higher ratings. For reference, AP-42 Section 11.24 has a rating of "C" for primary crushing emission factor. AP-42 Section 11.19 has no emission factor for primary crushing, but states that tertiary crushing can be used for primary and secondary crushing and the rating for tertiary crushing is "E", the lowest rating assigned by AP-42. Setting aside the choice of using an emission factor for Non-Metallic Minerals instead of the Metallic Minerals, IDEQ has not evaluated the available emission factors based on the rating, as required by its own Guidance.

EPA's document AP-42 Metallic Mineral Processing Plants – Background Information for Proposed Standards Volume 2 Appendices (EPA-450/3-81.009b) lists visits and emission testing at various mineral processing and mining operations. Appendix C – Summary of Test Data includes data on nine plants that processed metallic minerals. Table C-1 specifically includes testing at processing equipment at a gold mine with baghouse control. Thus, the metallic mineral processing plants evaluated and tested to form the basis for the emissions factors in AP-42 Section 11.24 are most similar to the metallic mineral processing emission units at the SGP. These background documents clearly indicate that the emissions factors in Section 11.24 are most appropriate for estimating emissions from the SGP.

Multiplying the emission factor found in AP-42 Section 11.24 by the production limitation on the primary crusher (OC7) results in an emission estimate over 90 tons of PM per year for that unit alone. Similarly, if AP-42 Section 11.24 emission factors are multiplied by the production limits for the remaining emission units OC1 through OC13, potential PM emissions from that collection of units *exceeds 800 tons PM per year*. Given the PSD threshold of 250 tons per year and the fact that even Section 11.24 is an average emission factor (and approximately half of all emission units will emit above an average rate), the PTC fails to restrict emissions below major source thresholds.

---

[21] RTC at pp. 3; 23; 25-26.

[22] Guidance available at https://www2.deq.idaho.gov/admin/LEIA/api/document/download/5521.

Based on the above information, IDEQ did not follow DEQ Guidance, did not support the use of the chosen emission factor, and was arbitrary when choosing emission factors for the ore processing emission units. Accordingly, the PTC does not restrict the Facility's PTE below major source thresholds as a legal and practical matter.

b. Underestimation of Emissions from Lime Plant Emission Units

EPA previously commented that IDEQ's emission estimates for the lime production emission units are not technically accurate because they do not appear to be based on emission factors that are representative of the emission sources. For example, EPA commented that AP-42 Section 11.17 Lime Manufacturing emission factors applies to the processing of lime derived from marble. However, IDEQ used AP-42 emissions factors from Section 11.19.2 Crushed Stone Processing. In addition, the limestone excavating emission estimates (Material Load & Unload) appear to use emission factors from Section 11.19.2 Crushed Stone Processing instead of Section 11.9 Western Surface Coal Mining emission factors that are representative and specific to mining excavation activities. The permitting record does not explain why emission factors from AP-42 Section 11.19.2 were selected over those from Sections 11.17 and 11.9. If IDEQ does not have a good technical reason for their selection of emission factors, the most conservative emission factor should be used for emission units.[23]

IDEQ responded to EPA and other commenters that: "As described previously in the Representativeness and Uncertainty of Emissions section, although some degree of uncertainty is present in all emission factors used in estimating emissions, all emission factors were adequately supported and the approach of estimating potential to emit (PTE) at design capacity was considered a conservative approach. Emission factors with control efficiencies built into them were adequately supported by that corresponding control device listed in the permit. Representative emission factors from EPA's AP-42 Section 11.17, 11.19.2 and 11.9 were used to estimate emissions from the lime plant, lime plant support equipment, and marble overburden mining, respectively. The facility's emission inventory includes crushers, screens, and conveyors controlled by water sprays. EPA's AP-42 11.19.2 (08/2004) provides representative emission factors for these specific processes and controls."[24]

Consistent with the evaluation in Section 1.a., above, DEQ failed to apply appropriate emission factors to the lime plant emission units, did not follow IDEQ guidance specific to emission factor use in permits and failed to create an enforceable restriction on the lime plant's potential to emit below major source thresholds (e.g., 100 tons PM per year).

IDEQ's selection of emissions factors for the lime plant and basis therefor suffer from the same deficiencies as the ore processing units evaluated in Section 1.a., above. IDEQ relied upon sections of AP-42 that are not specific to the process units being permitted. For instance, IDEQ relied upon non-metallic mineral processing emission estimates in EPA's AP-42 Section 11.19 instead of evaluating EPA's emission factors for lime manufacturing, Section 11.17. A single example of how important it is to accurately estimate emissions is illustrated by a process unit in

[23] March 16, 2022, EPA Comment 11.
[24] RTC at pp. 27-28.

the Lime Plant, LS3/LS4 (primary Screen/Secondary Crusher). If the emission factor for secondary crushers (0.62 lb/ton) in Section 11.17 is applied to those production units, potential emissions would exceed 100 tons PM per year from those units alone. The same result applies to emission unit LS5 (secondary screen), resulting in an additional 128 tons PM per year. These two simple examples highlight the importance of accurately estimating future emissions from the proposed SGP.

Based on the above and corresponding issues highlighted in Section 1.a., IDEQ did not follow IDEQ Guidance, did not support the use of the chosen emission factor and was arbitrary when choosing emission factors for the lime processing emission units, and did not restrict the lime plant's PTE below major source thresholds.

c. Lack of Emission Limits

IDEQ's permit imposes only production limits for the ore processing units while relying on the unrepresentative emission factors that significantly underestimate emissions. While use of production limits alone to limit PTE may be acceptable in certain circumstances, such as when the limits are derived from conservative emission factors, this is not the case here.

In addition to inadequate production limits derived from unrepresentative emission factors, the Final Permit lacks emissions limits for several emission units, including the ore crushers, screens, and conveyors. This further undermines the enforceability of the synthetic minor limits. EPA advised IDEQ of this problem in its March 19, 2021, letter (Comments 1-4). Despite these comments, the Final Permit does not contain either source-wide emission limits applicable to all emission units or unit-specific limits on the mining and ore processing emission units.[25] As a result, enforcement of the synthetic minor limits is constrained to the inaccurate production limits with no corresponding limitation on the emissions from those units. As discussed above, IDEQ used emission factors that significantly underestimate the emissions from the ore processing units as well as the lime plant units. Based on the analysis above, DEQ's permit does not restrict the SGP's PM PTE to below PSD or Title V major source thresholds as a legal and practical matter.

d. Lack of Sufficient Monitoring, Recordkeeping and Reporting

EPA previously commented that the Draft Permit lacked sufficient monitoring, recordkeeping and reporting (MRR) to ensure the production and emission limits are enforceable as a practical matter.[26] EPA commented that the Final Permit did not include core monitoring, recordkeeping, and reporting (MRR) requirements directly, but rather allowed the permittee to develop these MRR requirements post permit issuance in an Operations and Maintenance Manual (O&M Manual). EPA, as well as many other commenters, raised procedural and substantive concerns with IDEQ's approach to incorporating MRR requirements into the permit. Procedurally, EPA commented that the O&M Manual ought to be developed and available for public comment prior to permit issuance and that any changes to the O&M Manual ought to be reviewed and approved

[25] Includes Drilling Activities, Blasting Activities, Excavating and hauling activities, Rock dumps and hauling activities, Prill Silos #1-2, OC1 through OC13.
[26] March 16, 2022 EPA Comments 6, 7, 12, 13, 22-25

by IDEQ prior to the change. Substantively, EPA commented that the permit condition specifying the minimum requirements for the O&M Manual lacked the necessary specificity to ensure the permit include adequate MRR.

IDEQ's RTC included some responses to EPA's comments. IDEQ revised PTC Condition 2.20 from draft to final to require that the O&M manual be developed 30 days prior to startup of any process equipment. Condition 2.20 also states: "The requirements in the O&M manual shall be incorporated by reference to this permit and shall be enforceable permit conditions." In addition, PTC Condition 2.21 requires: "The O&M manual shall be submitted for approval to DEQ 30 days prior to startup of any ore processing, ore concentration and refining, lime production, or aggregate production emission source regulated by this permit (as identified in Table 1.1) at the address provided (Permit Condition 2.26), and shall remain onsite at all times. Any changes to the O&M manual shall be submitted to DEQ for review, comment, and approval 30 days prior to the change."[27]

These conditions in the Final PTC and Idaho's RTC do not fully address EPA's concerns regarding the development and approval of the O&M Manual. IDEQ did not require the applicant to develop and submit the O&M Manual as part of its application. Accordingly, the O&M Manual will not be subject to public review and comment, even though the Manual will establish enforceable conditions in the permit. In addition, Conditions 2.20 and 2.21 do not mandate IDEQ *approval* prior to startup or a change to the O&M Manual, only that the Permittee submit the O&M Manual to IDEQ for approval. Finally, Condition 2.20 specifies that the O&M Manual shall be incorporated by reference into the permit. However, this condition does not make clear whether only the approved O&M Manual is incorporated by reference or any version of the O&M Manual submitted by the permittee. Moreover, given that the O&M Manual establishes permit conditions that bear on emission and compliance, revisions to the O&M Manual constitute permit revisions that ought to be subject to public review and comment.[28]

Condition 2.20 contains the minimum content requirements for the O&M Manual. In response to commenters questioning the sufficiency of these minimum requirements, IDEQ reasserted that Condition 2.20 contains the minimum requirements for the O&M Manual and that Condition 2.20 requires the permittee to describe various methods, procedures, and schedules to monitor emission units and control equipment.[29] Neither the Final Permit nor IDEQ's RTC adequately address EPA's concerns.

At the outset, these minimum requirements are vague and may not compel specific, enforceable conditions in the ultimate O&M Manual. For many critical monitoring and operational requirements, Condition 2.20 merely requires the permittee to "describe" the procedures and/or schedule. In addition, the requirement to "Describe the schedule and procedures for routine inspection (Permit Condition 2.10), maintenance, repair, and replacement of control equipment" does not specify any particular method (e.g. EPA Test Methods 9, 22) for visual observation of opacity or fugitive emissions. Accordingly, this vague condition will not lead to sufficient MRR in the O&M Manual.

---

[27] RTC at p. 15.
[28] *See* IDAPA 50.01.01.209.04.
[29] RTC at pp. 13-18; 20 (Comments 6, 7, 8, 11, 12, and 15).

In addition to these overarching concerns with Condition 2.20, numerous permit conditions reference the O&M Manual to satisfy MRR requirements. However, as illustrated in Table 1, below, Condition 2.20 does not mandate specific MRR for all of these corresponding production or emission limits.[30]

Table 1: Evaluation of O&M Manual Requirements

Conditions	O&M Manual Requirements	Evaluation
Conditions 3.11-3.12: • The permittee shall install and operate dust collection systems with a minimum control efficiency of 90% on all drilling rigs in accordance with the O&M manual. • The permittee shall install, operate, and maintain water sprays in accordance with the O&M manual (Permit Condition 2.20) to control PM emissions from each ore processing crusher and conveyor.	Condition 2.20 does not contain any specific minimum requirements for water sprays.	The MRR for drill rigs and rock crushing equipment is inadequate. The O&M manual contains no provisions regarding water sprays. While Condition 2.20 does require incorporation of certain manufacturer's guarantees, this requirement is specific to certain control devices: wet scrubber, vent gas cleaning tower, venturi scrubber, carbon filter, baghouse and bin vent filter cartridge control device.
Conditions 3.16-3.20: • The devices and methodologies used to measure weights shall be identified in the O&M Manual.	Condition 2.20 requires the O&M Manual to "Describe each monitoring device and methodology used to measure weight rates of materials to demonstrate compliance with each material throughput limit (Permit Conditions 3.5–3.9, 4.8–4.11, and 5.4–5.8). Procedures for proper installation, calibration, and maintenance shall be included."	This condition lacks specificity with respect to the scale used to determine the weights of materials, particularly daily ore loading conditions in 3.16-3.20. In order for these daily limits to be practically enforceable, the permit must contain monitoring, recordkeeping and reporting of total daily weights of ore. This necessitates use of an accurate scale. Condition 2.20

[30] Conditions 3.11-3.12; 3.16-3.20; 4.13-4.17; Table 4.2, Footnote C; 4.21-4.23; 4.29-4.32; 5.11-5.16; 5.17-5.26.

		does not mandate the use of any particular scale, or that the permittee maintain the scale within a certain percent accuracy. Without these minimum conditions in Condition 2.20, IDEQ has limited grounds to disapprove an O&M Manual that allows for inappropriate or inaccurate scales. See the regulation at 40 CFR 63.11646(a)(8)-(10) for detailed requirements for the measuring and recording of weights. Neither Condition 2.20 nor Conditions 3.16-3.20 contain required calculations for summing daily weights to demonstrate continuous compliance. In its response to comments, IDEQ stated that the permittee will use a weighometer to measure weights.[31] While this may be true, no condition in the permit requires the use of a weighometer.
Conditions 4.13-4.17 • The permittee shall install, operate, and maintain venturi scrubber (VS1), vent gas cleaning tower (ST1), vent gas steam condensation tower (CT1), and carbon filter (CA5) systems in accordance with the O&M manual (Permit	Describe the schedule and procedures for routine inspection (Permit Condition 2.10), maintenance, repair, and replacement of control equipment. • See-no-see visible emissions inspection of each wet scrubber, carbon filter, baghouse, and bin vent shall be	No conditions specify any specific methods for see-no-see inspections, e.g. Method 22 observations. Without referencing the method, the compliance determination is subjective and likely unenforceable.

[31] RTC at p. 15.

Condition 2.20) and consistent with manufacturer's recommendations. • The permittee shall install, operate, and maintain a carbon filter (CA2) in accordance with the O&M manual (Permit Condition 2.20) and consistent with manufacturer's recommendations.	conducted at least once per day. • Describe the schedule and procedures for corrective action that will be taken if visible emissions are present from wet scrubber (WS2, WS3), carbon filter (CA1, CA2, CA3, CA4, CA5), baghouse (BH2, BH3, BH4, BH5), or bin vent filter (LS, LS1, MillS2, ACS1, ACS2, ACS3, ACS4, CS1, CS2) control equipment at any time. Procedures should include how to determine whether filter cartridges are ruptured or are not appropriately secured in place, and how to determine whether the wet scrubber, condenser, and carbon filters are operating properly.	
Table 4.2 Footnote C Pounds per hour, as determined by a test method prescribed by IDAPA 58.01.01.157, EPA reference test method, continuous emission monitoring system (CEMS) data, or DEQ-approved alternative. Condition 4.8 The permittee shall process ore concentrate as the raw	Describe each monitoring device and methodology used to measure weight rates of materials to demonstrate compliance with each material throughput limit (Permit Conditions 3.5–3.9, 4.8–4.11, and 5.4–5.8). Procedures for proper installation, calibration, and maintenance shall be included. Establish operating ranges for control equipment, based on	Condition 2.20 does not contain MRR requirements specific to Venturi Scrubber (VS1) Vent Gas Cleaning Tower (ST1) or Vent Gas Steam Condensation Tower (CT1) used to control emissions from the Autoclave. Condition 2.20 contains a requirement to describe the schedule for taking corrective action if visible emissions are

material in the autoclave, and the maximum input to the autoclave shall not exceed 6,960 T/day. Condition 4.13 The permittee shall install, operate, and maintain venturi scrubber (VS1), vent gas cleaning tower (ST1), vent gas steam condensation tower (CT1), and carbon filter (CA5) systems in accordance with the O&M manual (Permit Condition 2.20) and consistent with manufacturer's recommendations. Conditions 4.21-4.23 • The devices and methodologies used to measure weights shall be identified in the O&M Manual, and the devices shall be installed in accordance with the requirements of NESHAP Subpart EEEEEEE. • The devices and methodologies used to measure weights shall be identified in the O&M Manual. • At least once per shift, the permittee shall monitor and record the circulation flow rate in the venturi scrubber, the circulation flow rate in the vent gas cleaning tower, the	manufacturer specifications and conditions measured during performance testing. • Minimum pressure drop across each wet scrubber, vent gas cleaning tower, and venturi scrubber; • Minimum circulation flow rate for each wet scrubber, vent gas cleaning tower, venturi scrubber; • Maximum inlet gas stream temperature to each carbon filter; • Maximum pressure drop across each carbon filter; • Minimum pressure drop across each baghouse. Describe the schedule and procedures for corrective action that will be taken if visible emissions are present from wet scrubber (WS2, WS3), carbon filter (CA1, CA2, CA3, CA4, CA5), baghouse (BH2, BH3, BH4, BH5), or bin vent filter (LS, LS1, MillS2, ACS1, ACS2, ACS3, ACS4, CS1, CS2) control equipment at any time. Procedures should include how to determine whether filter cartridges are ruptured or are not appropriately secured in place, and how to determine whether the wet scrubber, condenser, and carbon filters are operating properly.	present, but does not mandate any specific corrective actions. NESHAP Subpart EEEEEE contains detailed MRR requirements at 40 CFR 63.11646(a)(8)-(10), including maintenance and calibration requirements. However, Condition 4.21 does not require maintenance or calibration in accordance with NESHAP Subpart EEEEEEE, only installation in accordance with NESHAP Subpart EEEEEEE.

pressure drop across the venturi scrubber, and the pressure drop across the vent gas cleaning tower to ensure compliance with O&M specifications.		
Conditions 5.11-5.16 • The permittee shall install, operate, and maintain water sprays in accordance with the O&M manual (Permit Condition 2.20) to control PM emissions from each portable crushing and screening plant. Water sprays shall operate at all times, except as specified in the O&M manual during winter conditions, when this equipment is operated to ensure compliance with Fugitive Dust requirements (Permit Conditions 2.1–2.6). • The permittee shall install, operate, and maintain a baghouse system (BH4) in accordance with the O&M manual (Permit Condition 2.20) and consistent with manufacturer's recommendations. All emissions from the parallel flow regenerative kiln shall be ducted to the baghouse at all times	Establish operating ranges for control equipment, based on manufacturer specifications and conditions measured during performance testing. Describe the schedule and procedures for routine inspection (Permit Condition 2.10), maintenance, repair, and replacement of control equipment. The replacement dates for each baghouse and bin vent filter cartridge and for each activated carbon filter medium shall be recorded at the time of each replacement. For cartridges, records shall include the manufacturer and model. For carbon filters, records shall include the manufacturer, type, and form of medium added. Records shall also include any changes in supplier and other relevant information Describe the schedule and procedures for corrective action that will be taken if visible emissions are present from wet scrubber (WS2, WS3), carbon filter (CA1,	Condition 2.20 does not contain any specific minimum requirements for water sprays. Thus, the permit lacks sufficient MRR for these conditions.

to ensure compliance with parallel flow regenerative emission limits.	CA2, CA3, CA4, CA5), baghouse (BH2, BH3, BH4, BH5), or bin vent filter (LS, LS1, MillS2, ACS1, ACS2, ACS3, ACS4, CS1, CS2) control equipment at any time. Procedures should include how to determine whether filter cartridges are ruptured or are not appropriately secured in place, and how to determine whether the wet scrubber, condenser, and carbon filters are operating properly.	
Condition 5.3 Emissions from the lime production plant stacks shall not exceed any emission rate limit in the following table . . .	None	The permit does not contain any requirements to calculate emissions to demonstrate ongoing compliance with these emission limits. The permit does not contain any formulas, data reduction methods, or periodic calculation requirements to demonstrate continuous compliance with these emission limits.
Conditions 5.17-5.26 • The devices and methodologies used to measure weights shall be identified in the O&M Manual.	Describe each monitoring device and methodology used to measure weight rates of materials to demonstrate compliance with each material throughput limit (Permit Conditions 3.5–3.9, 4.8–4.11, and 5.4–5.8). Procedures for proper installation, calibration, and maintenance shall be included.	Same evaluation as Conditions 3.16-3.20.

In addition, the Permit does not require testing for the ore processing or lime production emission units to confirm the accuracy of emission factors. As discussed above, IDEQ used inaccurate emission factors to derive production limits for ore processing and lime production emission units. In its RTC, IDEQ acknowledges the uncertainty present in emission factors. However, IDEQ did not require initial or routine testing to confirm the accuracy of the emissions

factors used to establish production and emission limits. Given the low quality of the emissions factors used, such testing is critical to ensuring the adequacy of the synthetic minor limits. However, the Final Permit does not require any testing.

Given the absence of sufficient MRR requirements for the corresponding production limits, emission limits, and control equipment requirements, many of the synthetic minor emission limits are not enforceable as a practical matter.

2. The SGP, as permitted, will cause or contribute to a violation of the PM_{10} NAAQS.

a. Unsubstantiated estimates of fugitive dust control

EPA, as well as several other commenters, questioned the basis for IDEQ's determination that PRI could achieve a 93.3% control efficiency to control fugitive dust from haul roads at the SGP. Specifically, EPA commented that IDEQ did not provide a reasoned analysis demonstrating that the studies showing that 90% control efficiency is achievable using magnesium chloride reflect conditions at the SGP. EPA also commented that IDEQ did not include specific details necessary to support such a demonstration in the permitting record.[32]

In its RTC, IDEQ responded stating that 93.3% is an aggressive level of control and that PRI has committed to undertaking all measures to achieve this level of control. IDEQ further stated that, based on a review of test studies, the 93.3% level of control can be achieved using water and magnesium chloride dust suppressants (citing PRI's application). IDEQ explained that chemical and water dust suppressants are used in combination for the control of dust from haul roads, and that achieving the target combined control efficiency of 93.3% is ultimately important to ensure compliance with applicable standards. According to IDEQ, it is for this reason that the combined control efficiency was listed in the permit in lieu of separate chemical (90% control) and water (33.3%) dust suppressant control efficiencies.[33]

IDEQ's responses do not adequately address EPA's comments. IDEQ did not proffer further evidence that conditions at the SGP are comparable to areas where studies indicating a 90% control efficiency on fugitive dust is achievable. Even so, these studies do not support IDEQ's contention that a control efficiency of *93.3%* is achievable. Ultimately, IDEQ appears to have back-calculated the control efficiency necessary to demonstrate NAAQS compliance, rather than determine a control efficiency that is achievable in practice.[34]

b. Underestimation of Fugitive Dust Emissions

With respect to demonstrating NAAQS compliance, EPA commented that IDEQ's use of a median silt content of 4.0% underestimates fugitive dust emissions from haul roads. EPA commented that the arithmetic average silt content for haul roads based on Perpetua's site-specific data is 4.3%. Use of the 4.3% average value results in about 7% more fugitive dust emissions from the haul roads than estimated using the median value. IDEQ's modeling

[32] March 16, 2022, EPA Comment 19.
[33] RTC at p. 3.
[34] SOB at p. 59; 65-66 (Table 28).

sensitivity study showed values just below the NAAQS, such that an 7% increase in fugitive dust from haul roads would have resulted in 24-hour PM_{10} NAAQS violations.[35]

In response, IDEQ stated the use of site-specific median values for silt content is commonly accepted by DEQ, and the values used in calculations were supported by PRI.[36] This response does not adequately justify why a median value rather than the arithmetic average is more appropriate taking into consideration the site-specific sampling. Given that a small difference in the silt content will result in an exceedance of the NAAQS, IDEQ's insistence on using a median silt content appears arbitrary and unreasonable and indicates that PRI has not demonstrated that the emissions will not cause or contribute toa NAAQS violation. On the contrary, operation of the SGP will likely cause or contribute to a violation of the PM_{10} NAAQS.

c. Lack of Conditions to Ensure Continuous Compliance with PM_{10} NAAQS

EPA, along with several other commenters, commented that the permit lacks conditions sufficient to ensure continuous compliance with the PM_{10} NAAQS. Specifically, EPA raised concerns with the adequacy and practical enforceability of the Fugitive Dust Control Plan (FDCP). Specifically, EPA raised concerns that the permit did not contain specific conditions necessary to ensure continuous compliance with the 93.3% control efficiency, but rather allowed the permittee to develop these conditions as part of an FDCP after permit issuance and allowed the permittee to change the FDCP without IDEQ approval. EPA also commented that the permit lacks conditions necessary to make the 93.3% control efficiency practically enforceable, such as frequency of dust suppression, requirements for when to use chemical dust suppression, amount of dust suppression that must be applied, vehicle weight, vehicle speed, vehicle daily miles traveled, and road silt content.[37] With respect to Condition 2.5 requiring PRI to apply fugitive dust control measures such that visible emissions are below 10% opacity, EPA also commented that permitting record does not support a correlation of the 10% opacity requirement in Condition 2.5 with a 93.3% control efficiency.[38]

In response to these comments, IDEQ updated permit condition 2.8 to require IDEQ approval of the FDCP 30 days prior to startup and after any subsequent changes. IDEQ also responded that the permit contains activity rate limits that serve as surrogate limits for fugitive sources. IDEQ also stated that it typically does not include vehicle speed, type, and miles traveled in permits. IDEQ also asserted that Conditions 2.1-2.6 contain the minimum requirements for the contents of the fugitive dust plan.[39] Finally, IDEQ responded that "An instantaneous 10% opacity limit for vehicle traffic on haul roads is considered a very conservative control trigger level to ensure that an appropriate control measure is taken to reasonably control emissions of fugitive dust (Permit condition 2.5)."[40]

---

[35] March 16, 2022 EPA Comment 20.
[36] RTC at p. 4.
[37] March 16, 2022, EPA Comments 16 – 19
[38] *Id.* at Comment 19.
[39] RTC at p. 9.
[40] *Id.*

These responses do not fully address EPA's comments with respect to the practical enforceability of emission limits necessary for NAAQS compliance. Condition 2.8 does not require that IDEQ approve the FDCP prior to startup, only that the permittee submit the FDCP 30 days prior to startup. Similarly, Condition 2.8 does not clearly require IDEQ approval of FDCP changes prior to the permittee making the changes.

Conditions 2.1 through 2.6 are insufficient to ensure the permittee achieves 93.3% fugitive dust control efficiency on haul roads. First, the permitting record indicates that application of magnesium chloride is necessary to achieve up to 90% control of fugitive dust. However, Conditions 2.1 through 2.6 do not require the permittee to use magnesium chloride for dust suppression. Rather, Condition 2.6 merely requires that the FDCP contain reasonable precautions including: "apply water or suitable dust suppressant (e.g. magnesium chloride, calcium chloride) to disturbed areas, haul roads, equipment staging areas, parking areas, and storage piles during the dry season and at other times as necessary to control fugitive dust." Moreover, magnesium chloride degrades over time. However, the permit does not require the permittee to reapply magnesium chloride at regular intervals.

Similarly, IDEQ assumed a combined control efficiency of water and chemical dust suppression to achieve 93.3%. However, Conditions 2.1 through 2.6 contain no explicit requirements that the permittee use both water and chemical dust suppression in a manner necessary to achieve the 93.3% control efficiency. Magnesium chloride does not perform as a dust suppressant in dry conditions. Therefore, supplemental watering will be necessary. However, the permit does not require supplemental watering to ensure the magnesium chloride performs as a dust suppressant.

With respect to vehicle weight and vehicle miles traveled, compliance with the NAAQS is dependent on vehicle miles traveled staying at or below 7,758 per day.[41] However, the permit contains no such limit. IDEQ also did not make clear how the activity limits, including Condition 2.4 (Blasting Limits) and Condition 3.5 (Daily Hauling and Excavating Limits), would necessarily restrict vehicle miles traveled to at or below 7,758 per day. There are no requirements or restrictions on the manner the permittee uses the haul roads.

Regarding the silt content, the permit does not contain conditions to ensure the silt content on haul roads remains at or below 4%. Condition 3.13 contains the minimum requirements for the Haul Road Capping Plan (HRCP). According to IDEQ, Condition 3.13 limits maximum silt content to 4.0%. This is not accurate. Condition 3.13 states that "The permittee shall use capping material with a maximum of 4.0% silt content." This condition does not require the permittee to maintain the haul road silt content to at or below 4.0%. Nor does the requirement account for mixing of the capping material with the base or wearing of the cap over time. Condition 3.13 also contain no explicit sampling or compliance demonstration methods. Rather, Condition 3.13 allows the permittee to develop a "silt content sampling plan including standard operational procedure for sampling, frequency of sampling, and ASTM (or equivalent) method of analysis for silt content."

Finally, IDEQ's response to EPA's comment on the basis for the 10% opacity limit in Condition 2.5 does not provide additional basis for a correlation between opacity and the 93.3% control.

[41] SOB at Appendix B, p. 65

The permit contains no testing requirements to establish a correlation between fugitive dust control and opacity. Nor does the permit contain any specific method for determining opacity or the frequency or location of opacity observations.

3. Neither the permit record nor permit conditions demonstrate that the entirety of the SGP ought to be excluded from the scope of "ambient air."

"Ambient air" is defined as that portion of the atmosphere, external to buildings, to which the general public has access."[42] General public includes "any person(s) other than those who are permitted access to the property as employees or business invitees of a specific stationary source (including trespassers)."[43] EPA interprets access to encompass two key concerns: legal access and physical or practical access.[44] Legal access concerns whether the general public has the right or permission to enter a specific property. Physical access addresses whether the general public is able to, under actual circumstances, enter a particular parcel of land. In order to preclude physical access to a parcel of land, the source must employ measures, which may include physical barriers, that are effective in precluding access to the land by the general public.[45] Such measures can include video surveillance, monitoring, clear signage, and routine security patrols.[46] Measures can be effective even if there is not 100 percent certainty that they will prevent public access.[47] Measures must be reasonable taking into consideration the nature of the measure used, source location, type and size of source and property to be excluded, and surrounding area.[48]

a. Legal Right to Exclude General Public

As stated above, legal access concerns whether the general public has the right or permission to enter a specific property. IDEQ asserts in the SOB and RTC that PRI has "complete and sole authority to control access to or through the facility, granting access at their discretion to anyone wishing to visit the site or pass through the site."[49] Neither the SOB nor the RTC, however, evaluate PRI's claims. In light of the fact that the SGP encompasses the East Fork South Fork Salmon River and is located within National Forest lands, the permitting record ought to contain a more thorough evaluation of PRI's legal authority and members of the general public's right of access to the SGP area of operations.

b. Measures to Exclude General Public as a Practical Matter

EPA commented that the permit lacks conditions to ensure PRI employs sufficient measures such that the entirety of the SGP is appropriately excluded from the definition of ambient air. Specifically, EPA raised concerns that the general public may be able to access the SGP,

---

[42] IDAPA 58.01.01.006.10; 40 CFR 50.1(e).
[43] "Revised Policy on Exclusions from 'Ambient Air'" Memorandum from Andrew R. Wheeler to Regional Administrators, December 2, 2019, at p. 6.
[44] *Id.* at 5.
[45] *Id.* at 9.
[46] *Id.* at 7.
[47] *Id.* at 8.
[48] *Id.*
[49] RTC at p. 21.

regardless of their legal right to do so.[50] The basis for EPA's comment was that the permit does not contain specific measures the permittee will take to exclude members of the public from the SGP. Rather, the permit allows the permittee to develop an Access Management Plan ostensibly designed to exclude members of the public. In response, IDEQ asserted that Condition 2.7 contains the requirements for the ACP, including adequately informing anyone approaching an access point that travel beyond the established gate involves entering an active mine site as a guest of the permittee and providing verbal and written requirements that must be followed while on the SGP site.[51] The SOB also states that the primary and secondary access points are controlled by adjacent natural features, such as streams and creeks, steep topography, and areas of thick vegetation and undergrowth.[52] In addition, the SOB states that PRI will place boulders across trails and adjacent to the train to prevent vehicle access.[53] Finally, according to the SOB, PRI security personnel will routinely patrol mine facilities and roadways for unauthorized individuals.[54]

IDEQ's responses and statements in the SOB do not adequately address EPA's concerns. As permitted, the general public will likely have physical or practical access to portions of the SGP. The SGP operations area boundary covers 2,372 acres of land within the Payette and Boise National Forests. The SGP is located in Valley County, Idaho. The nearest settlement is the village of Yellow Pine, Idaho, approximately 14 miles by road.[55] The Payette National Forest includes the Frank Church River of No Return Wilderness. The Salmon River runs through the Payette National Forest. The SGP is surrounded by numerous recreation areas in the Payette and Boise National Forests.[56] National Forest roads 374, 440, and 640 provide vehicle access to the site.[57]

Given the scale of the SGP, proximity to recreation opportunities, and multiple access points, the permittee should employ multiple measures to preclude public access. However, condition 2.7 is vague and leaves the permittee considerable latitude on the methods used to exclude members of the general public. While the SOB indicates that placement of boulders on secondary roadways is necessary to prevent access, Condition 2.7 contains no such requirement. Also, Condition 2.7 does not specify a minimum patrol frequency or minimum signage requirements. Nor does Condition 2.7 require the permittee to post or monitor the vast operations boundary to effectively preclude recreators from entering the site. Condition 2.7 only requires the permittee to employ measures to "discourage" access to secondary roadways and trails. This does not meet the standard to effectively exclude members of the general public. Similarly, EPA questions whether the entire boundary surrounding the operations area incorporates natural features that preclude access. Given the numerous recreational opportunities in the surrounding wilderness areas, access by recreators off trail appears possible. Therefore, the Final PTC does not ensure that the

entirety of the SGP is appropriately excluded from the definition of ambient air. This implicates IDEQ's determination that the SGP will not cause or contribute to a violation of the PM_{10} NAAQS.

BEFORE THE BOARD OF ENVIRONMENTAL QUALITY
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047	
NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON, Petitioners, v. DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent, and PERPETUA RESOURCES IDAHO, INC., Intervenor.	BEQ Case No. 0101-22-01 OAH Case No. 23-245-01 SCHEDULING ORDER ON MOTIONS RELATED TO RECENT EPA LETTER

BACKGROUND

On August 10, 2023, EPA sent a letter to Idaho DEQ Director Jess Byrne, expressing three concerns regarding the air permit issued to Perpetua Resources in this matter (the "EPA Letter"). The Letter requests a meeting between EPA and DEQ representatives to discuss those concerns. Ultimately, the Letter suggests that DEQ should issue a revised permit.

On August 28, 2023, Perpetua Resources and DEQ filed a joint motion in limine requesting exclusion of the EPA Letter and any press releases about it from consideration in this proceeding. Under the default rules of procedure, the deadline for Petitioners to respond to this motion would be

September 11. However, on August 31, Perpetua and DEQ filed a motion to establish September 6 as the Petitioners' response deadline and to expedite consideration of the motion in limine. The motion also requests permission to file a reply brief.

On September 1, the Petitioners filed two motions. One motion requests a stay of these proceedings, including postponing the September 21 summary judgment hearing and setting a status conference in October to discuss the status of this matter. The other motion requests the Hearing Officer to augment the record in this matter with the EPA Letter. Under the default rules of procedure, the deadline for responses to these two motions is September 15.

Given the proximity of these motions to the summary judgment hearing scheduled for September 21, the Hearing Officer convened an informal status conference with the parties on September 6 to discuss the pending motions. At that status conference, the Petitioners informed the Hearing Officer and other parties that they intend to file a motion to amend their petition in this matter in the near future based upon one or more of the concerns expressed in the EPA Letter. Counsel for the Petitioners indicated it would be possible to file such a motion by Friday, September 8. In addition, both Perpetua and DEQ expressed a strong preference for keeping the September 21 summary judgment hearing in place.

DISCUSSION

Hearings Officers have broad authority to control the scheduling of cases to which they are assigned. *See* BEQ Rule of Procedure 003.08; AG Rule of Procedure 413. At the September 6 informal status conference, the parties agreed that the scheduling of matters related to these pending motions is within the discretion of the Hearing Officer.

The permit in this matter was issued on June 17, 2022, and these administrative proceedings have been pending since the filing of the initial petition on July 22, 2022. The record in this matter

establishes that EPA was aware of the permit application and was in communication with DEQ representatives during the processing of the application. Yet, EPA did not issue its Letter until August 10, 2023—420 days after the permit was issued.

At the September 6 status conference, Perpetua and DEQ were strongly in favor of keeping the existing summary judgment hearing in place. This is significant to the Hearing Officer. Arguably, these two parties face the most severe consequences if the three concerns expressed in the EPA Letter truly amount to legal "deficiencies," in the words of EPA. For example, if DEQ is not in compliance with EPA requirements, it risks losing authority to administer the Clean Air Act permitting programs within Idaho.

Presumably, this is not a result that Perpetua would desire, because—at least in the Hearing Officer's experience—regulated entities prefer dealing with more local permitting authorities. According to the Idaho Legislature, "the goals to protect human health and the environment can be best achieved by vesting responsibility for environmental protection…in a ***state department*** which has as its sole mission, protection for human health and the environment for the state of Idaho and its residents…." IDAHO CODE § 39-102A(5) (emphasis added); *see also* IDAHO CODE § 39-175A (legislative findings and purposes in obtaining state delegation of Clean Water Act NPDES permitting programs).

This contested case proceeding has been pending for more than one year. The Petitioners have had ample time to more fully explore and develop the errors alleged in their petition. EPA had ample opportunity to participate and comment as the permit was developed. If DEQ and Perpetua desire to keep the September 21 summary judgment hearing on the calendar, the Hearing Officer believes it is appropriate to preserve that hearing date for the time being by truncating the briefing schedule for the pending motions. The Hearing Officer will address the merits of the Petitioners'

motion for stay at the appropriate time, but believes preserving the ability for that hearing to proceed for the time being is the appropriate course of action.

ORDER

Based on the foregoing, the following procedures shall govern the five motions related to the EPA Letter:

1) The Petitioners shall file any written response to the DEQ/Perpetua motion in limine no later than 6:00 p.m. Friday, September 8.

2) The Petitioners shall file any motions to amend their petition in this matter no later than 6:00 p.m. Friday, September 8.

3) DEQ and Perpetua shall have until 6:00 p.m. Monday, September 11 to file written responses to the Petitioners' motion for stay, motion to augment, and anticipated motion to amend.

4) No reply briefs are needed.

5) Brevity is encouraged.

6) Combined briefs and jointly filed briefs are encouraged.

7) The filing of any other motions or briefs not specifically contemplated by this Order shall require leave from the Hearing Officer.

8) The Hearing Officer's goal will be to issue a decision on these motions and provide the parties with a description of issues to discuss at the summary judgment hearing, if it proceeds, by 6:00 p.m. on Friday, September 15.

Dated this 6th day of September, 2023.

Dylan Lawrence
Hearing Officer

Attorney for Save the South Fork Salmon

BEFORE THE OFFICE OF ADMINISTRATIVE HEARINGS
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047	Agency Case No. 0101-22-01
	OAH Case No. 23-245-01
NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON Petitioners, v. IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent, and PERPETUA RESOURCES IDAHO, INC., Intervenor.	**PETITIONERS' RESPONSE IN OPPOSITION TO MOTION IN LIMINE**

INTRODUCTION

Petitioners Nez Perce Tribe, Idaho Conservation League, and Save the South Fork Salmon ("Petitioners") file this response opposing DEQ's and Perpetua's August 28, 2023 Joint Motion in Limine. The motion concerns the August 10, 2023 letter from EPA Regional Administrator Casey Sixkiller to DEQ Director Jess Byrne (the "EPA Letter"), raising concerns with the Permit to Construct for the Stibnite Gold Project (the "PTC") and requesting a personal and in-person meeting with DEQ Director Byrne, including with appropriate members of the agency's permit and legal teams, within 30 days, "[g]iven the seriousness of the concerns raised by the EPA and the need to reach a timely resolution."

As set forth in Petitioners' Motion to Stay and Motion to Supplement (both filed on September 1, 2023, and incorporated herein by reference), the Board of Environmental Quality Contested Case Rules and the Attorney General Rules favor admitting relevant evidence to develop the agency record in a contested case. Furthermore, the EPA Letter is relevant to the pending cross motions for summary judgment, and granting this motion to supplement is not prejudicial. DEQ's and Perpetua's Motion in Limine is unfounded, as the EPA Letter will not improperly influence the Hearing Officer, nor taint the proceedings. It is also not hearsay. The Hearing Officer should thus deny the Motion in Limine and reject DEQ's and EPA's request to ignore relevant information in the EPA Letter.

ARGUMENT

I. The Rules Favor the Inclusion of Relevant Evidence in a Contested Case

DEQ and Perpetua argue that, because Petitioners' challenges to the PTC arise under the Idaho Administrative Procedure Act ("APA), the Hearing Officer's review is limited to "the

permitting record before [DEQ] at the time it took the action of issuing the permit." Mot. in Limine at 3. That depiction is flatly incorrect.

Under Idaho Code Sections 39-107 and 67-5244, the Board of Environmental Quality ("Board") has final authority to determine whether the PTC issued by DEQ is in accordance with all relevant legal requirements and supported by the facts. The Hearing Officer's job is to develop a full factual record and assess the issues presented in a contested case petition, and issue a Recommended Order for the Board's review and ultimate decision. IDAPA 58.01.23.720. Thus, as discussed further in Petitioners' Motion to Supplement, the Board's Contested Case Rules (IDAPA 58.01.01) and the Attorney General's Rules (IDAPA 04.11.01) do not limit documentary evidence to those before the agency at the time of the permit issuance, but favor including all relevant matters that may affect the Board's review.

Reflecting these principles, the January 19, 2023 Scheduling Order ("Order") in this case never limited the documents to those considered by DEQ in making its decision to issue the PTC. The Order states it "governs" the "discovery parameters." Although formal discovery in the form of interrogatories and requests for production were limited to "documents or information in the possession of" DEQ, the Order did not limit documents to only those *considered by DEQ* in reviewing the permit application. In fact, Petitioners' discovery requests went beyond those documents that were considered by DEQ at the time the PTC decision was made. For example, Petitioners requested communications related to several interrogatories, "includ[ing] those generated prior and up to the data of the issuance of the [permit] as well as after the date of the issuance of the [permit] and up to the present day," and "all air permits issued by IDEQ . . . that applied a 70-year 'lifetime' average for any carcinogenic [toxic air pollutant]." Pet'rs' First Discovery Requests and Requests for Production of Documents

(Attachment 1). Because Petitioners' requests for production were consistent with the Order, DEQ provided responses and documents to such requests, and it never argued that requesting such documents was improper because they were not in front of DEQ when it made the decision to issue the permit.

Moreover, the Order also allowed both Perpetua and Petitioners to add "*any additional documentary evidence* they deem relevant to these proceedings" without limiting it to documents that were considered by DEQ during issuance of the PTC. Neither DEQ nor Perpetua attempted to exclude any of the additional documents that Petitioners served on the parties because they were not before DEQ at the time of its decision. To the contrary, both Perpetua and DEQ submitted post-PTC declarations in support of their summary judgment motions, after the discovery period closed. *See, e.g.,* Perpetua's Lewis Declaration (submitted June 23, 2023 in support of Perpetua's summary judgment reply brief); DEQ's Floyd, Simon, Schilling Declarations (submitted May 15, 2023 in support of DEQ's summary judgment motion).

Thus, this contested case has never been strictly limited to documents that were in front of DEQ at the time it issued the permit; and it should not be so construed now to preclude a significant source of information relating to the fundamental flaws in the permit, as identified by the EPA Letter. Accordingly, the fact that the EPA Letter was not before DEQ when it made its decision is not a basis for excluding it from this case, and the Hearing Officer should deny the Motion in Limine.

II. The EPA Letter Will Not "Taint" the Proceedings, and Can Be Addressed at the Hearing on Motions for Summary Judgment.

Perpetua and DEQ further argue that the EPA Letter should be excluded because it may "taint" the current proceedings. Mot. in Limine at 2. That argument, however, appears to be based on the fact that they do not like the information contained in the EPA Letter—not that the

EPA Letter is illegal, without basis, or has in some way been corrupted. The fact that the EPA identifies significant flaws in the permit that reiterate Petitioners' challenges does not constitute some kind of improper "taint."

Additionally, DEQ and Perpetua's argument that the EPA Letter should be excluded because it was sent after briefing and is evidence that was not disclosed under Idaho Rule of Civil Procedure (IRCP) 26(e)(3) should be rejected. Mot. in Limine at 4. IRCP 26(e)(3) governs exclusion of testimony or evidence not disclosed by a supplement required under the rules of discovery. For one, the EPA Letter is clearly being disclosed in this process and in the Petitioners' Motion to Supplement with August 10, 2023 EPA Letter, and it is being disclosed prior to the hearing. Moreover, the EPA Letter is not the type of evidence that requires disclosure by a supplementation of discovery under IRCP 26(e) (duty to supplement incorrect disclosures, or duty to identify persons having knowledge of discoverable matters). The Motion in Limine should therefore again be denied.

III. The Letter Is Not Hearsay

Lastly, Pereptua and DEQ contend that the EPA Letter should be excluded from evidence in this case because it is hearsay based on Rule 802 of the Idaho Rules of Evidence ("IRE"). Mot. in Limine at 4-5. However, the EPA Letter falls into the public records exception of IRE 803(8). IRE 803(3) excludes application of the rule against hearsay for certain evidence "regardless of whether the declarant is available as a witness" and including "[a] record or statement of a public office." IRE 803(8).

The EPA Letter meets all the requirements of IRE 803(8) as a public record. EPA is indisputedly a "public office" created by federal statutes within the executive branch, and EPA is the federal agency with authority and responsibility for enforcing State Implementation Plans

under the Clean Air Act.[1] The EPA Letter was sent by EPA Regional Administrator Sixkiller to DEQ Director Byrne pursuant to EPA's conduct of its Clean Air Act oversight responsibilities over the Idaho SIP, under which EPA "has the authority and responsibility to take direct action" if a "state partner is not taking timely or appropriate action to address threats to public health and the environment," as directed by EPA Administrator Regan in a February 2023 memorandum to all EPA regional administrators.[2] The EPA Letter was thus created as part of "regularly recorded and regularly conducted activities," and neither DEQ nor Perpetua has "show[n] that the source of information or other circumstances indicate a lack of trustworthiness" of the EPA Letter under IRE 803(8)(B). The EPA Letter is thus not improper hearsay under IRE 803 and is properly considered by the Hearing Officer.

CONCLUSION

For the foregoing reasons, the Hearing Officer should deny the Motion in Limine.

Dated this 8th day of September 2023.

Attorney for Save the South Fork Salmon

BEFORE THE BOARD OF ENVIRONMENTAL QUALITY
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047	
	CASE DOCKET NO. 0101-22-01
NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON Petitioners, v. IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent, and PERPETUA RESOURCES IDAHO, INC. Intervenor.	**PETITIONERS' FIRST DISCOVERY REQUESTS AND REQUESTS FOR PRODUCTION TO RESPONDENT IDEQ**

TO: Respondent Idaho Department of Environmental Quality and its attorney of record:

PLEASE TAKE NOTICE that Petitioners Nez Perce Tribe, Idaho Conservation League, and Save the South Fork Salmon hereby submit the the following Interrogatories and Requests of Production of Documents to Respondent Idaho Department of Environmental Quality ("IDEQ" or the "Department"). These Discovery Requests are issued to you pursuant to the Hearing Officer's January 19, 2023 *Scheduling Order* ("Discovery Order"); IDEQ's Contested Case Rules (IDAPA §§ 58.01.23 *et seq.*); the Idaho Rules of Administrative Procedure of the Attorney General (IDAPA §§ 04.11.01 *et seq.*) ("AG Rules") sections 520 through 532, which are incorporated by reference in IDEQ's Rules (IDAPA 58.01.23.003.11); and the Idaho Rules of Civil Procedure (IRCP) sections 26 through 37, which are incorporated in part by reference in the AG Rules (IDAPA § 04.11.01.520.02). Specifically, these Discovery Requests include Interrogatories and Requests for Production pursuant to AG Rule 524 and IRCP 33 and 34.

Pursuant to the *Scheduling Order*, <u>your responses, answered in writing, and production of documents are due on or before February 14, 2023</u>.

INSTRUCTIONS

1. Unless otherwise indicated, these Interrogatories and Requests for Production refer to Air Quality Permit to Construct P-2019-0047.

2. In responding to this Discovery Request, base your responses on all information available to you, not merely information within your own personal knowledge; please include information in the possession of your attorneys, experts, employees, agents, representatives, members, and consultants, whether past or present.

3. If documents supporting a Request for Production have already been provided via the Project File, sent by IDEQ to the parties on or about October 22, 2022, there is no need to

reproduce that information here. Instead, the Respondent may refer to the relevant document in the Project File by file name, including reference to relevant page(s) and/or section(s), if appropriate.

4. Whether for privilege or other reasons, if you do not provide a complete response to any Interrogatory or Request for Production, state with respect to such Interrogatory or Request for Production that a complete response is not provided and state the reason for the incomplete response.

5. If you contend that any information response to any of the following Interrogatories or Requests for Production is privileged, in whole or in part, or should otherwise not be disclosed, or otherwise object to any part of the discovery request, you should identify with particularly each piece of information for which you claim a privilege or to which you object, state the grounds for exclusion or reasons for your objection, and describe the information withheld or objected to in terms of its subject matter, the time at which it was acquired or communicated, the parties who possessed and/or exchanged such information, and other information as may be reasonably needed by Petitioners to understand the basis of your objection to disclosure.

6. These Interrogatories and Requests for Production are deemed continuing in nature, and your answers are to be supplemented as additional information and knowledge become available to you.

7. Produce all documents in searchable PDF format with Bates numbers, with the exception of Microsoft Excel based files. These types of files are requested to be produced in their original Excel format. Provide input and output files for modeling simulations in format that can be opened with standard public-domain software, or provide the necessary software that

allows for proprietary format or other non-standard format files to be opened, viewed, and for the subject data to be comprehended by a human viewer.

DEFINITIONS

1. "AACC" refers to Acceptable Ambient Concentration for a Carcinogen as found in IDAPA 58.01.01.106.02.

2. The terms "and" and "or" are used interchangeably, and shall be construed either disjunctively or conjunctively as necessary to bring within the scope the Discovery Requests and any document that otherwise might be outside the scope of the Discovery Request.

3. "Describe," "identify," or "explain" mean to provide a detailed description of all the facts, relevant actions or inactions, and the identity of all documents that are responsive or utilized in responding to these Discovery Requests.

4. "General public" means a member of the public not associated with the operation of a facility or a business invitee of a facility (including contractors or delivery persons).

5. "Communication(s)" or "Correspondence" shall mean any transmission of words, thoughts, or information between or among two or more persons, and includes, but is not limited to spoken words, conversations, conference, correspondence, discussions, talks, and reports, whether transmitted in person or by any electronic device, such as a temphone, computer, or radio, and/or by Documents as defined below.

6. "IDEQ" means the Idaho Department of Environmental Quality.

7. "Documents" shall mean the original, all copies, and all translations of any writing, drawings, calculations, graphs, sound recordings, images, and other data or data compilations stored in any medium (paper or other tangible format, as well as any electronic format) from which information can be obtained.

8. "EPA" means the U.S. Environmental Protection Agency.

9. "Project File" means the "Perpetua Project File" prepared by IDEQ for the Air Quality Permit to Construct P-2019-0047, and sent on a flash drive to Petitioners by letter dated October 24, 2022.

10. "PTC" means Air Quality Permit to Construct P-2019-0047.

11. "TAP" means Toxic Air Pollutant as defined in IDAPA 58.01.01.124.

12. "T-RACT" means Toxic Air Pollutant Reasonably Available Control Technology as defined in IDAPA 58.01.01.007.12.

RELATED INTERROGATORIES & REQUESTS FOR PRODUCTION

INTERROGATORY NO. 1: Identify and describe all air emissions inventory calculations conducted by IDEQ, or conducted by anyone else and which IDEQ is aware of, related to development of the PTC for which the results were not presented in the Statement of Basis, including by describing the results of the other emissions inventory calculations and by describing the inputs, data set(s), and/or assumptions used in the other emissions inventory calculations which differ from those for which the results are presented in the Statement of Basis.

REQUEST FOR PRODUCTION NO. 1: Provide all Documents that support or relate to your answer to Interrogatory No. 1.

INTERROGATORY NO. 2: Identify and describe all air dispersion modeling simulations conducted by IDEQ, or conducted by anyone else and which IDEQ is aware of, related to development of the PTC for which the results were not presented in the Statement of Basis, including by describing results of the modeling simulations and by describing the inputs, data set(s), and/or assumptions used in the modeling simulations which differ from those for which the results are presented in the Statement of Basis.

REQUEST FOR PRODUCTION NO. 2: Provide all Documents that support or relate to your answer to Interrogatory No. 2.

ADDITIONAL REQUESTS FOR PRODUCTION

INSTRUCTION FOR REQUESTS FOR PRODUCTION NOS. 3–6: "Communications" for Interrogatories Nos. 3 through 6 means all communications, including but not limited to all letters, emails, calls, voicemails, text messages, meetings, meeting notes, reports, status updates, memos to file, and all Documents included with such Communications, and includes those generated prior and up to the date of the issuance of the PTC as well as after the date of the issuance of the PTC and up to the present day.

REQUEST FOR PRODUCTION NO. 3: Provide all internal IDEQ communications related to the development and issuance of the PTC

REQUEST FOR PRODUCTION NO. 4: Provide all Communications, both internal and external, related to or between IDEQ and EPA regarding the development and issuance of the PTC.

REQUEST FOR PRODUCTION NO. 5: Provide all Communications, both internal and external, related to or between IDEQ and Midas Gold, Perpetua Resources, or any of their consultants, experts, or contractors regarding development and issuance of the PTC.

REQUEST FOR PRODUCTION NO. 6: Provide all Communications, both internal and external, related to or between IDEQ and any other person, agency (local, state, or federal), or entity regarding the development and issuance of the PTC.

REQUEST FOR PRODUCTION NO. 7: Provide all guidance, policies, memos to file, or other Documents supporting use of a 70-year "lifetime" average for arsenic emissions in comparison to the AACC for the PTC.

REQUEST FOR PRODUCTION NO. 8: Provide all air permitsissued by IDEQ, other than the PTC, that applied a 70-year "lifetime" average for any carcinogenic TAP in comparison to the associated AACC, including the statements of basis.

REQUEST FOR PRODUCTION NO. 9: Provide all guidance, policies, memos to file, or other Documents related to defining an ambient air boundary.

REQUEST FOR PRODUCTION NO. 10: Provide all air permitsissued by IDEQ, other than the PTC, for which the general public had regular, conditional access to any location within the facility's ambient air boundary, including the statements of basis.

REQUEST FOR PRODUCTION NO. 11: To the extent not previously disclosed in the Project File or in response to any of the above, provide all Documents stored in the project folder in IDEQ's electronic records management system for Project 62288.

REQUEST FOR PRODUCTION NO. 12: To the extent not previously disclosed in the Project File or in response to any of the above, provide all Documents stored under the facility folder for Midas Gold and/or Perpetua Resources (or any similar variation) in IDEQ's electronic records management system.

Attorney for Save the South Fork Salmon

BEFORE THE BOARD OF ENVIRONMENTAL QUALITY
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047	)	
	)	CASE DOCKET NO. 0101-22-01
NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON	)	**PETITIONERS' MOTION TO AMEND CONTESTED CASE PETITION**
Petitioners,	)	
v.	)	
IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY,	)	
Respondent,	)	
and	)	
PERPETUA RESOURCES IDAHO, INC.	)	
Intervenor.	)	

Petitioners Nez Perce Tribe (the "Tribe"), Idaho Conservation League ("ICL"), and Save the South Fork Salmon ("SSFS") hereby move to amend their contested case petition in this matter through the [Proposed] Second Amended Petition to Initiate Contested Case, submitted herewith as Attachment 1. Petitioners bring this motion to amend under Idaho Rules of Administrative Procedure of the Attorney General Rule 04.11.01.305 and Idaho Rule of Civil Procedure ("I.R.C.P.") 15(a)(2).

Petitioners propose to amend the existing First Amended Petition by adding an additional claim challenging the Permit to Construct ("PTC") at issue here, regarding the adequacy of the Idaho Department of Environmental Quality's ("DEQ") determination that Perpetua Resources's Stibnite Gold Project will not exceed threshold levels of pollutant emissions such that it could proceed in issuance of a permit to construct as a minor source, rather than a major source permit under the Prevention of Significant Deterioration program of the Clean Air Act.

As Petitioners' counsel explained during the recent informal status conference with the Hearing Officer, this is the first issue raised in the August 10, 2023 letter from EPA Regional Administrator Casey Sixkiller to DEQ Director Jess Byrne (the "EPA Letter"), but is not directly raised in the current First Amended Petition, although the second and third issues in the EPA Letter are presented in the First Amended Petition and addressed in the parties' current summary judgment briefings.

BRIEF IN SUPPORT

I. Leave to Amend Shall Be Freely Given.

DEQ's Contested Case Rule 58.01.23.003.01 adopts the Idaho Rules of Administrative Procedure of the Attorney General Rule 305, which states: "The presiding officer may allow any pleading to be amended or corrected or any omission to be supplied." IDAPA 04.11.01.305.

Similarly, after a responsive pleading has been filed, the Idaho Rules of Civil Procedure allow the pre-trial amendment of a pleading either with the opposing party's written consent or with the court's leave, and states that "[t]he court should freely give leave when justice so requires." I.R.C.P. 15(a)(2).

"The twin purposes behind the rule are to allow claims to be determined on the merits rather than on technicalities, and to make pleadings serve the limited role of providing notice of the nature of the claim and the facts at issue." *Carl H. Christensen Family Trust v. Christensen*, 133 Idaho 866, 871 (1999) (citation omitted). Thus, "motions for leave to amend pleadings are to be liberally granted," *Taylor v. McNichols*, 149 Idaho 826, 847 (2010), and the burden is on the party opposing the amendment "to show why a court should not grant leave to amend a [petition]." *Clark v. Olsen*, 110 Idaho 323, 326 (1986). A district court's refusal to grant leave to amend without any justifying reason is, per se, an abuse of discretion. *Id.* (holding district court abused its discretion by denying a motion to amend without a justifying reason even though seven years separated the original and amended complaints and defendants had moved for summary judgment prior to the motion to amend).

"In considering whether to grant a motion for leave to amend, a trial court may consider whether the amended pleading sets out a valid claim, whether the opposing party would be prejudiced by any undue delay, or whether the opposing party has an available defense to the newly added claim." *Spur Products Corp v. Stoel Rives LLP*, 142 Idaho 41, 44 (2005) (citation omitted). "Timeliness of a motion for leave to amend is not decisive, but it is important in view of factors such as undue delay, bad faith, and prejudice to the opponent." *Id.* (quotation and citation omitted).

II. The Proposed Amendment Sets Forth a Valid Claim.

The proposed amendment sets forth a valid claim under the Idaho Administrative Procedure Act, Idaho Code § 67-5279. Specifically, the amendment alleges that DEQ relied on technically inaccurate emissions factors and unsupported assumptions to approve Perpetua's PTC for the Stibnite Gold Project as a minor source permit without a reasoned explanation of why it used those emission factors; and that DEQ failed to follow agency guidance documents on estimating emission factors from stationary sources, such as from ore crushing and other mineral processing facilities and mining operations, and failed to provide a reasoned explanation for deviation from that guidance. As such, the amendment alleges that DEQ's decision to issue the PTC was arbitrary and capricious.[1] *See* Attach. 1.

As with the other claims already pled, DEQ and Pereptua do not have a valid defense against this amendment. Petitioners have exhausted their administrative remedies for this amendment as the issue was raised in Petitioners' and other commenters' letters on the final draft permit. *See* PET 638 (ICL/SSFS Comment Letter); PET 661 (Tribe Comment Letter); PET 665-66 (EPA Comment Letter). DEQ was thus on notice of the issue, and had the opportunity to respond during the administrative process and prior to issuing the permit.

III. Petitioners' Motion to Amend Is Timely.

Petitioners' Motion is timely under the circumstances. The earliest that the EPA Letter was available to the parties was August 10, 2023, and Petitioners are promptly moving to amend their contested case petition within just a few weeks of that date. Petitioners have not somehow

[1] "The court may not [ ] weigh the sufficiency of the evidence related to the additional claim." *Spur Prods.*, 142 Idaho at 44.

been dilatory in moving to present the EPA Letter and their proposed amendment in light of that timing.

"[T]imliness is important in view of the [other] factors such as undue delay, bad faith, and prejudice to the opponent." *Christensen*, 133 Idaho at 871. As discussed below, combined with the lack of unfair prejudice and undue delay, Petitioners' Motion to Amend is timely, and the motion should be granted.

IV. Amending the Petition Would Not Cause Unfair Prejudice or Undue Delay.

DEQ and Perpetua will not be unfairly prejudiced by granting Petitioners' Motion to Amend. The amendment does not seriously impair DEQ's or Perpetua's ability to adequately present their case; it does not necessitate further expenditure of significant additional resources; and it will not cause undue delay of already scheduled proceedings.

First, the amendment is based on the same set of facts and documentary evidence already in the case record that were served on the parties during discovery, and therefore will not require re-opening of discovery or additional evidence or witness gathering.[2]

Furthermore, the amendment also would not significantly delay the resolution of the case. The amendment is independent of the other claims and can be resolved in its own summary judgment proceeding. The amendment does propose to amend the prior claims by either adding fact or other legal theories to those claims that are subject to the current summary judgment motions, and thus will not impact or require delay of the September 21st hearing on those motions. Thus, the amendment will not cause undue delay of this case.

[2] "The court may not [ ] weigh the sufficiency of the evidence related to the additional claim." *Spur Prods.*, 142 Idaho at 44. Regardless, Petitioners' ability to present their case does not rely on the EPA Letter being admitted into evidence for this case. Furthermore, Petitioners will not seek to reopen discovery if the Motion to Amend is granted.

Moreover, amending the petition would not create undue hardship for Perpetua in the construction or operation of the Project or in its progress for securing other state and federal permits. The proposed Stibnite Gold Project has yet to be approved by the U.S. Forest Service, which has still not issued any Final Environmental Impact Statement under the National Environmental Policy Act; and the Forest Service does not anticipate a decision until March 2024 at the earliest.[3] Moreover, Perpetua has to secure several other major permits and federal agency reviews prior to construction and operation of the mine, including an Army Corps of Engineers' permit under Clean Water Act Section 404, a Clean Water Act Idaho Pollution Discharge Elimination System permit, and completion of Section 7 consultation with U.S. Fish and Wildlife Service and NOAA Fisheries under the Endangered Species Act.[4] Amending the petition will neither delay nor impact any of those needed decisions or permits, nor delay construction or operation of the mine.

Therefore, there is no showing of unfair prejudice or undue delay that would allow denial of the amendment. The Hearing Officer should therefore grant Petitioners' motion to amend the petition.

V. It is in the Public's Interest to Ensure DEQ Issues Permits that are in Compliance with the Clean Air Act.

Granting Petitioners' Motion to Amend is in the public interest. DEQ is charged with the responsibility of protecting the public health and environment by ensuring that facilities that

[3] *See* Payette National Forest Schedule of Proposed Actions (July 2023 through September 2023), available at: https://www.fs.usda.gov/sopa/components/reports/sopa-110412-2023-07.pdf (last visited Sept. 8, 2023).

[4] *See* Perpetua Resources, Permitting, available at: https://perpetuaresources.com/permitting/ (stating that Perpetua "must earn more than 50 permits from federal, state, and local agencies . . . .") (last visited Sept. 8, 2023).

operate in the State of Idaho comply with federal and state environmental laws. The issue of whether the Stibnite Gold Project complies with the Clean Air Act is of significant importance to the quality of Idaho's air, the health of Idaho's public, and to the Nez Perce Tribe who use the area to exercise its treaty reserved rights to hunt, fish, gather, and pasture in the immediate area.

Moreover, the EPA Letter underscores that the federal agency charged with ultimate compliance and enforcement of the federal Clean Air Act—namely, EPA—has identified substantial concerns about DEQ's decision to approve a PTC for the Stibnite Gold Project based on faulty emission factors and estimates, underscoring EPA's concerns about threats to Idaho air quality and public health. Since the Hearing Officer's duty is to ensure a full record is prepared and provide a Recommended Order to the Board of Environmental Quality, which has ultimate responsibility for reviewing the PTC and determining Petitioners' challenges to it, the Hearing Officer should not allow Perpetua and DEQ to prevent developing the full record and arguments at this contested case hearing stage.

In short, the proposed amendment raises a touchstone issue of whether DEQ appropriately and reasonably analyzed the amount of emissions from the facility such that it ensures that the mine would not emit pollutants that would exceed threshold emissions requiring a different permit issued under an entirely different program with consideration of different factors. Ensuring that DEQ had a reasoned basis for the emission factors that it chose to analyze this mine as a minor source of pollutants is critical to protecting Idaho's air quality, the surrounding environment, and the public's health.

CONCLUSION

As discussed above, the amendment is timely, it does not cause prejudice, undue delay, or hardship. Petitioners' Motion to Amend should be granted.

Dated this 8th day of September 2023.

Respectfully submitted,

s/ Julia Thrower

** This [Proposed] Second Amended Petition uses underscoring to highlight the additions made to the First Amended Petition, as illustrated here. For clarity, changes to paragraph numbers, however, are not indicated.

INTRODUCTION

1. Petitioners Nez Perce Tribe, Idaho Conservation League ("ICL"), and Save the South Fork Salmon ("SSFS"), by and through their attorneys of record, file this Petition to Initiate Contested Case ("Petition") before the Idaho Board of Environmental Quality ("Board") pursuant to Idaho Code § 39-107(5) and IDAPA 58.01.23. This Petition challenges the Air Quality Permit to Construct P-2019.0047 ("PTC") issued by the Idaho Department of Environmental Quality ("DEQ") on June 17, 2022, to mining company Perpetua Resources Idaho, Inc. ("Perpetua") for its proposed Stibnite Gold Project ("SGP").

2. The SGP is in the headwaters of the East Fork of the South Fork of the Salmon River approximately ten miles east of the town of Yellow Pine, Idaho. The SGP is geographically located within the Nez Perce Tribe's aboriginal homeland and within the area over which the Nez Perce Tribe has Treaty-reserved rights and resources. As proposed, Perpetua would use conventional mining techniques to extract ore from three open pits, process gold, and dispose of mine waste at the SGP site.

3. The PTC being challenged here authorizes emissions of air pollutants from the SGP that will occur over the mine's anticipated 16-year life span. These emissions include massive quantities of dust generated by mining, hauling, and processing. The dust includes particulate matter and arsenic—pollutants which can cause serious harm to human health and the environment.

4. When it issued the PTC, DEQ failed to comply with the federal Clean Air Act and with Idaho rules, regulations, and guidance for Clean Air Act permitting, and DEQ acted arbitrarily and capriciously, acted on unlawful procedure, and abused its discretion, under the Idaho Administrative Procedure Act, Idaho Code § 67-5279, in multiple ways set forth below.

Petitioners respectfully request that the Board reverse and set aside the PTC and remand to DEQ to correct these errors.

LISTING OF REPRESENTATIVES

5. Copies of all pleadings, correspondence, and official documents shall be served on the Petitioners' counsel listed below:

For the Nez Perce Tribe and the Idaho Conservation League:

JURISDICTION, STANDARD OF REVIEW, PARTIES, AND STANDING

6. Pursuant to Idaho Code § 39-107(5), IDAPA 58.01.23, and IDAPA 58.01.01 (the "Idaho Air Rules"), the Board has jurisdiction over this contested case challenging DEQ's action issuing PTC P-2019.0047 for the SGP on June 17, 2022. The original Petition was timely filed on July 22, 2022, within thirty-five (35) days of the date of DEQ's June 17, 2022 decision. *See* IDAPA 58.01.23.060. The~~is~~ First Amended Petition was filed on December 6, 2022. This Second Amended Petition is proper under IDAPA 58.01.23.003.01, IDAPA 04.11.01.305, and Idaho Rule of Civil Procedure 15(a)(2).

7. An agency action, such as DEQ's issuance of the PTC being challenged here, may be reversed if it is in violation of constitutional or statutory provisions, is in excess of statutory

authority, is made on unlawful procedure, or is arbitrary, capricious, or an abuse of discretion. Idaho Code ("I.C.") § 67-5279. When an agency action is not affirmed, it shall be set aside, in whole or in part, and remanded for further proceedings as necessary. *Id.*

8. Pursuant to IDAPA 58.01.23.002.02: "Any person aggrieved by an action or inaction of the Department may file a petition to initiate a contested case pursuant to Chapter 52, Title 67, Idaho Code." An aggrieved person is defined as "any person or entity with legal standing to challenge an action or inaction of the Department, including but not limited to permit holders and applicants for permits challenging Department permitting actions." IDAPA 58.01.23.005.01.

9. PETITIONER NEZ PERCE TRIBE is a federally-recognized Indian tribe with headquarters on the Nez Perce Reservation in Lapwai, Idaho; and with offices in Orofino, McCall, and Powell, Idaho, and Joseph, Oregon.

10. The Nez Perce Tribe has standing to bring this contested case. The Nez Perce people, the *Nimiipuu*, exclusively occupied, since time immemorial, over thirteen million acres encompassing a large part of what is today Idaho, Oregon, and Washington—stretching from the Bitterroot Mountains to the Blue Mountains. Nez Perce also traveled far beyond this homeland to fish, hunt, gather, and pasture—frequently going east to buffalo country, in what is today the state of Montana, and west along the Snake and Columbia rivers to the Pacific Ocean. The Nez Perce actively maintain their connection to the land, water, and resources of their vast homeland. The Nez Perce's intimate knowledge and continuous use of their homeland over millennia have created a unique and reverential bond between people and place that defines Nez Perce culture and identity.

11. When the Nez Perce Tribe entered into a treaty with the United States in 1855, it sought to reserve the rights central to maintaining its culture and way of life. The 1855 Treaty reserved to the Tribe, for its "exclusive use and benefit," 7.5 million acres of its more than thirteen-million- acre homeland, including an area spanning present-day north-central Idaho, southeast Washington, and northeast Oregon as well as:

> [T]he right of taking fish at all usual and accustomed places in common with citizens of the Territory; and of erecting temporary buildings for curing, together with the privilege of hunting, gathering roots and berries, and pasturing their horses and cattle upon open and unclaimed land.

Treaty with the Nez Perces, art. 3, June 11, 1855, 12 Stat. 957. Nez Perce Tribal members, pursuant to the Nez Perce Tribe's Treaty-reserved rights, continue to fish, hunt, gather, and pasture across the Nez Perce Tribe's vast aboriginal homeland and at traditional places, including areas within and surrounding the SGP. The Nez Perce Tribe, as a co-manager of its treaty-reserved resources, also plays a leading role in the restoration of the East Fork South Fork Salmon River and South Fork Salmon River fisheries, expending approximately $2.5 million annually to restore Chinook salmon runs in both rivers through hatchery supplementation, fishery research, and watershed restoration.

12. The Nez Perce Tribe will suffer physical, cultural, spiritual, and economic injury caused by excessive air pollutants resulting from DEQ's issuance of the PTC. Clean, clear air is a critical component to ensuring the health and resiliency of the Nez Perce Tribe's Treaty-reserved rights and resources. Air pollution reduces visibility, which impairs cultural and ceremonial practices for Tribal members and reduces enjoyment of these special places. Air pollution causes a host of environmental and human health problems, including damage to culturally important plants, sensitive forests, and fish habitat, acidification of lakes and streams, depletion of soil nutrients, aggravated asthma, heart attacks, and premature death. Impacts can be especially

harmful to at-risk ecosystems and especially harmful for sensitive human populations such as asthmatics, children, the elderly, people with diabetes, and people with heart or lung disease.

13. To safeguard its rights and interests, the Nez Perce Tribe has participated extensively in DEQ's review process, including submitting comments on October 12 and November 10, 2020, March 8, 2021, and March 14, 2022. A favorable decision in the Contested Case will redress these injuries suffered by the Tribe.

14. PETITIONER IDAHO CONSERVATION LEAGUE is an Idaho non-profit conservation organization. Its main office is located in Boise, Idaho, and it has three field offices in Sandpoint, Ketchum, and McCall. ICL represents approximately 50,000 supporters dedicated to protecting and conserving Idaho's clean water, air, public lands, and wildlife.

15. ICL has standing to bring this contested case. ICL supporters, staff, and board members ("ICL members") regularly visit the SGP and/or nearby areas where air quality would be affected by the SGP for professional, recreational, aesthetic, and other purposes. ICL members will suffer health, environmental, and aesthetic injuries from the particulate matter and arsenic air pollution emitted by the SGP and authorized by DEQ's issuance of the PTC. A favorable decision in the Contested Case will redress ICL's injuries. Neither the claim asserted, nor the relief requested, requires participation of these individual ICL members in the lawsuit. The interests ICL seeks to protect are germane to the organization's purpose in protecting Idaho's clean water, clean air, wildlife, and public lands.

16. In furtherance of its mission, ICL participated extensively in the public processes for the PTC, including by submitting formal public comments to DEQ on October 12 and November 11, 2020, March 19, 2021, and March 16, 2022.

17. PETITIONER SAVE THE SOUTH FORK SALMON is a community-based, non-profit conservation organization headquartered in McCall, Idaho. SSFS represents members and supporters dedicated to preserving the South Fork Salmon River watershed and ecosystem.

18. SSFS has standing to bring this contested case. SSFS members, supporters, and members of the Board of Directors ("SSFS members") regularly visit the South Fork Salmon River watershed and the SGP site, where the emission of excessive air pollutants due to DEQ's issuance of the PTC would impact professional, economic, recreational, aesthetic, environmental, and human health interests. SSFS members would suffer injury from DEQ's issuance of the PTC from environmental, health, and aesthetic harms caused by the emission of harmful air pollutants, including particulate matter and arsenic. A favorable decision in the Contested Case will redress these injuries suffered by SSFS members. Neither the claims asserted, nor the relief requested, requires participation of these individual supporters in the lawsuit. The interests SSFS seeks to protect are germane to the organization's mission of protecting and preserving the South Fork Salmon River watershed and ecosystem, and protecting public health, the river, the fish, and recreational opportunities in the area.

19. In furtherance of this mission, SSFS participated extensively in the public process for the PTC, including submitting formal public comments to DEQ on October 12 and November 11, 2020, March 19, 2021, and March 16, 2022.

20. RESPONDENT IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY is an executive department and administrative agency organized under the laws of the State of Idaho, pursuant to the Idaho Constitution (Article IV, Section 20) and Idaho Code section 39-104(1). Its principal offices are located at 1410 N. Hilton, Boise, Idaho 83706. DEQ, through its

Director, and subject to Board oversight, is responsible for issuing air quality PTCs under the Idaho Air Rules, IDAPA 58.01.01.

21. On June 17, 2022, DEQ issued PTC P-2019.0047, which is the subject of this contested case. On July 22, 2022, Petitioners timely filed the original Petition to Initiate Contested Case. On July 28, 2022, the Hearing Officer Dylan Lawrence was assigned to preside over this matter. On August 12, 2022, Perpetua filed a Petition to Intervene. On August 22, 2022, Perpetua's Petition to Intervene was granted. On September 6, 2022, Perpetua filed a Motion to Dismiss. On November 15, 2022, the Hearing Officer issued the Order on Motion to Dismiss, denying the motion with respect to the majority of Petitioners' claims, dismissing or partially dismissing four claims, and declining to allow the pleadings to be amended unless Petitioners file for consideration a formal motion to amend the Petition.

FACTUAL SUPPORT FOR PETITION

I. OVERVIEW OF SGP & CHRONOLOGY OF DEQ'S ISSUING THE PTC

22. Perpetua is currently in the process of seeking multiple permits and other approvals from multiple agencies and other authorities for the proposed SGP. As described by DEQ in the Statement of Basis ("SOB") document prepared with the PTC:

> Perpetua proposes to construct and operate the SGP, consisting of conventional open-pit mining, ore preparation, and gold extraction operations. The SGP is to be located in Valley County at the intersection Forest Service roads NF-374 and NF-412 (Stibnite Road), approximately 10 miles east of Yellow Pine. The project will be located on a combination of public national forest and private lands. The mining operations boundary within which public access will be excluded is defined in Figure 1. This operations boundary also defines the ambient air boundary that was used in all ambient air quality impact analyses as part of the development process of the PTC.
>
> The SGP will require the construction of significant infrastructure, including a power transmission line, a primary mine site access road, onsite haul roads, an ore processing facility, onsite workspaces, employee housing and recreation, water storage and distribution facilities, and sewage disposal facilities.

Conventional open-pit mining methods including drilling, blasting, excavating, and hauling will be used to extract ore and waste rock, termed development rock (DR). Hydraulic shovels and front-end loaders will be used to load ore and DR into haul trucks. DR will be used for construction, restoration, and backfilling, or hauled to the dedicated development rock storage facilities (DRSF). Approximately 340 million tons of DR will be handled over the life of the mine.

The SGP will include three years of pre-mining development and construction activities, followed by an operating mine life of approximately 12 years. Mining will occur in three open pits: Yellow Pine Pit (YPP), Hangar Flats pit (HFP), and West End pit (WEP). Although there will be overlap in mine development, construction and operations, the general sequence of mining will be the YPP deposit, followed by the HFP and WEP deposits. Legacy tailings from the Meadow Creek valley (Bradley Tailings [BT]) will also be reclaimed and reprocessed during the initial project schedule. Surface exploration drilling will occur within the pits and within the Scout Prospect decline (underground exploration) throughout the mine operation period. Restoration and reclamation of other legacy mining features will occur prior to mining, throughout the life of the mine, and as part of the mine closure.

Ore will be hauled to the primary crusher area, where it will be fed directly into the crusher dump pocket or stockpiled. The ore crushing plant will be designed to operate at a maximum rate of 25,000 tons per calendar day (T/day). Approximately 100 million tons of ore will be mined from the three pits over the life of the project. The metal-recovery process from ore will include conventional crushing and grinding, followed by froth-flotation circuits that will generate separate gold-silver and antimony-silver concentrates. The antimony-silver concentrate will be shipped offsite for refining, whereas additional onsite processing of the gold-silver concentrate will include pressure oxidation, carbon-in-leach circuits, and refining processes to recover gold and minor amounts of silver. The finely ground leftover ore material from the mineral recovery process, termed tailings, will be neutralized, thickened, and transported via a pipeline to the tailings storage facility. A diagram of ore processing and ore concentration and refining process flows is provided in Figure 2.

23. Perpetua (previously Midas Gold) submitted a PTC application for the SGP to DEQ on August 20, 2019. As shown in the "Application Chronology" section of the SOB, between that date and March 6, 2020, DEQ determined that the application was incomplete, requested additional information, and received supplementary materials from Perpetua no fewer than four times. On May 15, 2020, DEQ deemed Perpetua's application complete.

24. Between May 15, 2020, and March 16, 2022, DEQ developed three versions of the draft PTC and released them for public comment. As noted in comments submitted by the Nez Perce Tribe, ICL, and SSFS, the first two draft versions of the PTC (herein referred to the September 2020 and February 2021 draft PTCs) contained significant shortcomings. As a result, the September 2020 draft PTC was considered deficient and required updated information from Perpetua, including updated hazardous air pollutants ("HAP") and toxic air pollutants ("TAP") emissions estimates, a HAP/TAP addendum to the application, updated TAP modeling analyses, supporting references, and updated modeling files with corrections for formaldehyde and sulfuric acid.

25. DEQ subsequently updated the draft PTC and in February 2021, provided a revised draft PTC for public comment. Following additional comments, DEQ again determined that the February 2021 draft PTC was deficient and required additional information from Perpetua, including Prevention of Significant Deterioration emissions estimates and regulatory applicability for the lime manufacturing plant, as well as an updated TAP/HAP addendum including an updated emission inventory and modeling files.

26. DEQ revised theFebruary 2021 draft PTC and released it for public comment on January 13, 2022. Comments were submitted by the Nez Perce Tribe, ICL, SSFS, the U.S. Environmental Protection Agency ("EPA") Region 10, and Ian von Lindern of Terragraphics International Foundation. Commenters raised numerous concerns with the draft PTC and urged DEQ to gather additional information, to perform additional modeling and analysis, and to develop additional enforceable permit conditions and limits prior to issuing a final PTC. On June 17, 2022, DEQ issued the final PTC, along with responses to comments and the SOB.

While DEQ made limited updates to the PTC, it rejected most of the issues raised by the commenters.

27. On August 10, 2023, EPA Regional Administrator Casey Sixkiller wrote a letter to Idaho Department of Environmental Quality ("DEQ") Director Jess Byrne (the "EPA Letter"), expressing ongoing concerns with the PTC. The EPA Letter stated:

> The Agency has three primary concerns with the Department's Permit: (1) the Permit's emission limits are not adequate to limit the Stibnite Gold Project's potential to emit below the Prevention of Significant Deterioration permitting threshold; thus, construction of the Stibnite Gold Project would constitute construction of a major stationary source without a Prevention of Significant Deterioration permit, (2) the Permit's emission limits are not adequate to protect the particulate matter National Ambient Air Quality Standard, and (3) the Department's delineation between the Stibnite Gold Project boundary and the ambient air—where the National Ambient Air Quality Standards apply—is not adequately supported. Details of the Agency's evaluation of the final permit are enclosed for your review.

28. In the supporting enclosure to the EPA Letter, EPA provided more detailed information and analysis regarding its concerns with the PTC, including providing detailed information about EPA's concern that DEQ failed to use appropriate emissions factors to estimate emissions from the SGP's ore processing and lime plant units.

29. The EPA Letter also stated that EPA "believes that the deficiencies in the Permit outlined in the enclosure and articulated in prior comments can be rectified through issuance of a revised permit to construct with adequate and enforceable conditions." *Id.* The EPA Letter requested an in-person meeting aimed at a timely resolution of EPA's concerns, such as by issuing a revised PTC.

II. PM_{10} & ARSENIC EMISSIONS FROM THE SGP

30. While the SGP will emit numerous air pollutants, PM_{10} and arsenic are the air pollutants of greatest concern and are the pollutants at issue in this contested case.

A. PM_{10} Pollution and Regulation

31. Particulate matter ("PM") contains microscopic solids or liquid droplets that are so small that they can be inhaled and cause serious health problems. Some particles less than 10 micrometers in diameter can get deep into a person's lungs, and some may even get into the person's bloodstream. Numerous scientific studies have linked particle pollution exposure to a variety of problems, including premature death in people with heart or lung disease; nonfatal heart attacks; irregular heartbeat; aggravated asthma; decreased lung function; and increased respiratory symptoms, such as irritation of the airways, coughing or difficulty breathing. People with heart or lung diseases, children, and older adults are the most likely to be affected by particle pollution exposure.

32. In addition to causing human health problems, PM causes environmental damage. Particles can be carried over long distances by wind and then settle on ground or water. Depending on their chemical composition, the effects of settling may include making lakes and streams acidic; changing the nutrient balance in river basins; depleting nutrients in soil; damaging sensitive forests and crops; affecting diversity of ecosystems; and contributing to acid rain.

33. Under Sections 108 and 109 of the federal Clean Air Act, EPA is required to establish National Ambient Air Quality Standards ("NAAQS") for each "criteria air pollutant" to protect the nation's public health and welfare. "[E]ffects on welfare include[ ], but [are] not limited to, effects on soils, water, crops, vegetation, manmade materials, animals, wildlife,

weather, visibility, and climate, damage to and deterioration of property, and hazards to transportation, as well as effects on economic values and on personal comfort and well-being, whether caused by transformation, conversion, or combination with other air pollutants." 42 U.S.C. § 7602(h).

34. PM is a criteria air pollutant. EPA has established primary and secondary NAAQS for coarse particulate matter, or "PM_{10}," 40 C.F.R. § 50.6, and for fine particulate matter, or "$PM_{2.5}$," *id.* at § 50.7. PM_{10} consists of inhalable particles with diameters that are generally ten micrometers and smaller. 42. U.S.C. § 7602(t). $PM_{2.5}$ consists of inhalable particles that are 2.5 micrometers and smaller. The NAAQS specify a maximum amount of PM to be present in the outdoor air. *See* 40 C.F.R. §§ 50.6, 50.7.

35. EPA has delegated to DEQ authority to issue air quality permits in Idaho. Under the Clean Air Act, State air rules like DEQ's "shall" include "enforceable emission limitations" and other control measures, means, or techniques as necessary or appropriate to meet Clean Air Act requirements. 42 U.S.C. § 7410(a)(2)(A). State plans "shall" include a "program to provide for the enforcement" of the limitations and measures described in subparagraph (A), and for the "regulation of the modification and construction of any stationary source . . . to assure that [NAAQS] are achieved." *Id.* § 7410(a)(2)(C). EPA's Clean Air Act regulations require each State plan to "set forth legally enforceable procedures" that enable the State to determine whether the construction of a facility will result in a violation of its air pollution control strategies or interfere with attaining or maintaining the NAAQS. 40 C.F.R. § 51.160(a). These legally enforceable procedures: must include means by which the State will prevent construction if the facility will violate air pollution control strategies or will interfere with attaining or maintaining the NAAQS; and must provide for the applicant to submit information on the

"location, design, construction, and operation of such facility . . . as may be necessary" to permit the state to "to make the determination" that the facility will comply with its air pollution control strategies and the NAAQS. *Id.* § 51.160(b)–(c). "The legally enforceable procedures in § 51.160(b) must also require" the State to provide opportunity for public comment on information submitted by the applicant and on the State's analysis of the effects on ambient air quality. *Id.* § 51.161(a). Under the Rules for the Control of Air Pollution in Idaho, DEQ is required to ensure that no PTC shall be granted for a new or modified stationary source unless the applicant shows to the satisfaction of DEQ that the source would not cause or significantly contribute to a violation of any NAAQS. IDAPA 58.01.01.203.02. To satisfy these requirements, DEQ must assess air impacts using maximum potential emissions as limited by either the capacity of the unit/operation or as limited by enforceable permit provisions. *See* IDAPA 58.01.01.006.88. Prior to issuing a permit to contruct, DEQ must provide an opportunity for public comment by making available DEQ's proposed action together with information provided by the applicant and with DEQ's analysis of air quality impacts. IDAPA 58.01.01.209.c.

B. PM_{10} Pollution from the SGP & Flaws in the PTC

36. According to DEQ's Statement of Basis for the SGP, the SGP has the potential to emit 55.7 tons per year of PM_{10} from a variety of sources. The generation of dust from ore haul trucks traveling along haul roads is the most significant source, estimated to be approximately 55% of all modeled PM_{10} emissions. The next most significant source is open pit drilling fugitive emissions, estimated by DEQ to account for approximately 24% of all modeled emissions.

37. DEQ modeled receptors at various locations along the SGP's ambient air boundary and determined that the maximum potential emissions will be below (and thus comply

with) the 24-hour PM_{10} NAAQS. DEQ found the maximum 24-hour PM_{10} pollution from the SGP would be 123.5 ug/m^3, which is 82.3% of the NAAQS.

38. For each of the reasons below, DEQ's determination that the SGP will not cause or contribute to a violation of the PM_{10} NAAQS and its action approving the PTC violates the Clean Air Act, violates EPA's Clean Air Act regulations, violates the Idaho Air Rules, and is otherwise arbitrary, capricious, made on unlawful procedure, and an abuse of discretion and must be set aside under I.C. § 67-5279.

39. First, important variables affecting the quantity of PM_{10} generated by the ore haul trucks are not directly limited and enforceable as PTC permit conditions. Perpetua estimated the quantity of PM_{10} that would be emitted by the ore haul trucks based on EPAs compilation of air emissions factors (AP-42 Chapter 13.2.2) and their subsequent analysis of sources used by the EPA to develop Chapter 13.2.2. Critical variables that Perpetua used as inputs to PM emission calculations include: the average empty weight of ore haul trucks; the average loaded weight of ore haul trucks; the total number of larger versus smaller ore haul trucks (CAT 789D versus CAT 740B); the silt content of the haul road being traveled; the number of days per year with precipitation greater than or equal to 0.01 inches per day; and the total number vehicle miles traveled by ore haul trucks. However, only one of these critical variables is directly limited and enforceable as a condition in the PTC: the silt content of the haul roads. *See* PTC condition 3.13.

40. Instead of developing PTC conditions for these other critical variables, DEQ relied on a surrogate limit in the PTC (total ore haulage per day, *see* PTC conditions 3.5) and on plans that have not yet been developed and have not been subject to public comment,—a Fugitive Dust Control Plan ("FDCP") and a Haul Road Capping Plan ("HRCP")—to claim the PTC ensures enforceable compliance with 24-hour PM_{10} NAAQS. Without developing the

FDCP and HRCP first, without taking public comment on them, and without including important variables as enforceable permit conditions, there is no assurance the SGP will comply with the 24-hour PM_{10} NAAQS, even with the total ore haulage per day limit. Perpetua used a very specific combination of these variables to arrive at a quantity of ore haul truck generated PM_{10} that they contend ensures compliance with the NAAQS. Changing these variables in any number of ways (ways which are not precluded by any conditions in the PTC) can result in higher PM_{10} levels—levels so high that they exceed the NAAQS. As just one example, merely changing the ratio of large to small ore haul trucks used by Perpetua (to include more small trucks) could cause a violation of the NAAQS.

41. Second, DEQ assumed 93.3% of all haul road PM_{10} emissions from the SGP can be controlled by using an unspecified combination, volume, and frequency of water sprays and chemical dust suppressants. This extremely high level of control which DEQ assumed Perpetua can achieve is based on Perpetua's interpretation of AP-42 Chapter 13.2.2. AP-42 Chapter 13.2.2 discusses the critically important variables surrounding control efficiencies (in particular to chemical suppressants, some of which can reasonably be assumed to apply to water too):

> The control effectiveness of chemical dust suppressants appears to depend on (a) the dilution rate used in the mixture; (b) the application rate (volume of solution per unit road surface area); (c) the time between applications; (d) the size, speed and amount of traffic during the period between applications; and (e) meteorological conditions (rainfall, freeze/thaw cycles, etc.) during the period. Other factors that affect the performance of dust suppressants include other traffic characteristics (e. g., cornering, track-on from unpaved areas) and road characteristics (e. g., bearing strength, grade). The variabilities in the above factors and differences between individual dust control products make the control efficiencies of chemical dust suppressants difficult to estimate. Past field testing of emissions from controlled unpaved roads has shown that chemical dust suppressants provide a PM-10 control efficiency of **about 80 percent when applied at regular intervals of 2 weeks to 1 month (**emphasis added**).**

42. None of the above variables, however, have any specific and enforceable permit conditions within the PTC to ensure a 93.3% control efficiency. Instead, the PTC has a permit condition (permit condition 2.6) only requiring the permittee to develop and submit the FCDP and HRCP, which merely describe how these variables will be addressed 30 days before start-up of the SGP. Permit condition 2.6 details what variables contributing to PM_{10} control effectiveness must be detailed in the FCDP, but the specific details that are so important to control efficiency (e.g., the amount of water or chemical suppressants applied and the frequency of application) are undetermined at present, have not been subject to public comment, and are left to Perpetua to decide at a later date. A lesser control efficiency, even just slightly lesser, could result in large enough PM_{10} emissions to violate the NAAQS. In fact, if the SGP were to instead achieve 80% control (as EPA found through past field testing of chemical dust suppressants), then the SGP's PM_{10} emissions could exceed the NAAQS.

43. Third, DEQ relied on monitoring and record keeping (permit condition 3.16) using devices and methodologies in the Operation and Maintenance ("O&M") Manual for the potential to emit limit associated with the 180,000 tons per day hauling in permit condition 3.5. However, the O&M Manual has not yet been developed, submitted to the public for comment, ~~or~~ reviewed and revised by DEQ, or incorporated into and made enforceable under the Permit. The O&M Manual is critical to ensuring the 180,000 tons per day hauling condition is satisfied, and the 180,000 tons per day is critical to DEQ's determination under IDAPA 58.01.01.203.02 that the SGP will not exceed the NAAQS. Additionally, DEQ is authorized to require plans and to impose any reasonable conditions on permits, but instead of doing so here, it is letting Perpetua do this later, outside of the permit process. *See* IDAPA 58.01.01.202.03 (authorizing DEQ to obtain from permit applicant "[a]ny additional information, plans, specifications, evidence or

documents the Department may require to make the determinations required under [the PTC sections of the Air Rules]"); IDAPA 58.01.01.211 (authorizing DEQ to "impose any reasonable conditions upon an approval" of a PTC); IDAPA 58.01.01.121 (authorizing DEQ to require schedules, reports, records, monitoring, and plans to ensure compliance with Air Rules); IDAPA 58.01.01.122.03.g (authorizing DEQ to issue an information order to provide any "information the Department may require").

44. Fourth, DEQ assumed there would be 120 days of recordable precipitation at the SGP (defined as recording precipitation of 0.01 inch or greater) as a variable in its ore haul road fugitive PM emission calculations. This 120 days comes from general geographic guidance from AP-42 Chapter 13.2.2-1. DEQ, however, should have used local meteorological data. Section 6.8 (Meteorological Data) of DEQ's *Guideline for Performing Air Quality Impact Analyses* states: "The meteorological data used in the modeling analysis should be representative of the meteorological conditions at the particular site of the proposed construction or modification." Days of recordable precipitation is an important variable affecting the SGP's emissions of PM_{10} from ore haul roads. DEQ's failure to use the most representative site data is counter to this guidance and increases the risk of miscalculation of ore haul road emissions. As a result, DEQ failed to ensure PM_{10} emissions from the SGP will comply with the NAAQS.

C. Arsenic Pollution & Regulation

45. Arsenic is a naturally occurring element in soils and minerals. When soil or rock containing arsenic is disturbed, arsenic may enter the air, water, and land from wind-blown dust and from run-off and leaching. The EPA classifies inorganic arsenic as a "human carcinogen," based on evidence in human studies of links to lung, bladder, kidney, skin, and liver cancers.

46. Arsenic released from the soil and rock as airborne dust causes environmental damage. Airborne arsenic pollutes soil, plants, and water resources when it is removed from the air by rain, snow, or gradually settling. Studies have shown that there is a strong correlation between arsenic concentrations in water and in the tissues of fish collected from arsenic-polluted waters. Plants may also absorb arsenic in their leaves and root system from arsenic-polluted soil. The health effects of long-term ingestion of arsenic include developmental effects, diabetes, pulmonary disease, cardiovascular disease, and skin, bladder, or lung cancer.

47. Arsenic is a Toxic Air Pollutant regulated by DEQ. DEQ is required to ensure that no permit to construct shall be granted for a new or modified stationary source unless emissions of TAPs from the constructed source would not injure or unreasonably affect human or animal life or vegetation as required by Section 161. IDAPA 58.01.01.203.03. Section 161 states, "any contaminant which is by its nature toxic to human or animal life or vegetation shall not be emitted in such quantities or concentrations as to alone, or in combination with other contaminants, injure or unreasonably affect human or animal life or vegetation." IDAPA 58.01.01.161.

48. To comply with these TAPs regulations, emissions from a facility must not exceed the Acceptable Ambient Concentrations of Carcinogens ("AACC") at the ambient air boundary. For each carcinogenic TAP, IDAPA 58.01.01.586 lists the applicable TAP and its AACC in ug/m^3 as an annual average. The AACC can practically be defined as the concentration of a TAP that, if an individual was exposed to yearly over a 70-year lifetime, would equate to a cancer development probability risk of 1 in 1,000,000. *See* IDAPA 58.01.01.006.125 & 58.01.01.210.12.

49. In order to determine a facility's TAP concentration at their ambient air boundary, and as noted similarly for PM_{10} emissions, DEQ must assess air impacts using maximum potential emissions as limited by either the capacity of the unit/operation or as limited by enforceable permit provisions. *See* IDAPA 58.01.01.006.88.

D. Arsenic Pollution from the SGP & Flaws in the PTC

50. There are numerous arsenic sources at the SGP, including drilling, blasting, excavating, hauling, silos, rock dumps, and storage and tailing piles. Table 3 in the SGP TAPs Addendum indicates that the maximum arsenic Potential Total Emissions ("PTE") is 0.544 lbs/hr at the maximum mine production rate of 180,000 tons/day. The largest source of arsenic emissions are haul roads estimated at 0.464 lbs/yr (Table B1-W3 in SOB). PTE estimates for arsenic are calculated using the same formulas and Emission Factors as total particulate and PM_{10} emission rates. As such, like the PM and PM_{10} emission estimates discussed already, the arsenic emission estimates are similarly underestimated and equally unreliable.

51. During the permitting process, DEQ determined that the SGP's estimated arsenic emissions and concentrations at the ambient air boundary were excessive and would not meet the AACC for arsenic. To get around this problem, Perpetua chose to employ a process known as T-RACT. T-RACT is a demonstration that allows a permittee to analyze and employ reasonably available control technologies ("RACT") that could be applied to a source of TAPs. If RACT does not sufficiently reduce toxic emissions to below the AACC, then the permittee is allowed a 10-fold increase in the AACC and can employ production limitations to ensure compliance with the now 10-times-bigger AACC. These production limitations should then be incorporated as enforceable permit conditions. *See* IDAPA 58.01.01.210.13–14.

52. As part of the T-RACT determination process, the applicant must supply, and DEQ must consider, information on a variety of factors relevant to determining a "reasonable" control technology including, but not limited to, control effectiveness, economic costs, operational feasibility, and associated environmental impact. IDAPA 58.01.01.210.14a–d.

53. Perpetua submitted to DEQ a T-RACT demonstration for arsenic emissions from open-pit drilling and ore haul roads. Perpetua determined that the most effective RACT for open-pit drilling was dry drilling with dust collectors and that the most effective RACT for ore haul roads was water sprays and chemical suppressants. In its T-RACT demonstration, Perpetua included limited qualitative discussion, and no quantitative support, regarding economic considerations. Perpetua failed to provide any discussion of environmental impacts.

54. DEQ approved Perpetua's T-RACT demonstration and granted Perpetua a 10-fold increase in allowable arsenic pollution, subject to operational limitations to reduce PTE. And as modeled by DEQ, arsenic pollution from the SGP would comply with this larger AACC.

55. For each of the reasons below, DEQ's approval of Perpetua's T-RACT demonstration for arsenic, its analysis determining the SGP will not exceed the AACC and thus will not injure or unreasonably affect human or animal life or vegetation, and its action approving the PTC violates the Clean Air Act, violates EPA's Clean Air Act regulations, violates the Idaho Air Rules, and is otherwise arbitrary, capricious, made on unlawful procedure, and an abuse of discretion and must be set aside under I.C. § 67-5279.

56. First, the T-RACT demonstration contained no persuasive economic information and no discussion at all regarding associated environmental impacts, despite the requirements to do so in IDAPA 58.01.01.210.14. There will be water quality and biological impacts associated with Perpetua's use of substantial amounts of chemical dust suppressants and water that have not

been considered in the PTC. For example, the use of chemical dust suppressants like magnesium chloride can cause toxicity in trees and can lead to tree death. Magnesium chloride is also known to adversely affect aquatic ecosystems. Moreover, the proposed water source for dust control is primarily water collected in runoff ponds (captured rain or snowfall that has become contaminated through the contact of mine facilities), groundwater, and surface water from the East Fork of the South Fork of the Salmon River. USGS sampling indicates elevated arsenic in these waters. The environmental impact of using magnesium chloride or arsenic-polluted water as dust suppression methods was never considered as part of the T-RACT demonstration. Likewise, the T-RACT demonstration did not provide sufficient economic support for Perpetua's decision to use water and chemical dust suppressants as compared to paving the haul roads, even though paving was shown to achieve the highest reasonable dust control efficiency.

57. Second, because the underlying particulate and PM_{10} emissions estimates and particulate control assumptions are unreliable in numerous respects, as already discussed above, so too are the estimated arsenic emissions. The SGP's estimated arsenic emissions were based on its PM_{10} emissions. PM_{10} emissions from the SGP may be higher, and their control effectiveness may be lower, than DEQ assumed, in which case arsenic emissions would also be higher and might exceed the AACC.

58. Third, Perpetua's and DEQ's TAPs analyses substantially reduce the SGP's purported arsenic emissions using three improper averaging tactics: (1) averaging emissions over a 5-year period for the T-RACT input to ambient toxics modeling; (2) averaging the estimated annual ambient modeling impacts across two multi-year scenarios; and (3) averaging the resultant 16-year total emissions over the 70-year human lifetime to assert compliance. Nothing in the Idaho Air Rules allows for multi-year emissions averaging and ambient air concentration

adjustments. Rather, the arsenic AACC is an annual average. *See* IDAPA 58.01.01.586). DEQ's T-RACT regulations require comparing the estimated maximum annual ambient air arsenic concentration to 10 times the listed annual AACC. IDAPA 58.01.01.12.b. Therefore, to determine compliance with the AACC requires that DEQ estimate the SGP's maximum 1-year annual arsenic emissions and compare it to the annual arsenic AACC.

59. By relying on these improper averaging tactics, DEQ fails to show the SGP will satisfy the arsenic AACC and the resulting analysis masks potentially severe human health and environmental impacts of SGP's potential arsenic emissions. The underlying analyses supporting the TAPs requirements allows for a 1-in-1,000,000 excess cancer risk factor. The T-RACT approval increases that risk 10-fold to a 1-in-100,000 excess cancer risk factor. IDAPA 58.01.01.12.b. Perpetua's multi-year averaging of emission rates combined with DEQ's decision to allow the full lifetime exposure (70 years) to be imposed on receptors during the 16-year estimated life of mine increases the cancer risk by another order of magnitude to the 1-in-10,000 range or higher. Combined with uncertainties associated with the underlying particulate emissions calculations noted above, the SGP may result in extremely dangerous arsenic exposures.

60. While not the basis for a separate claim for relief, Petitioners note that excacerbating this cancer risk is the fact that under DEQ's incremental TAPs regulations (*see* IDAPA 58.01.01.585), when DEQ considers permitting any additional sources of arsenic in the area over the next 70 years (such as an extension of the life of the SGP, expansion of the facility itself, and/or any adjacent facilities seeking a similar permit, like the potential Horse Heaven project), DEQ will not have to consider the arsenic emissions authorized by this PTC.

E. DEQ's Ambient Air Boundary for the SGP

61. The Clean Air Act and Idaho Air Rules require meeting various air standards, including the NAAQS and TAPs, in ambient air. *See*, *e.g.*, IDAPA 58.01.01.006.11 (NAAQS), 58.01.01.006.125 (TAPs). EPA defines "ambient air" as "that portion of the atmosphere, external to buildings, to which the general public has access." 40 C.F.R. § 50.1(e). In defining an ambient air boundary, the EPA has long followed a policy that exempts "the atmosphere over land owned or controlled by the source and to which public access is precluded . . ." from ambient air. EPA's Revised Policy on Exclusions from "Ambient Air" (Nov. 2018) states that "it is appropriate to exclude the atmosphere over land owned or controlled by the stationary source, where the owner or operator of the source employs measures, which may include physical barriers, that are effective in deterring or precluding access to the land by the general public."

62. The Idaho Air Rules define "ambient air" as "[t]hat portion of the atmosphere, external to building, to which the general public has access." IDAPA 58.01.01.005.09. To exclude areas from consideration as ambient air, the following conditions must be met: (1) the permittee must have the legal authority to exclude the general public from the area; (2) the boundary to ambient air must be clearly discernible to the general public; (3) the general public must be effectively precluded from assessing the facility; and (4) the general public is not considered employees of the facility; those having official business with the facility; guests of the facility, including participants in facility routes and those seeking access for a specific purpose.

63. Perpetua established an operations boundary (the active industrial site where mining activities and heavy equipment operation will occur) for the purposes of excluding this area from ambient air analysis, and for excluding public access. The area includes the current

Stibnite Road point of entry and proposed site access via the Burntlog Route. According to Perpetua, access inside the operations boundary will be restricted for the life of the mine by physical barriers at points of potential access, as well as natural features of the landscape that prevent public access.

64. DEQ's determination to exclude the access route from ambient air protections, and its action approving the PTC violates the Clean Air Act, violates EPA's Clean Air Act regulations, violates the Idaho Air Rules, and is otherwise arbitrary, capricious, made on unlawful procedure, and an abuse of discretion and must be set aside under I.C. § 67-5279.

65. Perpetua has indicated that it intends to allow access to the general public through the mine site between Stibnite Road at Sugar Creek and Thunder Mountain Road at Meadow Creek. Furthermore, this roadway is currently accessible to and has been regularly used by the general public. And while Perpetua claims that it has "legal and practical ability to enforce its control over roadway access," the Forest Service has not yet completed its NEPA analysis and approval of the SGP, which would include a decision on whether it will require or will not permit general public access through the mine site.

66. DEQ states that the route would be managed in accordance with the Stibnite Road Access Management Plan ("AMP"). DEQ, however, relied on an ambiguous description of measures and requirements to preclude public access and ensure that those traveling over the road can be classified as "guests" of the mine.

67. PTC condition 2.7 requires the development of an AMP to address whether the NAAQS apply to the mine's access road through the Perpetua site given the extent of public access allowed. PTC condition 2.8 allows the AMP to be developed later, after the PTC was issued and without public comment, and it does not require the AMP to be enforceable. For the

AMP to preclude the applicability of the NAAQS along the access road, the AMP must be reviewed and approved by DEQ, it must be reviewed through public comment, and it must be enforceable under the PTC.

68. Without full disclosure and knowledge of the exact measures and requirements in the AMP and enforceable permit limits, DEQ cannot make a determination of whether exclusion of the access road from ambient air protections complies with EPA's ambient air policy and the Idaho Air Rules, nor can DEQ determine whether the SGP will comply with the NAAQS and TAPs.

F. DEQ's Failure to Require Ambient Air Monitoring for the SGP

69. DEQ has the authority to require ambient air monitoring to determine the effect emissions from the stationary source or facility may have on the air quality of the area potentially impacted by the source. IDAPA 58.01.01.211.01(d).

70. DEQ received comments from the Nez Perce Tribe, EPA Region 10, ICL, and SSFS urging the PTC to require ambient air monitoring to verify the SGP's compliance with the NAAQS and TAPs increments. But DEQ declined, stating in the Response to Comments (pg. 16): "DEQ disagrees that a PM/PM_{10} ambient monitoring network is necessary to make the PTC practically enforceable." DEQ states in the Response to Comments that any violation of the permit would be processed in accordance with DEQ's enforcement procedures manual.

71. However, without ambient air monitoring, it will be impossible for DEQ to assess whether the SGP's operation is in compliance with NAAQS and TAPs increments at any given time. Ambient air monitoring is necessary because of the large uncertainty surrounding dust control efficiency and emissions factors associated with the SGP for PM_{10} and arsenic, as well as

the lack of enforceable permit conditions for many important variables, as already described in this Petition.

H. DEQ's Improper Use of Emission Factors for Ore Processing

72. To estimate emissions from the SGP's ore processing units, DEQ used AP-42 emission factors from Section 11.19 Crushed Stone Processing, instead of using emission factors from AP-42 Section 11.24 Metallic Minerals Processing. The Crushed Stone Processing emission factors apply to non-metalic mineral processing. The Metallic Mineral Processing emission factors are more representative of the SPG's gold mining. As estimated in the EPA Letter from August 10, 2023, had DEQ instead used the Metallic Minerals Processing emission factors for ore crushers 1 through 13, potential PM emissions from just those units exceeds 800 tons per year, which is multiple times higher than the 250 tons per year threshold for minor source permitting. When it chose to use the Crushed Stone Processing emission factors, DEQ failed to demonstrate the AP-42 Crushed Stone Processing emissions factors are representative and appropriate to use for the SGP and failed to consider or explain this massive difference in emissions had it instead used the Metallic Minerals Processing emission factors.

73. Similarly, to estimate emissions from the SGP's Lime Plant, DEQ again used non-metallic mineral processings emission estimates from AP-42 Section 11.24, instead of using EPA's emission factors for lime manufacturing in Section 11.17. As estimated in the EPA Letter from August 10, 2023, had DEQ used Section 11.17 emission factors for Lime Plant units LS3/LS4 (primary Screen/Secondary Crusher), potential emissions would exceed 100 tons of PM per year for those units alone. Similarly, as estimated int eh EPA Letter, applying Section 11.17 emission factors to Lime Plant unit LS5 (secondary screen), another 128 tons of PM per year could be emitted. But DEQ chose, instead, to use Section 11.24 emission factors without

demonstrating that doing so was accurate, and without acknowledging the large difference in emissions had it used other emission factors for the Lime Plant.

74. The use of the AP-42 must be done with careful consideration, per the fifth (and most recent) edition of AP-42:

> "Use of these (AP-42) factors as source-specific permit limits and/or as emission regulation compliance determinations is not recommended by EPA. Because emission factors essentially represent an average of a range of emission rates, approximately half of the subject sources will have emission rates greater than the emission factor and the other half will have emission rates less than the factor. As such, a permit limit using an AP-42 emission factor would result in half of the sources being in noncompliance."

Furthermore, AP-42 also warns:

> "The extent of between-source variability that exists, even among similar individual sources, can be large depending on process, control system, and pollutant. Although the causes of this variability are considered in emission factor development, this type of information is seldom included in emission test reports used to develop AP-42 factors. As a result, some emission factors are derived from tests that may vary by an order of magnitude or more. Even when the major process variables are accounted for, the emission factors developed may be the result of averaging source tests that differ by factors of five or more."

75. The EPA Letter recommends the use of different AP-42 emission factors than those used by Perpetua. When given multiple opportunities through draft PTC public comment to provide a reasoned basis for the use of Perpetua's preferred AP-42 emission factors, DEQ failed to provide any justification. In choosing to accept the unjustified use of Perpetua's preferred AP-42 emission factors, IDEQ's decision to use Perpetua's preferred AP-42 emission factors was arbitrary and capricious.

76. IDEQ did not consider additional emission quantification techniques including stack/enclosure testing, vendor guarantees and stack/enclosure test data from similar facilities, optical remote sensing, or material balance calculations, all of which are emission quantification techniques recommended by the EPA when AP-42 emission factors may not be appropriate.

77. Higher PM emissions from the ore processing and lime plant units could contribute to a violation of the PM/PM_{10}/$PM_{2.5}$ NAAQS and the arsenic AACCs. These higher emissions could also exceed the thresholds under the Prevention of Significant Deterioration ("PSD") permitting pro.

78. PSD permitting generally applies to new or modified stationary emissions sources that have the potential to emit (generally defined has having the legal, *i.e,* permitted, and practical ability to emit at a certain level) more than 250 tons per year of a criteria pollutants (for a specific list of facilities, including lime processing plants, that threshold is reduced to 100 tons per year). Facilities subject to PSD permitting require: installation of the "Best Available Control Technology" (BACT); an airshed level air quality analysis; an additional impacts analysis; and prescribed public involvement. As per the EPA, "PSD permitting is designed to protect public health and welfare; preserve, protect, and enhance the air quality in national parks, national wilderness areas, national monuments, national seashores and other areas of special national or regional natural, recreational, scenic, or historic value; insure that economic growth will occur in a manner consistent with the preservation of existing clean air resources; and assure that any decision to permit increased air pollution in any area to which this section applies is made only after careful evaluation of all the consequences of such a decision and after adequate procedural opportunities for informed public participation in the decision making process." PSD permitting is generally required for only the most serious sources for air pollution that will have significant impacts on air quality.

79. Based on the flaws in DEQ's issuance of the PTC described above, DEQ's action is in violation of these provisions of the Idaho Air Rules, the Clean Air Act, and EPA's Clean

Air Act regulations, and is otherwise arbitrary, capricious, made on unlawful procedure, and an abuse of discretion and must be reversed.

RELIEF REQUESTED

80. An agency action, like DEQ's issuance of the PTC, may be reversed if it is in violation of constitutional or statutory provisions, is in excess of statutory authority, is made on unlawful procedure, or is arbitrary, capricious or an abuse of discretion. I.C. § 67-5279. When an agency action is not affirmed, it shall be set aside, in whole or in part, and remanded for further proceedings as necessary. *Id.*

81. As stated above, under the Idaho Air Rules, DEQ must not issue a PTC unless it determines: (1) "the stationary source or modification would comply with all applicable local, state or federal emission standards"; (2) "the stationary source would not cause or significantly contribute to a violation of any ambient air quality standard"; and (3) "the emissions of toxic air pollutants from the stationary source or modification would not injure or unreasonably affect human or animal life or vegetation as required by Section 161." IDAPA 58.01.01.203. Prior to issuing a permit to contruct, DEQ must provide an opportunity for public comment by making available DEQ's proposed action together with the information provided by the applicant and with DEQ's analysis. IDAPA 58.01.01.209.c. To ensure compliance with the NAAQS and other air pollution control strategies, the Clean Air Act and EPA's Clean Air Act regulations require state air rules like DEQ's: to include "enforceable emission limitations" and other measures, 42 U.S.C. § 7410(a)(2)(A); to include a "program to provide for the enforcement" of such measures, and to regulate the construction of any stationary source, *id.* § 7410(a)(2)(C); to "set forth legally enforceable procedures" for determining whether the construction of a facility will comply with control strategies and NAAQS, 40 C.F.R. § 51.160(a); to require sufficient information needed

"to make the determination" whether the facility will comply with air pollution control strategies and the NAAQS, i*d.* § 51.160(c); and to provide opportunity for public comment on information submitted by the applicant and on the agency's analysis of the effects to air quality. *Id.* § 51.161(a). Based on the flaws in DEQ's issuance of the PTC described above, DEQ's action is in violation of these provisions of the Idaho Air Rules, the Clean Air Act, and EPA's Clean Air Act regulations, and is otherwise arbitrary, capricious, made on unlawful procedure, and an abuse of discretion and must be reversed.

82. By issuing the PTC in its current form, DEQ failed to adequately protect the public and environment from harmful air pollution causing injury to the Nez Perce Tribe, ICL, SSFS, and their members and supporters. To redress these injuries, Petitioners respectfully request the Board set aside and remand the PTC and direct DEQ to correct the following errors prior to issuing any new or revised PTC:

Ore Haul Road PM_{10} & Arsenic Emissions

A. DEQ must develop and include in the PTC enforceable permit conditions for the maximum average empty weight of ore haul trucks, the maximum average loaded weight of ore haul trucks, the maximum total number vehicle miles traveled annually by ore haul trucks, the silt content of the roadbed, the arsenic content of the silt in the roadbed, and any other important variables affecting the SGP's fugitive emissions of PM_{10} and arsenic from vehicle traffic on mine haul roads. To develop such permit conditions and ensure compliance with the NAAQS and TAP limits, DEQ must reevaluate and recalculate fugitive emissions of PM_{10} and arsenic.

B. Silt and arsenic levels should be included as permit conditions and monitored regularly *in situ,* rather than from stockpiles as applied to the roadbed.

C. Instead of assuming 120 days of recordable precipitation at the SGP as a variable within ore haul road fugitive PM emission calculations, as done by the applicant based off general geographic guidance from AP-42 chapter 13.2.2-1, DEQ must recalculate all fugitive emissions after analyzing local meteorological data sources to determine a more accurate and representative number of days with recordable precipitation.

FDCP, AMP, O&M Manual, & HRCP

D. DEQ must require Perpetua to submit the FDCP, AMP, O&M Manual, and HRCP (collectively, "Plans"), must provide for public comment on the Plans, must review and revise Plans to ensure the SGP's emissions comply with IDAPA 58.01.01.203, and must incorporate the Plans as enforceable PTC conditions.

Arsenic Averaging

E. DEQ must remove the 5-year averaging for arsenic emissions, the averaging of estimated annual ambient modeling impacts across two multi-year scenarios, and the 16/70 life of mine versus lifetime exposure adjustment for the SGP's maximum arsenic ambient concentration it used to assess arsenic TAPs compliance. DEQ must use the SGP's highest 1-year arsenic emission rates for each scenario evaluated and repeat the modeling analyses using these rates. DEQ must use the maximum annual ambient arsenic concentration from the single emission scenario producing the highest annual concentration for any 1-year as the point of compliance. *See* IDAPA 58.01.01.210.03b ("The point of compliance is the receptor site that is estimated to have the highest ambient concentration of the toxic air pollutant of all the receptor sites that are located either at or beyond the facility property boundary or at a point of public access . . . ."). DEQ must assess the impact of the SGP's maximum 1-year annual emissions from the single emission configuration by comparing to the T-RACT AACC for arsenic (10 times the

AACC value published in IDAPA 58.01.01.586), without averaging over multiple years, and without adjusting for the alleged 16-year life of the mine or the 70-year lifetime exposure.

Ambient Air Boundary Monitoring

F. As part of any PTC for the SGP, DEQ must require ambient air boundary monitoring, as provided for by IDAPA 58.01.01.211.01(d), to ensure compliance with the NAAQS and the TAPs increments. DEQ must require Perpetua to submit an ambient air boundary monitoring plan ("AABMP"), must take public comment on the AABMP, must review and revise the AABMP, and must incorporate the AABMP as enforceable PTC conditions. At a minimum, the AABMP must provide a strategy for monitoring the ambient air concentrations of PM_{total}, PM_{10}, $PM_{2.5}$ and arsenic at the SGP's ambient air boundary. The AABMP must be developed according to best industry and regulatory practices, consulting contemporary sources (e.g., DEQ or EPA guidance, similarly established plans for other state permits, etc.). At a minimum, monitoring stations must be required for areas of the ambient air boundary in which DEQ ambient air modeling results (specifically results using operating scenario W3 and BULKRN meteorological data) show receptors with 24-hour PM_{10} or arsenic concentrations within 70% of the applicable NAAQS or AACC (without consideration to multi-year emissions averaging and 16/70 adjustment).

Environmental & Economic Impacts of Arsenic Control Technology

G. DEQ must require Perpetua to update their T-RACT analysis to include analysis of "environmental impacts caused by the control technology that cannot be mitigated, including, but not limited to, water pollution and the production of solid wastes," including the use of magnesium chloride and its aquatic life and tree toxicity effects, as well as using arsenic-contaminated water sources for dust suppression. IDAPA 58.01.01.210.14.c.ii. DEQ must also

require the updated T-RACT to adequately address the "economic feasibility of a control technology or other requirement, including the costs of necessary mitigation measures, for a particular source," including detailed consideration of the economic feasibility of paving haul roads to better control fugitive dust emissions. IDAPA 58.01.01.210.14.d. DEQ must provide the updated T-RACT demonstration for public comment, must review and revise the T-RACT demonstration, and must incorporate enforceable PTC conditions from the T-RACT demonstration in the PTC.

Accurate Emissions Factors

H. DEQ must develop, scientifically support, and use representative emission factors for the SGP's ore processing. DEQ must also develop, scientifically support, and use representative emission factors for the SGP's lime plant. Using these representative emission factors, DEQ must ensure the SGP complies with the applicable NAAQS, AACCs, and PSD requirements, including by requiring additional enforceable emission limits and/or requiring a PSD permit.

CONCLUSION

83. When it issued the PTC for the SGP, DEQ violated the federal Clean Air Act, EPA's Clean Air Act regulations, and the Idaho Air Rules; and it acted arbitrarily, capriciously, and on unlawful procedure and abused its discretion under I.C. § 67-5279. Accordingly, the Board should vacate and withdraw the PTC and remanded to DEQ to correct all errors.

Case Docket No. 0101-22-01

JOINT OPPOSITION TO PETITIONERS' MOTION TO AMEND CONTESTED CASE PETITION

The Idaho Department of Environmental Quality (the "Department") and Perpetua Resources Idaho, Inc. ("Perpetua") respectfully submit this opposition to Petitioners' Motion to Amend Contested Case Petition.

I. INTRODUCTION

Petitioners seek to amend their First Amended Petition to add claims that the Department erred in determining that the Stibnite Gold Project is a minor source instead of a major source under the Prevention of Significant Deterioration program of the Clean Air Act ("CAA"). Petitioners' motion to amend is untimely because this proceeding has now been pending for more than a year and is days away from a hearing on competing summary judgment motions, reflects avoidable delay because the proposed claims are based on evidence that was readily available to Petitioners when they initiated this contested case proceeding, and prejudices the Department and Perpetua because significant work was performed to narrow the claims subject to review and brief those claims for summary judgment. Accordingly, Petitioners motion for leave to amend should be denied.

II. ARGUMENT

The Idaho Rules of Administrative Procedure of the Attorney General and Rule 15(a) of the Idaho Rules of Civil Procedure provide the Hearing Officer discretion to allow pleadings to be amended. *See* IDAPA 04.11.01.305. However, the Hearing Officer need not grant leave to amend when the amendment will cause prejudice to the opposing party, is sought in bad faith, produces an undue delay in litigation, or is futile. *See Zeyen v. Pocatello/Chubbuck Sch. Dist. No. 25*, 165 Idaho 690, 695, 451 P.3d 25, 30 (2019). A Hearing Officer is well within his discretion to deny leave to amend when the party seeking leave to amend could have raised the claims in its original Petition, but failed to do so. *See id.* at 696; *accord Scannell v. Wash. State*

Bar Ass'n, 671 F. App'x 529, 531 (9th Cir. 2016) (upholding denial of leave to amend where amendment was based on previously available evidence).

A. Petitioners' proposed amendment is untimely, prejudicial, and based on previously available evidence.

The Department issued the final air quality Permit to Construct on June 17, 2022. In July 2022, Petitioners filed their Petition to Initiate Contested Case and subsequently filed a First Amended Petition in January 2023. Following the First Amended Petition, the parties meet and conferred and filed a proposed scheduling order, which the Hearing Officer entered on January 19, 2023. The parties did not contemplate any further amendment of pleadings and thus did not include any such deadline. The parties then exchanged discovery requests and eventually filed cross motions for summary judgment on Petitioners' First Amended Petition. Summary judgment briefing began on April 4, 2023, and was completed on June 23, 2023. A hearing on the pending motions for summary judgment is set for September 21, 2023.

Now over a year after the original Petition was filed, seven months after the First Amended Petition was filed, two months after briefing on summary judgment was completed, and less than two weeks before oral argument is scheduled, Petitioners move to amend their contested case petition for the second time. Petitioners move to amend their petition again based on what they view as newly discovered evidence, a letter from the U.S. Environmental Protection Agency ("EPA") to the Department, dated August 10, 2023 (the "EPA Letter"). The EPA Letter, however, does not contain newly discovered evidence, and Petitioners motion to amend is untimely and prejudicial because the substance of the proposed amendment was within the original, existing record.

In the proposed second amended petition, Petitioners allege that the Department erred in determining that the SGP is a synthetic minor stationary source instead of a major stationary

source. *See* Petitioners' Motion to Amend Contested Case Petition ("Pet. Mot.") at 1; *see also id.*, Attach. 1 ("Proposed Petition") ¶¶ 72-79. Petitioners' Proposed Petition alleges that the Department used the wrong emission factors in estimating the SGP's potential to emit. *Id.* Petitioners further allege that the Department failed to consider additional stationary source emission quantification techniques, which may have more accurately determined emissions from the SGP. *Id.* ¶ 76. Petitioners allege that higher emissions may exceed the thresholds under the Prevention of Significant Deterioration program. *Id.* ¶ 77.

Although Petitioners justify the timing of the proposed amendment with the arrival of the EPA Letter, this is disingenuous. Petitioner Nez Perce Tribe presented a similar question to the Department during the public comment period on the draft Permit. *See* PET 555, 566. Additionally, as the EPA Letter recognizes repeatedly, EPA already provided these comments to the Department, and the Department found them meritless. EPA repeatedly noted that the Department chose the wrong emission factors, PET 573, 576-77, and failed to consider additional emission quantification techniques, *id.*; *see also id.* at 574, 575. Petitioners failed to include the proposed claim in the original Petition or First Amended Petition. Now Petitioners seek an opportunity to expand the contested case review.

Petitioners contend that their additional claims do not rely on the EPA Letter being admitted into evidence and will not require more discovery. Pet. Mot. at 4 n.2. If that is true, Petitioners had all the information they needed to assert this claim in 2022 when the original Petition was filed, in 2023 when the First Amended Petition was filed, and certainly since the close of discovery in February 2023. Yet Petitioners failed to assert the claim in original and amended petitions and then waited six months after discovery closed to seek leave to amend. Petitioners were aware of these additional facts since well before they filed their original

Petition. Comments from both the Nez Perce Tribe and the EPA provided Petitioners with ample notice of these claims, yet Petitioners did not act until the EPA Letter. "[P]rejudice may be presumed to flow from unexcused and unreasonably delay." *Roberts v. Verner*, 116 Idaho 575, 578, 777 P.2d 1248, 1251 (Ct. App. 1989).

B. Granting leave to amend will cause undue delay and unfair prejudice to the Department and Perpetua.

Again, Petitioners waited until after briefing on summary judgment was completed and until 10 days before oral argument to file their motion for leave to amend. Petitioners did not present this claim in their summary judgment motions. Allowing this amendment at this late date will result in undue delay in final resolution of the merits of this contested case proceeding.

Petitioners argue that the amendment would not cause significant delay because the new claim is "independent of the other claims and can be resolved in its own summary judgment proceeding." Yet Petitioners also seek to stay the contested case and delay the current summary judgment hearing. Granting leave to amend will unquestionably cause undue delay of the ultimate resolution of this case. This is especially egregious where Petitioners had all the facts they needed to raise this new claim long before Petitioners' filed their original Petition and long before the parties briefed the pending summary judgment motions. *See AmerisourceBergen Corp. v. Dialysist W., Inc.*, 465 F.3d 946, 953 (9th Cir. 2006) ("[I]n evaluating undue delay, we also inquire 'whether the moving party knew or should have known the facts and theories raised by the amendment in the original pleading.'" (*quoting Jackson v. Bank of Hawaii*, 902 F.2d 1385, 1388 (9th Cir. 1990)).

While Petitioners argue there will be no unfair prejudice, they ignore that granting leave to amend will require the Department and Perpetua to expend significant resources in analyzing Petitioners' new claim and briefing additional motions for summary judgment. Petitioners

diminish the impact of prejudice on Perpetua stating that there are many permits yet to be obtained. Pet. Mot. at 5. This indifference ignores that Perpetua will be prejudiced by the ongoing legal uncertainty related to the Permit. *AmerisourceBergen Corp.*, 465 F.3d at 953 (upholding denial of leave to amend where plaintiff sought to add new legal theory to case even though discovery was still open).The merits of Petitioners' motion to amend must be evaluated in the context of these proceedings, not the broader context of the SGP development.

III. CONCLUSION

For the foregoing reasons, the Department and Perpetua respectfully request that the Hearing Officer deny Petitioners' Motion to Amend Contested Case Petition.

Case Docket No. 0101-22-01

JOINT RESPONSE IN OPPOSITION TO PETITIONERS' MOTION TO SUPPLEMENT WITH AUGUST 10, 2023 EPA LETTER

The Idaho Department of Environmental Quality (the "Department") and Perpetua Resources Idaho, Inc. ("Perpetua") respectfully submit this response in opposition to Petitioners' Motion to Supplement with August 10, 2023 EPA Letter. The Department and Perpetua also incorporate by reference the argument contained in their Joint Motion *in Limine* to Exclude Communications from U.S. EPA Sent After Permit was Issued (filed August 28, 2023).

I. INTRODUCTION

On August 10, 2023, the Administrator for Region 10 of the United States Environmental Protection Agency ("EPA") transmitted the letter referred to in Petitioners' Motion to Supplement to the Department (the "EPA Letter"). Petitioners' Motion to Supplement should be denied for the following reasons: First, because the contents of the letter are either entirely irrelevant or, where relevant, repeat EPA's and Petitioners' comments that are already contained in the contested case record. EPA is not a party to the pending contested case proceeding. Second, the EPA Letter was received over one year after the Department issued its Permit to Construct to Perpetua Resources Idaho, Inc. on June 17, 2022 (the "Permit"), over one year after Petitioners filed their contested case petition, and months after briefing on the motions for summary judgment concluded. Finally, the Department did not rely on the contents of the EPA Letter in its deliberations or in the development of the Permit and nothing in the EPA Letter affects the administrative standard of review of the Department's action in this contested case proceeding under the Board of Environmental Quality's contested case rules. Accordingly, Perpetua and the Department respectfully request that the Hearing Officer deny Petitioners' Motion to Supplement the Record.

II. ARGUMENT

The Hearing Officer has discretion to supplement the record with newly discovered evidence, where that evidence was not reasonably available to the moving party prior to the request to supplement, and the newly discovered evidence is relevant and not cumulative. *See Roberts v. Bonneville County*, 125 Idaho 588, 592, 873 P.2d 842, 846 (1994). However, a party cannot supplement the record with legal arguments that could have been made previously or with facts that could have been offered, but were not. *See Zimmerman v. City of Oakland*, 255 F.3d 734, 740 (9th Cir. 2001).

A. The contents of the EPA Letter are not new evidence

Although the EPA Letter itself was sent well after briefing on summary judgment concluded, the contents of the EPA Letter are not new evidence. As EPA repeatedly references in the letter, much of its commentary was previously provided to the Department in the form of comments on the various drafts of the Permit. *See* EPA Letter, Attach. at 3, 5, 6, 7, 14, 15, 16, 17, 18; PET 549-634. The EPA Letter takes issue with some of the Department's responses to its comments, and slightly refines its previous comments, but it does not provide new evidence that was previously unavailable to the Petitioners.[1] Instead, the EPA Letter recycles arguments previously advanced by the EPA and, as to at least one issue, by Petitioners, referring to elements contained in the administrative record.

B. Portions of the EPA Letter are irrelevant and highly prejudicial to this proceeding

In the EPA Letter, EPA suggests that the Department underestimated emissions from stationary sources at the Project for purposes of determining major stationary source permitting

[1] The EPA Letter is akin to an expert report in that it provides no actual evidence, only opinions based on the evidence available to EPA. If the EPA Letter were an expert report, it would clearly be untimely.

thresholds. Namely EPA suggests the Department underestimated emissions from ore processing units and the lime plant based on what, in its view, was consideration of the wrong chapters of AP-42 Compilation of Air Pollutant Emission Factors ("AP-42"). EPA Letter, Attach. at 3-5. AP-42 provides emissions factors to be used in determining the potential for a stationary source to emit regulated pollutants. *See id.* at 2. Although EPA previously presented these concerns in its comments to the Department, *id.* at 3, 5, Petitioners did not raise a claim relating to the Department's choice of emissions factors in their Petition or First Amended Petition. EPA's opinions on the use of emissions factors are irrelevant to this contested case proceeding. *See generally* Petition (filed July 22, 2022); First Amended Petition (filed Jan. 11, 2023).

EPA also previously commented that the Department should impose either source-wide emission limits applicable to all emission units or unit-specific emission limits. EPA Letter, Attach. at 6. Again, although these comments were in the record prior to Petitioners initiating this contested case, Petitioners failed to raise claims relating to source-wide emission limits or unit-specific emission limits in their Petition or First Amended Petition. EPA's opinions on the type of emission limits to include are irrelevant to this proceeding.

Finally, although Petitioners suggest that EPA's comments related to the ambient air boundary are relevant to their claims, Petitioners' Mot. at 3, they are not. The EPA Letter primarily concerns the enforceability of requirements to preclude access at secondary access points, and to preclude public access from the overall ambient air boundary by reliance on natural features. EPA Letter, Attach. at 18. Entirely different is Petitioners' claim that the ambient air boundary should specifically include the proposed through road by which Perpetua will control access by certain individuals who pass through the site. *See* First Amended Petition ¶¶ 58-65. Again, although these facts were in the existing record prior to Petitioners initiating

this contested case, Petitioners did not raise claims relating to overall site access and control of the ambient air boundary in their Petition or First Amended Petition. EPA's opinions on the overall boundary controls are irrelevant to this proceeding.

Even under the permissive rules for the admission of evidence under the Idaho Rules of Administrative Procedure of the Attorney General, evidence must still be relevant. IDAPA 04.11.01.600 ("The presiding officer … may exclude evidence that is irrelevant …."). As described above, the EPA Letter is irrelevant to Petitioners' claims and should be excluded.

Perpetua and the Department will be prejudiced by the admission of this evidence because while Petitioners' review of the existing record could have led to similar claims, no such claims were raised as issues in this case. And no such claims were addressed in the parties' summary judgment briefs. To the extent that Petitioners, at the eleventh hour, now attempt to expand their claims based on the EPA Letter, the substance of which was available to them in 2022 and prior to August 10, 2023, Perpetua and the Department have not had the opportunity to brief these issues.[2]

C. The rest of EPA's comments are unduly repetitious and cumulative and should be excluded

As Petitioners recognize in their motion, to the extent EPA's comments are relevant they "confirm[] the concerns EPA already raised in its public comments on the draft PTC, and which Petitioners have already raised" making EPA's opinions repetitious. Specifically, the EPA Letter addresses the Department's approach to recordkeeping and reporting, EPA Letter, Attach. at 6, and estimation of and control of fugitive dust from haul roads, *id.*, Attach. at 14-16. For example,

[2] The Department and Perpetua address the prejudice inherent from the introduction of the EPA Letter this late into this contested case proceedings in their Joint Response in Opposition to Petitioners' Motion to Stay, filed herewith.

like the Petitioners, EPA repeats previously expressed opinions that the Permit does not contain sufficient conditions to ensure that Perpetua complies with the National Ambient Air Quality Standards ("NAAQS") for PM10. For increased enforceability of conditions that limit emissions, EPA directs the Department to require preparation of the Operations and Maintenance Plan, Haul Road Capping Plan, Fugitive Dust Control Plan, and Access Management Plan during the permit application review period and to publish those plans for public comment prior to issuing the Permit. Consistent with its delegated authority from EPA under the Clean Air Act, the Department thoroughly addressed its approaches to NAAQS compliance, to enforceability of the Permit, and to the plans in the Department's Responses to Comments and extensively in the parties' briefing. *See, e.g.*, DEQ's Response to Petitioners' Motion for Summary Judgment and Brief in Support of Cross Motion at 13-16 (May 12, 2023); Pet. Br. at 19, 26-28; Perpetua Memorandum in Support of Intervenor-Respondent's Motion for Summary Judgment at 22-29, 32-37 (May 12, 2023). The EPA Letter provides no new information on these claims.

To the extent that EPA's comments are relevant to Petitioners' claims, they are cumulative and unduly repetitious of EPA's, and Petitioners', previous comments.

Additionally, EPA takes issue with how the Department responded to EPA's previous comments on the draft Permit. These opinions are best left to interagency communications. The question presented in the parties' cross motions for summary judgment is not whether the Department satisfied EPA in its response to comments, but whether the Department acted arbitrarily and capriciously, abused its discretion, or acted contrary to the Idaho Air Rules. As addressed in Perpetua's Motion for Summary Judgment, EPA does not have authority to "question the wisdom of a State's choices of emission limitations." Memorandum in Support of Perpetua's Motion for Summary Judgment at 15 (May 12, 2023) (*quoting Train v. Nat. Res. Def.*

Council, Inc., 421 U.S. 60, 79 (1975)). Therefore, while EPA's comments may overlap with Petitioners' evidence and arguments, EPA's opinions are best excluded from this contested case proceeding to determine whether the Department erred in issuing the Permit based on the applicable standard of review.

III. CONCLUSION

For the foregoing reasons, Perpetua and the Department respectfully request that the Hearing Officer deny Petitioners' Motion to Supplement with August 10, 2023 EPA Letter.

DATED: September 11, 2023.

v.

IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY,

Respondent,

and

PERPETUA RESOURCES IDAHO, INC.,

Intervenor-Respondent.

Case Docket No. 0101-22-01

JOINT RESPONSE IN OPPOSITION TO PETITIONERS' MOTION TO STAY THE CASE

The Idaho Department of Environmental Quality (the "Department") and Perpetua Resources Idaho, Inc. ("Perpetua") respectfully submit this response in opposition to Petitioners' Motion to Stay the Case.

I. INTRODUCTION

The Department and Perpetua oppose Petitioners' request for a stay of this contested case proceeding. The basis for the stay request is purportedly to allow the Department time to meet with the United States Environmental Protection Agency ("EPA") regarding the concerns raised in the Regional Administrator's August 10, 2023 letter (the "EPA Letter"). A stay is not warranted and Petitioners' motion should be denied.

First, EPA is clearly not a party to this legal proceeding, the requested meeting has not been scheduled between the Department and EPA (although the Department has suggested a date that falls in mid-October), and no outcome from a proposed future meeting has any impact on these issues before the Hearing Officer. Moreover, the EPA Letter presents concerns that, while previously raised by EPA and addressed by the Department, are not part of Petitioners' contested case petition. How and when the two agencies communicate about EPA's latest correspondence is not relevant to this ongoing proceeding initiated by Petitioners.

Second, this case has been pending for well over a year. The parties have spent significant time and expense fully briefing the summary judgment motions, which are now pending and set for hearing on September 21. Further delay of this contested case proceeding will prejudice the Department and Perpetua by delaying a final decision on the merits of the Permit. Accordingly, the Department and Perpetua respectfully request that Petitioners' motion to stay be denied.

II. ARGUMENT

The decision whether to grant or deny a stay is a matter vested in the discretion of the Hearing Officer. *See Cont'l Cas. Co. v. Brady*, 127 Idaho 830, 834, 907 P.2d 807, 811 (1995). The party seeking a stay bears the burden of establishing its need. *See Clinton v. Jones*, 520 U.S. 681, 708 (1997).

Petitioners argue that a stay may allow time for the Department and EPA to meet and resolve EPA's concerns, which may address Petitioners' concerns. There are several problems with Petitioners' request. First, the EPA Letter addresses issues that are not raised in Petitioners' contested case petition. The EPA Letter concerns three issues: (1) whether the Stibnite Gold Project is a major stationary source under the Clean Air Act ("CAA"); (2) whether fugitive dust from the Project's haul roads will cause or contribute to a violation of the PM10 NAAQS; and (3) whether the Permit includes sufficient measures to exclude the general public from the entirety of the Project for purposes of the ambient air boundary. Only the second issue is raised and addressed in Petitioners' contested case petition.[1]

Second, Petitioners can only speculate about interagency interactions that may or may not occur in response to the EPA Letter. Unless Petitioners or their clients are directly involved in the discussions between the Department and EPA, then they can only guess how or when the discussions might, at some point in the future, resolve their concerns related to the Permit. Meanwhile, Petitioners' claims are live in this proceeding. Motions for summary judgment are fully briefed (and have been since June 23, 2023) and set for oral argument in 10 days. The most

[1] While Petitioners challenge the ambient air boundary in their contested case, they challenge the boundary based on the Stibnite Access Route. They did not raise the same issue EPA addresses, namely whether the Permit conditions are sufficiently enforceable to preclude physical or practical access by the general public to the entire ambient air boundary for the Project.

just and efficient path forward is to hear the summary judgment oral arguments on September 21, 2023, and decide the merits of Petitioners' claims, applying the legal standard for review of the Department's actions.

As Perpetua explained in its Motion for Summary Judgment, the CAA creates a partnership between the federal government and the states to prevent and control air pollution. *See* Memorandum in Support of Perpetua's Motion for Summary Judgment and in Opposition to Petitioners' Motion for Summary Judgment (May 12, 2023) at 14 (citing *Cal. Dump Truck Owners Ass'n v. Nichols*, 784 F.3d 500, 502 (9th Cir. 2015)). Although EPA is charged with setting the National Ambient Air Quality Standards ("NAAQS") and approving Idaho's State Implementation Plan ("SIP"), EPA has "no authority to question the wisdom of a state's choices of emission limitations." *Id.* at 15 (quoting *Train v. Nat. Res. Def. Council, Inc.*, 421 U.S. 60, 79 (1975)). Thus, while the Department welcomes a constructive conversation with EPA, it is ultimately responsible for developing and enforcing the Permit.

Consistent with the CAA partnership, EPA submitted multiple comments on the Permit during the three-year review process, and the Department responded in the normal course of permit issuance. *See generally* PET 549-634. Then, without any precedent known to the Department and Perpetua, the EPA Letter repeats many of those comments over a year after issuance of the Permit and just before the summary judgment hearing in this live contested case proceeding.

The Department is currently evaluating the legal and technical bases of the feedback in the EPA Letter and intends to schedule a meeting with EPA after a thorough evaluation. Declaration of Tiffany Floyd ("Floyd Decl.") ¶ 4; *id.* Ex. A. The earliest the Department will be able to meet with EPA is October 13; however, no meeting is yet confirmed. *See* Floyd Decl. ¶ 5,

Ex. A. The Department also expects that more time will be needed following a meeting with EPA to determine what, if any, action the Department may take in response. There is only speculation currently about the merits of the comments presented in the EPA Letter, the Department's responses, and the timing of future interagency communications. The outcome of the discussions between EPA and the Department is unknown and far from certain. There is only delay, uncertainty, and inaction if the pending contested case is postponed by a stay of this proceeding.

Third, when determining whether to grant a stay, courts weigh competing interests including (1) the possible damage which may result from the granting of a stay, (2) the hardship or inequity that a party may suffer in being required to go forward, and (3) the orderly course of justice measured in terms of simplifying or complicating issues, proof, and questions of law which could be expected to result from a stay. *See CMAX, Inc. v. Hall*, 300 F.2d 265, 268 (9th Cir. 1962).

Here, granting a stay will further delay resolution of this contested case for issues that are simply not before the Board and will deny Perpetua and the Department certainty regarding the legal sufficiency of the Permit under the Idaho Air Rules. This directly conflicts with Idaho's general policy favoring a decision on the merits. *See Dorion v. Keane*, 153 Idaho 371, 376, 283 P.3d 118, 123 (Ct. App. 2012). Although Petitioners have not moved to stay the effectiveness of the Permit, these proceedings cast a cloud over the sufficiency of the Permit and create significant legal uncertainty that can only be resolved through decisions on the merits.

Petitioners will not face any hardship or inequity from going forward in this contested case. Petitioners filed their contested case petition in July 2022 and an amended petition in January 2023. Discovery and summary judgment briefing was completed months ago; the only

thing that is left is oral argument on September 21, 2023, and decisions on the pending cross motions for summary judgment. With their motion for a stay at this stage of the contested case, Petitioners only seek to delay resolution of their claims and to maintain the cloud of uncertainty around the Permit.

Additionally, Petitioners raised claims that are absent from the EPA Letter, for example the Department's selection of T-RACT and averaging of arsenic emissions that have no analogue in the CAA and are not addressed in the EPA Letter. Therefore, no matter the outcome of any interagency communication, there are live and different issues remaining in this contested case.

A stay at this stage of the live contested case is unnecessary, inefficient, and prejudicial. Instead, the most efficient path forward is for the Hearing Officer to hear from the parties on September 21, 2023, to consider the issues that are directly at issue under the contested case petition, and to decide the merits of the pending cross motions for summary judgment. *See Posey v. Lake Pend Oreille Sch. Dist. No. 84*, No. CV05-272-N-EJL, 2007 U.S. Dist. LEXIS 7829, at *7 (D. Idaho Feb. 2, 2007) (reversed on other grounds) (denying stay where summary judgment fully briefed).

If the Hearing Officer stays this contested case pending resolution of the EPA Letter, the duration of any postponement is likely indefinite and will concern issues not raised in this contested case proceeding, the delay in an already extended legal process drags on, and the parties will still be required to litigate the remaining issues beyond the scope of the EPA Letter. A stay at this stage of a live contested case wastes the resources already devoted to this matter by the parties and exacerbates the uncertainly for Department and Perpetua.

III. CONCLUSION

For the foregoing reasons, Perpetua and the Department respectfully request that the Hearing Officer deny Petitioners' Motion to Stay the Case.

DATED: September 11, 2023.

STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047	Agency Case No. 0101-22-01
	OAH Case No. 23-245-01
NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON Petitioners, v. IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent, and PERPETUA RESOURCES IDAHO, INC., Intervenor.	DECLARATION OF TIFFANY FLOYD OPPOSING THE MOTION TO STAY

I, Tiffany Floyd, hereby declare under penalty of perjury pursuant to the law of the State of Idaho that the following is true and correct:

1. My name is Tiffany Floyd, and I am employed by the State of Idaho, Department of Environmental Quality ("the Department") as the Air Quality Division Administrator ("Air Administrator").

2. I have been working for the Department as the Air Administrator for 11 years.

3. On August 11, 2023, I received a letter from the EPA ("the EPA letter") regarding the Department's PTC for the Stibnite mine project. In that letter, the EPA requests an in-person meeting with appropriate permitting and legal staff.

4. At this time, the Department does intend to meet with the EPA to discuss its

concerns, which are currently under review by our permitting team and legal counsel.

5. The Department has offered to host a meeting with the EPA on October 13, 2023. That offer was extended by Director Byrne in a letter dated September 8, 2023. I have attached a true and correct copy of that letter to this declaration. At this time, no meeting date has been agreed upon.

6. The Department does not require or request a pause in these administrative proceedings to meet with the EPA and therefore opposes the Petitioners' motion to stay.

Exhibit A

1410 N Hilton Street
Boise, ID 83706 • (208) 373-0502

Brad Little, Governor
Jess Byrne, Director

September 8, 2023

Mr. Casey Sixkiller
Regional Administrator, Region 10
United States Environmental Protection Agency
1200 Sixth Avenue, Suite 155
Seattle, WA 98101

Dear Mr. Sixkiller,

I received your letter dated August 10, 2023, regarding Perpetua Resources Idaho, Inc.'s ("Perpetua") permit to construct. I feel it is important to respond by reiterating that the Idaho Department of Environmental Quality (DEQ) is confident that the permit issued to Perpetua complies with the Clean Air Act and protects air quality. It also incorporates countless hours of staff time that went into gaining an operational understanding of the site while developing the permit. The permit to construct utilizes well-established practices and processes that are consistent with numerous similar permits within Idaho and other states.

DEQ takes our responsibility to protect air quality seriously, as demonstrated by the fact that all airsheds within the state currently meet the national ambient air quality standards. In recent years, airsheds that historically did not meet or attain those standards have been brought into attainment, due in large part to DEQ's efforts. Additionally, various proactive and voluntary measures have been taken in airsheds approaching the health-based standards that have resulted in improved air quality. All of this has been accomplished amid unprecedented population growth, which has resulted in increased emission sources. Our Air Quality Division staff, including our Permitting Bureau, have worked tirelessly to get us to this point and proudly implement a successful federally approved state program.

If the intent of EPA's unprecedented interest in Perpetua's permit to construct is to change decades of commonly accepted approaches, practices, and processes, it should be done at a national level through the development of formal oversight plans, updated guidance, and proactive communication with states that are on the front lines of protecting air quality. It should not be done through a draft permit public comment period, or a letter sent 420 days after the issuance of a permit to construct.

Despite our frustration with the timing of the letter and overall approach, we have considered your request to meet to discuss EPA's concerns and have identified October 13, 2023, as the earliest date that the appropriate staff from my office would be available for a meeting in

Boise. If that date does not work for EPA, we would have to look at additional dates further out. I will have my executive assistant, Elaine Ganino, reach out to Ms. Fraser to follow up.

Sincerely,

Jess Byrne
Director

v.	)	ORDER ON MOTIONS RELATED TO RECENT EPA LETTER
DEPARTMENT OF ENVIRONMENTAL QUALITY,	)	
Respondent,	)	
and	)	
PERPETUA RESOURCES IDAHO, INC.,	)	
Intervenor.	)	

I. BACKGROUND

On August 10, 2023, EPA sent a letter to Idaho DEQ Director Jess Byrne, expressing three concerns regarding the air permit issued to Perpetua Resources in this matter (the "EPA Letter"). The Letter requests a meeting between EPA and DEQ representatives to discuss those concerns. Ultimately, the Letter suggests that DEQ should issue a revised permit. (*See* Mot. to Stay of 9/8/23, Ex. A, p. 1.) Issuance of the letter has spawned the following five motions from the parties:

On August 28, 2023, Perpetua Resources and DEQ filed a joint motion in limine requesting exclusion of the EPA Letter and any press releases about it from consideration in this proceeding.

On August 31, Perpetua and DEQ filed a motion to shorten the Petitioners' deadline to respond to the motion in limine and to expedite consideration of the motion in limine.

On September 1, the Petitioners filed two motions. One motion requests a stay of these proceedings, including postponing the September 21 summary judgment hearing and setting a status conference in October to discuss the status of this matter. The other motion requests supplementation of the record in this matter with the EPA Letter.

On September 8, the Petitioners filed a motion to amend their petition based upon one of the concerns expressed in the EPA Letter.

Based upon the August 31 motion, a status conference, and the impending summary judgment hearing, the hearing officer issued a scheduling order on September 6 establishing a truncated briefing schedule for the other four motions. Briefing is now complete and a decision on all four motions is appropriate.

II. LEGAL ANALYSIS

A. Petitioners' Motion to Amend Petition

Petitioners request leave to amend their petition based upon one of the concerns expressed in the EPA Letter. More specifically, according to EPA, "the Permit's emission limits are not adequate to limit the [SGP]'s potential to emit below the Prevention of Significant Deterioration permitting threshold…." (Mot. to Stay of 9/1/23, Ex. A, p. 1.) Based on that assertion, the Petitioners seek to add a new alleged error—that DEQ improperly used emission factors for crushed stone processing instead of those for metallic minerals processing. (*See* Mot. to Amend of 9/8/23, Att. 1, pp. 27-29, 34.)

1. Applicable Standards

The applicable administrative procedural rule states that, "[t]he presiding officer may

allow any pleading to be amended or corrected or any omission to be supplied." BEQ R.PROC. 003.05; AG R.PROC. 305. In the absence of additional standards in the administrative rules, presumably, this decision is within the sound discretion of the hearing officer. Reference to principles under the Idaho Rules of Civil Procedure is not mandated by AG Procedural Rule 052 but is still be helpful.

Were this proceeding governed by the judicial rules, the applicable rule would read: "In all other cases [*i.e.*, before trial and when there is no longer a right to amend], a party may amend its pleading only with the opposing party's written consent or the court's leave. The court should freely give leave ***when justice so requires***." IDA.R.CIV.PROC. 15(a)(2) (emphasis added). Due in part to this "when justice so requires" language, the Idaho Supreme Court has held that "the decision to grant or refuse permission to amend [a pleading] is left to the sound discretion of the trial court." *Jones v. Watson*, 98 Idaho 606, 570 P.2d 284, 288 (1977); *see also Zeyen v. Pocatello/Chubbuck School District No. 25*, 451 P. 3d 25, 29-32, 165 Idaho 690 (2019) (affirming denial of request to amend pleadings).

The courts recognize several situations in which it is appropriate to deny leave to amend pleadings. *See Clark v. Olsen*, 110 Idaho 323, 715 P.2d 993 (Idaho 1986) (*citing Foman v. Davis*, 371 U.S. 178, 182, 83 (1962)). "Undue delay and prejudice are proper standards on which to deny a motion to amend." *Spur Products Corp. v. Stoel Rives LLP*, 142 Idaho 41, 122 P. 3d 300, 304 (2005).

2. Analysis

The hearing officer finds that justice does not require amendment of the petition under these circumstances for two separate reasons. First, waiting this long to assert this new alleged error constitutes undue delay by Petitioners. The permit in this matter was issued on June 17,

2022, and these administrative proceedings have been pending since July 22, 2022. Under the stipulated scheduling order Petitioners agreed to, discovery opened on January 13, 2023, and the Petitioners had until April 14, 2023 to file their motion for summary judgment. (Sched. Order of 1/19/23, p. 2.) From the issuance of the permit to their summary judgment deadline, the Petitioners had 302 days to analyze the permit in detail for potential errors.

While Petitioners argue they "have not somehow been dilatory in moving to present the EPA Letter," in the opinion of the hearing officer, the period of time between the issuance of the EPA Letter and the filing of the motion to amend is not the relevant inquiry. This is because the EPA Letter is not a new event or changed circumstance. The Petitioners filed a very detailed initial petition in this matter which demonstrates a high level of understanding of federal and state air quality regulation and a high degree of scrutiny of the permitting process generally, and the permit issued to Perpetua specifically. (*See* Pet. to Initiate Contested Case of 7/22/22.)

In fact, during summary judgment, the Petitioners filed a declaration of counsel that included DEQ's response to comments as an exhibit. (Hurlbutt Decl. of 4/14/23, Ex. 3.) This includes responses by DEQ to multiple comments by EPA specifically dealing with emission factors and their impacts on the "potential to emit" calculation. (R., pp. PET573-577.) Regardless of whether these precisely mimic the concerns expressed in the EPA Letter, they were sufficient to put the Petitioners on notice of them.

Indeed, in their proposed amended petition, the Petitioners state that, "[w]hen given multiple opportunities through draft PTC public comment to provide a reasoned basis for the use of Perpetua's preferred AP-42 emission factors, DEQ failed to provide any justification." (Mot. to Amend of 9/8/23, Ex. A, p. 28, ¶ 75.) This acknowledgment that the public comment record references similar concerns expressed in the EPA Letter demonstrates there is no reason the

Petitioners could not have identified those concerns earlier in this proceeding.

Second, granting leave to amend the Petition in this matter would constitute undue prejudice to DEQ and Perpetua. On this issue, Petitioners first argue there will be no prejudice because "amendment…would not significantly delay the resolution of the case." (Mot. to Amend of 9/8/23, p. 4.) The hearing officer disagrees. If the pending motion were granted, DEQ and Perpetua would then need to file updated responsive pleadings, after which there would likely be additional discovery needed, another round of summary judgment briefing, additional declarations from DEQ staff members explaining their actions, another summary judgment hearing, and an order. This would likely add at least three months to the proceeding. In addition, this places an undue burden on DEQ and Perpetua to again mobilize resources for further case develop and briefing, after the parties agreed among themselves to an extended summary judgment schedule with generous deadlines. (*See* Stip. of 1/13/23; Sched. Order of 1/19/23.)

The Petitioners next argue that "[a]mending the petition will neither delay nor impact any of those needed decisions or permits [from various other agencies], nor delay construction or operation of the mine." (Mot. to Amend of 9/8/23, pp. 4-5.) The hearing officer understands the term "prejudice" to refer specifically to prejudice within the context of this administrative proceeding, not to the overall project. Moreover, the hearing officer finds the assertions regarding impacts to other permits and the timing of construction and operation of the SGP to be speculative and outside the scope and record of this proceeding.

3. Conclusion

Petitioners' motion for leave to further amend their petition in this matter based upon the EPA Letter is denied.

B. Petitioners' Motion for Stay

Petitioners request the hearing officer to vacate the summary judgment hearing scheduled for September 21, 2023 and stay these proceedings to allow time for DEQ to respond to the EPA Letter. Applicable procedural rules authorize stays of orders generally, either upon petition of a party or by the agency itself upon its own motion. *See* BEQ PROC.R. 003.22; AG PROC.R. 780. The hearing officer and parties agree this decision is within the sound discretion of the hearing officer pursuant to BEQ Procedural Rule 003.08 and AG Procedural Rule 413. (*See* Mot. to Stay of 9/1/23, p. 1; Joint Resp. in Opp. to Mot. to Stay of 9/11/23, p. 3.)

The question, then, is whether it is appropriate to stay the effectiveness of the Scheduling Order of January 19, 2023, which was based upon the January 13, 2023 joint motion and stipulation among the parties. Clearly, had the motion for leave to amend the petition been granted, some relief from the Scheduling Order would be necessary, though that does not necessarily require an outright "stay" of the proceedings. Regardless, having denied the motion to amend motion, the need to vacate the summary judgment hearing and stay the proceeding is much less compelling.

Admittedly, having to address the EPA Letter so close to the summary judgment hearing interferes with preparation for that hearing. However, that is an issue that applies similarly to everyone involved—DEQ, Perpetua, the Petitioners, and the hearing officer. Both Perpetua and DEQ strongly oppose further delay. Where the permit being challenged has been issued to Perpetua and the EPA Letter is addressed to DEQ, the hearing officer would need a more compelling need to delay the summary judgment hearing over their objections than mere interference with hearing preparation that affects all of the parties.

The Petitioners' motion to vacate the summary judgment hearing and stay this proceeding is denied.

C. Perpetua and DEQ's Motion in Limine; Petitioners' Motion to Supplement Record

For the most part, these two motions are two sides of the same coin: The Petitioners want the EPA Letter included in the record, and DEQ and Perpetua want it excluded. Therefore, this order will deal with both motions simultaneously.

Regarding the admissibility of evidence, the applicable procedural rule provides:

> ***Evidence should be taken by the agency to assist the parties' development of the record, not excluded to frustrate that development. The presiding officer at hearing is not bound by the Idaho Rules of Evidence.*** No informality in any proceeding or in the manner of taking testimony invalidates any order. ***The presiding officer, with or without objection, may exclude evidence that is irrelevant***, unduly repetitious, inadmissible on constitutional or statutory grounds, or on the basis of any evidentiary privilege provided by statute or recognized in the courts of Idaho. All other evidence may be admitted if it is of a ***type commonly relied upon by prudent persons*** in the conduct of their affairs. The agency's experience, technical competence and specialized knowledge may be used in evaluation of evidence.

BEQ PROC.R. 003.13; AG PROC.R. 600 (emphasis added).

As an initial matter, the parties disagree as to whether the EPA Letter constitutes inadmissible hearsay. However, the above rule clearly states that this decision is not governed by the Idaho Rules of Evidence and that any evidence "commonly relied upon by prudent persons" is admissible. Therefore, a detailed analysis of the hearsay rule and its exceptions is not necessary. Given EPA's critical role in administering the Clean Air Act, a "prudent person" may indeed rely on EPA's interpretation of its terms. Also, in proceedings that do not involve a jury as the fact-finder, the rules of evidence are generally more liberal. *See generally State v. Powell*, 120 Idaho 707, 819 P. 2d 561, 563-564 (1991). These factors all favor admissibility of the EPA Letter.

On the other hand, DEQ and Perpetua raise a valid concern: For any alleged errors that are not resolved on summary judgment, it is conceivable, perhaps even likely, that depositions

and testimony at a hearing on the merits will be necessary. Because EPA is not a party to these proceedings, DEQ and Perpetua would not have the opportunity to conduct discovery and cross-examination of EPA regarding the contents of the Letter. It would not be fair to allow the Petitioners to use the EPA Letter as a "sword" to establish error while simultaneously depriving DEQ and Perpetua of the "shields" of discovery and cross examination.

To balance these competing standards and interests, the hearing officer believes it is appropriate to supplement the record with the EPA Letter, but limit the purposes for which it may be considered, as follows:

First, the EPA Letter should only be referenced to the extent it is relevant to alleged errors that are already within the scope of this proceeding. Consistent with the above ruling on the motion to amend the petition, the EPA Letter should not be used to add new alleged errors to this proceeding.

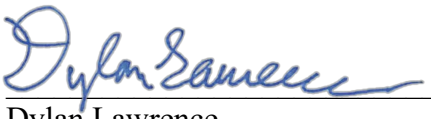
Second, to the extent the EPA Letter includes factual information or data that is not already within the existing record, that information should not be considered. The purpose of this proceeding is to determine whether DEQ committed reversible error when it issued the permit on June 17, 2022, based upon the information available to it at that time.

Third, the EPA Letter cannot be used as a proxy for expert testimony from the Petitioners. To the extent any declarations or affidavits adduced by DEQ or Perpetua qualify as expert testimony, the EPA Letter cannot be used to rebut such testimony.

Finally, DEQ and Perpetua's motion in limine requests exclusion of media coverage of the EPA Letter. However, the Petitioners' subsequent motion to supplement the record was limited to the EPA Letter. Unless and until there is a more overt request to supplement the record with any such media materials, it is unnecessary to rule on that aspect of the motion.

III. ORDER

In summary:



The Petitioners' motion to amend their petition in this matter is denied.

The Petitioners' motion to stay these proceedings is denied.

The Petitioners' motion to supplement the record in this matter with the EPA Letter is granted, subject to the limitations described above.

The motion in limine filed by DEQ and Perpetua is granted in part and denied in part. It is denied in the sense that the EPA Letter is being admitted into the record, but granted to the extent of the limitations described above.

Dated this 15th day of September, 2023.

Dylan Lawrence
Hearing Officer

BEFORE THE BOARD OF ENVIRONMENTAL QUALITY
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047	
NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON, Petitioners, v.	BEQ Case No. 0101-22-01 OAH Case No. 23-245-01 NOTICE REGARDING SUMMARY JUDGMENT HEARING
DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent, and PERPETUA RESOURCES IDAHO, INC., Intervenor.	

Pursuant to BEQ Procedural Rule 003.08 and AG Procedural Rule 413.01, the Hearing Officer hereby notifies the parties regarding general procedures for, and questions/issues to address at, the summary judgment hearing scheduled for Thursday, September 21. The goal of this notice is to provide for more efficient hearing preparation for counsel and a more efficient hearing for everyone involved.

Typically, summary judgment hearings proceed party-by-party, in that the moving party begins oral argument, the opposing party goes next, and the moving party then concludes. For a few reasons, this approach does not make sense in this proceeding.

First, all of the parties have pending motions for summary judgment on the same issues. Everyone is a movant, and everyone is an opposing party. Second, there are several complex, highly technical issues involved in this proceeding, such that proceeding issue-by-issue will be more efficient. Third, and perhaps most importantly, the summary judgment briefs and declarations are voluminous, approaching comprehensiveness.

Based on these factors and his review of the summary judgment briefs, the hearing officer would like the summary judgment hearing to focus primarily on the exclusion of the access road from ambient air (Claim Nos. 11 and 12).[1] Attachment A to this notice contains a series of questions related to this issue that will be helpful for the parties to address. Secondarily, it may be helpful for the parties to walk the hearing officer through the language of DEQ's Air Rule 214, as it pertains to the evaluation of economic and environmental factors in DEQ's T-RACT determination (Claim Nos. 6 and 7).

To the extent the parties wish to provide oral argument on other issues, they may do so. However, given the comprehensive nature of the existing summary judgment briefs, the parties should not feel the need to re-explain their arguments orally. The hearing officer's suggested sequence is provided below:

1) Alleged errors relevant to ambient air
   a) Exclusion of access road from ambient air (Claim Nos. 11 and 12)
   b) Lack of required ambient air monitoring (Claim No. 13)
2) Alleged errors relevant to PM_{10} emissions
   a) Reliance on plans to be developed later instead of enforceable limitations on average empty weight of ore haul trucks, average loaded weight of ore haul trucks, and total number of

[1] Claim numbers refer to those assigned in the November 15, 2022 Order on Motion to Dismiss.

vehicle miles traveled by ore haul trucks (Claim No. 1)

b) Assumption of control of 93.3% of PM_{10} emissions without related enforceable conditions (Claim No. 2)

c) Assumption of 120 days of recordable precipitation data instead of use of local weather data (Claim No. 5)

3) Alleged errors relevant to arsenic emissions

a) Whether errors in estimating PM_{10} emissions result in errors as to arsenic emissions (Claim No. 8)

b) Exclusion of economic and environmental evaluations in T-RACT analysis (Claim Nos. 6 and 7)

c) Averaging of projected arsenic emissions (Claim No. 9)

4) Standing, aggrieved party status, and prejudice of substantial rights under Idaho Code Section 67-5279(4)

Dated this 15th day of September, 2023.

Dylan Lawrence
Hearing Officer

Attachment A

(Questions Regarding Exclusion of Access Road From Ambient Air)

1. The Petitioners appear to assert two separate bases of error: (1) Perpetua lacks the legal authority to preclude access (Claim No. 11), and (2) the permit provisions regarding access control are inadequate (Claim No. 12). Is this an accurate characterization?

2. Is there anything in the record regarding the general public's need to utilize the road through the SGP, for example, to access, trails, campgrounds, other communities, *etc.*?

3. Is there anything in the record regarding the nature of Perpetua's property interests in the SGP and its legal ability to control access?

4. To the extent DEQ relies on representations by a permit applicant regarding its ability to control access, are there any legal authorities addressing the extent to which DEQ may so rely and/or the extent to which DEQ is responsible for verifying that information?

5. To what extent are DEQ's enforcement authorities relevant to these issues?

6. Is there anything in the record discussing the difference between guests of the facility and members of the general public, and how Perpetua will determine who is allowed access and who is not?

7. How do the DEQ guidance document in the record at PET743-744 and the EPA email attached to the Schilling Declaration affect the determination of ambient air?

BEFORE THE BOARD OF ENVIRONMENTAL QUALITY
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047	
	BEQ Case No. 0101-22-01
NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON, Petitioners, v.	OAH Case No. 23-245-01 MEMORANDUM DECISION ON MOTIONS FOR SUMMARY JUDGMENT AND PRELIMINARY ORDER
DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent, and PERPETUA RESOURCES IDAHO, INC., Intervenor.	

I. FACTUAL AND PROCEDURAL HISTORY

Perpetua Resources Idaho, Inc. is in the process of applying for a variety of permits for its proposed Stibnite Gold Project ("SGP") in Valley County, Idaho. The SGP would consist of conventional open-pit mining, ore preparation, and gold extraction operations. In August 2019, Perpetua applied to the Idaho Department of Environmental Quality ("DEQ") for an air quality permit for the construction and operation of the SGP, pursuant to the Rules for the Control of Air Pollution in Idaho in IDAPA 58.01.01 (the "Air Rules"). DEQ issued the final version of air quality permit-to-construct P-2019.0047 (the "Permit") on June 17, 2022.

On July 22, 2022, the Nez Perce Tribe, Idaho Conservation League, and Save the South Fork Salmon ("Petitioners") filed a joint petition to initiate a contested case (the "Petition") regarding the Permit. The Petition alleges DEQ committed several errors in its development of the Permit and asks the Board of Environmental Quality ("Board" or "BEQ") to vacate and withdraw the Permit and remand it to DEQ to correct such errors. After some motion practice, the Petitioners filed an amended Petition on January 11, 2023.

DEQ filed its response to the initial Petition on August 12, 2022 and its response to the amended Petition on January 17, 2023. DEQ's response admits many of the Petition's allegations regarding general background information and applicable law, but ultimately denies DEQ committed any errors in issuing the permit, and requests its actions in issuing the Permit be affirmed.

On August 12, 2022, Perpetua filed a petition to intervene in the contested case proceeding pursuant to Rule 353.01 of the Board's Contested Case Rules in IDAPA 58.01.23 (the "BEQ Procedural Rules"), which the hearing officer granted on August 22, 2022. Perpetua filed its response to the amended Petition on December 13, 2022. Similar to DEQ's responsive pleading, Perpetua's response admits many of the Petition's allegations regarding general background information and applicable law, but ultimately denies that DEQ committed any errors in issuing the Permit and requests the Permit be affirmed and the Petition dismissed.

On September 6, 2022, Perpetua filed a motion to dismiss the Petition. The hearing officer ruled on that motion on November 15, 2022. In doing so, the hearing officer identified 13 individual claims of error in the Petition. The order granted the motion to dismiss as to Claim Nos. 3, 4, and 10 and partially granted the motion as to Claim No. 8. As to the remaining claims, the order denied the motion. Therefore, Claim Nos. 1, 2, 5, 6, 7, 9, 11, 12, 13, and a portion of Claim No. 8 survived.[1]

[1] On pages 22, 23, and 24 of the order on the motion to dismiss, there are incorrect references to

Pursuant to a stipulated scheduling order, the Petitioners filed a motion for summary judgment on April 14, 2023, and DEQ and Perpetua filed motions for summary judgment on May 12, 2023. Briefing on those motions and two related motions to strike was complete as of July 20, 2023. The hearing officer ruled on the motions to strike on July 31, 2023, and the parties and hearing officer held a hearing on the summary judgment motions on September 21, 2023.

II. RELEVANT LEGAL STANDARDS

A. Standards on Motions for Summary Judgment

Motions for summary judgment filed in administrative proceedings before the BEQ are governed by the Idaho Rules of Civil Procedure. *In the Matter of Simmons Sanitation*, Findings of Fact, Conclusions of Law, and Preliminary Order on Motion for Summary Judgment of 9/23/05, at p. 3 (BEQ Dkt. No. 0106-05-01). Those rules provide in pertinent part:

> A party may move for summary judgment, identifying each claim or defense, or the part of each claim or defense, on which summary judgment is sought. The court must grant summary judgment if the movant shows that there is no genuine dispute as to any material fact and the movant is entitled to judgment as a matter of law.
>
> ***
>
> A party asserting that a fact cannot be or is genuinely disputed must support the assertion by…citing to particular parts of materials in the record, including depositions, documents, electronically stored information, affidavits or declarations, stipulations (including those made for purposes of the motion only), admissions, interrogatory answers, or other materials; or…showing that the materials cited do not establish the absence or presence of a genuine dispute, or that an adverse party cannot produce admissible evidence to support the fact.
>
> ***
>
> An affidavit used to support or oppose a motion must be made on personal knowledge, set out facts that would be admissible in evidence, and show that the affiant or declarant is competent to testify on the matters stated. Sworn or certified copies of all papers or parts of papers referred to in an affidavit must be attached to

---

Claim Nos. 10, 11, and 12 at the end of the sections discussing Claim Nos. 11, 12, and 13, respectively. The heading of each of those sections is correct.

> or served with the affidavit. The court may permit affidavits to be supplemented or opposed by depositions, answers to interrogatories, or further affidavits.

IDA.R.CIV.PROC. 56(a), (c)(1), (c)(4).

Air permit matters are often technical in nature, requiring the decision-maker to understand the relevant science and to analyze long, detailed regulations. Therefore, discussion of the rules governing expert witness testimony at the summary judgment stage is warranted. In the context of legal malpractice cases, the Idaho Supreme Court has held:

> When a defendant-attorney files a motion for summary judgment, the plaintiff ordinarily has an obligation to provide expert affidavits that explain how the lawyer's conduct fell below the standard of care and how the conduct proximately caused damages. The reason for this rule is that ***laypeople sitting on a jury usually do not have the knowledge or experience necessary*** to determine the standard of care that applies to an attorney or how the attorney's performance of that duty may or may not harm a client. The only recognized exception to this rule is where the attorney's alleged malpractice is so obvious that it is within the ordinary knowledge and experience of laymen, such as when an attorney allows a statute of limitations to run.
>
> When Smith filed his motion for summary judgment, he also filed an affidavit and report from an expert witness stating that 'in [his] opinion, Mr. Smith met and exceeded the applicable standard of care in representing Ms. Greenfield in both the Criminal and Civil Cases.' The report analyzed the various deficiencies alleged by Greenfield and concluded that any alleged deficiency was not the cause of the jury's adverse verdict. ***Greenfield did not file any expert affidavits to refute these opinions*** and never disclosed any expert witnesses during the course of discovery. Instead, she filed her own affidavit setting forth the ways she believed that Smith's performance was deficient.
>
> ***
>
> These alleged deficiencies are not simple matters like an attorney allowing a statute of limitations to run…. ***Without expert testimony, Greenfield could not demonstrate that there were genuine issues of material fact*** as to whether Smith's performance fell below the standard of care or proximately caused her damages. As such, the district court ***properly granted summary judgment*** in favor of Smith.

Greenfield v. Smith, 395 P.3d 1279, 1285-1286, 162 Idaho 246, 252-253 (Idaho 2017) (emphasis added) (citations omitted); *see also Samuel v. Hepworth, Nungester & Lezamiz, Inc*., 996 P.2d 303, 134 Idaho 84 (Idaho 2000); *Rich v. Hepworth Holzer, LLP*, at p. 10-11, Ida. Sup. Ct. Dkt. No. 49300

(Sept. 6, 2023) (reaffirming *Greenfield* principles).

The test for whether a summary judgment respondent is required to adduce an expert affidavit is whether the relevant evidence is "the type that would be within the ordinary knowledge and experience of a layperson." *Ciccarello v. Jeffrey Bo Davies, & Marcus, Christian, Hardee & Davies, LLP*, 166 Idaho 153, 161, 456 P.3d 519, 527 (Idaho 2019). "Judges, after all, are lay persons, no matter how well-read they are in science." *Earl v. Cryovac, A Div. of W.R. Grace Co*., 772 P.2d 725, 728, 115 Idaho 1087, 1090 (App. 1989) (citation omitted).

Many of the errors alleged by Petitioners are not "the type that would be within the ordinary knowledge and experience of a layperson." Therefore, as to each alleged error, it is important to determine if expert witness testimony is necessary to render a decision, and if so, to evaluate the sufficiency of the expert testimony.

B. Idaho APA Judicial Standards of Review

The pleadings, motions, and briefs in this matter frequently invoke Idaho Code Section 67-5279. That statute contains the standards of review applicable when a petition for judicial review of an agency decision has been filed pursuant to the Idaho Administrative Procedure Act, Idaho Code Sections 67-5201 – 67-5292 (the "APA"). After a final order has been issued in this matter, if a party appeals to the judicial system, Section 67-5279 contains the standards governing the court's evaluation of the final order.

Even though APA standards are not directly applicable to the pending motions, it is still important to understand the standards that will ultimately govern judicial review of the Board's decision. As the Board itself has recognized, in a contested case proceeding, "the Board must determine whether DEQ has acted reasonably and in accordance with law." *In the Matter of Sunnyside Park Utilities' Application for Sewage Disposal Permit*, Final Order on Petition for

Review of Preliminary Order, at p. 10 (BEQ Dkt. 0103-07-02, Apr. 7, 2009).[2]

Pursuant to DEQ Procedural Rule 003.18 and AG Procedural Rule 740, the Board will render a decision in this matter by issuing a final order. Therefore, subsection (3) of Section 67-5279 applies to judicial review, and the court would affirm the Board's decision unless it finds:

- DEQ and the Board acted in violation of constitutional or statutory provisions;
- DEQ and the Board acted in excess of their statutory authority;
- DEQ's approval of the Permit and the Board's decision to uphold it were made upon unlawful procedure;
- The Board's decision was not supported by substantial evidence on the record as a whole; or
- DEQ and the Board otherwise acted in a manner that qualifies as arbitrary, capricious, or an abuse of discretion.

IDAHO CODE § 67-5279(3)

C. Deference to DEQ

According to the Idaho Supreme Court, "[t]he actions of an agency…are afforded a ***strong presumption of validity***." *Duncan v. State Bd. of Accountancy*, 232 P. 3d 322, 324, 149 Idaho 1 (Idaho 2010) (emphasis added).

> Where an agency interprets a statute or rule, this Court applies a four-pronged test to determine the appropriate level of deference to the agency interpretation. This Court must determine whether: (1) the agency is responsible for administration of the rule in issue; (2) the agency's construction is reasonable; (3) the language of the rule does not expressly treat the matter at issue; and (4) any of the rationales underlying the rule of agency deference are present. There are five rationales underlying the rule of deference: (1) that a practical interpretation of the rule exists; (2) the presumption of

[2] The hearing officer is aware that Board members have previously expressed concern regarding application of Section 67-5279 standards too early in an administrative hearing process. (*See generally* Order of 9/23/22, *taking administrative notice of* Tr. of 12/4/14, 47:5-9 (BEQ Dkt. No. 0101-14-01)). Because those are the standards that ultimately govern the disposition of this matter, it is still necessary to reference them on summary judgment. As with a cause of action in a civil lawsuit, it is still necessary at the summary judgment stage to reference and understand the legal standards and claim elements that would govern at trial.

> legislative acquiescence; (3) reliance on the agency's expertise in interpretation of the rule; (4) the rationale of repose; and (5) the requirement of contemporaneous agency interpretation.

Id. (citations omitted).

This matter requires a detailed review of the Air Rules. Clearly, DEQ is responsible for administering those Rules. Therefore, unless an issue is squarely addressed by the Air Rules, the hearing officer will defer to "practical" interpretations of the Air Rules by DEQ.

III. ANALYSIS

A. Standing and the Petitioners' Status as "Aggrieved Parties"

Both DEQ and Perpetua moved for summary judgment on the basis that each of the three Petitioners lacks standing. This order will address standing before proceeding to the alleged errors.

1. Discussion of Applicable Standards

BEQ's Rules of Procedure state that "[a]ny person aggrieved by an action or inaction of the Department may file a petition to initiate a contested case pursuant to" the APA. BEQ PROC. RULE 002.02. The rules define "person aggrieved" as "[a]ny person or entity with legal standing to challenge an action or inaction of the Department…." BEQ PROC. RULE 005.01. Regarding legal standing, the BEQ has held:

> The petitioner to a contested case proceeding can be either an individual or an organization. In order to satisfy standing, an individual petitioner must demonstrate: (1) an injury in fact which is real, concrete and particularized, and actual or imminent, and not just speculative or hypothetical; (2) a causal connection between the challenged action and the injury; and (3) the likelihood that the injury will be redressed by a favorable decision.
>
> An organization may obtain associational or representational standing on behalf of its members. To achieve standing on behalf of its members, an organization must show that: (1) its members would otherwise have standing to sue individually; (2) the interests the organization seeks to protect are germane to the organization's purpose; and (3) neither the claim asserted, nor the relief requested, requires participation of individual members in the lawsuit.

Solomon v. Idaho Dept. of Env. Quality, Order of 12/17/03, at p. 4 (BEQ Dkt. No. 0101-03-01) (citations omitted).

2. Idaho Conservation League

The Idaho Conservation League (ICL) filed declarations of Allison Fowle, Asa Menlove, and Jonathan Oppenheimer to establish standing. Ms. Fowle testifies, among other things, that she is a member of ICL; that she has used the Stibnite Road through the SGP many times; that she plans to continue visiting the area to recreate; and that she is concerned about the health effects from dust and arsenic if she continues to recreate in the area while the mine is operating. (Fowle Decl., ¶¶ 2-8.) The Menlove Declaration contains similar assertions. (*See* Menlove Decl., ¶¶ 2, 4, 9, 10.) Mr. Oppenheimer testifies that he is both a member and employee of ICL; that he has recreated in the general area and plans to continue to do so; and that he is concerned about the health effects of particulate matter and arsenic emissions from the SGP. (Oppenheimer Decl., ¶¶ 2, 9-13, 15-16.) All of these factual assertions are uncontradicted.

All three declarants appear to satisfy the standards for individual standing. Their concerns over health effects from particulate and arsenic emissions are sufficiently "concrete and particularized" to satisfy the first prong of the test, particularly given that they have recreated in the area in the past and plan to continue to do so, which distinguishes their concerns from those suffered alike by all citizens and taxpayers of the state. There is a sufficient causal connection between the challenged action (issuance of a permit allowing emissions of air pollutants) and the claimed injury (health effects from breathing emissions authorized by the permit) to satisfy the second prong of the individual standing test. For the third prong, there is a sufficient likelihood that the declarants' health concerns will be addressed by a decision in ICL's favor in this matter.

As to organizational standing, Mr. Oppenheimer testifies extensively regarding ICL's

purpose, history, and advocacy efforts related to the environment generally, and air quality specifically. (Oppenheimer Decl., ¶¶ 3-7.) In a prior case, the Board approved ICL's petition to intervene in a matter involving water quality at mining facilities in north Idaho. The Board found that ICL had established a sufficient "direct and substantial" interest in that matter based upon an affidavit similar to the ICL declarations in this case. S*ee Hecla Mining Co. v. Idaho Dept. of Env. Quality*, Order on Intervention, pp. 3-4 (BEQ Dkt. No. 0102-03-13).

Moreover, there is no reason ICL's claims of error or relief requested in this matter require the participation of Ms. Fowle, Mr. Menlove, or Mr. Oppenheimer individually. If ICL relied on Mr. Oppeheimer's declaration and its exhibits to establish substantive error, the third prong of organizational standing may not have been satisfied as to him. However, because ICL has clarified, and the hearing officer has ruled, that Mr. Oppenheimer's declaration will only be considered to evaluate standing, the third prong is satisfied as to him.

Based on the foregoing, the DEQ and Perpetua motions for summary judgment on the basis that ICL lacks standing are hereby DENIED.

3. Nez Perce Tribe

The Nez Perce Tribe (NPT) filed declarations of Joseph Oatman and Emmit Taylor, Jr. to establish standing. Among other things, Mr. Oatman and Mr. Taylor testify that they have fished within the boundaries of the SGP; that they intend to do so in the future; and that they are concerned about adverse health effects from air pollutants generated by the SGP. (Oatman Decl., ¶ 7; Taylor Decl., ¶ 9.) These assertions are uncontradicted and appear to satisfy the individual standing standards of concrete injury, causal connection, and redressability.

Similarly, the organizational standing standards of individual standing, germane protectable interests, and not needing the individuals' participation are sufficient to shift the burden back to

DEQ and Perpetua for summary judgment purposes. Here, it is worth noting the relatively cursory analysis of the standing issue by DEQ and Perpetua. The only discussion specific to whether the NPT has standing appears in DEQ's May 12 brief, filed ***before*** the Oatman and Taylor Declarations were filed on June 9. DEQ chose not to discuss the NPT declarations in its June 23 "Non-Reply," and Perpetua did not discuss the NPT specifically at all. (*See* Perpetua Mem. in Supp. of 5/12/23, pp. 13-14; Perpetua Reply of 6/23/23, p. 5.) "The burden is upon the party moving for summary judgment…to establish that there is no genuine issue of material fact." *G & M Farms v. Funk Irr. Co*., 808 P.2d 851, 863, 119 Idaho 514 (1991). Without more explanation from DEQ and Perpetua as to why the NPT does not satisfy the relevant standards, they have not carried their burden as summary judgment movants.

Based on the foregoing, the DEQ and Perpetua motions for summary judgment that the NPT lacks standing are hereby DENIED.

4. Save Our South Fork Salmon

Save the South Fork Salmon (SSFS) filed declarations of Drew Hollenback and Zak Sears to establish standing. They both testify, among other things, that they have been financial supporters of SSFS since 2016; that they have recreated in the area and utilized the access road through the SGP in the past and plan to continue to do so in the future; and that they are concerned about air pollution from the SGP if they continue to recreate in the area. (Hollenback Decl. of 6/9/23, ¶¶ 2, 4, 5, 7, 8, 10-12; Sears Decl. of 6/9/23, ¶¶ 2, 5-7, 12, 14, 15, 19.) For summary judgment purposes, this is adequate to shift the burden back to DEQ and Perpetua as to individual and organizational standing. As with the NPT, after SSFS adduced these declarations, neither DEQ nor Perpetua attempted to explain why or how they do not satisfy standing, aside from Perpetua's highly conclusory paragraph on the issue. (*See* Perpetua Reply Mem. of 6/23/23, p. 5.)

Based on the foregoing, the DEQ and Perpetua motions for summary judgment that SSFS lacks standing are hereby DENIED.

B. Evaluation of Declarations as Expert Testimony

Having denied the motions for summary judgment on standing, the remainder of this order addresses the individual alleged errors. Before doing so, it is necessary to determine which declarations, if any, are admissible as expert testimony. *See* IDA.R.CIV.PROC. 56(c)(4) (affidavits must be admissible in evidence and show that the declarant is competent to testify on the matters stated); *Hecla Min. Co. v. Star-Morning Min. Co*., 122 Idaho 778, 784, 839 P.2d 1192, 1198 (Idaho 1992) (recognizing that on a motion for summary judgment, "[t]he question of admissibility is a threshold question to be answered before applying the liberal construction and reasonable inferences rule to the admissible evidence").

> A witness who is qualified as an expert by knowledge, skill, experience, training, or education may testify in the form of an opinion or otherwise if the expert's scientific, technical, or other specialized knowledge will help the trier of fact to understand the evidence or to determine a fact in issue.

IDA.R.EVID. 702.

The Petitioners supported their motion for summary judgment with one declaration, a declaration of counsel that was limited to authentication of documents from the record. (Hurlbutt Decl. of 4/14/23.) When DEQ moved for summary judgment, it adduced declarations of Tiffany Floyd, Kevin Schilling, and Mike Simon. Mr. Schilling testifies, among other things, that he has a B.S. in environmental science with a minor in chemistry; has a M.S. in environmental engineering with an emphasis on atmospheric chemistry, meteorology, air pollution monitoring, and atmospheric pollutant dispersion; has worked for the State of Idaho and within the private sector in some capacity relating to air quality science and engineering since the spring of 1989; and has been a Stationary

Source Air Modeling Supervisor for DEQ since September 2004. (Schilling Decl. of 5/12/23, p. 2.) Mr. Simon testifies, among other things, that he has a B.S. in electrical engineering and has over 30 years of air quality experience that includes conducting air quality analyses, writing air quality permits, processing air quality enforcement cases, managing air quality programs, and installation, operation, calibration, and maintenance of meteorological and navigational equipment. (Simon Decl. of 5/12/23, p. 2.)

On their face, both the Schilling and Simon Declarations appear to satisfy the Rule 702 standards.[3] Both witnesses testify regarding education and experience that qualifies them as experts on the issues involved in this matter, and then they explain the basis for DEQ's actions in issuing the Permit to Perpetua as they pertain to the alleged errors. Moreover, because Schilling and Simon are DEQ employees, their testimony is entitled to deference. *See generally Chisholm v. Idaho Dept. of Water Resources*, 125 P.3d 515, 518, 142 Idaho 159 (Idaho 2005).

The Petitioners do not challenge the admissibility of the DEQ declarations as expert testimony. They also do not rebut the DEQ declarations with their own expert declarations. The declarations filed by Petitioners on June 9, 2023, are primarily dedicated to challenging the contention that they lack standing. Petitioners themselves describe them as "standing declarations." (Petitioners' Resp./Reply Br. of 6/9/23, pp. 2-4, 35; Petitioners' Resp. to Mot. to Strike of 7/7/23, pp. 1, 4.) The Oppenheimer Declaration purports to discuss technical air quality issues, but the hearing officer has ruled that declaration should only be considered for standing purposes. (Order on Perpetua's Mot. to Strike of 7/31/23, p. 6.) Mr. Oatman and Mr. Taylor have impressive education and experience, but their backgrounds are in fisheries. This does not "help the trier of fact to understand the evidence or to determine a fact in issue" in an air permitting matter.

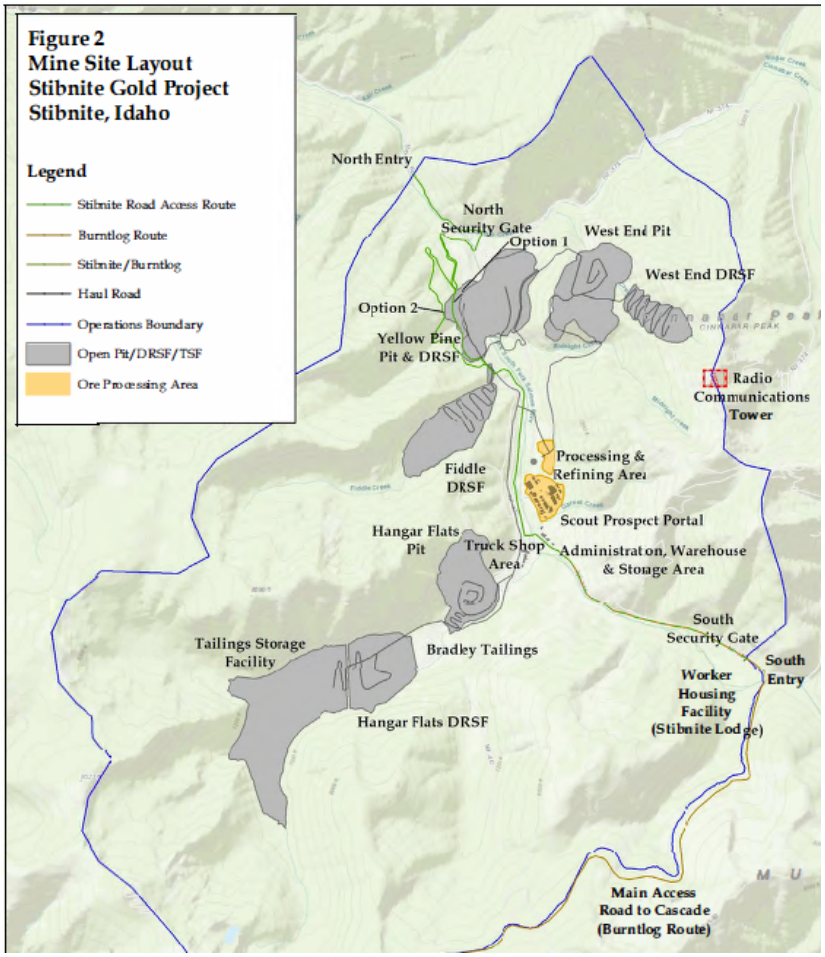
[3] The Idaho Rules of Evidence do not strictly apply. BEQ R.PROC. 003.13; AG R.PROC. 600.

C. Exclusion of Stibnite Access Road From Ambient Air

The Petition alleges multiple errors regarding ambient air boundaries and monitoring. Even though the phrase "ambient air" appears in the Permit one time, (*see* Permit, p. 41, § 7.13), it is an important concept behind many Permit conditions. Therefore, before addressing each individual alleged error, it will be helpful to discuss the concept of ambient air within the Air Rules.

1. Ambient Air Generally

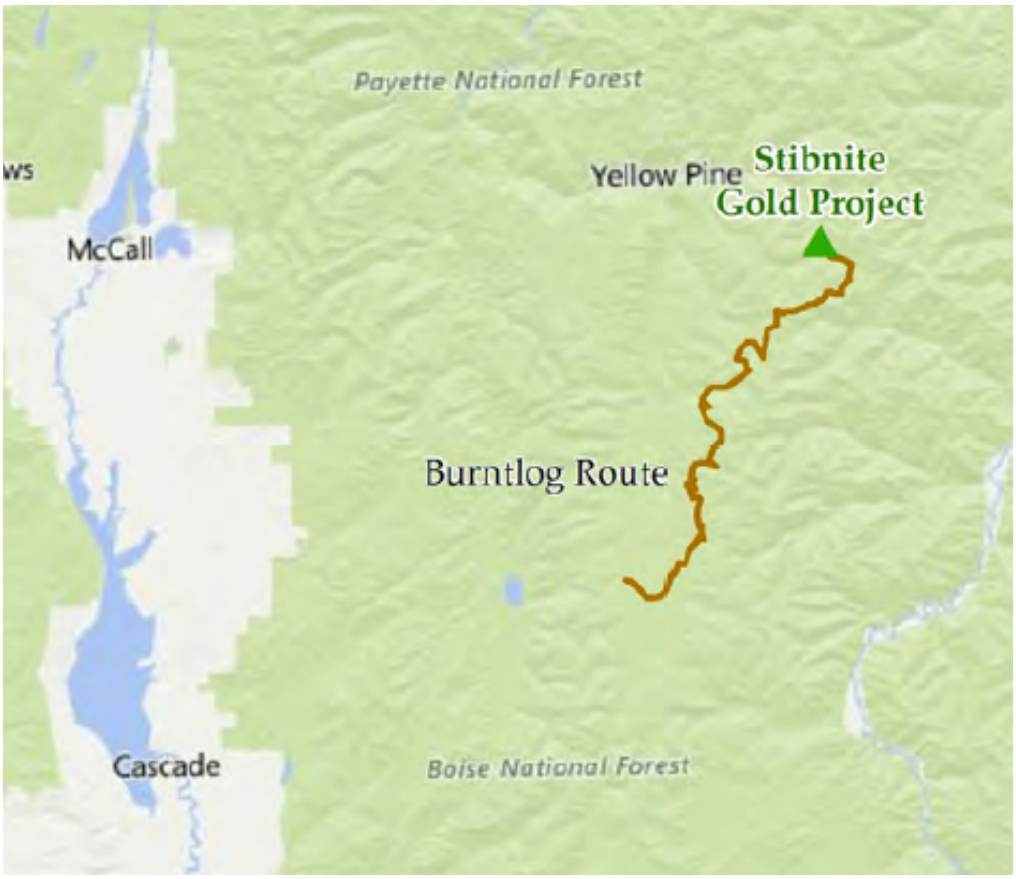
Under the federal Clean Air Act, EPA is required to establish national ambient air quality standards (NAAQS) for a handful of "criteria" air pollutants, including PM_{10}. *See generally* 42 U.S.C. § 7602(t); 40 C.F.R. § 50.6. When DEQ evaluates an application for a permit to construct, it must determine that "[t]he stationary source or modification would not cause or significantly contribute to a violation of any ambient air quality standard." AIR RULES § 203.02. Based on the federal definition, the Air Rules define "ambient air" as "[t]hat portion of the atmosphere, external to buildings, to which the general public has access." AIR RULES § 006.05.



The Petition alleges—and DEQ agrees—that to exclude areas from ambient air, the following must be true: (1) the permittee must have the ***legal authority to exclude the general public*** from the area; (2) the boundary to ambient air must be clearly discernable to the general public; (3) the general public must be ***effectively precluded*** from assessing the facility; and (4) the general public is not considered (a) employees of the facility; (b) those having official business with the facility; or (c) guests of the facility, including participants in facility routes and those seeking access for a specific purpose. (Pet., ¶ 59; DEQ Resp., p. 5 (emphasis added)).

2. The SGP and the Access Road

The SGP is located in a relatively remote location administered by the Payette National Forest. (R., at p. PRI00000418.) Its elevation ranges from approximately 6,421 feet and 6,936 feet



above sea level. (*See generally* R., at pp. PRI00000450-453.) Between December and May, it has an average snow depth between 21 inches and 84 inches. (R., at p. PRI00000419.) It is approximately 37 miles as the crow flies due east of McCall, and approximately 43 miles as the crow files northeast of Cascade.

The SGP is bisected by a U.S. Forest Service ("USFS") road that runs from the northern portion of the SGP to the south-southeast (or conversely, from the southeast portion of the SGP to the north-northwest). Generally speaking, this creates two ways to access the SGP by road. One could drive east from McCall to reach the North Entry of the SGP, passing through the community of Yellow Pine along the way, or one could drive northeast from Cascade to reach the South Entry of the SGP. (*See generally* R., at p. PET 527.)

(R., at p. PET533.)

Perpetua proposed year-round access to the SGP would be accomplished via the "Burntlog Route," which would involve the improvement and extension of the existing Burntlog Road and portions of Thunder Mountain Road. (R., at p. PRI00000418.) The Burntlog Route would provide year-round access to the south side of the SGP.

(R., at p. PRI00000416.)

The community of Yellow Pine is approximately 10 road miles west of the SGP's North Entry, and there are seasonal recreational destinations outside the SGP's South Entry. (*See* R., at p. PRI00000418.) Therefore, if access through the SGP is precluded, those traveling from Yellow Pine to access those recreational areas would have to travel much farther and around the SGP to do so.

Indeed, Perpetua initially proposed public access through the SGP would be prohibited. (R.,

at p. PET 527.) In response to public comments, Perpetua then proposed to allow "restricted seasonal [non-winter] access through the SGP site," which would "allow limited access to the Thunder Mountain recreational area from the town of Yellow Pine similar to the existing seasonal route." (R., at p. PRI00000418; *see also* R., at pp. PET 527, 530.) Alternative 2 under consideration by USFS under the National Environmental Policy Act ("NEPA") would allow continued access through the SGP. (R., at p. PET 527.)

For the purposes of the air modeling, Perpetua proposed to treat the access road within the operational boundary of the SGP as part of the SGP. The access road within the SGP was not treated as "ambient air," the result being that Perpetua was not required to demonstrate NAAQS compliance within that portion of the road. According to the Petition, that access road should have been treated as ambient air, not excluded from it, such that compliance with NAAQS would be required within the road. (*See generally* Pet. ¶¶ 60, 62.)

3. Whether Perpetua Has Adequate Legal Authority to Exclude the General Public (Claim No. 11)

The Petitioners argue there is not sufficient evidence in the record demonstrating Perpetua's legal authority to preclude access by the general public, in part because USFS's evaluation of the SGP under NEPA is not complete. (*See* Pet. ¶ 62; Br. in Supp. of MSJ of 4/14/23, pp. 14-18.) DEQ and Perpetua's primary response is that DEQ reasonably relied upon Perpetua's representation in its permit application that it will have the legal authority to control access.

In advance of the summary judgment hearing, the hearing officer requested the parties identify "any legal authorities addressing the extent to which DEQ may so rely [on representations by a permit applicant] and/or the extent to which DEQ is responsible for verifying that information." (Not. Re SJ Hearing of 9/15/23, Att. A, No. 4.) At the hearing, the only specific legal authority cited by any party was Petitioners' reference to *Ctr. for Biological Diversity v. U.S. Fish & Wildlife*

Serv., 33 F.4th 1202 (9th Cir. 2022), referred to as the "*Rosemont*" case because it involved a project proposed by the Rosemont Copper Company. *Rosemont* involved a determination of the scope of rights provided to claimants of mining claims on federal land under the federal Mining Law of 1872. *Id*. at 1208. At its core, that case involves the ***legal interpretation*** of that particular set of federal statutes; it does not squarely address the issue of the extent to which an agency may rely upon ***factual representations*** by an applicant.

In the absence of a specific legal requirement on this issue, the hearing officer must affirm DEQ's decision unless there is not substantial evidence in the record of Perpetua's legal ability to exclude the public or it was otherwise arbitrary or capricious to so rely. In its permit application materials, Perpetua makes the following representations:

> Midas Gold[4] ***will legally control the SGP***, an active industrial site where mining activities will occur, such as heavy equipment operation. Most areas of the mine will require strict safety protocols and controlled access. Midas Gold has established an operations boundary to identify the area ***where public access will be excluded***. Public access inside the operations boundary ***will be restricted for the life of the mine*** by physical barriers at points of potential access, including the current Stibnite Road point of entry and proposed site access via the Burntlog Route, as well as natural features of the landscape that prevent access.

(R., at p. PRI00000467 (emphasis added).)

The next section of this opinion discusses Section 2.7 of the Permit in detail. For now, it is adequate to note that Section 2.7 requires Perpetua to take actions to both "discourage" and "preclude" public access to the SGP. The Air Rules state:

> All documents, including but not limited to, ***application forms for permits to construct***, application forms for operating permits, progress reports, records, monitoring data, supporting information, requests for confidential treatment, testing reports or compliance certifications submitted to the Department must contain a certification by a responsible official. ***The certification must state that, based on information and belief formed after reasonable inquiry, the statements and information in the document are true, accurate, and complete***.

[4] Midas Gold Corp. formally changed its name to Perpetua Resources Corp. in Februrary 2021.

***

> Persons are prohibited from knowingly making any ***false statement, representation, or certification*** in any form, notice, or report required under any permit, or any applicable rule or order in force pursuant thereto.

AIR RULES 123, 125 (emphasis added).

Perpetua acknowledged the certification requirement in its application materials. (R., p. PRI00000167-168, 381.) It is also worth noting that DEQ has broad enforcement authorities. *See* IDAHO CODE §§ 39-105, 39-108, 39-109. If the representations that Perpetua "will legally control the SGP" in a manner in which "public access will be excluded" and "restricted for the life of the mine" were not true at the time they were made, then Perpetua would be subject to enforcement by DEQ. If Perpetua ultimately lacks the ability to preclude public access as a result of the NEPA process, operating the SGP anyway would be in plain violation of Section 2.7 of the Permit, which requires Perpetua to "preclude" and "discourage" public access.

In the experience of the hearing officer, it is not unusual for an agency to rely on representations made in a permit application, even as to an issue as fundamental as the nature of the applicant's interests in the relevant property. *See* APPLICATION FOR PERMIT TO APPROPRIATE THE PUBLIC WATERS OF THE STATE OF IDAHO, Item No. 11, *available at* https://tinyurl.com/yc5p48ss (last visited Oct. 15, 2023). Under these circumstances, the hearing officer finds DEQ's reliance on Perpetua's representation that it will eventually have the ability to control access reasonable and supported by substantial evidence in the record.

As to Claim No. 11, the Petitioners' motion for summary judgment is hereby DENIED, and the motions for summary judgment filed by DEQ and Perpetua are hereby GRANTED.

4. Whether the Permit Adequately Precludes Access by the General Public (Claim No. 12)

The Petitioners argue the Permit does not adequately preclude access by the general public

through the SGP. Sections 2.6 and 2.7 of the Permit require Perpetua to develop an "Access Management Plan (AMP)" that, among other things, "clearly specifies measures used to discourage public access to the facility," and that "shall be submitted to DEQ for approval 30 days prior to startup…." (R., at p. PET 010.) The Petition alleges that, "[w]ithout full disclosure and knowledge of the exact measures and requirements in the AMP and enforceable permit limits, DEQ cannot make a determination of whether exclusion of the access road from ambient air protections complies with EPA's ambient air policy and the Idaho Air Rules, nor can DEQ determine whether the SGP will comply with the NAAQS and TAPs." (Pet., ¶¶ 58, 59, 62, 65).

In contrast to many of the other errors alleged by Petitioners, the hearing officer finds establishment of ambient air boundaries as a matter that is within the common knowledge or a layperson. Therefore, expert testimony is not necessary. The hearing officer agrees that Perpetua and DEQ cannot demonstrate compliance by reference to a document that is not yet final. Therefore, consideration of this issue is limited to the "four corners" of the Permit, which states:

- Perpetua must "[o]bserve all primary access points to preclude unauthorized public access" and ensure "[o]nsite personnel [are] available for this purpose during active mining and mineral processing operations."
- Perpetua may control access at the North Entry and South Entry either "by the use of locked gates, barriers, or equivalent measures," by "manned guardhouses," or "by the use of security escort vehicles."
- Perpetua is required to "[p]ost warning signs and periodically patrol secondary access points to the facility [*i.e.*, secondary roadways and trails traversing the SGP] to preclude public access" and to make onsite personal available for this purpose.
- Perpetua may only provide "registered guests of the facility" with access to or

through the SGP "for the sole purpose of passing through the facility to another destination," and is required to provide literature that "explains Perpetua's requirements for accessing the site" and that "identifies potential hazards of the site." (R., at p. PET 010.)

Aside from the relatively brief definition of "ambient air," the Air Rules do not articulate legal standards for when the general public has adequate "access" to the atmosphere and when it does not. As a result, the parties refer to guidance documents promulgated by EPA and DEQ.

According to EPA's 2019 ambient air policy: (1) it is appropriate to exclude areas from ambient air where measures are employed that are "effective in precluding access to the land by the general public;" (2) such measures can include physical barriers, but physical barriers are not required; (3) determinations by the agency are discretionary on a case-by-case basis; (4) the permit applicant must have the legal ability to preclude access by the general public and must employ measures that actually preclude the general public as a practical matter; (5) in evaluating the adequacy of the preclusion measures, the agency applies a "rule of reason" as to whether the general public will have access "under reasonably anticipated circumstances." (R., at p. PET772-785.)

DEQ's 2021 guidance document asks a series of questions to determine if access by the general public is sufficiently precluded. If there is a fence or other physical barrier, it is appropriate to establish the ambient air boundary at that location. If access by the general public is discouraged by the nature or remote location of the facility and the facility either posts "no trespassing" signs or has security personnel who will ask trespassers to leave, then it is appropriate to establish the ambient air boundary at the property boundary. If none of the above are true, then the ambient air boundary is determined by a variety of factors. (*See* R., at pp. PET743-744.)

Again, the specific error alleged by Petitioners is that exclusion of the access road from

ambient air was error. This is not an evaluation of the entire ambient air boundary adopted by DEQ. In this regard, the requirements in the Permit enumerated above are consistent with both agency guidance documents and the conclusion that the access road is appropriately excluded from ambient air. At a minimum, the Permit makes it clear that Perpetua is required to preclude unauthorized access by the general public and that members of the public can become guests of the facility only if they are seeking to pass through to access another destination. Even Petitioners acknowledge their understanding that members of the general public who become guests of the SGP for the purpose of passing through will not be able to stop within the SGP. (*See* Tr. of 9/21/23 at 34:7-15.) And, if Perpetua does not take measures to discourage and preclude access by the general public, DEQ states that would be a violation of the Permit—likely a "major" violation. (Tr. of 9/21/23 at 40:8-18.)

While it is always possible to suggest ways in which a particular permit provision could be drafted differently, the hearing officer does not believe his role is to nitpick the language DEQ drafted in the Permit. Even without considering the yet-to-be-developed AMP, the hearing officer finds Section 2.7 of the Permit to adequately require Perpetua to preclude access by the general public for the purpose of excluding the access road from the definition of "ambient air."

Therefore, the Petitioners' motion for summary judgment as to Claim Nos. 11 and 12 is hereby DENIED, and the summary judgment motions filed by DEQ and Perpetua as to Claim Nos. 11 and 12 are hereby GRANTED.

D. Lack of Requirements for Ongoing Ambient Air Monitoring (Claim No. 13)

The Permit contains a variety of provisions requiring Perpetua to take actions to minimize air pollution. Section 1.2 and Table 1.1 identify and categorize the various discrete activities that will take place throughout the SGP and identify the pollution "control equipment" required for each individual activity. (R., at pp. PET 003-007.) The Permit also contains facility-wide requirements to

control fugitive dust, visible emissions, and odors. (R., at pp. PET 008-011.). The Permit also contains several monitoring and recordkeeping requirements. Generally applicable requirements to the SGP appear in Section 7.10, which states:

> The permittee shall maintain sufficient records to ensure compliance with all of the terms and conditions of this permit. Monitoring records shall include, but not be limited to, the following: (a) the date, place, and times of sampling or measurements; (b) the date analyses were performed; (c) the company or entity that performed the analyses; (d) the analytical techniques or methods used; (e) the results of such analyses; and (f) the operating conditions existing at the time of sampling or measurement. All monitoring records and support information shall be retained for a period of at least five years from the date of the monitoring sample, measurement, report, or application. Supporting information includes, but is not limited to, all calibration and maintenance records, all original strip-chart recordings for continuous monitoring instrumentation, and copies of all reports required by this permit. All records required to be maintained by this permit shall be made available in either hard copy or electronic format to DEQ representatives upon request.

(R., at p. PET 040).

The same "General Provisions" portion of the Permit contains multiple reporting requirements. (*See* R., at pp. PET 041-042.) In addition, the portion of the Permit applicable to fugitive dust contains several monitoring and recordkeeping requirements. (*See* R., at pp. 008 (§ 2.2), 011 (§ 2.10), and 012-014 (§ 2.20).) Moreover, the Permit incorporates several portions of the Code of Federal Regulations, including 40 C.F.R. Part 60, Subpart A (General Provisions), which includes requirements related to recordkeeping (40 C.F.R. § 60.7), monitoring (40 C.F.R. § 60.13), and reporting (40 C.F.R. § 60.19.) (*See* R., at p. PET 014 (§ 2.22).)

The Permit does not require ongoing monitoring of the quality of the ambient air while the SGP is operating. The Petition alleges that "without ambient air monitoring, it will be impossible for DEQ to assess whether the SGP's operation is in compliance with NAAQS and TAPs increments at any given time." (Pet., ¶ 68). Air Rule 211.01(d) expressly authorizes—but does not require—DEQ to include reasonable ambient air monitoring requirements in a permit-to-construct. Therefore, the

question is whether it was arbitrary, capricious, or an abuse of discretion for DEQ not to require ongoing ambient air quality monitoring.

Recognizing that ambient air quality monitoring is not legally required in all cases, Mr. Schilling describes the circumstances in which ambient air quality monitoring is typically appropriate. These include situations in which (1) "postconstruction air quality is projected to be so close to the NAAQS that monitoring is needed to certify attainment;" (2) "uncertainties in source or emissions characteristics result in significant uncertainties about the projected impact of the source or modification; and (3) when there are nearby sensitive receptors such as hospitals and schools. (*See* Schilling Decl., pp. 14-19.) According to Mr. Schilling, DEQ normally utilizes very conservative assumptions that overstate emissions in order to ensure NAAQS compliance is achieved. Upon discovery that a non-conservative figure for median silt content was used during the evaluation of Perpetua's Permit application, Mr. Schilling testifies:

> The options at this point were: 1) recalculate PM_{10} emissions from haul roads using a more conservative statistic for road silt than the median value, then revise the air impact modeling analyses; 2) require post construction ambient air monitoring to increase the assurance of NAAQS compliance; 3) use the 4.0 percent silt value as a maximum allowable value in the permit, requiring periodic monitoring of the road silt content during mining operations; and/or 4) develop other means by which lower levels of fugitive emissions from vehicle traffic could be attained and assured through monitoring (monitoring other than ambient air monitoring).
>
> Requiring ambient air monitoring for the SGP was discussed within the Air Division, including stationary source staff, ambient monitoring staff, and State Implementation Plan (SIP) staff. From the perspective of air permit modeling verification, I believe the requirement of PM_{10} ambient air monitoring to assure NAAQS compliance is of limited value for the SGP because of the following:
>
> - Monitored values showing compliance with the NAAQS only demonstrates compliance for that point in space and time. While a monitored exceedance likely indicates a failure to adequately control emissions (unless the exceedance may be caused by elevated background concentrations), compliance doesn't assure compliance at other ambient air locations.
>
> - Selecting a single monitoring location to represent worst-case impacts is

nearly impossible. In general, atmospheric dispersion models perform reasonably well at predicting the magnitude of maximum impacts (provided the inputs of emissions and emission release parameters is reasonably accurate); however, they perform poorly at predicting the location of maximum impacts in most cases. The accuracy of predicted locations of maximum impacts is even worse for analyses involving complex terrain, complex meteorological conditions, and emission sources involving atypical release characteristics (fugitive emissions from vehicle traffic, blasting operations, ore handling, *etc*.). Monitoring results that show compliance with NAAQS may portray a false confidence of NAAQS compliance on a facility-wide scale.

- No sensitive receptors have been identified near the facility. Sensitive receptors are locations where there is likely to be a concentration of the general public present. These include private residences, schools, hospitals, care centers, retail stores, parks, and resorts. DEQ believes the confidence of NAAQS compliance must be higher at these locations than at locations where there is a lower probability of public exposure. Ambient air monitoring at these locations can provide the additional assurance that air pollutant impacts from a neighboring industry will not violate standards and impact the health of the general public at sensitive receptor locations.

After internal discussions, Option 3 was selected, changing the 4.0 percent silt content limit from the median value to a maximum value. If the required sampling and testing of road material indicates a maximum silt content above 4.0 percent, it will be a permit violation. The permittee must then work with DEQ to develop a way to further reduce emissions, adjust operations, and/or revise impact analyses to enable NAAQS compliance to be demonstrated. This would likely require a permit modification.

(Schilling Decl., pp. 18-20.)

In addition, Mr. Simon testifies as follows:

DEQ did consider the option of requiring a PM_{10} ambient air monitor in the PRI PTC. In considering this option, staff reviewed DEQ's history of decisions requiring ambient air monitors in permits. Where DEQ did require an ambient monitor in a permit, the facility had already been in operation for many years and there was a recent modeled NAAQS (National Ambient Air Quality) violation. In these cases, DEQ negotiated with the facility to site and operate an ambient air monitor and develop a corrective action plan for the facility. This allowed the facility to monitor air quality while it made process changes and modified its permit to demonstrate a return to NAAQS compliance. Once the changes were implemented or approved, the facility would then demonstrate NAAQS compliance through modeling analysis. The monitor was eventually removed from their respective permits. In these few situations, DEQ never had an ambient air monitored violation.

> In all cases where DEQ processed a PTC application for a new or modified facility, DEQ required the applicant to demonstrate NAAQS pre-construction compliance using DEQ's approved modeling procedures as outlined in the 'State of Idaho Guideline for Performing Air Quality Impact Analysis.' DEQ will not issue a final PTC if the applicant has not demonstrated pre-construction NAAQS compliance to the satisfaction of the Department.
>
> DEQ also considered the location of the proposed PRI facility, the proximity of nearby residences and the implementation costs of requiring an ambient monitor. Given all of these factors, DEQ ultimately decided not to require an ambient air monitor in the permit. DEQ did reach out to PRI prior to final PTC issuance to see if they would voluntarily install an ambient monitor but declined at that time.

(Simon Decl., pp. 10-11.)

DEQ recognized that whether to require ambient air quality monitoring is within its discretion, and Schilling and Simon describe a reasoned, logical explanation for why DEQ did not require such monitoring in this case. This is unrebutted expert testimony on an issue that is not within the common knowledge of a layperson. The Petitioners identify various ways NAAQS violations could occur hypothetically, but these are arguments in a brief. Without expert testimony explaining why monitoring should have been required in this case, the hearing officer lacks discretion to find that DEQ committed error by not requiring ambient air quality monitoring.

Based on the foregoing, the Petitioners' motion for summary judgment as to Claim No. 13 is hereby DENIED. The motions for summary judgment filed by DEQ and Perpetua as to Claim No. 13 are hereby GRANTED.

E. Reliance on Plans Instead of Enforceable Limitations for Control of PM_{10} Emissions (Claim No. 1)

The Petition asserts error occurred because "important variables affecting the quantity of PM_{10} generated by the ore haul trucks are not directly limited and enforceable as PTC permit conditions." (Pet., ¶ 36). More specifically, even though Perpetua used multiple "[c]ritical variables…as inputs to PM emission calculations," the Petition argues DEQ erred by "rel[ying] on a

surrogate limit in the PTC," "[i]nstead of developing PTC conditions for these other critical variables." (Pet., ¶¶ 36-37). According to the Petition, the three "critical variables" lacking relevant Permit conditions are the average empty weight of ore haul trucks, the average loaded weight of ore haul trucks, and the total number of vehicle miles traveled by ore haul trucks.[5] (*See* Pet. ¶ 36). Without enforceable limitations on those three variables, Petitioners argue "DEQ could not reasonably claim when it issued the Permit that the facility will not cause or contribute" to violations of applicable air quality standards. (Mem. in Supp. of MSJ of 4/14/23, p. 24.)

Petitioners do not point to an Air Rule specifically requiring every modeling input and variable to be the subject of a specific permit condition or limitation. Therefore, this issue is governed by Air Rule 210.01, which provides DEQ with discretion to impose reasonable conditions on a permit to construct. The inquiry here is whether it was arbitrary, capricious, or an abuse of discretion for DEQ not to include Permit conditions specifically regulating the average empty weight of ore haul trucks, the average loaded weight of ore haul trucks, and the total number of vehicle miles traveled by ore haul trucks. On this issue, Mr. Simon testifies:

> In reviewing the mean vehicle weight variable used in calculating haul road emissions, PRI proposed the use of 20 large Cat 789D mining trucks and 12 smaller CAT 740B dump trucks. PRI stated that the ratio of large to small trucks would be 20:12. Mean vehicle weight used in the calculation for haul road emissions include the total mean vehicle weight from fully loaded trucks. ***Rather than developing a methodology in the permit to measure and determine average vehicle weight each day, DEQ developed a haul road usage limit of 180,000 tons of ore and development rock per day (PTC condition 3.5). This limit accounts for the average loaded vehicle weight of all trucks as well as the average round-trip distance traveled as presented in the application***. The monitoring methodology required to measure daily ore and development rock hauling is addressed in the required Operations and Maintenance Manual (PTC condition 2.20).

(Simon Decl., p. 9 (emphasis added).)

[5] The Petition acknowledges that an enforceable Permit condition was included for silt content of haul roads.

This is unrebutted testimony from an expert witness on an issue that is not within the common knowledge of the layperson. On its face, this is a reasonable explanation that is consistent with DEQ's response to comments:

> Enforceable monitoring, recordkeeping, and reporting [MMR] requirements were established in the permit. PM/PM_{10}/$PM_{2.5}$ emissions limits for point sources were established with supporting activity rate limits and MRR requirements. ***While emissions limits and emission factors are not commonly included in the permit for fugitive sources, activity rate limits and MRR requirements were established for those sources that were identified as process rate-limiting (as summarized in Table 1.1 of the permit). These activity rate limits serve as surrogate emissions limits for PM, PM_{10}, $PM_{2.5}$, HAP and TAP from fugitive sources***. And while documented in the Statement of Basis and application materials, underlying parameters associated with calculating emissions such as vehicle speed limit, type, and miles traveled are not typically included in the permit ***but can be found in the application materials*** (Appendix A).

(R., at p. PET 557 (emphasis added).)

In other words, due to the nature of fugitive emissions, DEQ chose to control those emissions by limiting the amount of ore and development rock that can be hauled per day, with both a daily haulage limit and a limit on the five-year rolling average of daily haulage. (*See* R., at p. Pet 019 (Permit § 3.5).) If the representations of vehicle weights and miles traveled in Perpetua's application materials end up being materially different from reality, those discrepancies will be well documented via the various plans, monitoring, and reporting required by the Permit, and DEQ will have enforcement capabilities pursuant to Air Rules 123, 125, and 202 and Idaho Code Sections 39-105, 39-108, and 39-109.

Based on the foregoing, the hearing officer hereby DENIES Petitioners' motion for summary judgment as to Claim No. 1. The motions for summary judgment filed by DEQ and Perpetua as to Claim No. 1 are hereby GRANTED.

F. Assumption of Control of 93.3% of PM10 Emissions Without Related Enforceable Conditions (Claim No. 2)

Section 3.1 and Table 3.2 of the Permit provide in pertinent part:

Table 3.1 contains a description of control equipment used to control emissions from mining and ore processing activities.

Table 3.1 Mining and Ore Processing Control Device Descriptions

Emission Sources	Control Devices
Mining	
Excavating and hauling activities	Reasonable control & FDCP Chemical suppression and water sprays ***Control efficiency: 93.3% for PM/PM10 (haul roads)*** Haul road capping with low-arsenic quartzite

(*See* R., PET018 (emphasis added).)

The Petition asserts error occurred because "DEQ assumed 93.3% of all haul road PM_{10} emissions from the SGP can be controlled by using an unspecified combination, volume, and frequency of water sprays and chemical dust suppressants" without also including "specific and enforceable permit conditions within the PT to ensure a 93.3% control efficiency." (Pet. ¶¶ 38-39). According to the Petition, "[a] lesser control efficiency, even just slightly lesser, could result in large enough PM_{10} emissions to violate the NAAQS." (*Id*. at ¶ 39).

On summary judgment, the Petitioners further elaborate on these three distinct but related points: First, DEQ's assumption that Perpetua can achieve 93.3% control efficiency is without an adequate basis. Second, DEQ's assumption that Perpetua can achieve 93.3% control efficiency is aggressive because "[i]t is challenging to consistently and continuously achieve 93.3 percent control." (Tr. of 9/21/23 at 67:10-14.) According to Petitioners, this provides only a "razor thin" margin of error, such that if the 93.3% figure is not achieved, violations of the NAAQS will

necessarily result. (Tr. of 9/21/23, 66:13.) Third, given the first two points, it was error for DEQ not to include more specific requirements to ensure 93.3% control efficiency is achieved.

1. Without Adequate Basis

As to the first point, it is helpful to note that the 93.3% control efficiency figure is based on two separate assumptions regarding the control efficiency for chemical suppressants and the control efficiency for water. Regarding the control efficiency for chemical suppressants, Simon explains:

> PRI's consultant, Air Sciences, Inc., provided information in their application from their research of AP-42: Compilation of Air Emission Factors, Section 13.2.2, emission factors for unpaved roads (EPA 2006). According to AP-42, test studies on various unpaved industrial roads where chemical dust suppressants were applied documented a range from 90 to 99 percent dust control efficiency for PM_{10}. Based on this data, PRI proposed to use a 90% dust control efficiency for PM_{10} when utilizing chemical dust suppressants on unpaved roads.

(Simon Decl., pp. 5-6.)

Regarding the control efficiency for water, Simon explains:

> In addition to using the chemical dust suppressant, controlled PM_{10} emission calculations for unpaved haul roads also incorporate the control efficiency for water. For annual dust control from water, AP-42 accounts for this in an equation that uses annual precipitation data. When using the 120 days of precipitation obtained from AP-42 section 13.2.2, the precipitation term accounts for natural mitigation in calculating the annual unpaved road emissions. Staff reviewed and approved this methodology. The daily unpaved road emission calculations use an applied water control efficiency of 33%. This value was supported by permit staff based on an evaluation of figure 13.2.2-2 of AP-42 for water control effectiveness on unpaved roads.

(Simon Decl., p. 8.)

Stated in layman's terms, the 93.3% control efficiency is essentially calculated as follows: Chemical dust suppressants will control 90% of the dust emissions from unpaved roads, and water will control 33% of the remaining uncontrolled 10%. (*See generally* R., at pp. PET 551, 557-558.)

DEQ has adduced expert testimony explaining the basis for the 93.3% control efficiency figure, an issue not within the common knowledge of the layperson. The Petitioners have not

offered expert testimony to rebut it. At oral argument, the Petitioners cited to the EPA Letter. However, the hearing officer has ruled the EPA Letter cannot be relied on as a proxy for expert testimony, in part because EPA is not a party and therefore not subject to cross-examination. Without admissible expert testimony, under *Greenfield*, the hearing officer must affirm DEQ's action unless there is some obvious flaw in DEQ's reasoning. Seeing none, the hearing officer finds DEQ's adoption of the 93.3% control efficiency figure adequately supported.

2. Razor Thin Margin

As to Petitioners' second point, again, Mr. Simon has testified that the 90% control efficiency assumption for chemical suppressants is on the low end of the 90-99% range identified in AP-42. Mr. Schilling testifies:

> Late in the review process, PRI determined that the West End Development Rock Storage Facility will not be constructed, thereby eliminating the modeling operational scenario W5. Scenario W5 was the scenario where modeled exceedances of the 24-hour PM_{10} NAAQS were shown when using the BULKRN-processed meteorological data. When Scenario W5 is removed, the highest impacting operational scenario is W3, which represents the transport of development rock from the West End Pit to the Hanger Flats Development Rock Storage Facility. Maximum impacts still slightly exceed the NAAQS when using a single value background concentration value, ***but are well below NAAQS when seasonal backgrounds are used*** (82% of the NAAQS at 123.5 μg/m3).

(Schilling Decl., pp. 17-18 (emphasis added).)

Mr. Schilling further testifies that DEQ's modeling group did not learn until later in the review process that a non-conservative assumption of 4.0% silt content of the road surface was used in the modeling. Because he believed "NAAQS compliance could not be assured at a sufficiently high confidence level…even though there are other areas of the analyses that are very conservative," Mr. Schilling adopted 4.0% as the maximum allowable silt content value. (Schilling Decl., pp. 17, 19.) That limitation is in Section 3.13 of the Permit, (R., p. PET020), and "[i]f the required sampling and testing of road material indicates a maximum silt content above 4.0 percent, it will be a permit

violation." (Schilling Decl., p. 19.)

To support their argument that 93.3% control efficiency provides only a "razor thin" margin of error, the Petitioners rely on assertions by counsel and isolated references in the permitting record and the EPA Letter. By contrast, DEQ has adduced expert testimony describing multiple ways in which conservativism was utilized in the modeling and permit-writing process. In the absence of expert testimony to the contrary, the hearing officer finds DEQ's explanations reasonable.

3. Failure to Include More Specific Requirements to Ensure Compliance

Petitioners argue, "[t]he error is that there is…no 93.3 percent enforceable limitation or there is no other limitations that reasonably assure" 93.3% control is achieved. (Tr. of 9/21/23 at 67:24-68:2.) However, as to the first argument, as previously referenced, the Permit includes a specific requirement that 93.3% control efficiency be achieved. As to the second argument, the Petitioners do not cite to any legal standard requiring additional requirements or otherwise explaining how the existing Permit provision is legally inadequate. Moreover, the Petitioners have not offered expert testimony describing the terms they believe are necessary to ensure compliance. Without these, and given the presumption in favor of agency action on technical issues, the hearing officer finds no basis to conclude DEQ committed error.

4. Summary and Conclusion as to Claim No. 2

For the foregoing reasons, as to Claim No. 2, the hearing officer hereby DENIES the Petitioners' motion for summary judgment and GRANTS the motions filed by DEQ and Perpetua.

G. Assumption of 120 Days of Recordable Precipitation Data Instead of Use of Local Weather Data (Claim No. 5)

The Petition alleges that (1) "[d]ays of recordable precipitation is an important variable affecting the SGP's emissions of PM_{10} from ore haul roads;" (2) "DEQ assumed there would be 120 days of recordable precipitation at the SGP" based on "general geographic guidance" instead of

"local meteorological data;" and (3) "DEQ's failure to use the most representative site data…increases the risk of miscalculation of ore haul road emissions." (Pet., ¶ 41). The Petitioners moved for summary judgment on this issue, arguing:

> Rather than use available site-specific meteorological data to calculate fugitive dust emissions from haul roads, DEQ used a generic value in EPA guidance to assume that there are 120 days of recordable precipitation at the Project site. See PET 146; see also PET 805 (map). This was arbitrary and counter to DEQ guidance.
>
> For modeling ambient air impacts, Section 6.8 of DEQ's Guideline for Performing Air Quality Impact Analyses states: "The meteorological data used in the modeling analysis should be representative of the meteorological conditions at the particular site of the proposed construction or modification."

(Pets.' Br. ISO MSJ of 4/12/23, p. 25.)

That same DEQ guidance document goes on to state that, "[t]here are several sources of meteorological data besides on-site collected data." (R., at p. PET 746.) Ultimately, the relevance of this issue is that "precipitation can reduce fugitive dust emissions." (Pets.' Br. ISO MSJ of 4/12/23, p. 25.) In other words, a higher number of precipitation days per year is generally associated with lower expected fugitive dust emissions from the ore haul roads. In response, Mr. Schilling makes several important clarifications:

First, the 120 annual precipitation days is derived from EPA's AP42 guidance document, which includes a map for the entire United States that is contoured based on climatological data. According to Schilling, "[t]he resolution provided by the AP42 map is adequate to provide reasonably accurate emission estimation, well within the general uncertainty of the factor and other inputs…that can be taken to reduce emissions." (Schilling Decl., p. 13).

Second, the Taylor Ranch station raised by Petitioners "is over 40 kilometers from the SGP site, making it questionably more representative than the AP42 map." (*Id*.)

Third, "the Taylor Ranch data indicated there was an average of 113 [precipitation] days each

year…effectively matching the 120-day value obtained from the AP42 map." (*Id.*)

Fourth, the onsite data from 2014 "indicates there were 155 [precipitation] days…." (*Id.*) In other words, use of the onsite data (which has 35 more precipitation days than the AP42 figure) presumably would have lowered expected emissions substantially more than the heightened expected emissions had the Taylor Ranch data (which has 7 fewer precipitation days) been used. Ultimately, DEQ did not use the 155-day figure because the "onsite data were only collected for one year," making it "questionable whether it can be considered more representative than the AP42 map for typical conditions because of the year-to-year variability…." (Schilling Decl., p. 13.)

With these explanations, DEQ has satisfied its burden as a summary judgment movant and has shifted the burden to Petitioners to explain why the decision to utilize the 120 precipitation days figure from AP42 was arbitrary, capricious, or an abuse of discretion. Because the selection of proper precipitation data is not within the common knowledge of a layperson, expert testimony was required to rebut DEQ's expert testimony. "If an expert is qualified to render an opinion, based on his expertise in the subject, then he must be accorded substantial deference in the selection of data upon which he chooses to base his opinion." *Earl v. Cryovac, A Div. of W.R. Grace Co*., 772 P.2d 725, 728, 115 Idaho 1087, 1090 (App. 1989). In order to create a disputed, triable issue of material fact for a hearing on the merits, the Petitioners were required to adduce expert testimony explaining more specifically how DEQ's use of the AP42 figure could be error. Without such testimony, summary judgment in favor of DEQ and Perpetua is appropriate.

Therefore, as to Claim No. 5, the Petitioners' motion for summary judgment is DENIED, and the motions for summary judgment filed by DEQ and Perpetua are GRANTED.

H. Whether Errors in Estimating PM_{10} Emissions Result in Errors as to As Emissions (Claim No. 8)

Paragraph 54 of the Petition alleges:

> Second, because the underlying particulate and PM_{10} emissions estimates and particulate control assumptions are unreliable in numerous respects, as already discussed above, so too are the estimated arsenic emissions. The SGP's estimated arsenic emissions were based on its PM_{10} emissions. PM_{10} emissions from the SGP may be higher, and their control effectiveness may be lower, than DEQ assumed, in which case arsenic emissions would also be higher and might exceed the AACC [Acceptable Concentrations of Carcinogens].

(Pet. ¶ 54).

Because the hearing officer has granted summary judgment in favor of DEQ and Perpetua as to all of the alleged errors related to PM_{10} emissions as described above, the disposition of this particular claim is automatic. As to Claim No. 8, the motions for summary judgment filed by DEQ and Perpetua are hereby GRANTED, and the motion for summary judgment filed by the Petitioners is hereby DENIED.

I. Exclusion of Economic and Environmental Evaluations in T-RACT Analysis (Claim Nos. 6 and 7)

The Petition alleges DEQ's evaluation of "reasonably available control technologies" ("RACT") for the toxic air pollutant arsenic ("T-RACT") "contained no persuasive economic information and no discussion at all regarding associated environmental impacts" resulting from "Perpetua's decision to use water and chemical dust suppressants as compared to paving the haul roads, even though paving was shown to achieve the highest reasonable dust control efficiency." (Pet. ¶¶ 48, 53). According to the Petition, this violated Air Rule 210.14. T-RACT is defined in the Air Rules as:

> An emission standard based on the lowest emission of toxic air pollutants that a particular source is capable of meeting by the application of control technology that is reasonably available, as determined by the Department, considering ***technological and economic feasibility***. ***If control technology is not feasible, the emission standard may be based on the application of a design, equipment, work practice or operational requirement, or combination thereof.***

AIR RULE 210 (emphasis added).

The first step in the T-RACT process is for the applicant to "submit information to [DEQ] identifying and documenting which control technologies or other requirements the applicant believes to be T-RACT." AIR RULE 210.14(a). DEQ must then review the information submitted by the applicant and determine if it has proposed T-RACT "on a case-by-case basis" considering separate factors for both technological feasibility and economic feasibility. AIR RULE 210.14(b), (c).

Based upon the T-RACT definition above, these feasibility determinations are relevant to whether the control technology is "reasonably available" for use by the applicant. For economic feasibility, DEQ must consider a non-exclusive list of factors, including costs of necessary mitigation measures, capital costs, cost effectiveness, and the difference in costs between the particular source and other sources, if any, that have implemented emissions reductions. AIR RULE 210.14(d). For technological feasibility, the Air Rules specifically require DEQ's evaluation to include consideration of "[t]he environmental impacts caused by the control technology that cannot be mitigated, including, but not limited to, water pollution and the production of solid wastes." AIR RULE 210.14(c)(ii). "If [DEQ] determines that the applicant has proposed T-RACT, [it] shall determine which of the options, or combination of options, will result in the lowest emission of toxic air pollutants, develop the emission standards constituting T-RACT and incorporate the emission standards into the permit to construct." AIR RULE 210.14(e).

The Simon Declaration describes DEQ's five-step process for determining T-RACT:

1. Identify all available control options.

2. Eliminate technically infeasible options.

3. Rank remaining control technologies.

4. Consider the energy, environmental, and economic impacts.

5. Select the most effective control technology not eliminated in Step 4.

(Simon Decl., pp. 11-12.)

While these five steps do not necessarily repeat the language of Air Rule 210.14 verbatim, they are not inconsistent with it either. Given the deference given to an agency in interpreting its rules, the hearing officer has no basis to question this five-step process. According to Simon:

> In reviewing T-RACT analysis for haul roads, PRI identified the following possible control options:
>
> 1. Paving roads
>
> 2. Application of chemical dust suppressants and water
>
> Paving haul roads was determined to be technically infeasible by PRI and permit staff because paving is not feasible for mining roads utilizing very heavy trucks which would exceed the design limitations of paving.

(Simon Decl. of 5/12/23, p. 13.)

More specifically, Perpetua submitted information indicating that paved haul roads would only be capable of supporting vehicles with weights up to 10 tons. (R., at p. PET 547.) However, Perpetua's loaded haul trucks will weigh between 60 tons and 260 tons. (*Id*.) The Petitioners do not rebut Mr. Simon's explanation for elimination of paving as technically infeasible with their own expert testimony that it is feasible. On its face, Mr. Simon's explanation is otherwise reasonable and supported by the record. Therefore, elimination of paving as T-RACT was not error.

The next question is whether it was error for DEQ not to evaluate the environmental impacts of the control technology that was chosen, a combination of chemical dust suppressants and water. This is where a careful reading of the language of Air Rule 210.14 in connection with the definition of T-RACT is important.

According to the language of the rules, evaluation of environmental impacts occurs specifically within the context of evaluating technological feasibility. The purpose of evaluating both economic feasibility and technological feasibility is to determine whether a particular control

technology is "reasonably available." According to Mr. Simon, the combination of chemical dust suppressants and water is already known by DEQ to be "reasonably available" because:

> Application of chemical dust suppressants and water is an effective dust control method which is a common control technology for unpaved haul roads. Magnesium chloride and water combinations are widely used and effective dust suppressant by state, county, and industrial unpaved roadways. DEQ is not aware of any negative environmental impacts as long as the operators apply the dust suppressant according to manufacturer's recommendations.[6]

(Simon Decl., p. 13.)

This issue is not within the common knowledge of the layperson. Mr. Simon's declaration is unrebutted expert testimony that is otherwise reasonable, so there is no basis for the hearing officer to find that DEQ's decision lacked adequate basis. Without the ability to establish factual error, the Petitioners can establish error only by demonstrating that DEQ's T-RACT process violated the plain language of the Air Rules.

In this regard, Petitioners argue DEQ's reliance on its pre-existing knowledge regarding the availability of chemical suppressants and water as dust control technology violated the requirement to determine T-RACT on a "case-by-case basis" under Air Rule 210.14. In effect, Petitioners argue DEQ must ignore what it already knows about the availability of chemical suppressants and water as a control technology and determine anew that it is "reasonably available." It is also notable that, elsewhere in the Air Rules, "suitable chemicals" are specifically recognized as a "reasonable precaution" for controlling dust from dirt roads. *See* AIR RULE 651.02.

In addition to the requirement to defer to DEQ's interpretation of its rules, there is a canon of construction that disfavors absurd results. *See, e.g., Friends of Farm to Market v. Valley County*, 137 Idaho 192, 46 P.3d 9, 14 (Idaho 2002). To the hearing officer, interpreting the "case-by-case"

[6] The Permit, in turn, requires that "[c]hemical dust suppressants shall be applied consistent with manufacturer's instructions and recommendations." (R., at p. PET 010.)

language in Rule 210.14 to require DEQ to ignore Air Rule 651.02, ignore the technical knowledge it possesses as the entity with statutory responsibility to administer Idaho's air permitting programs, and to engage in a brand-new feasibility evaluation every time an applicant proposes a well-established control technology would be an absurd result. It is also notable that Air Rule 210.14 further defines what constitutes a "case-by-case" evaluation by stating "as follows" and then enumerating the T-RACT steps previously described. The Simon Declaration describes DEQ's process for evaluating the T-RACT information submitted by Perpetua pursuant to Air Rule 210.14. The hearing officer finds that explanation adequate to satisfy Rule 210.14.

Finally, it is helpful to recall that the Air Rules are concerned with the control of "air pollution," which is defined by statute as follows:

> The presence in the outdoor atmosphere of any air pollutant or combination thereof in such quantity of such nature and duration and under such conditions as would be injurious to human health or welfare, to animal or plant life, or to property, or to interfere unreasonably with the enjoyment of life or property.

IDAHO CODE § 39-103(2).

While this definition allows for regulation of pollution "injurious…to animal or plant life," it does so specifically within the context of pollutants that are "presen[t] in the outdoor atmosphere." The term "atmosphere" is not defined in the Air Rules, the Clean Air Act, or Black's Law Dictionary. The Clean Air Act does, however, define "air pollutant" as pollutants emitted into the "ambient air," a phrase this opinion has already discussed in detail. *See* 42 U.S.C. § 7602(g). The Petitioners allege:

> There will be water quality and biological impacts associated with Perpetua's use of substantial amounts of chemical dust suppressants and water that have not been considered in the PTC. For example, the use of chemical dust suppressants like magnesium chloride can cause toxicity in trees and can lead to tree death. Magnesium chloride is also known to adversely affect aquatic ecosystems.

> Moreover, the proposed water source for dust control is primarily water collected in runoff ponds (captured rain or snowfall that has become contaminated through the contact of mine facilities), groundwater, and surface water from the East Fork of the South Fork of the Salmon River. USGS sampling indicates elevated arsenic in these waters. The environmental impact of using magnesium chloride or arsenic-polluted water as dust suppression methods was never considered as part of the T-RACT demonstration.

(Pet. ¶ 53.)

The Petitioners may indeed have legitimate concerns regarding the impacts of chemical dust suppressants on trees and aquatic ecosystems, but this air permit proceeding is not the appropriate forum for them. The "air pollutant" at issue in the T-RACT determination is arsenic (not magnesium chloride) that is present in the "outdoor atmosphere" and "ambient air" (not bodies of water). The Petitioners' concerns on these issues are more appropriately raised through authorities such as IDAPA 58.01.02 (Water Quality Standards) and 58.01.05 (Rules & Standards for Hazardous Waste).

In short, the Petitioners have not established that DEQ's reliance upon existing knowledge of chemical suppressants and water as "reasonably available" control technologies was error. Based on the Simon declaration, DEQ has offered expert testimony and a reasonable explanation for its T-RACT analysis. Therefore, the Petitioners' motion for summary judgment as to Claims 6 and 7 is hereby DENIED, and DEQ's and Perpetua's motions for summary judgment as to Claims 6 and 7 are hereby GRANTED.

J. Averaging of Projected As Emissions (Claim No. 9)

The Petition alleges DEQ utilized "three improper averaging tactics: (1) averaging emissions over a 5-year period for the T-RACT input to ambient toxics modeling; (2) averaging the estimated annual ambient modeling impacts across two multi-year scenarios; and (3) averaging the resultant 16-year total emissions over the 70-year human lifetime to assert compliance." (Pet. ¶ 55.) According to the Petitioners, the Air Rules do not allow "multi-year emissions averaging" and

instead require DEQ to "estimate the SGP's maximum 1-year annual arsenic emissions and compare it to the annual arsenic AACC" in Air Rule 586. (*Id*.) In effect, the Petitioners allege DEQ employed a "tactic" that is contrary to the plain language of the Air Rules.

All three sets of parties moved for summary judgment on this issue. Before discussing the motions, it will be helpful to summarize the relevant Air Rules. The starting place is Air Rule 203:

> No permit to construct shall be granted for a new…stationary source unless the applicant shows to the satisfaction of the Department all of the following:
>
> ***
>
> **Toxic Air Pollutants.** ***Using the methods provided in Section 210***, the emissions of toxic air pollutants from the stationary source…would not injure or unreasonably affect human health or animal life or vegetation ***as required by Section 161***. Compliance with all applicable toxic air pollutant carcinogenic increments and toxic air pollutant non-carcinogenic increments ***will also demonstrate preconstruction compliance with Section 161*** with regards to the pollutants listed in Sections 585 and 586.

AIR RULE 203.03 (emphasis added).

Section 161, in turn, provides:

> Any contaminant which is by its nature toxic to human or animal life or vegetation shall not be emitted in such quantities or concentrations as to alone, or in combination with other contaminants, ***injure or unreasonably affect human or animal life or vegetation***.

AIR RULE 161 (emphasis added).

The use of the phrase "will also demonstrate preconstruction compliance" in Section 203.03 effectively creates two regulatory paths. First, the applicant and DEQ can use "the methods in Section 210" to show that emissions will not "injure or unreasonably affect human or animal life or vegetation." Section 210, in turn, consists of six-and-a-half pages of detailed, technical, complex regulations, and any attempt by the hearing officer to summarize Section 210 in a manner that is both useful and accurate would be an exercise in futility. Regardless, the relevant legal standard—

"injure or unreasonably affect"—is not further defined within the Air Rules.

Effectively, the second path—compliance with Sections 585 and 586—provides applicants with a safe harbor. If an applicant demonstrates "[c]ompliance with all applicable toxic air pollutant carcinogenic increments and toxic air pollutant non-carcinogenic increments…with regards to the pollutants listed in Sections 585 and 586," then satisfaction of Section 161 is automatic and application of the "injure or unreasonably affect" standard unnecessary. Section 586, in turn, identifies "acceptable ambient concentrations" (AACCs) for a variety of pollutants, including "arsenic compounds." According to the plain language of that Rule, these AACCs are expressed as "annual averages." For arsenic compounds, the applicable AACC is $2.3E^{-04}$ $\mu g/m^3$. So, if an applicant can demonstrate arsenic emissions will not exceed that AACC, then the Section 203.03 analysis for arsenic is over. As a matter of law, the legal standard of Section 161 is satisfied.

While out of sequence with the order of the motions filed, it is helpful to begin with a discussion of the summary judgment motions filed by DEQ and Perpetua. Broadly speaking, DEQ provides the factual background regarding its decision-making process on this issue through the Schilling Declaration, and Perpetua's briefing includes a "deep dive" into the language of the relevant and complex Air Rules.

According to Mr. Schilling, DEQ analyzed Perpetua's application under Air Rule 210.12. (Schilling Decl., p. 10.) That section contains somewhat of a trade-off: If an applicant demonstrates it is utilizing T-RACT as pollution control technology for a particular toxic air pollutant, then it satisfies Section 161 if its modeled emissions for that toxic pollutant is less than 10 times the applicable AACC. *See* AIR RULE 210.12. This effectively creates another "safe harbor" that allows an applicant to demonstrate compliance with Section 161 through the quantitative standards in Section 586 instead of the qualitative toxicity standard. According to that Rule:

> If the source's…approved T-RACT ambient concentration at the point of compliance is less than or equal to the amount of the air pollutant that would contribute an ***ambient air cancer risk probability of less than one to one hundred thousand (1:100,000)***, no further procedures for demonstrating preconstruction compliance will be required for that toxic air pollutant as part of the application process.

AIR RULE 210.12(c) (emphasis added).

The preceding subsection explains that the "ambient air cancer risk probability of less than one to one hundred thousand (1:100,000)" is "equivalent to ten (10) times the applicable [AACC] in Section 586." AIR RULE 210.12(b). So again, if Perpetua's approved T-RACT ambient concentration for arsenic at the point of compliance is less than 10 times the AACC in Section 586, compliance with Section 161 is achieved as a matter of law.

Paraphrasing Mr. Schilling, DEQ determined that Perpetua proposed T-RACT for arsenic emissions and, therefore, evaluated modeled emissions under Air Rule 210.12 as described above. DEQ started with very conservative assumptions that overestimate emissions. Using those conservative assumptions, the modeling showed exceedances of the 10x AACC standard. As a result, he and DEQ then conducted a "refinement of exposure calculations to provide a more representative comparison to the AACC." (Schilling Decl., pp. 9-11.)

The issue here is that the AACCs are based on an assumed lifetime exposure to the relevant carcinogen over a 70-year period because for permitting and conservatism principles, DEQ normally assumes the project life will exceed that 70-year period. Clearly, if a project will only operate for 16 years and AACC compliance is still achieved, that is the end of the inquiry, because exposure to a carcinogen at a certain level for only 16 years cannot result in a higher cancer risk than exposure to the same carcinogen at the same level for 70 years. But, if a project will only operate for 16 years and AACC compliance is not achieved, that does not automatically mean that the cancer risk exceeds the 1 in 1,000,000,000 or 1 in 100,000 standards. This is because comparison of emissions

that will only take place for 16 years to a standard that is based on an assumed 70-year exposure period is an "apples to oranges" comparison. Based upon his knowledge that the AACCs are based on a lifetime cancer risk over a 70-year period, Mr. Schilling and DEQ made a more refined exposure calculation that proceeds as follows:

First, they reviewed the 14 modeling scenarios provided by PRI for the 16-year period of operations. From this set of 224 data points, they chose the highest modeled concentration of arsenic emissions.

Next, they multiplied that highest annual concentration by the 16-year operational period to calculate a conservative figure for total arsenic emission exposure over the life of the mine.

Next, they divided that figure by the 70-year exposure period on which the AACCs are based.

Finally, they compared that figure to the AACC for arsenic. Because it was less than the AACC, DEQ concluded there was not an unreasonable risk or injury posed to human life. (*See* R., at pp. PET 332, 344; Schilling Decl., pp. 8-12).

The Petitioners may indeed be correct that DEQ's approach is not strictly consistent with Section 586. However, that is not the end of the inquiry. As previously described, and as DEQ and Perpetua correctly note, if strict compliance with the quantitative standards in Sections 585 and 586 is not achieved, then the applicable standard to be met is the qualitative one, that the toxic air pollutant "shall not be emitted in such quantities or concentrations as to alone, or in combination with other contaminants, ***injure or unreasonably affect human or animal life or vegetation***." AIR RULE 161 (emphasis added). Among other things, Mr. Schilling testifies as follows:

> The typical permitting approach is to use worst-case assumptions and data in a limited number of analyses that will confidently show that allowable operations, as described and limited in the permit and permit-required plans and procedures, cannot result in impacts that exceed applicable standards. When this approach is applied to

mining operations, results of the impact modeling tend to greatly overstate actual impacts that will occur or even could occur.

***

The number of TAP-applicable arsenic emission sources for the SGP was expanded late in the permit application review process, after it was determined that some sources had been incorrectly excluded from analysis as per Idaho Air Rules Section 210. The incorrect exclusion was confirmed by the DEQ Permit Writer, the DEQ Permitting Supervisor, and the DEQ Stationary Source Bureau Chief after considering comments received during a public comment period. Without completely reworking the complex and still very conservative approach used to assess carcinogenic TAP impacts, compliance could not be demonstrated using the typical approach outlined above. I then undertook the task of evaluating whether a more refined approach could be used to demonstrate compliance with TAP rules of Section 210.

A first step in refinement of impacts or adjustment of allowable impacts was to assure that reasonably available control technologies were used for all sources of arsenic. This level of control is referred to as T-RACT and its use in the evaluation of carcinogenic TAPs is described in Idaho Air Rules Section 210.12. If T-RACT is used to control emissions from sources, then the allowable impact is ten times that of the AACCs, corresponding to a lifetime cancer risk of 1 in 100,000. The AACC conservatively represents a long-term exposure (70 years) that would result in a 1 in 1,000,000 cancer risk.

***

A worst-case conservative but simplistic approach used for the SGP did not show compliance with the arsenic AACC, or even the AACC multiplied by a factor of ten to reflect the allowable impact when using T-RACT. ***DEQ then reviewed the basis for the AACCs to further evaluate refinement of exposure calculations to provide a more representative comparison to the AACC***. AACCs were established in Idaho Air Rules to protect against a project-caused lifetime excess cancer risk of more than 1-in-1,000,000, or 1-in-100,000 where T-RACT is used to control emissions from sources.

***

Although a lifetime risk is the benchmark, DEQ listed annual averages for the AACCs in Idaho Air Rules because that timeframe 1) is long enough to establish a good representation of long-term impacts for most sources requiring a permit, 2) is short enough to provide compliance assurance early in the life of the industrial operation, and 3) is convenient for compliance monitoring and reporting, providing a practically enforceable limit on operations. ***Use of an annual limit is not key to attaining a limit on the lifetime cancer risk; and, since a lifetime risk is the***

> ***benchmark, use of annual averaged emissions to show compliance with the AACC on an annual basis could be unnecessarily restrictive where processes vary considerably year-to-year and have a project lifetime substantially shorter than 70 years, such as mining processes.***
>
> PRI indicated that the SGP will have a 16-year maximum project lifetime. To calculate a project-based arsenic concentration representative of the project, appropriate for comparison to the AACC (based on a 70-year exposure), the modeled impact was adjusted by the factor 16/70.

(Schilling Decl., pp. 9-11.)

Even if the 16/70 adjustment is not specifically authorized by Sections 210.12 and 586, the hearing officer finds Mr. Schilling's testimony adequate to support DEQ's decision under the qualitative standard of Section 161. Mr. Schilling recognizes that the over-arching legal standard is the toxicity standard in Section 161 and explains why strict compliance with standards expressed as annual limitations is not always necessary to satisfy that standard, particularly when the exposure period is considerably shorter than the assumed 70-year exposure period on which the AACCs are based. Overall, he provides a thoughtful and conservative approach to ensuring arsenic emissions will not exceed the 1-in-100,000 lifetime cancer risk standard when T-RACT is used.

The Schilling Declaration is unrebutted expert testimony on an issue clearly not within the common knowledge of the layperson. To be clear, the hearing officer understands and appreciates the Petitioners' argument that in applying the 16/70 exposure refinement, DEQ "assumed the cancer risk probability from high dose/short-term exposure was equivalent to low dose/long term exposure." (Pet.'rs' Resp. of 6/9/23, p. 44.) It is unclear to the hearing officer if "normalizing" arsenic exposure for a 16-year project in order to compare it to a health standard based on a 70-year lifetime exposure period is truly as simple as applying the 16/70 adjustment factor.

On the other hand, Petitioners do not question the accuracy of the 16-year operational

period,[7] and it is illogical for this issue to turn solely on satisfaction of a standard that is based on a 70-year exposure period, when the permitted project is expected to operate for less than one-fourth of that time. Given the deference accorded to DEQ in the interpretation of its rules, the presumption DEQ acted reasonably, and the layers of conservatism built into the TAP evaluation process described by Mr. Schilling, without expert testimony from the Petitioners explaining why the 16/70 adjustment could cause injury to human life or is otherwise arbitrary, capricious, or an abuse of discretion, Petitioners have not sufficiently rebutted Mr. Schilling.

Based on the foregoing, the hearing officer hereby DENIES the motion for summary judgment filed by Petitioners as to Claim No. 9. The hearing officer hereby GRANTS the motions for summary judgment filed by DEQ and Perpetua as to Claim No. 9.

IV. SUMMARY, CONCLUSION, AND PRELIMINARY ORDER

The Petition alleges thirteen discrete errors. On November 15, 2022, the hearing officer dismissed Claim Nos. 3, 4, and 10, and partially dismissed Claim No. 8. As to the remaining claims, based on the foregoing, it is hereby ordered that:

The motion for summary judgment filed by Petitioners as to Claim Nos. 1, 2, 5, 6, 7, 9, 11, 12, 13, and the remainder of Claim No. 8 is hereby DENIED.

The motions for summary judgment filed by DEQ and Perpetua as to Claim Nos. 1, 2, 5, 6, 7, 9, 11, 12, 13, and the remainder of Claim No. 8 are hereby GRANTED.

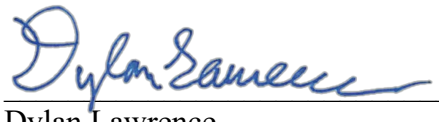
[7] It is worth noting that Air Rule 210.12(d) requires DEQ to "include emission limits and other permit terms for the toxic air pollutant in the permit to construct that assure that the facility will be operated in the manner described in the preconstruction compliance demonstration." To the extent Petitioners are concerned the 16-year mine life was not adopted as a limitation within the Permit, DEQ explains that the hauling limits in Permit Condition 3.6 acts as "a life of mine hauling and excavating limit." (R., at p. PET 597.)

V. RULE 730 NOTICE

Pursuant to Idaho Code Sections 67-5243 and 67-5245, BEQ Rule of Procedure 730, and AG Rule of Procedure 730:

This is a preliminary order of the Hearing Officer and will become final without further action of the Idaho Board of Environmental Quality unless any party appeals to the Board by filing a petition for review of the preliminary order.

Within fourteen (14) days of the service date of this preliminary order, any party may take exceptions to any part of this preliminary order by filing a petition for review of the preliminary order. Otherwise, this preliminary order will become a final order of the Board. The basis for review must be stated in the petition. The Board may review the preliminary order on its own motion.



If any party files a petition for review of the preliminary order, the Board will allow all parties an opportunity to file briefs in support of or taking exceptions to the preliminary order and may schedule oral argument in the matter before issuing a final order. The hearing coordinator will issue a notice setting out the briefing schedule and date and time for oral argument. The Board will issue a final order within fifty-six (56) days of receipt of the written briefs or oral argument, whichever is later, unless waived or extended by the parties or for good cause shown. The Board may hold additional hearings or may remand the matter for further evidentiary hearings if further factual development of the record is necessary before issuing a final order.

Pursuant to Idaho Code Sections 67-5270 and 67-5272, if this preliminary order becomes final, any party aggrieved by the final order or orders previously issued in this case may appeal the final order and all previously issued orders in this case to district court by filing a petition in the district court of the county in which: (1) a hearing was held; (2) the final agency action was taken;

(3) the party seeking review of the order resides or operates its principal place of business in Idaho; or (4) the real property or personal property that was the subject of the agency action is located.

This appeal must be filed within twenty-eight (28) days of this preliminary order becoming final. *See* IDAHO CODE § 67-5273. The filing of an appeal to district court does not itself stay the effectiveness or enforcement of the order under appeal.

Dated this 31st day of October 2023.

Dylan Lawrence
Hearing Officer

Case Docket No. 0101-22-01

JOINT MOTION FOR RECONSIDERATION AND/OR CLARIFICATION

The Idaho Department of Environmental Quality (the "Department") and Perpetua Resources Idaho, Inc. ("Perpetua") respectfully submit this Motion for Reconsideration and/or Clarification of the Memorandum Decision on Motions for Summary Judgment and Preliminary Order issued on October 31, 2023 ("Memorandum Decision"). This motion is brought pursuant to Idaho Code § 67-5243(3), IDAPA 04.11.01.730, IDAPA 04.11.01.770, and IDAPA 58.01.23.73. This motion is supported by the Memorandum in Support filed concurrently herewith and the briefs and pleadings filed in this matter.

The Department and Perpetua respectfully request that the Hearing Officer clarify that "Petition" or "Pet.," as used in the Memorandum Decision, refers to the Amended Petition, that the Memorandum Decision dismissed the Petitioners' Amended Petition in its entirety, and reconsider whether Petitioners' Claim 3 was revived in the Amended Petition and is addressed to resolve this proceeding completely.

BEFORE THE BOARD OF ENVIRONMENTAL QUALITY
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047 NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON, Petitioners, v. IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY,	Case Docket No. 0101-22-01 **MEMORANDUM IN SUPPORT OF JOINT MOTION FOR RECONSIDERATION AND/OR CLARIFICATION**

Respondent,

and

PERPETUA RESOURCES IDAHO, INC.,
Intervenor-Respondent.

The Idaho Department of Environmental Quality (the "Department") and Perpetua Resources Idaho, Inc. ("Perpetua") respectfully submit this memorandum in support of their Joint Motion for Reconsideration and/or Clarification.

I. INTRODUCTION

Pursuant to Idaho Code § 67-5243(3), IDAPA 04.11.01.730, IDAPA 04.11.01.770, and IDAPA 58.01.23.730, the Department and Perpetua jointly request that the Hearing Officer reconsider and/or clarify the Memorandum Decision on Motions for Summary Judgment and Preliminary Order issued October 31, 2023 (the "Memorandum Decision") in the following respects. First, the Department and Perpetua request that the Hearing Officer clarify whether "Petition or Pet." as used in the Memorandum Decision references the Petition to Initiate Contested Case: Air Quality Permit to Construct P-2019.0047 filed on July 22, 2022 (the "Petition") or the Amended Petition to Initiate Contested Case: Air Quality Permit to Construct P-2019.0047 filed on December 6, 2022 and refiled on January 11, 2023 (the "Amended Petition"). Second, the Department and Perpetua request that the Hearing Officer clarify whether the Memorandum Decision dismissed the Amended Petition in its entirety. Third, the Department and Perpetua request that the Hearing Officer reconsider and/or clarify the outcome of Claim 3.

II. BACKGROUND

Petitioners initiated this contested case by filing the Petition on July 22, 2022. On September 6, 2022, Perpetua filed a motion to dismiss the Petition, which the Department joined. *See* Perpetua Resources Idaho's Motion to Dismiss and Supporting Brief (Sept. 6, 2022). After briefing and argument, the Hearing Officer issued an order granting in part and denying in part the motion to dismiss. *See* Order on Motion to Dismiss (Nov. 15, 2022). The Order on Motion to Dismiss categorized Petitioners' allegations into 13 claims. *See* Order at 8-9. That Order dismissed Claims 3, 4, and 10, and dismissed Claim 8 in part. *Id.*

On December 6, 2022, Petitioners filed a motion to amend the Petition, which neither the Department nor Perpetua opposed. *See* Order Granting Motion to File First Amended Petition (Jan. 6, 2023). On January 6, 2023, the Hearing Officer granted Petitioners' motion, and Petitioners filed the Amended Petition on January 11, 2023. *See id.*

The Amended Petition added allegations to Paragraph 40 and Paragraph 70 ostensibly reviving the allegation presented in Claim 3 of the Petition. Amended Petition ¶¶ 40, 70. Thus, on summary judgment, Petitioners, the Department, and Perpetua all moved for summary judgment on the allegations contained in Paragraphs 40 and 70 of the Amended Petition and on Claim 3. *See* Petitioners' Opening Brief in Support of Motion for Summary Judgment at 28-31 (April 14, 2023).[1]

[1] *See also* DEQ's Response to Petitioners' Motion for Summary Judgment and Brief in Support of Cross Motion for Summary Judgment at 23-24 (May 12, 2023); Memorandum in Support of Perpetua's Motion for Summary Judgment and in Opposition to Petitioners' Motion for Summary Judgment at 34-38 (May 12, 2023); Petitioners' Response to Respondent DEQ's Cross-Motion for Summary Judgment and Intervenor Perpetua's Motion for summary Judgment and Petitioners' Reply in Support of Petitioners' Motion for Summary Judgment at 27-34 (June 9, 2023); Reply Memorandum in Support of Intervenor-Respondent Perpetua's Motion for Summary Judgment at 18-21 (June 23, 2023).

III. ARGUMENT

Idaho Code § 67-5243(3) and the Idaho Rules of Administrative Procedure, IDAPA 04.11.01.730, authorize parties to a contested case proceeding to seek reconsideration of a recommended or preliminary order within 14 days of the service date of the order. The Department and Perpetua appreciate the thorough analyses presented in the Memorandum Decision and only seek reconsideration and/or to clarify certain elements of the Memorandum Decision.

A. It is unclear whether the Memorandum Decision cites to and addresses the claims presented in the Petition or the Amended Petition.

In recounting the procedural history of this matter, the Memorandum Decision notes that Petitioners filed the Amended Petition. *See* Mem. Dec. at 2. However, the Memorandum Decision defines "Petition" as the filing on July 22, 2022, not the Amended Petition filed on January 11, 2023. *Id*. From there, when describing Petitioners' claims, the Memorandum Decision cites "Pet." with corresponding paragraph numbers. *See e.g.*, Mem. Dec. at 13, 16. Notably, the paragraph numbers of the Petition and the Amended Petition did not change. Thus, it is not clear whether the Memorandum Decision refers to and addresses the Petition or the Amended Petition.

When Petitioners filed the Amended Petition, it became the operative pleading, and the Petition was superseded. See *Hammer v. Ribi*, 162 Idaho 570, 573, 401 P.3d 148, 151 (2017) ("[T]he amended complaint supersedes the original, the latter being treated thereafter as non-existent."). The Department and Perpetua respectfully request clarification that "Petition" and "Pet." referenced throughout the Memorandum Decision are references to the Amended Petition.

B. It is unclear whether the Memorandum Decision fully resolves all previously undecided claims and necessarily results in dismissal of the Amended Petition.

In their motion for summary judgment, Petitioners requested that the Hearing Officer set aside and remand the Final Permit to the Department. *See* Pet. Mot. Summary Judgment at 2 (April 14, 2023). In their competing motions for summary judgment, the Department and Perpetua requested that the Hearing Officer dismiss Petitioners' Amended Petition. *See* Perpetua's Mot. Summary Judgment at 2 (May 12, 2023); DEQ's Cross-Motion for Summary Judgment at 2 (May 12, 2023). Although the Memorandum Decision is identified as a preliminary order and grants the Department's and Perpetua's respective motions for summary judgment, and denies Petitioners' motion, as to Claims 1, 2, 5, 6, 7, 8, 9, 11, 12, and 13, it does not explicitly dismiss the Amended Petition. *See* Mem. Dec. at 46-47.

The Department and Perpetua respectfully request that the Hearing Officer clarify that the Memorandum Decision resolved all issues in this contested case proceeding and resulted in dismissal of Petitioners' Amended Petition.

C. It is unclear whether Claim 3 was revived in the Amended Petition and should have been decided in the Memorandum of Decision.

The Memorandum Decision correctly stated that Petitioners' Claim 3 was dismissed in the Order on Motion to Dismiss. *See* Mem. Dec. at 2, 46. Subsequently, however, Petitioners amended Paragraphs 40 and 70 to revive Claim 3. Amended Petition ¶¶ 40, 70. Additionally, the Amended Petition requested that the work plans required by the Final Permit be provided for public comment prior to becoming enforceable permit conditions. *Id.* ¶ 71.D. The parties addressed this claim in their summary judgment papers. *See* Petitioners' Opening Brief in Support of Motion for Summary Judgment at 28-31 (April 14, 2023); *see also supra* note 1.

The Department and Perpetua agree that Claim 3 was dismissed in the Order on Motion to Dismiss and surmise that Claim 3 was revived in the Amended Petition. The Department and

Perpetua request that the Hearing Officer reconsider whether Claim 3 was revived by the Amended Petition, and if so, decide the outcome of this claim. The Department and Perpetua note that since this issue was fully briefed by the parties on summary judgment, it does not require additional briefing to address.

IV. CONCLUSION

For the foregoing reasons, the Department and Perpetua respectfully request that the Hearing Officer clarify that "Petition or Pet.," as used in the Memorandum Decision, refers to the Amended Petition, that the Memorandum Decision dismissed the Petitioners' Amended Petition in its entirety, and reconsider whether Petitioners' Claim 3 was revived in the Amended Petition and is addressed to resolve this proceeding completely.

PERPETUA RESOURCES IDAHO, INC.	)	
Intervenor.	)	

Petitioners Nez Perce Tribe, Idaho Conservation League ("ICL"), and Save the South Fork Salmon ("SSFS") hereby petition the Idaho Board of Environmental Quality (the "Board") for review of the October 31, 2023 Preliminary Order issued by the Hearing Officer in this matter. This Petition for Review of Preliminary Order is brought under Idaho Code §§ 67-5243(3), 67-5245(2) and IDAPA 58.01.23.730. The Preliminary Order should be modified, amended, or revoked, and the Permit should be vacated and remanded to DEQ, based on the following errors:

1. The Hearing Office erred, factually and legally, in upholding DEQ's determination that Perpetua has legal control of the Stibnite Road Access Route such that the Route need not comply with ambient air quality standards;

2. In finding that Perpetua will preclude the general public from accessing locations within the ambient air boundary, the Hearing Officer lacked a reasonable factual basis and misapplied applicable regulations, policy, and guidance;

3. The Hearing Officer failed to decide Petitioners' claim that DEQ violated the Clean Air Act and applicable state and federal rules and regulations by allowing Perpetua to submit plans with important project details in the future–after Permit issuance and without public comment; or to the extent that this claim was decided, the Hearing Officer erred;

4. The Hearing Officer erroneously determined that the Permit includes enforceable conditions that will achieve 93.3% dust control.

5. The Hearing Officer misinterpreted and misapplied applicable rules to uphold DEQ's decision to artificially dilute the ambient arsenic concentrations attributable to the SGP by 16/70;

Petitioners request that the Board set out a briefing schedule on this petition as required under IDAPA 58.01.23.730.03.

BACKGROUND

In this contested case, Petitioners challenge the Idaho Department of Environmental Quality's ("DEQ" or "Department") approval of a permit to construct (the "Permit") issued to Perpetua Resources Idaho, Inc. ("Perpetua") for the proposed Stibnite Gold Project ("SPG" or "Project"): a massive open-pit mine in Valley County, Idaho. As proposed, Perpetua would excavate 340 million tons of waste rock to mine and process approximately 100 million tons of ore, using 55 miles of haul truck routes over 16 years. Blasting, excavating, ore hauling, and other Project activities will emit air pollutants, including coarse particulate matter ("PM_{10}") and arsenic. PM_{10} and arsenic are regulated under the federal Clean Air Act and Idaho's air pollution regulations, because they can cause significant and severe health and environmental hazards.

On June 17, 2022, DEQ issued permit to construct ("PTC") P-2019.0047, which is the Permit at issue in this contested case. On July 22, 2022, Petitioners timely filed the original Petition to Initiate Contested Case. On July 28, 2022, the Hearing Officer Dylan Lawrence was assigned to preside over this matter. On August 12, 2022, Perpetua filed a Petition to Intervene. On August 22, 2022, Perpetua's Petition to Intervene was granted. On September 6, 2022, Perpetua filed a Motion to Dismiss. On November 15, 2022, the Hearing Officer issued the Order on Motion to Dismiss, denying the motion with respect to the majority of Petitioners' claims, dismissing or partially dismissing four claims, and declining to allow the pleadings to be amended unless Petitioners file for consideration a formal motion to amend the Petition. On January 11, 2022, Petitioners filed their First Amended Petition to Initiate Contested Case.

After DEQ produced a Project Record and the Parties engaged in limited discovery, Petitioners filed a Motion for Summary Judgment on all claims remaining in the contested case on April 14, 2023. DEQ and Perpetua filed Cross Motions for Summary Judgment.

On August 28, 2023, Perpetua and DEQ filed a joint Motion in Limine to exclude an August 10, 2023 letter from EPA Region 10 Administrator Casey Sixkiller to IDEQ Director Jess Byrne requesting an in-person meeting to discuss EPA's concerns with the Permit. In the letter, EPA raised three primary concerns with the Permit, including concerns that: DEQ used the wrong emission factors, and had it used proper emission factors, the SGP's potential to emit would exceed the major source permitting threshold; DEQ's emission limits were inadequate to demonstrate compliance with NAAQS for particulate matter; and DEQ's delineation of the SGP's ambient air boundary was not supported. Further explanation of the EPA's concerns were detailed in a 19-page enclosure. Three days later, Petitioners filed a Motion to Supplement with EPA's letter and enclosure, and on September 8, 2023, filed a Motion to Amend Contested Case Petition to add a claim regarding the issue EPA raised in its letter about whether DEQ used improper emission factors and was thus wrong when it concluded the SGP's potential to emit will be below major source thresholds. On September 15, 2023, the Hearing Officer denied Perpetua and DEQ's motion in limine, granted Petitioners' motion to supplement with the EPA letter, and denied Petitioners' motion to amend.

On September 21, 2023, the Hearing Officer held a hearing on the cross motions for summary judgment. On October 31, 2023, the Hearing Officer issued a Memorandum Decision on Motions for Summary Judgment and Preliminary Order (the "Preliminary Order").[1]

[1] On November 10, DEQ and Perpetua filed a Joint Motion for Reconsideration and/or Clarification. Petitioners will timely respond to the Joint Motion for Reconsideration and/or Clarification. However, because the DEQ contested case rules at IDAPA 58.01.23.730 differ

In the Preliminary Order, the Hearing Officer rejected DEQ's and Perpetua's arguments that Petitioners lacked standing to pursue this contested case, finding each Petitioner had standing to challenge the Permit. But the Hearing Officer ruled against Petitioners on all claims addressed in the Preliminary Order and granted Summary Judgment to DEQ and Perpetua. The Preliminary Order, however, never addressed one of Petitioners' bases for review: DEQ's allowing Perpetua to defer the submittal of project plans until later, after the Permit is already issued, outside of the normal permitting process, and without public comment.

Petitioners hereby seek review of the October 31, 2023 Preliminary Order, including review of the issue never addressed by the Hearing Officer, as well as review of additional issues set forth below on which the Hearing Officer erred.

BASES FOR PETITION

1. The Hearing Office erred, factually and legally, in upholding DEQ's determination that Perpetua has legal control of the Stibnite Road Access Route such that the Route need not comply with ambient air quality standards.

The Clean Air Act ("CAA") and the Rules for the Control of Air Pollution in Idaho ("Air Rules"), IDAPA 58.01.01 *et seq.*, require Perpetua to meet various air quality standards, including the National Ambient Air Quality Standards ("NAAQS") and acceptable ambient concentrations of carcinogens ("AACCs") for toxic air pollutants ("TAPs"), in ambient air. *See*, *e.g.*, Air Rules Sections 006.11 (NAAQS), 006.125 (TAPs). The U.S. Environmental Protection Agency ("EPA") CAA regulations define "ambient air" as "that portion of the atmosphere, external to buildings, to which the general public has access." 40 C.F.R. § 50.1(e).

---

from the Attorney General rules at IDAPA 04.11.01 and do not explicitly provide for motions for reconsideration or clarification of preliminary orders, Petitioners now file this Petition for Review of Preliminary Order within the deadline set forth in the DEQ rules for seeking the Board's review of a preliminary order. *See* IDAPA 58.01.23.730. Petitioners reserve the right to re-file this, or file a new Petition for Review, upon any resolution of the Joint Motion for Reconsideration and/or Clarification. *See* IDAPA 04.11.01.730.02.b.

The Stibnite Road Access Route ("Route") is a road that passes through what Perpetua and DEQ have defined as the mine's operations boundary and the ambient air boundary, and the inside of that boundary is the active industrial site where Project mining activities and heavy equipment operation will occur. Perpetua has indicated that it will not cut off public access along the Stibnite Road Access Route during mine operations, and as explained by DEQ, Perpetua "will manage an access route to provide the general public with limited access through the [Project] site between Stibnite Road at Sugar Creek and Thunder Mountain Road at Meadow Creek."

Petitioners presented evidence that Perpetua lacks authority to control access along the Stibnite Access Route. This included evidence that there is an ongoing process where the United States Forest Service is reviewing Perpetua's proposed mine, and that Perpetua's authority to control access along the Stibnite Access Route depends on the outcome of that ongoing process. In the Preliminary Order, the Hearing Officer concluded that DEQ could rely on Perpetua's assertions in its submissions to DEQ that it has authority to control access. The Hearing Officer ignored the evidence to the contrary and misapplied the law.

Petitioners seek review of this issue, and ask the Board to vacate and remand the Permit and hold that Perpetua lacks the required authority to control access on the Stibnite Access Route for purposes of determining the Project's ambient air boundary.

2. In finding that Perpetua will preclude the general public from accessing locations within the ambient air boundary, the Hearing Officer lacked a reasonable factual basis and misapplied applicable regulations, policy, and guidance.

Even if Perpetua has authority to control access, Perpetua does not plan to (and the Permit does not require Perpetua to) preclude access. Instead, as the evidence in the record shows, Perpetua plans to allow public access. Petitioners presented evidence showing that Perpetua will allow anyone to use the Stibnite Access Route, so long as they check in and agree

to be "guests of the mine." Petitioners showed that under applicable laws, regulations, guidance, and policy, these people are general public, requiring ambient air quality standards to be met along the Stibnite Access Route.

In ruling against Petitioners, the Hearing Officer stated: "the Permit makes it clear that Perpetua is required to preclude unauthorized access by the general public and that members of the public can become guests of the facility only if they are seeking to pass through to access another destination." Prelim. Order at 21. The Hearing Officer failed to address Petitioners' specific argument that under the CAA, the Air Rules, and EPA's and DEQ's guidance, "guests of the facility" who are passing through to access another destination still count as the general public. Perpetua cannot simply convert the general public to something else by labeling them "guests," and it does not matter whether they are passing through to another destination versus lingering on site. By authorizing people to use the Stibnite Access Road to pass through the site and access other destinations is letting the general public in, and ambient air standards must, therefore, be met along the Stibnite Access Route. The Hearing Officer erred in simply assuming that by labeling them "guests of the facility," people Perpetua will allow on site are not the general public.

Petitioners seek review of this issue, and ask the Board to vacate and remand the Permit and hold that "guests of the facility" traveling the Stibnite Access Route are entitled to ambient air quality protections.

3. The Hearing Officer failed to decide Petitioners' claim that DEQ violated the Clean Air Act and applicable state and federal rules and regulations by allowing Perpetua to submit plans with important project details in the future–after Permit issuance and without public comment; or to the extent that this claim was decided, the Hearing Officer erred.

EPA has delegated to DEQ authority to issue air quality permits in Idaho. Under the Clean Air Act, State air rules like DEQ's "shall" include "enforceable emission limitations" and

other control measures, means, or techniques as necessary or appropriate to meet Clean Air Act requirements. 42 U.S.C. § 7410(a)(2)(A). State plans "shall" include a "program to provide for the enforcement" of the limitations and measures described in subparagraph (A), and for the "regulation of the modification and construction of any stationary source . . . to assure that [NAAQS] are achieved." *Id.* § 7410(a)(2)(C).

EPA's Clean Air Act regulations require each State plan to "set forth legally enforceable procedures" that enable the State to determine whether the construction of a facility will result in a violation of its air pollution control strategies or interfere with attaining or maintaining the NAAQS. 40 C.F.R. § 51.160(a). These legally enforceable procedures: must include means by which the State will prevent construction if the facility will violate air pollution control strategies or will interfere with attaining or maintaining the NAAQS; and must provide for the applicant to submit information on the "location, design, construction, and operation of such facility . . . as may be necessary" to permit the state to "to make the determination" that the facility will comply with its air pollution control strategies and the NAAQS. *Id.* § 51.160(b)–(c). "The legally enforceable procedures in § 51.160(b) must also require" the State to provide opportunity for public comment on information submitted by the applicant and on the State's analysis of the effects on ambient air quality. *Id.* § 51.161(a).

Under the Rules for the Control of Air Pollution in Idaho, DEQ is required to ensure that no PTC shall be granted for a new or modified stationary source unless the applicant shows to the satisfaction of DEQ that the source would not cause or significantly contribute to a violation of any NAAQS. IDAPA 58.01.01.203.02. To satisfy these requirements, DEQ must assess air impacts using maximum potential emissions as limited by either the capacity of the unit/operation or as limited by enforceable permit provisions. *See* IDAPA 58.01.01.006.88. Prior

to issuing a permit to construct, DEQ must provide an opportunity for public comment by making available DEQ's proposed action together with information provided by the applicant and with DEQ's analysis of air quality impacts. IDAPA 58.01.01.209.c.

Under the Permit, Perpetua is required to submit the following plans in the future: the Fugitive Dust Control Plan; the Haul Road Capping Plan; the Operation and Maintenance Manual; and the Stibnite Road Access Management Plan. These plans are not subject to public comment, and while DEQ will review them, it will do so outside of the permitting process set forth in the Air Rules. Despite devoting extensive briefing to this issue, the Hearing Officer did not decide this specific issue in the Preliminary Order. Alternatively, to the extent that the Hearing Officer decided this issue, he erred.

Petitioners seek review of this issue, and ask the Board to vacate and remand the Permit and hold that DEQ must require Perpetua to submit the plans as part of the public permitting process.

4. The Hearing Officer erroneously determined that the Permit includes enforceable conditions to achieve 93.3% dust control.

Under the Air Rules, DEQ cannot issue a PTC unless it determines that the facility: (1) "would comply with all applicable federal emissions standards;" (2) "would not cause or significantly contribute to a violation of any ambient air quality standards" (i.e., the NAAQS); and (3) "emissions of toxic air pollutants . . . would not injure or unreasonably affect human or animal life or vegetation as required by Section 161." Air Rules Section 203.

A critical factor affecting the SGP's fugitive dust emissions, and therefore whether DEQ can make the required determinations under Air Rules Section 203 that the Project will comply with the PM_{10} NAAQS and arsenic AACC limits, is the degree to which Perpetua will effectively control dust from haul roads. When it approved the Permit, DEQ assumed that Perpetua will

achieve a 93.3% control efficiency of all haul road dust by using a combination of water sprays and chemical dust suppressants. However, as EPA and other commenters pointed out, it is highly questionable whether 93.3% fugitive dust control is realistically attainable for this Project, and even if it were technically possible, the Permit lacks conditions necessary to ensure that Perpetua will achieve such a high level of control.

In the Preliminary Order, the Hearing Officer concluded that DEQ properly concluded that the Project will achieve 93.3% control because "the Permit includes a specific requirement that 93.3% control efficiency be achieved." Preliminary Order at 31. This is incorrect. The Permit does not include a specific requirement to achieve 93.3% or any other level of dust control. The Permit does include requirements for Perpetua to develop a Fugitive Dust Control Plan and a Haul Road Capping Plan. And while the Permit requires specific things to be included in those plans, none of them ensure any specific control efficiency be achieved--let alone an aggressive 93.3% control efficiency.

The Hearing Officer also faulted Petitioners for not offering "expert testimony describing the terms they believe are necessary to ensure compliance." Preliminary Order at 31. The Hearing Officer ignored the expert testimony in the form of public comments and other submissions to DEQ made by the EPA, Petitioners, and others with technical expertise on this very issue, including testimony that conditions specifying the combinations, volumes, and frequencies for applying water sprays and chemical dust suppressants are necessary.

Petitioners seek review of this issue, and ask the Board to vacate and remand the Permit and hold that DEQ must include enforceable permit limits on the combinations, volumes, and frequencies for applying water sprays and chemical suppressants sufficient to achieve 93.3% dust control.

5. The Hearing Officer misinterpreted and misapplied applicable rules to uphold DEQ's decision to artificially dilute the ambient arsenic concentrations attributable to the SGP by 16/70.

No PTC can be granted unless DEQ determines the applicant showed: "Using the methods provided in Section 210, the emissions of toxic air pollutants from the . . . source . . . would not injure or unreasonably affect human health or animal life or vegetation as required by Section 161." Air Rules Section 203.03. Section 161 states, "[a]ny contaminant which is by its nature toxic to human or animal life or vegetation shall not be emitted in such quantities or concentrations as to alone, or in combination with other contaminants, injure or unreasonably affect human or animal life or vegetation." Air Rules Section 161.

For each carcinogenic TAP, including arsenic, the Air Rules set Acceptable Ambient Concentrations of Carcinogens ("AACC"), where each AACC is an annual average in ug/m3. Air Rules Section 586. The applicable TAPs "carcinogenic increments" that must be met to satisfy Section 203.03 are the AACCs, which are *annual average* ambient concentrations. *See* Air Rules Section 586.

The "methods provided in Section 210" that must be followed to satisfy Section 203.03 spell out in detail how to estimate TAPs emissions and ambient concentrations. *See* Air Rules Section 210. The Air Rules include explicit exceptions to meeting the normal AACCs, allowing less stringent AACCs either where: (a) a project is five years or less; or (b) a T-RACT demonstration is done. Air Rules Sections 210.12, 210.15. There are no other exceptions in the Air Rules.

Because the Stibnite Gold Project is for 16 years (which is longer than five years or less), it is not eligible for the short-term source exception. DEQ did grant the T-RACT exception to Perpetua. Even with the T-RACT adjusted arsenic AACC—which allows Perpetua 10 times the normal limit—DEQ recognized that the Project would still exceed the arsenic AACC. To avoid

this problem, DEQ contrived a new tactic to artificially reduce the apparent arsenic exposure by spreading out the actual arsenic exposure resulting from the 16-year Project over a longer 70-year human lifetime. This new trick artificially reduces the apparent concentration of arsenic to a mere 23% (16/70 x 100) of what the arsenic concentration will actually be each year during the Project.

In accepting DEQ's approach, the Hearing Officer stated that "unless an issue is squarely addressed by the Air Rules, the hearing officer will defer to 'practical' interpretations of the Air Rules by DEQ." Prelim. Order at 7. Here, the Hearing Officer improperly deferred to DEQ's interpretation of the Air Rules and ignored the fact that the Air Rules squarely address this issue: the Air Rules provide two specific exceptions to meeting the arsenic AACC, and do not allow for other exceptions. The Hearing Officer effectively allowed DEQ to rewrite the Rules without following the rulemaking process and allowed DEQ to create a new exception--found nowhere in the Air Rules --to the requirement to comply with the arsenic AACCs following the methods in Section 210.

Petitioners seek review of this issue, and ask the Board to vacate and remand the Permit and order that DEQ must comply with the methods in Air Rules Section 210 and cannot authorize the Permit unless it will comply with the arsenic AACCs, as adjusted by the T-RACT, without any 16/70 adjustment.

CONCLUSION

Petitioners request that the Board issue an order remanding to DEQ and vacating the Permit, and/or remand to the Hearing Officer for additional proceedings.

Dated: November 14, 2023

BEFORE THE BOARD OF ENVIRONMENTAL QUALITY
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047	
NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON, Petitioners, v. DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent, and PERPETUA RESOURCES IDAHO, INC., Intervenor.	BEQ Case No. 0101-22-01 OAH Case No. 23-245-01 ORDER ON POST PRELIMINARY ORDER PROCEDURES

On October 31, 2023, the hearing officer issued a Memorandum Decision on Motions for Summary Judgment and Preliminary Order. Under BEQ's rules of procedure, a preliminary order becomes a final order of the BEQ unless a party files a petition for review of the order within fourteen days. BEQ R.PROC. 730.02(b). When a petition for review is filed, the review process takes place before the BEQ and is coordinated by its hearing coordinator. BEQ R.PROC. 730.03.

In addition to that petition for review process, BEQ has adopted Rule 770 of the rules of procedure adopted by the Idaho Attorney General. BEQ R.PROC. 003.21. That rule allows a party affected by any order (including a preliminary order) to file a "petition" to clarify the order and to

combine that petition with a petition for reconsideration. AG R.PROC. 770. Curiously, Rule 770 does not expressly specify a deadline for filing such petitions. However, because a preliminary order automatically becomes final unless a petition for review is filed within fourteen days, at least as to preliminary orders, there is an effective fourteen-day deadline. Once a Rule 770 petition has been filed, other parties then have 21 days to file an "answer." AG R. PROC. 230.01(b), 270.01.

On November 10, 2023, DEQ and Perpetua filed a Joint Motion for Reconsideration and/or Clarification, requesting the hearing officer to clarify issues related to the fact that the Petitioners amended their initial petition and to "reconsider whether Petitioners' Claim 3 was revived in the Amended Petition and is addressed to resolve this proceeding completely." (Joint Mot. of 11/10/23, p. 2.) On November 14, 2023, the "original" Petitioners (Idaho Conservation League, Nez Perce Tribe, and Save the South Fork Salmon) filed a petition for review of the Preliminary Order by BEQ.

This is perhaps a situation in which the BEQ procedural rules, AG procedural rules, and Idaho Administrative Procedure Act could be integrated a little better. Under Idaho Code Section 67-5243(3), a petition for reconsideration not acted on within 21 days is deemed denied. Therefore, if the original Petitioners took the full 21 days to answer DEQ and Perpetua's Rule 770 petition, by statute, the request for reconsideration would be automatically denied before the hearing officer would have time to act on it.

Thankfully, the original Petitioners have voluntarily agreed to file their answer/response to the Rule 770 petition by Monday, November 20. Therefore, based on the foregoing, it is hereby ordered that the Idaho Conservation League, Nez Perce Tribe, and Save the South Fork Salmon shall file a response/answer to the November 10 Joint Motion on or before Monday, November 20, 2023.

Dated this 17th day of November, 2023.

Dylan Lawrence
Hearing Officer

Attorney for Save the South Fork Salmon

BEFORE THE BOARD OF ENVIRONMENTAL QUALITY
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047	
	CASE DOCKET NO. 0101-22-01
NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON Petitioners, v. IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent, and PERPETUA RESOURCES IDAHO, INC. Intervenor-Respondent.	**PETITIONERS' RESPONSE TO JOINT MOTION FOR RECONSIDERATION AND/OR CLARIFICATION**

Petitioners Nez Perce Tribe, Idaho Conservation League ("ICL"), and Save the South Fork Salmon ("SSFS") file this Response to the Joint Motion for Reconsideration and/or Clarification filed by Respondent Idaho Department of Environmental Quality ("DEQ") and Intervenor-Respondent Perpetua Resources Idaho, Inc. ("Perpetua"). Petitioners agree with DEQ and Perpetua that what they are calling "Claim 3"—DEQ's reliance of various future plans to be submitted by Perpetua violates procedural requirements of the Air Rules and the Clean Air Act and its regulations—was raised in the Amended Petition, was fully briefed by all parties in the cross motions for summary judgment, but was not addressed by the Hearing Officer in the October 31, 2023 Memorandum Decision and Preliminary Order. Petitioners, thus, do not oppose reconsideration and/or clarification on this issue.[1] However, Petitioners request that upon any reconsideration and/or clarification, the Hearing Officer grant summary judgment in favor of Petitioners on Claim 3 for the reasons set forth in the summary judgment briefing and vacate and remand the Permit.

First, the Amended Petition raised this "Claim 3" issue: that DEQ violated the CAA and the Air Rules by failing to require Perpetua to submit the Fugitive Dust Control Plan ("FDCP"), the Haul Road Capping Plan ("HRCP"), the Operation and Maintenance Manual ("O&M Manual"), and the Access Management Plan ("AMP"). Both the original Petition and the Amended Petition included a Relief Requested section titled "FDCP, AMP, O&M Manual, & HRCP" which states as follows:

[1] Petitioners filed a Petition for Review of Preliminary Order on November 14, 2023, seeking review by the Idaho Board of Environmental Quality (the "Board") of this "Claim 3" issue, and other issues. DEQ's contested case rules explicitly provide for seeking the Board's review of a preliminary order by filing a petition for review within 14 days, as Petitioners have done. IDAPA 58.01.23.730. Petitioners reserve the right to re-file their Petition for Review by the Board as necessary, or to file a new Petition for Review, upon any resolution of the Joint Motion for Reconsideration and/or Clarification.

> DEQ must require Perpetua to submit the FDCP, AMP, O&M Manual, and HRCP (collectively, "Plans"), must provide for public comment on the Plans, must review and revise Plans to ensure the SGP's emissions comply with IDAPA 58.01.01.203, and must incorporate the Plans as enforceable PTC conditions.

Petition at ¶ D; Amended Petition at ¶ D. After the Hearing Officer's decision on the Motion to Dismiss, Petitioners revised Paragraphs 32 and 70 to add CAA regulation and Idaho Air Rule provisions related to the permit review process requirements, including public comment requirements, in the Amended Petition. The FDCP and HRCP were already discussed in the original Petition in Paragraphs 37 and 39, including stating that these plans had not yet been developed but were being relied upon by DEQ. After the decision on the Motion to Dismiss, Paragraph 37 was revised to add references raising the issue that DEQ failed to take public comment on the FDCP and HRCP in the Amended Petition. The O&M Manual was already discussed in the original Petition in Paragraph 40, and after the decision on the Motion to Dismiss, Paragraph 40 was revised to add additional information about the O&M Manual and about Air Rule permit process requirements, including requirement for submitting project plans and for taking public comment. The AMP was already discussed in the original Petition in Paragraphs 63 through 65, including raising the issue that DEQ was relying on the AMP even though it had not yet been written and would not go through public comment.

Second, this "Claim 3" issue was fully briefed on summary judgment. Petitioners' opening brief devoted an entire section to this specific issue: Section III, titled "DEQ's Reliance on Future Plans to be Prepared by Perpetua Outside of the PTC Process Violates the Air Rules and CAA." Pet'rs' Opening Br. at 28–31. In that section of the opening brief, Petitioners argued that DEQ violated the Air Rules and the CAA by relying on the FDCP, HRCP, O&M Manual, and AMP without preparing these plans during the permitting process set forth in the Air Rules and CAA, including without taking public comment on the plans. DEQ and Perpetua responded,

opposing this specific claim on the merits, and without arguing the claim had been dismissed or was not raised in the Amended Petition. DEQ Resp. Br. at 23–24; Perpetua Resp. Br. at 34–38. Petitioners' reply brief again devoted an entire section to this issue: Section IV, titled "DEQ's Reliance on Future Plans to be Prepared by Perpetua Outside of the Permit Process Violates the Air Rules and the Clean Air Act." Pet'rs' Reply Br. at 27–34. In fact, this was the lengthiest argument section of Petitioners' reply brief.

Third, while the Preliminary Order discusses some of the future plans in relation to some of Petitioners' other claims, it never addresses this "Claim 3" issue. To be sure, other claims Petitioners raised do involve some of these same future plans; however, those claims contest the adequacy of the required content of those plans, and the adequacy of Permit provisions related to the plans. *See*, *e.g.*, Pet'rs' Opening Br. at 21–24, 26–27. Whereas Claim 3 is concerned with whether the procedures set forth in the Air Rules and CAA allow relying on future plans in the manner that DEQ did here. *See* Pet'rs'Opening Br. at 28–31; Pet'rs' Reply Br. at 27–34.

For these reasons, Petitioners do not oppose reconsideration and/or clarification regarding "Claim 3", and if any decision is issued on reconsideration or clarification, Petitioners ask that the Hearing Officer grant summary judgment for Petitioners on Claim 3.

Dated: November 20, 2023

Respectfully submitted,

BEFORE THE BOARD OF ENVIRONMENTAL QUALITY
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047	
NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON, Petitioners, v.	BEQ Case No. 0101-22-01 OAH Case No. 23-245-01 ORDER ON JOINT MOTION FOR RECONSIDERATION AND/OR CLARIFICATION
DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent, and PERPETUA RESOURCES IDAHO, INC., Intervenor.	

On October 31, 2023, the hearing officer issued a Memorandum Decision on Motions for Summary Judgment and Preliminary Order (the "Preliminary Order"). On November 10, 2023, DEQ and Perpetua filed a joint motion requesting the hearing officer to:

1. Clarify that citations to "Petition" or "Pet." in the Preliminary Order refer to the First Amended Petition to Initiate Contested Case filed by the Petitioners on January 11, 2023, as opposed to the initial Petition to Initiate Contested Case filed by the Petitioners on July 22, 2022;

2. Clarify whether the Preliminary Order dismissed the Amended Petition in its entirety; and

3. Reconsider whether Claim No. 3 was revived in the Amended Petition, and if so, to decide the outcome of that claim.

The Petitioners filed their response to the Motion on November 20, 2023. They do not oppose the Motion and request the hearing officer to grant summary judgment in their favor on Claim No. 3.

Regarding the first issue, unless otherwise stated, any references or citations in the Preliminary Order to "Pet." or to the "Petition" relate to the Amended Petition of January 11, 2023. Contemporaneously with this order, the hearing officer is issuing an Amended Memorandum Decision on Motions for Summary Judgment and Preliminary Order ("Amended Preliminary Order") that includes a new footnote 1 clarifying this point.

Regarding the second issue, Section IV of the Preliminary Order reflects that the Preliminary Order grants summary judgment in favor of DEQ and Perpetua on all claims that had not already been dismissed in the November 15, 2022 Order on Motion to Dismiss. In addition, Section V of the Preliminary Order contains the Rule 730 notice language. This is notable because BEQ Rule of Procedure 003.17 adopts AG Rules of Procedure 710 and 711 governing interlocutory orders. AG Rule of Procedure 710 establishes that (1) interlocutory orders are orders that do not decide all previously undecided issues, and (2) an order accompanied by Rule 730 notice language is not interlocutory. In other words, inclusion of the Rule 730 notice language inherently indicates that all claims for relief have been resolved. With that said, Section IV of the Amended Preliminary Order now includes additional language that is more explicit on this issue.

Regarding the third issue, it is important to recall the sequence of events. The hearing officer issued an order formally dismissing Claim No. 3 on November 15, 2022. The Petitioners filed their Motion to File First Amended Petition on December 6, 2022. The Petitioners describe the intent of

that motion as "merely…to correct deficiencies the Hearing Officer found with respect to some claims and to provide additional detail and clarity regarding each claim being pursued in this contested case…." (Mot. to File Am. Pet. of 12/6/22, p. 3.) That motion did not contain any express references to Claim No. 3. The Petitioners formally filed their Amended Petition on January 11, 2023. The Amended Petition added some additional content to Paragraph 40, the portion of the original Petition most closely associated with Claim No. 13. But, it did not otherwise reference Claim No. 3 or request the hearing officer to take any action regarding Claim No. 3.

Generally speaking, when a judge or hearing officer renders a formal, written decision on an issue, that ruling is then the established "law of the case" for the remainder of the proceeding. The only way to reverse a prior ruling is to formally ask the judge or hearing officer to reconsider that prior ruling. Indeed, even DEQ—one of the movants for clarification/reconsideration—actively decided not to advance further argument regarding Claim No. 3 on summary judgment because it had been dismissed. (*See* DEQ Resp. and Br. in Supp. of MSJ of 5/12/23, p. 16.)

The Petitioners did not accompany either their December 6, 2022 motion to amend or their Amended Petition with any formal request to re-visit the dismissal of Claim No. 3. Neither of those filings specifically reference Claim No. 3. In this regard, it is helpful to recall that the Amended Petition contains 30 pages of lengthy, detailed allegations. It is unrealistic to expect adding a few additional sentences to an allegation within a 30-page pleading to adequately inform the hearing officer and BEQ of a belief that a claim has been automatically revived, in spite of a prior formal ruling dismissing it. In this regard, it is helpful to recall that, even though the standards for amending pleadings are easily met, amending a pleading still requires approval; it is not done "as of right." *See* BEQ R.PROC. 003.05; AG R.PROC. 305.

For the foregoing reasons, the hearing officer finds that Claim No. 3 was not revived simply

by the filing of the Amended Petition. However, the hearing officer understands that, in the event he is reversed on this issue, it will be more efficient to have addressed the substance of the claim too, particularly given that Petitioners and Perpetua have briefed it on summary judgment. Therefore, the Amended Preliminary Order contains a new section addressing Claim No. 3.

Based on the foregoing, the Joint Motion for Reconsideration and/or Clarification is hereby GRANTED by the issuance of the Amended Preliminary Order filed contemporaneously herewith.

Dated this 5th day of December, 2023.

Dylan Lawrence
Hearing Officer

BEFORE THE BOARD OF ENVIRONMENTAL QUALITY
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047	
	BEQ Case No. 0101-22-01
NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON, Petitioners, v. DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent, and PERPETUA RESOURCES IDAHO, INC., Intervenor.	OAH Case No. 23-245-01 AMENDED MEMORANDUM DECISION ON MOTIONS FOR SUMMARY JUDGMENT AND PRELIMINARY ORDER

I. FACTUAL AND PROCEDURAL HISTORY

Perpetua Resources Idaho, Inc. is in the process of applying for a variety of permits for its proposed Stibnite Gold Project ("SGP") in Valley County, Idaho. The SGP would consist of conventional open-pit mining, ore preparation, and gold extraction operations. In August 2019, Perpetua applied to the Idaho Department of Environmental Quality ("DEQ") for an air quality permit for the construction and operation of the SGP, pursuant to the Rules for the Control of Air Pollution in Idaho in IDAPA 58.01.01 (the "Air Rules"). DEQ issued the final version of air quality permit-to-construct P-2019.0047 (the "Permit") on June 17, 2022.

On July 22, 2022, the Nez Perce Tribe, Idaho Conservation League, and Save the South Fork Salmon ("Petitioners") filed a joint petition to initiate a contested case (the "Petition") regarding the Permit. The Petition alleges DEQ committed several errors in its development of the Permit and asks the Board of Environmental Quality ("Board" or "BEQ") to vacate and withdraw the Permit and remand it to DEQ to correct such errors. After some motion practice, the Petitioners filed an amended Petition on January 11, 2023.[1]

DEQ filed its response to the initial Petition on August 12, 2022 and its response to the amended Petition on January 17, 2023. DEQ's response admits many of the Petition's allegations regarding general background information and applicable law, but ultimately denies DEQ committed any errors in issuing the permit, and requests its actions in issuing the Permit be affirmed.

On August 12, 2022, Perpetua filed a petition to intervene in the contested case proceeding pursuant to Rule 353.01 of the Board's Contested Case Rules in IDAPA 58.01.23 (the "BEQ Procedural Rules"), which the hearing officer granted on August 22, 2022. Perpetua filed its response to the amended Petition on December 13, 2022. Similar to DEQ's responsive pleading, Perpetua's response admits many of the Petition's allegations regarding general background information and applicable law, but ultimately denies that DEQ committed any errors in issuing the Permit and requests the Permit be affirmed and the Petition dismissed.

On September 6, 2022, Perpetua filed a motion to dismiss the Petition. The hearing officer ruled on that motion on November 15, 2022. In doing so, the hearing officer identified 13 individual claims of error in the Petition. The order granted the motion to dismiss as to Claim Nos. 3, 4, and 10 and partially granted the motion as to Claim No. 8. As to the remaining claims, the order denied the

[1] For ease of reference, unless otherwise stated, references in this Order to "Pet." or the "Petition" are references to the Amended Petition of January 11, 2023.

motion. Therefore, Claim Nos. 1, 2, 5, 6, 7, 9, 11, 12, 13, and a portion of Claim No. 8 survived.[2]

Pursuant to a stipulated scheduling order, the Petitioners filed a motion for summary judgment on April 14, 2023, and DEQ and Perpetua filed motions for summary judgment on May 12, 2023. Briefing on those motions and two related motions to strike was complete as of July 20, 2023. The hearing officer ruled on the motions to strike on July 31, 2023, and the parties and hearing officer held a hearing on the summary judgment motions on September 21, 2023.

The hearing officer issued a Memorandum Decision on Motions for Summary Judgment and Preliminary Order on October 31, 2023. DEQ and Perpetua filed a Joint Motion for Reconsideration and/or Clarification on November 10, 2023, requesting the hearing officer clarify issues related to the Amended Petition and whether Claim No. 3 had been revived by it. The hearing officer issues this Amended Memorandum Decision on Motions for Summary Judgment and Preliminary Order in response to the November 10 joint motion. This will provide the parties and the Board with a single, unified decision document for the purposes of the Petition for Review of Preliminary Order filed by the Petitioners on November 14, 2023.

II. RELEVANT LEGAL STANDARDS

A. Standards on Motions for Summary Judgment

Motions for summary judgment filed in administrative proceedings before the BEQ are governed by the Idaho Rules of Civil Procedure. *In the Matter of Simmons Sanitation*, Findings of Fact, Conclusions of Law, and Preliminary Order on Motion for Summary Judgment of 9/23/05, at p. 3 (BEQ Dkt. No. 0106-05-01). Those rules provide in pertinent part:

A party may move for summary judgment, identifying each claim or defense, or the

[2] On pages 22, 23, and 24 of the order on the motion to dismiss, there are incorrect references to Claim Nos. 10, 11, and 12 at the end of the sections discussing Claim Nos. 11, 12, and 13, respectively. The heading of each of those sections is correct.

> part of each claim or defense, on which summary judgment is sought. The court must grant summary judgment if the movant shows that there is no genuine dispute as to any material fact and the movant is entitled to judgment as a matter of law.
>
> ***
>
> A party asserting that a fact cannot be or is genuinely disputed must support the assertion by…citing to particular parts of materials in the record, including depositions, documents, electronically stored information, affidavits or declarations, stipulations (including those made for purposes of the motion only), admissions, interrogatory answers, or other materials; or…showing that the materials cited do not establish the absence or presence of a genuine dispute, or that an adverse party cannot produce admissible evidence to support the fact.
>
> ***
>
> An affidavit used to support or oppose a motion must be made on personal knowledge, set out facts that would be admissible in evidence, and show that the affiant or declarant is competent to testify on the matters stated. Sworn or certified copies of all papers or parts of papers referred to in an affidavit must be attached to or served with the affidavit. The court may permit affidavits to be supplemented or opposed by depositions, answers to interrogatories, or further affidavits.

IDA.R.CIV.PROC. 56(a), (c)(1), (c)(4).

Air permit matters are often technical in nature, requiring the decision-maker to understand the relevant science and to analyze long, detailed regulations. Therefore, discussion of the rules governing expert witness testimony at the summary judgment stage is warranted. In the context of legal malpractice cases, the Idaho Supreme Court has held:

> When a defendant-attorney files a motion for summary judgment, the plaintiff ordinarily has an obligation to provide expert affidavits that explain how the lawyer's conduct fell below the standard of care and how the conduct proximately caused damages. The reason for this rule is that ***laypeople sitting on a jury usually do not have the knowledge or experience necessary*** to determine the standard of care that applies to an attorney or how the attorney's performance of that duty may or may not harm a client. The only recognized exception to this rule is where the attorney's alleged malpractice is so obvious that it is within the ordinary knowledge and experience of laymen, such as when an attorney allows a statute of limitations to run.
>
> When Smith filed his motion for summary judgment, he also filed an affidavit and report from an expert witness stating that 'in [his] opinion, Mr. Smith met and exceeded the applicable standard of care in representing Ms. Greenfield in both the

> Criminal and Civil Cases.' The report analyzed the various deficiencies alleged by Greenfield and concluded that any alleged deficiency was not the cause of the jury's adverse verdict. ***Greenfield did not file any expert affidavits to refute these opinions*** and never disclosed any expert witnesses during the course of discovery. Instead, she filed her own affidavit setting forth the ways she believed that Smith's performance was deficient.
>
> ***
>
> These alleged deficiencies are not simple matters like an attorney allowing a statute of limitations to run….***Without expert testimony, Greenfield could not demonstrate that there were genuine issues of material fact*** as to whether Smith's performance fell below the standard of care or proximately caused her damages. As such, the district court ***properly granted summary judgment*** in favor of Smith.

Greenfield v. Smith, 395 P.3d 1279, 1285-1286, 162 Idaho 246, 252-253 (Idaho 2017) (emphasis added) (citations omitted); *see also Samuel v. Hepworth, Nungester & Lezamiz, Inc*., 996 P.2d 303, 134 Idaho 84 (Idaho 2000); *Rich v. Hepworth Holzer, LLP*, at p. 10-11, Ida. Sup. Ct. Dkt. No. 49300 (Sept. 6, 2023) (reaffirming *Greenfield* principles).

The test for whether a summary judgment respondent is required to adduce an expert affidavit is whether the relevant evidence is "the type that would be within the ordinary knowledge and experience of a layperson." *Ciccarello v. Jeffrey Bo Davies, & Marcus, Christian, Hardee & Davies, LLP*, 166 Idaho 153, 161, 456 P.3d 519, 527 (Idaho 2019). "Judges, after all, are lay persons, no matter how well-read they are in science." *Earl v. Cryovac, A Div. of W.R. Grace Co*., 772 P.2d 725, 728, 115 Idaho 1087, 1090 (App. 1989) (citation omitted).

Many of the errors alleged by Petitioners are not "the type that would be within the ordinary knowledge and experience of a layperson." Therefore, as to each alleged error, it is important to determine if expert witness testimony is necessary to render a decision, and if so, to evaluate the sufficiency of the expert testimony.

B. Idaho APA Judicial Standards of Review

The pleadings, motions, and briefs in this matter frequently invoke Idaho Code

Section 67-5279. That statute contains the standards of review applicable when a petition for judicial review of an agency decision has been filed pursuant to the Idaho Administrative Procedure Act, Idaho Code Sections 67-5201 – 67-5292 (the "APA"). After a final order has been issued in this matter, if a party appeals to the judicial system, Section 67-5279 contains the standards governing the court's evaluation of the final order.

Even though APA standards are not directly applicable to the pending motions, it is still important to understand the standards that will ultimately govern judicial review of the Board's decision. As the Board itself has recognized, in a contested case proceeding, "the Board must determine whether DEQ has acted reasonably and in accordance with law." *In the Matter of Sunnyside Park Utilities' Application for Sewage Disposal Permit*, Final Order on Petition for Review of Preliminary Order, at p. 10 (BEQ Dkt. 0103-07-02, Apr. 7, 2009).[3]

Pursuant to DEQ Procedural Rule 003.18 and AG Procedural Rule 740, the Board will render a decision in this matter by issuing a final order. Therefore, subsection (3) of Section 67-5279 applies to judicial review, and the court would affirm the Board's decision unless it finds:

- DEQ and the Board acted in violation of constitutional or statutory provisions;
- DEQ and the Board acted in excess of their statutory authority;
- DEQ's approval of the Permit and the Board's decision to uphold it were made upon unlawful procedure;
- The Board's decision was not supported by substantial evidence on the record as a whole; or

[3] The hearing officer is aware that Board members have previously expressed concern regarding application of Section 67-5279 standards too early in an administrative hearing process. (*See generally* Order of 9/23/22, *taking administrative notice of* Tr. of 12/4/14, 47:5-9 (BEQ Dkt. No. 0101-14-01)). Because those are the standards that ultimately govern the disposition of this matter, it is still necessary to reference them on summary judgment. As with a cause of action in a civil lawsuit, it is still necessary at the summary judgment stage to reference and understand the legal standards and claim elements that would govern at trial.

- DEQ and the Board otherwise acted in a manner that qualifies as arbitrary, capricious, or an abuse of discretion.

IDAHO CODE § 67-5279(3)

C. Deference to DEQ

According to the Idaho Supreme Court, "[t]he actions of an agency…are afforded a ***strong presumption of validity***." *Duncan v. State Bd. of Accountancy*, 232 P. 3d 322, 324, 149 Idaho 1 (Idaho 2010) (emphasis added).

> Where an agency interprets a statute or rule, this Court applies a four-pronged test to determine the appropriate level of deference to the agency interpretation. This Court must determine whether: (1) the agency is responsible for administration of the rule in issue; (2) the agency's construction is reasonable; (3) the language of the rule does not expressly treat the matter at issue; and (4) any of the rationales underlying the rule of agency deference are present. There are five rationales underlying the rule of deference: (1) that a practical interpretation of the rule exists; (2) the presumption of legislative acquiescence; (3) reliance on the agency's expertise in interpretation of the rule; (4) the rationale of repose; and (5) the requirement of contemporaneous agency interpretation.

Id. (citations omitted).

This matter requires a detailed review of the Air Rules. Clearly, DEQ is responsible for administering those Rules. Therefore, unless an issue is squarely addressed by the Air Rules, the hearing officer will defer to "practical" interpretations of the Air Rules by DEQ.

III. ANALYSIS

A. Standing and the Petitioners' Status as "Aggrieved Parties"

Both DEQ and Perpetua moved for summary judgment on the basis that each of the three Petitioners lacks standing. This order will address standing before proceeding to the alleged errors.

1. Discussion of Applicable Standards

BEQ's Rules of Procedure state that "[a]ny person aggrieved by an action or inaction of the Department may file a petition to initiate a contested case pursuant to" the APA. BEQ PROC.

RULE 002.02. The rules define "person aggrieved" as "[a]ny person or entity with legal standing to challenge an action or inaction of the Department…." BEQ PROC. RULE 005.01. Regarding legal standing, the BEQ has held:

> The petitioner to a contested case proceeding can be either an individual or an organization. In order to satisfy standing, an individual petitioner must demonstrate: (1) an injury in fact which is real, concrete and particularized, and actual or imminent, and not just speculative or hypothetical; (2) a causal connection between the challenged action and the injury; and (3) the likelihood that the injury will be redressed by a favorable decision.
>
> An organization may obtain associational or representational standing on behalf of its members. To achieve standing on behalf of its members, an organization must show that: (1) its members would otherwise have standing to sue individually; (2) the interests the organization seeks to protect are germane to the organization's purpose; and (3) neither the claim asserted, nor the relief requested, requires participation of individual members in the lawsuit.

Solomon v. Idaho Dept. of Env. Quality, Order of 12/17/03, at p. 4 (BEQ Dkt. No. 0101-03-01) (citations omitted).

2. Idaho Conservation League

The Idaho Conservation League (ICL) filed declarations of Allison Fowle, Asa Menlove, and Jonathan Oppenheimer to establish standing. Ms. Fowle testifies, among other things, that she is a member of ICL; that she has used the Stibnite Road through the SGP many times; that she plans to continue visiting the area to recreate; and that she is concerned about the health effects from dust and arsenic if she continues to recreate in the area while the mine is operating. (Fowle Decl., ¶¶ 2-8.) The Menlove Declaration contains similar assertions. (*See* Menlove Decl., ¶¶ 2, 4, 9, 10.) Mr. Oppenheimer testifies that he is both a member and employee of ICL; that he has recreated in the general area and plans to continue to do so; and that he is concerned about the health effects of particulate matter and arsenic emissions from the SGP. (Oppenheimer Decl., ¶¶ 2, 9-13, 15-16.) All of these factual assertions are uncontradicted.

All three declarants appear to satisfy the standards for individual standing. Their concerns over health effects from particulate and arsenic emissions are sufficiently "concrete and particularized" to satisfy the first prong of the test, particularly given that they have recreated in the area in the past and plan to continue to do so, which distinguishes their concerns from those suffered alike by all citizens and taxpayers of the state. There is a sufficient causal connection between the challenged action (issuance of a permit allowing emissions of air pollutants) and the claimed injury (health effects from breathing emissions authorized by the permit) to satisfy the second prong of the individual standing test. For the third prong, there is a sufficient likelihood that the declarants' health concerns will be addressed by a decision in ICL's favor in this matter.

As to organizational standing, Mr. Oppenheimer testifies extensively regarding ICL's purpose, history, and advocacy efforts related to the environment generally, and air quality specifically. (Oppenheimer Decl., ¶¶ 3-7.) In a prior case, the Board approved ICL's petition to intervene in a matter involving water quality at mining facilities in north Idaho. The Board found that ICL had established a sufficient "direct and substantial" interest in that matter based upon an affidavit similar to the ICL declarations in this case. S*ee Hecla Mining Co. v. Idaho Dept. of Env. Quality*, Order on Intervention, pp. 3-4 (BEQ Dkt. No. 0102-03-13).

Moreover, there is no reason ICL's claims of error or relief requested in this matter require the participation of Ms. Fowle, Mr. Menlove, or Mr. Oppenheimer individually. If ICL relied on Mr. Oppeheimer's declaration and its exhibits to establish substantive error, the third prong of organizational standing may not have been satisfied as to him. However, because ICL has clarified, and the hearing officer has ruled, that Mr. Oppenheimer's declaration will only be considered to evaluate standing, the third prong is satisfied as to him.

Based on the foregoing, the DEQ and Perpetua motions for summary judgment on the basis

that ICL lacks standing are hereby DENIED.

3. Nez Perce Tribe

The Nez Perce Tribe (NPT) filed declarations of Joseph Oatman and Emmit Taylor, Jr. to establish standing. Among other things, Mr. Oatman and Mr. Taylor testify that they have fished within the boundaries of the SGP; that they intend to do so in the future; and that they are concerned about adverse health effects from air pollutants generated by the SGP. (Oatman Decl., ¶ 7; Taylor Decl., ¶ 9.) These assertions are uncontradicted and appear to satisfy the individual standing standards of concrete injury, causal connection, and redressability.

Similarly, the organizational standing standards of individual standing, germane protectable interests, and not needing the individuals' participation are sufficient to shift the burden back to DEQ and Perpetua for summary judgment purposes. Here, it is worth noting the relatively cursory analysis of the standing issue by DEQ and Perpetua. The only discussion specific to whether the NPT has standing appears in DEQ's May 12 brief, filed ***before*** the Oatman and Taylor Declarations were filed on June 9. DEQ chose not to discuss the NPT declarations in its June 23 "Non-Reply," and Perpetua did not discuss the NPT specifically at all. (*See* Perpetua Mem. in Supp. of 5/12/23, pp. 13-14; Perpetua Reply of 6/23/23, p. 5.) "The burden is upon the party moving for summary judgment…to establish that there is no genuine issue of material fact." *G & M Farms v. Funk Irr. Co*., 808 P.2d 851, 863, 119 Idaho 514 (1991). Without more explanation from DEQ and Perpetua as to why the NPT does not satisfy the relevant standards, they have not carried their burden as summary judgment movants.

Based on the foregoing, the DEQ and Perpetua motions for summary judgment that the NPT lacks standing are hereby DENIED.

4. Save Our South Fork Salmon

Save the South Fork Salmon (SSFS) filed declarations of Drew Hollenback and Zak Sears to establish standing. They both testify, among other things, that they have been financial supporters of SSFS since 2016; that they have recreated in the area and utilized the access road through the SGP in the past and plan to continue to do so in the future; and that they are concerned about air pollution from the SGP if they continue to recreate in the area. (Hollenback Decl. of 6/9/23, ¶¶ 2, 4, 5, 7, 8, 10-12; Sears Decl. of 6/9/23, ¶¶ 2, 5-7, 12, 14, 15, 19.) For summary judgment purposes, this is adequate to shift the burden back to DEQ and Perpetua as to individual and organizational standing. As with the NPT, after SSFS adduced these declarations, neither DEQ nor Perpetua attempted to explain why or how they do not satisfy standing, aside from Perpetua's highly conclusory paragraph on the issue. (*See* Perpetua Reply Mem. of 6/23/23, p. 5.)

Based on the foregoing, the DEQ and Perpetua motions for summary judgment that SSFS lacks standing are hereby DENIED.

B. Evaluation of Declarations as Expert Testimony

Having denied the motions for summary judgment on standing, the remainder of this order addresses the individual alleged errors. Before doing so, it is necessary to determine which declarations, if any, are admissible as expert testimony. *See* IDA.R.CIV.PROC. 56(c)(4) (affidavits must be admissible in evidence and show that the declarant is competent to testify on the matters stated); *Hecla Min. Co. v. Star-Morning Min. Co*., 122 Idaho 778, 784, 839 P.2d 1192, 1198 (Idaho 1992) (recognizing that on a motion for summary judgment, "[t]he question of admissibility is a threshold question to be answered before applying the liberal construction and reasonable inferences rule to the admissible evidence").

A witness who is qualified as an expert by knowledge, skill, experience, training, or

> education may testify in the form of an opinion or otherwise if the expert's scientific, technical, or other specialized knowledge will help the trier of fact to understand the evidence or to determine a fact in issue.

IDA.R.EVID. 702.

The Petitioners supported their motion for summary judgment with one declaration, a declaration of counsel that was limited to authentication of documents from the record. (Hurlbutt Decl. of 4/14/23.) When DEQ moved for summary judgment, it adduced declarations of Tiffany Floyd, Kevin Schilling, and Mike Simon. Mr. Schilling testifies, among other things, that he has a B.S. in environmental science with a minor in chemistry; has a M.S. in environmental engineering with an emphasis on atmospheric chemistry, meteorology, air pollution monitoring, and atmospheric pollutant dispersion; has worked for the State of Idaho and within the private sector in some capacity relating to air quality science and engineering since the spring of 1989; and has been a Stationary Source Air Modeling Supervisor for DEQ since September 2004. (Schilling Decl. of 5/12/23, p. 2.) Mr. Simon testifies, among other things, that he has a B.S. in electrical engineering and has over 30 years of air quality experience that includes conducting air quality analyses, writing air quality permits, processing air quality enforcement cases, managing air quality programs, and installation, operation, calibration, and maintenance of meteorological and navigational equipment. (Simon Decl. of 5/12/23, p. 2.)

On their face, both the Schilling and Simon Declarations appear to satisfy the Rule 702 standards.[4] Both witnesses testify regarding education and experience that qualifies them as experts on the issues involved in this matter, and then they explain the basis for DEQ's actions in issuing the Permit to Perpetua as they pertain to the alleged errors. Moreover, because Schilling and Simon are DEQ employees, their testimony is entitled to deference. *See generally Chisholm v. Idaho Dept. of*

[4] The Idaho Rules of Evidence do not strictly apply. BEQ R.PROC. 003.13; AG R.PROC. 600.

Water Resources, 125 P.3d 515, 518, 142 Idaho 159 (Idaho 2005).

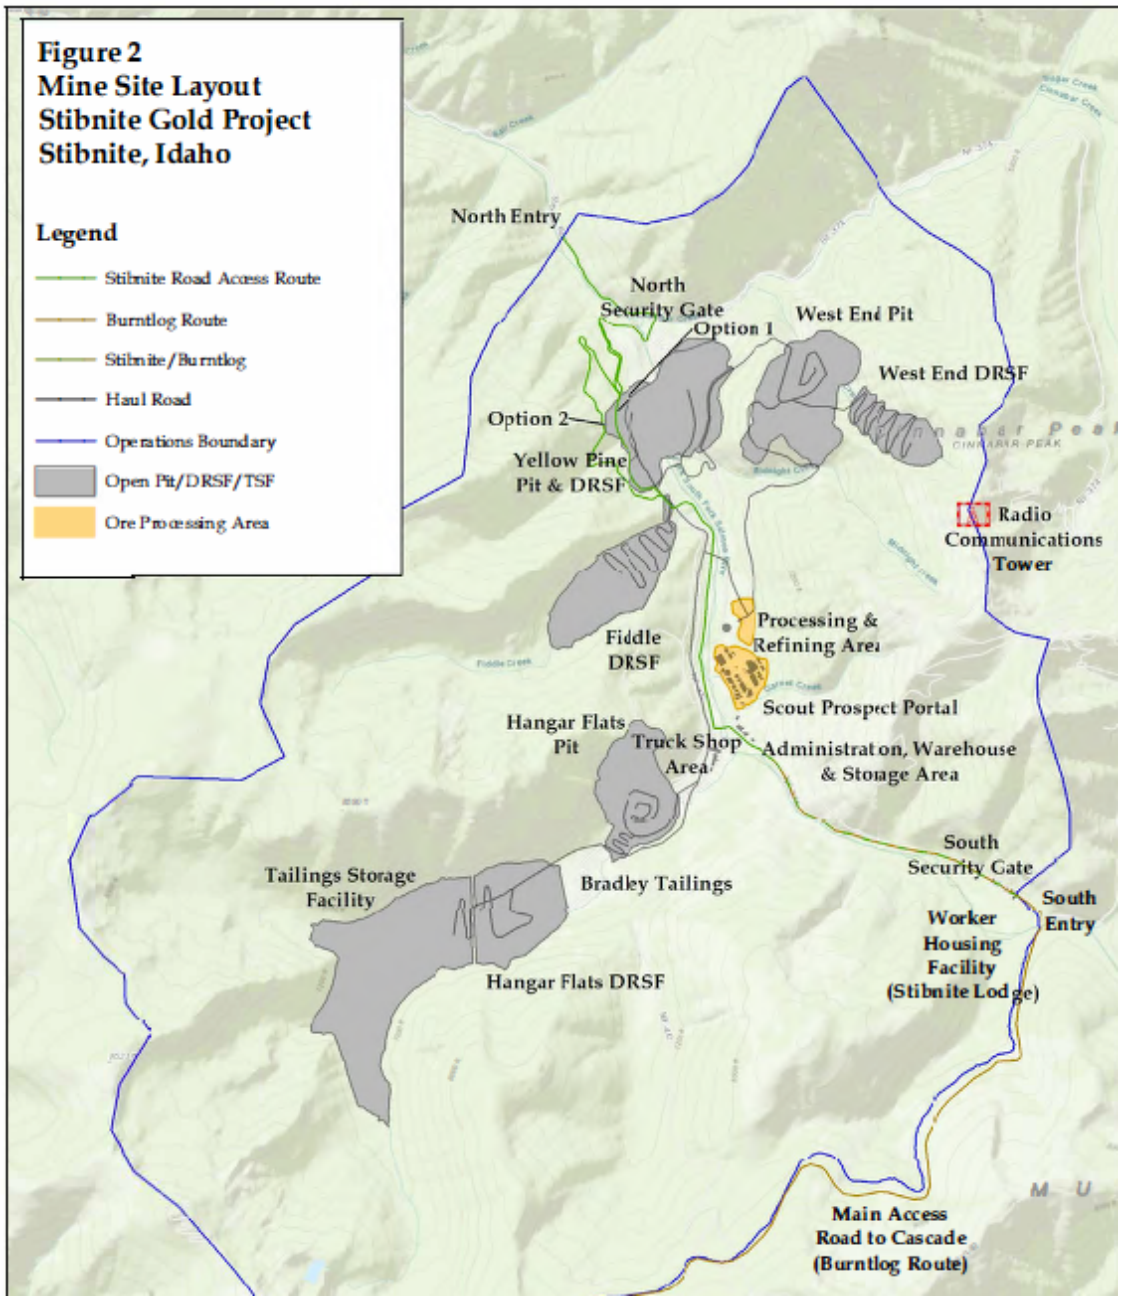
The Petitioners do not challenge the admissibility of the DEQ declarations as expert testimony. They also do not rebut the DEQ declarations with their own expert declarations. The declarations filed by Petitioners on June 9, 2023, are primarily dedicated to challenging the contention that they lack standing. Petitioners themselves describe them as "standing declarations." (Petitioners' Resp./Reply Br. of 6/9/23, pp. 2-4, 35; Petitioners' Resp. to Mot. to Strike of 7/7/23, pp. 1, 4.) The Oppenheimer Declaration purports to discuss technical air quality issues, but the hearing officer has ruled that declaration should only be considered for standing purposes. (Order on Perpetua's Mot. to Strike of 7/31/23, p. 6.) Mr. Oatman and Mr. Taylor have impressive education and experience, but their backgrounds are in fisheries. This does not "help the trier of fact to understand the evidence or to determine a fact in issue" in an air permitting matter.

C. Exclusion of Stibnite Access Road From Ambient Air

The Petition alleges multiple errors regarding ambient air boundaries and monitoring. Even though the phrase "ambient air" appears in the Permit one time, (*see* Permit, p. 41, § 7.13), it is an important concept behind many Permit conditions. Therefore, before addressing each individual alleged error, it will be helpful to discuss the concept of ambient air within the Air Rules.

1. Ambient Air Generally

Under the federal Clean Air Act, EPA is required to establish national ambient air quality standards (NAAQS) for a handful of "criteria" air pollutants, including PM_{10}. *See generally* 42 U.S.C. § 7602(t); 40 C.F.R. § 50.6. When DEQ evaluates an application for a permit to construct, it must determine that "[t]he stationary source or modification would not cause or significantly contribute to a violation of any ambient air quality standard." AIR RULES § 203.02. Based on the federal definition, the Air Rules define "ambient air" as "[t]hat portion of the atmosphere, external to



buildings, to which the general public has access." AIR RULES § 006.05.

The Petition alleges—and DEQ agrees—that to exclude areas from ambient air, the following must be true: (1) the permittee must have the ***legal authority to exclude the general public*** from the area; (2) the boundary to ambient air must be clearly discernable to the general public; (3) the general public must be ***effectively precluded*** from assessing the facility; and (4) the general public is not considered (a) employees of the facility; (b) those having official business with the facility; or (c) guests of the facility, including participants in facility routes and those seeking access for a specific purpose. (Pet., ¶ 59; DEQ Resp., p. 5 (emphasis added)).

2. The SGP and the Access Road

The SGP is located in a relatively remote location administered by the Payette National Forest. (R., at p. PRI00000418.) Its elevation ranges from approximately 6,421 feet and 6,936 feet above sea level. (*See generally* R., at pp. PRI00000450-453.) Between December and May, it has an average snow depth between 21 inches and 84 inches. (R., at p. PRI00000419.) It is approximately 37 miles as the crow flies due east of McCall, and approximately 43 miles as the crow files northeast of Cascade.

The SGP is bisected by a U.S. Forest Service ("USFS") road that runs from the northern portion of the SGP to the south-southeast (or conversely, from the southeast portion of the SGP to the north-northwest). Generally speaking, this creates two ways to access the SGP by road. One could drive east from McCall to reach the North Entry of the SGP, passing through the community of Yellow Pine along the way, or one could drive northeast from Cascade to reach the South Entry of the SGP. (*See generally* R., at p. PET 527.)

(R., at p. PET533.)

Perpetua proposed year-round access to the SGP would be accomplished via the "Burntlog Route," which would involve the improvement and extension of the existing Burntlog Road and portions of Thunder Mountain Road. (R., at p. PRI00000418.) The Burntlog Route would provide year-round access to the south side of the SGP.

(R., at p. PRI00000416.)

The community of Yellow Pine is approximately 10 road miles west of the SGP's North Entry, and there are seasonal recreational destinations outside the SGP's South Entry. (*See* R., at p. PRI00000418.) Therefore, if access through the SGP is precluded, those traveling from Yellow Pine to access those recreational areas would have to travel much farther and around the SGP to do so.
