CORRECTION TO AGENCY RECORD
SUMMARY | MAY 15, 2024

Agency record documents are stamped with sequential REC page numbers. Documents 095 through 105 were stamped with out-of-sequence page numbers resulting in duplicative REC numbers.

The agency record and Table of Contents have been corrected by adding the correct page numbers for documents 095 through 105 and identifying them as C-REC on the documents and in the Table of Contents. The out-of-sequence/duplicative numbers have also been retained on the documents and in the Table of Contents for future reference as the incorrect REC numbers may have been referred to and cited in documents filed between January 30, 2024, and May 9, 2024.

When referring to the corrected agency record documents for future filings, cite to C-REC page numbers.

INTRODUCTION

1. Petitioners Nez Perce Tribe, Idaho Conservation League ("ICL"), and Save the South Fork Salmon ("SSFS"), by and through their attorneys of record, file this Petition to Initiate Contested Case ("Petition") before the Idaho Board of Environmental Quality ("Board") pursuant to Idaho Code § 39-107(5) and IDAPA 58.01.23. This Petition challenges the Air Quality Permit to Construct P-2019.0047 ("PTC") issued by the Idaho Department of Environmental Quality ("DEQ") on June 17, 2022, to mining company Perpetua Resources Idaho, Inc. ("Perpetua") for its proposed Stibnite Gold Project ("SGP").

2. The SGP is in the headwaters of the East Fork of the South Fork of the Salmon River approximately ten miles east of the town of Yellow Pine, Idaho. The SGP is geographically located within the Nez Perce Tribe's aboriginal homeland and within the area over which the Nez Perce Tribe has Treaty-reserved rights and resources. As proposed, Perpetua would use conventional mining techniques to extract ore from three open pits, process gold, and dispose of mine waste at the SGP site.

3. The PTC being challenged here authorizes emissions of air pollutants from the SGP that will occur over the mine's anticipated 16-year life span. These emissions include massive quantities of dust generated by mining, hauling, and processing. The dust includes particulate matter and arsenic—pollutants which can cause serious harm to human health and the environment.

4. When it issued the PTC, DEQ failed to comply with the federal Clean Air Act and with Idaho rules, regulations, and guidance for Clean Air Act permitting in multiple ways set forth below. Petitioners respectfully request that the Board reverse and set aside the PTC and remand to DEQ to correct these errors.

LISTING OF REPRESENTATIVES

5. Copies of all pleadings, correspondence, and official documents shall be served on the Petitioners' counsel listed below:

For the Nez Perce Tribe and the Idaho Conservation League:

Bryan Hurlbutt
Advocates for the West

JURISDICTION, STANDARD OF REVIEW, PARTIES, AND STANDING

6. Pursuant to Idaho Code § 39-107(5), IDAPA 58.01.23, and IDAPA 58.01.01 (the "Idaho Air Rules"), the Board has jurisdiction over this contested case challenging DEQ's action issuing PTC P-2019.0047 for the SGP on June 17, 2022. This Petition is timely filed on July 22, 2022, within thirty-five (35) days of the date of DEQ's June 17, 2022 decision. *See* IDAPA 58.01.23.060.

7. An agency action, such as DEQ's issuance of the PTC being challenged here, may be reversed if it is in violation of constitutional or statutory provisions, is in excess of statutory authority, is made on unlawful procedure, or is arbitrary, capricious, or an abuse of discretion. Idaho Code ("I.C.") § 67-5279. When an agency action is not affirmed, it shall be set aside, in whole or in part, and remanded for further proceedings as necessary. *Id.*

8. Pursuant to IDAPA 58.01.23.002.02: "Any person aggrieved by an action or inaction of the Department may file a petition to initiate a contested case pursuant to Chapter 52, Title 67, Idaho Code." An aggrieved person is defined as "any person or entity with legal standing to challenge an action or inaction of the Department, including but not limited to permit holders and applicants for permits challenging Department permitting actions." IDAPA 58.01.23.005.01.

9. PETITIONER NEZ PERCE TRIBE is a federally-recognized Indian tribe with headquarters on the Nez Perce Reservation in Lapwai, Idaho; and with offices in Orofino, McCall, and Powell, Idaho, and Joseph, Oregon.

10. The Nez Perce Tribe has standing to bring this contested case. The Nez Perce people, the *Nimiipuu*, exclusively occupied, since time immemorial, over thirteen million acres encompassing a large part of what is today Idaho, Oregon, and Washington—stretching from the Bitterroot Mountains to the Blue Mountains. Nez Perce also traveled far beyond this homeland to fish, hunt, gather, and pasture—frequently going east to buffalo country, in what is today the state of Montana, and west along the Snake and Columbia rivers to the Pacific Ocean. The Nez Perce actively maintain their connection to the land, water, and resources of their vast homeland. The Nez Perce's intimate knowledge and continuous use of their homeland over millennia have created a unique and reverential bond between people and place that defines Nez Perce culture and identity.

11. When the Nez Perce Tribe entered into a treaty with the United States in 1855, it sought to reserve the rights central to maintaining its culture and way of life. The 1855 Treaty reserved to the Tribe, for its "exclusive use and benefit," 7.5 million acres of its more than

thirteen-million- acre homeland, including an area spanning present-day north-central Idaho, southeast Washington, and northeast Oregon as well as:

> [T]he right of taking fish at all usual and accustomed places in common with citizens of the Territory; and of erecting temporary buildings for curing, together with the privilege of hunting, gathering roots and berries, and pasturing their horses and cattle upon open and unclaimed land.

Treaty with the Nez Perces, art. 3, June 11, 1855, 12 Stat. 957. Nez Perce Tribal members, pursuant to the Nez Perce Tribe's Treaty-reserved rights, continue to fish, hunt, gather, and pasture across the Nez Perce Tribe's vast aboriginal homeland and at traditional places, including areas within and surrounding the SGP. The Nez Perce Tribe, as a co-manager of its treaty-reserved resources, also plays a leading role in the restoration of the East Fork South Fork Salmon River and South Fork Salmon River fisheries, expending approximately $2.5 million annually to restore Chinook salmon runs in both rivers through hatchery supplementation, fishery research, and watershed restoration.

12. The Nez Perce Tribe will suffer physical, cultural, spiritual, and economic injury caused by excessive air pollutants resulting from DEQ's issuance of the PTC. Clean, clear air is a critical component to ensuring the health and resiliency of the Nez Perce Tribe's Treaty-reserved rights and resources. Air pollution reduces visibility, which impairs cultural and ceremonial practices for Tribal members and reduces enjoyment of these special places. Air pollution causes a host of environmental and human health problems, including damage to culturally important plants, sensitive forests, and fish habitat, acidification of lakes and streams, depletion of soil nutrients, aggravated asthma, heart attacks, and premature death. Impacts can be especially harmful to at-risk ecosystems and especially harmful for sensitive human populations such as asthmatics, children, the elderly, people with diabetes, and people with heart or lung disease.

13. To safeguard its rights and interests, the Nez Perce Tribe has participated extensively in DEQ's review process, including submitting comments on October 12 and November 10, 2020, March 8, 2021, and March 14, 2022. A favorable decision in the Contested Case will redress these injuries suffered by the Tribe.

14. PETITIONER IDAHO CONSERVATION LEAGUE is an Idaho non-profit conservation organization. Its main office is located in Boise, Idaho, and it has three field offices in Sandpoint, Ketchum, and McCall. ICL represents approximately 50,000 supporters dedicated to protecting and conserving Idaho's clean water, air, public lands, and wildlife.

15. ICL has standing to bring this contested case. ICL supporters, staff, and board members ("ICL members") regularly visit the SGP and/or nearby areas where air quality would be affected by the SGP for professional, recreational, aesthetic, and other purposes. ICL members will suffer health, environmental, and aesthetic injuries from the particulate matter and arsenic air pollution emitted by the SGP and authorized by DEQ's issuance of the PTC. A favorable decision in the Contested Case will redress ICL's injuries. Neither the claim asserted, nor the relief requested, requires participation of these individual ICL members in the lawsuit. The interests ICL seeks to protect are germane to the organization's purpose in protecting Idaho's clean water, clean air, wildlife, and public lands.

16. In furtherance of its mission, ICL participated extensively in the public processes for the PTC, including by submitting formal public comments to DEQ on October 12 and November 11, 2020, March 19, 2021, and March 16, 2022.

17. PETITIONER SAVE THE SOUTH FORK SALMON is a community-based, non-profit conservation organization headquartered in McCall, Idaho. SSFS represents members and supporters dedicated to preserving the South Fork Salmon River watershed and ecosystem.

18. SSFS has standing to bring this contested case. SSFS members, supporters, and members of the Board of Directors ("SSFS members") regularly visit the South Fork Salmon River watershed and the SGP site, where the emission of excessive air pollutants due to DEQ's issuance of the PTC would impact professional, economic, recreational, aesthetic, environmental, and human health interests. SSFS members would suffer injury from DEQ's issuance of the PTC from environmental, health, and aesthetic harms caused by the emission of harmful air pollutants, including particulate matter and arsenic. A favorable decision in the Contested Case will redress these injuries suffered by SSFS members. Neither the claims asserted, nor the relief requested, requires participation of these individual supporters in the lawsuit. The interests SSFS seeks to protect are germane to the organization's mission of protecting and preserving the South Fork Salmon River watershed and ecosystem, and protecting public health, the river, the fish, and recreational opportunities in the area.

19. In furtherance of this mission, SSFS participated extensively in the public process for the PTC, including submitting formal public comments to DEQ on October 12 and November 11, 2020, March 19, 2021, and March 16, 2022.

20. RESPONDENT IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY is an executive department and administrative agency organized under the laws of the State of Idaho, pursuant to the Idaho Constitution (Article IV, Section 20) and Idaho Code section 39-104(1). Its principal offices are located at 1410 N. Hilton, Boise, Idaho 83706. DEQ, through its Director, and subject to Board oversight, is responsible for issuing air quality PTCs under the Idaho Air Rules, IDAPA 58.01.01.

21. On June 17, 2022, DEQ issued PTC P-2019.0047, which is the subject of this contested case.

FACTUAL SUPPORT FOR PETITION

I. OVERVIEW OF SGP & CHRONOLOGY OF DEQ'S ISSUING THE PTC

22. Perpetua is currently in the process of seeking multiple permits and other approvals from multiple agencies and other authorities for the proposed SGP. As described by DEQ in the Statement of Basis ("SOB") document prepared with the PTC:

> Perpetua proposes to construct and operate the SGP, consisting of conventional open-pit mining, ore preparation, and gold extraction operations. The SGP is to be located in Valley County at the intersection Forest Service roads NF-374 and NF-412 (Stibnite Road), approximately 10 miles east of Yellow Pine. The project will be located on a combination of public national forest and private lands. The mining operations boundary within which public access will be excluded is defined in Figure 1. This operations boundary also defines the ambient air boundary that was used in all ambient air quality impact analyses as part of the development process of the PTC.
>
> The SGP will require the construction of significant infrastructure, including a power transmission line, a primary mine site access road, onsite haul roads, an ore processing facility, onsite workspaces, employee housing and recreation, water storage and distribution facilities, and sewage disposal facilities.
>
> Conventional open-pit mining methods including drilling, blasting, excavating, and hauling will be used to extract ore and waste rock, termed development rock (DR). Hydraulic shovels and front-end loaders will be used to load ore and DR into haul trucks. DR will be used for construction, restoration, and backfilling, or hauled to the dedicated development rock storage facilities (DRSF). Approximately 340 million tons of DR will be handled over the life of the mine.
>
> The SGP will include three years of pre-mining development and construction activities, followed by an operating mine life of approximately 12 years. Mining will occur in three open pits: Yellow Pine Pit (YPP), Hangar Flats pit (HFP), and West End pit (WEP). Although there will be overlap in mine development, construction and operations, the general sequence of mining will be the YPP deposit, followed by the HFP and WEP deposits. Legacy tailings from the Meadow Creek valley (Bradley Tailings [BT]) will also be reclaimed and reprocessed during the initial project schedule. Surface exploration drilling will occur within the pits and within the Scout Prospect decline (underground exploration) throughout the mine operation period. Restoration and reclamation of other legacy mining features will occur prior to mining, throughout the life of the mine, and as part of the mine closure.
>
> Ore will be hauled to the primary crusher area, where it will be fed directly into the crusher dump pocket or stockpiled. The ore crushing plant will be designed

> to operate at a maximum rate of 25,000 tons per calendar day (T/day). Approximately 100 million tons of ore will be mined from the three pits over the life of the project. The metal-recovery process from ore will include conventional crushing and grinding, followed by froth-flotation circuits that will generate separate gold-silver and antimony-silver concentrates. The antimony-silver concentrate will be shipped offsite for refining, whereas additional onsite processing of the gold-silver concentrate will include pressure oxidation, carbon-in-leach circuits, and refining processes to recover gold and minor amounts of silver. The finely ground leftover ore material from the mineral recovery process, termed tailings, will be neutralized, thickened, and transported via a pipeline to the tailings storage facility. A diagram of ore processing and ore concentration and refining process flows is provided in Figure 2.

23. Perpetua (previously Midas Gold) submitted a PTC application for the SGP to DEQ on August 20, 2019. As shown in the "Application Chronology" section of the SOB, between that date and March 6, 2020, DEQ determined that the application was incomplete, requested additional information, and received supplementary materials from Perpetua no fewer than four times. On May 15, 2020, DEQ deemed Perpetua's application complete.

24. Between May 15, 2020, and March 16, 2022, DEQ developed three versions of the draft PTC and released them for public comment. As noted in comments submitted by the Nez Perce Tribe, ICL, and SSFS, the first two draft versions of the PTC (herein referred to the September 2020 and February 2021 draft PTCs) contained significant shortcomings. As a result, the September 2020 draft PTC was considered deficient and required updated information from Perpetua, including updated hazardous air pollutants ("HAP") and toxic air pollutants ("TAP") emissions estimates, a HAP/TAP addendum to the application, updated TAP modeling analyses, supporting references, and updated modeling files with corrections for formaldehyde and sulfuric acid.

25. DEQ subsequently updated the draft PTC and in February 2021, provided a revised draft PTC for public comment. Following additional comments, DEQ again determined that the February 2021 draft PTC was deficient and required additional information from

Perpetua, including Prevention of Significant Deterioration emissions estimates and regulatory applicability for the lime manufacturing plant, as well as an updated TAP/HAP addendum including an updated emission inventory and modeling files.

26. DEQ revised theFebruary 2021 draft PTC and released it for public comment on January 13, 2022. Comments were submitted by the Nez Perce Tribe, ICL, SSFS, the U.S. Environmental Protection Agency ("EPA") Region 10, and Ian von Lindern of Terragraphics International Foundation. Commenters raised numerous concerns with the draft PTC and urged DEQ to gather additional information, to perform additional modeling and analysis, and to develop additional enforceable permit conditions and limits prior to issuing a final PTC. On June 17, 2022, DEQ issued the final PTC, along with responses to comments and the SOB. While DEQ made limited updates to the PTC, it rejected most of the issues raised by the commenters.

II. PM_{10} & ARSENIC EMISSIONS FROM THE SGP

27. While the SGP will emit numerous air pollutants, PM_{10} and arsenic are the air pollutants of greatest concern and are the pollutants at issue in this contested case.

A. PM_{10} Pollution and Regulation

28. Particulate matter ("PM") contains microscopic solids or liquid droplets that are so small that they can be inhaled and cause serious health problems. Some particles less than 10 micrometers in diameter can get deep into a person's lungs, and some may even get into the person's bloodstream. Numerous scientific studies have linked particle pollution exposure to a variety of problems, including premature death in people with heart or lung disease; nonfatal heart attacks; irregular heartbeat; aggravated asthma; decreased lung function; and increased respiratory symptoms, such as irritation of the airways, coughing or difficulty breathing. People

with heart or lung diseases, children, and older adults are the most likely to be affected by particle pollution exposure.

29. In addition to causing human health problems, PM causes environmental damage. Particles can be carried over long distances by wind and then settle on ground or water. Depending on their chemical composition, the effects of settling may include making lakes and streams acidic; changing the nutrient balance in river basins; depleting nutrients in soil; damaging sensitive forests and crops; affecting diversity of ecosystems; and contributing to acid rain.

30. Under Sections 108 and 109 of the federal Clean Air Act, EPA is required to establish National Ambient Air Quality Standards ("NAAQS") for each "criteria air pollutant" to protect the nation's public health and welfare. "[E]ffects on welfare include[ ], but [are] not limited to, effects on soils, water, crops, vegetation, manmade materials, animals, wildlife, weather, visibility, and climate, damage to and deterioration of property, and hazards to transportation, as well as effects on economic values and on personal comfort and well-being, whether caused by transformation, conversion, or combination with other air pollutants." 42 U.S.C. § 7602(h).

31. PM is a criteria air pollutant. EPA has established primary and secondary NAAQS for coarse particulate matter, or "PM_{10}," 40 C.F.R. § 50.6, and for fine particulate matter, or "$PM_{2.5}$," *id.* at § 50.7. PM_{10} consists of inhalable particles with diameters that are generally ten micrometers and smaller. 42. U.S.C. § 7602(t). $PM_{2.5}$ consists of inhalable particles that are 2.5 micrometers and smaller. The NAAQS specify a maximum amount of PM to be present in the outdoor air. *See* 40 C.F.R. §§ 50.6, 50.7.

32. EPA has delegated to DEQ authority to issue air quality permits in Idaho. Under the Rules for the Control of Air Pollution in Idaho, DEQ is required to ensure that no PTC shall be granted for a new or modified stationary source unless the applicant shows to the satisfaction of DEQ that the source would not cause or significantly contribute to a violation of any NAAQS. IDAPA 58.01.01.203.02. To satisfy these requirements, DEQ must assess air impacts using maximum potential emissions as limited by either the capacity of the unit/operation or as limited by enforceable permit provisions. *See* IDAPA 58.01.01.006.88.

B. PM_{10} Pollution from the SGP & Flaws in the PTC

33. According to DEQ's Statement of Basis for the SGP, the SGP has the potential to emit 55.7 tons per year of PM_{10} from a variety of sources. The generation of dust from ore haul trucks traveling along haul roads is the most significant source, estimated to be approximately 55% of all modeled PM_{10} emissions. The next most significant source is open pit drilling fugitive emissions, estimated by DEQ to account for approximately 24% of all modeled emissions.

34. DEQ modeled receptors at various locations along the SGP's ambient air boundary and determined that the maximum potential emissions will be below (and thus comply with) the 24-hour PM_{10} NAAQS. DEQ found the maximum 24-hour PM_{10} pollution from the SGP would be 123.5 ug/m^3, which is 82.3% of the NAAQS.

35. DEQ's determination that the SGP will not cause or contribute to a violation of the PM_{10} NAAQS is flawed.

36. First, important variables affecting the quantity of PM_{10} generated by the ore haul trucks are not directly limited and enforceable as PTC permit conditions. Perpetua estimated the quantity of PM_{10} that would be emitted by the ore haul trucks based on EPAs compilation of air emissions factors (AP-42 Chapter 13.2.2) and their subsequent analysis of sources used by the

EPA to develop Chapter 13.2.2. Critical variables that Perpetua used as inputs to PM emission calculations include: the average empty weight of ore haul trucks; the average loaded weight of ore haul trucks; the silt content of the haul road being traveled; and the total number vehicle miles traveled by ore haul trucks. However, only one of these critical variables is directly limited and enforceable as a condition in the PTC: the silt content of the haul roads. *See* PTC condition 3.13.

37. Instead of developing PTC conditions for these other critical variables, DEQ relied on a surrogate limit in the PTC (total ore haulage per day, *see* PTC conditions 3.5) and on plans that have not yet been developed—a Fugitive Dust Control Plan ("FDCP") and a Haul Road Capping Plan ("HRCP")—to claim the PTC ensures enforceable compliance with 24-hour PM_{10} NAAQS. Without developing the FDCP and HRCP first, and without including important variables as enforceable permit conditions, there is no assurance the SGP will comply with the 24-hour PM_{10} NAAQS, even with the total ore haulage per day limit. Perpetua used a very specific combination of these variables to arrive at a quantity of ore haul truck generated PM_{10} that they contend ensures compliance with the NAAQS. Changing these variables in any number of ways (ways which are not precluded by any conditions in the PTC) can result in higher PM_{10} levels—levels so high that they exceed the NAAQS. As just one example, merely changing the ratio of large to small trucks used by Perpetua (to include more large trucks) could cause a violation of the NAAQS.

38. Second, DEQ assumed 93.3% of all haul road PM_{10} emissions from the SGP can be controlled by using an unspecified combination, volume, and frequency of water sprays and chemical dust suppressants. This extremely high level of control which DEQ assumed Perpetua can achieve is based on Perpetua's interpretation of AP-42 Chapter 13.2.2. AP-42 Chapter 13.2.2

discusses the critically important variables surrounding control efficiencies (in particular to chemical suppressants, some of which can reasonably be assumed to apply to water too):

> The control effectiveness of chemical dust suppressants appears to depend on (a) the dilution rate used in the mixture; (b) the application rate (volume of solution per unit road surface area); (c) the time between applications; (d) the size, speed and amount of traffic during the period between applications; and (e) meteorological conditions (rainfall, freeze/thaw cycles, etc.) during the period. Other factors that affect the performance of dust suppressants include other traffic characteristics (e. g., cornering, track-on from unpaved areas) and road characteristics (e. g., bearing strength, grade). The variabilities in the above factors and differences between individual dust control products make the control efficiencies of chemical dust suppressants difficult to estimate. Past field testing of emissions from controlled unpaved roads has shown that chemical dust suppressants provide a PM-10 control efficiency of **about 80 percent when applied at regular intervals of 2 weeks to 1 month (**emphasis added)**.**

39. None of the above variables, however, have any specific and enforceable permit conditions within the PTC to ensure a 93.3% control efficiency. Instead, the PTC has a permit condition (permit condition 2.6) only requiring the permittee to develop and submit the FCDP and HRCP, which merely describe how these variables will be addressed 30 days before start-up of the SGP. Permit condition 2.6 details what variables contributing to PM_{10} control effectiveness must be detailed in the FCDP, but the specific details that are so important to control efficiency (e.g., the amount of water or chemical suppressants applied and the frequency of application) are undetermined at present and are left to Perpetua to decide at a later date. A lesser control efficiency, even just slightly lesser, could result in large enough PM_{10} emissions to violate the NAAQS. In fact, if the SGP were to instead achieve 80% control (as EPA found through past field testing of chemical dust suppressants), then the SGP's PM_{10} emissions could exceed the NAAQS.

40. Third, DEQ relied on monitoring and record keeping (permit condition 3.16) using devices and methodologies in the Operation and Maintenance ("O&M") Manual for the

potential to emit limit associated with the 180,000 tons per day hauling in permit condition 3.5. However, the O&M Manual has not yet been developed, submitted to the public for comment, or reviewed and revised by DEQ. Further, the PTC itself does not include all monitoring, recordkeeping, and reporting necessary to assure compliance with the permit emission limitations and applicable requirements.

41. Fourth, DEQ assumed there would be 120 days of recordable precipitation at the SGP (defined as recording precipitation of 0.01 inch or greater) as a variable in its ore haul road fugitive PM emission calculations. This 120 days comes from general geographic guidance from AP-42 Chapter 13.2.2-1. DEQ, however, should have used local meteorological data. Section 6.8 (Meteorological Data) of DEQ's *Guideline for Performing Air Quality Impact Analyses* states: "The meteorological data used in the modeling analysis should be representative of the meteorological conditions at the particular site of the proposed construction or modification." Days of recordable precipitation is an important variable affecting the SGP's emissions of PM_{10} from ore haul roads. DEQ's failure to use the most representative site data is counter to this guidance and increases the risk of miscalculation of ore haul road emissions. As a result, DEQ failed to ensure PM_{10} emissions from the SGP will comply with the NAAQS.

C. Arsenic Pollution & Regulation

42. Arsenic is a naturally occurring element in soils and minerals. When soil or rock containing arsenic is disturbed, arsenic may enter the air, water, and land from wind-blown dust and from run-off and leaching. The EPA classifies inorganic arsenic as a "human carcinogen," based on evidence in human studies of links to lung, bladder, kidney, skin, and liver cancers.

43. Arsenic released from the soil and rock as airborne dust causes environmental damage. Airborne arsenic pollutes soil, plants, and water resources when it is removed from the

air by rain, snow, or gradually settling. Studies have shown that there is a strong correlation between arsenic concentrations in water and in the tissues of fish collected from arsenic-polluted waters. Plants may also absorb arsenic in their leaves and root system from arsenic-polluted soil. The health effects of long-term ingestion of arsenic include developmental effects, diabetes, pulmonary disease, cardiovascular disease, and skin, bladder, or lung cancer.

44. Arsenic is a Toxic Air Pollutant regulated by DEQ. DEQ is required to ensure that no permit to construct shall be granted for a new or modified stationary source unless emissions of TAPs from the constructed source would not injure or unreasonably affect human or animal life or vegetation as required by Section 161. IDAPA 58.01.01.203.03. Section 161 states, "any contaminant which is by its nature toxic to human or animal life or vegetation shall not be emitted in such quantities or concentrations as to alone, or in combination with other contaminants, injure or unreasonably affect human or animal life or vegetation." IDAPA 58.01.01.161.

45. To comply with these TAPs regulations, emissions from a facility must not exceed the Acceptable Ambient Concentrations of Carcinogens ("AACC") at the ambient air boundary. For each carcinogenic TAP, IDAPA 58.01.01.586 lists the applicable TAP and its AACC in ug/m^3 as an annual average. The AACC can practically be defined as the concentration of a TAP that, if an individual was exposed to yearly over a 70-year lifetime, would equate to a cancer development probability risk of 1 in 1,000,000. *See* IDAPA 58.01.01.006.125 & 58.01.01.210.12.

46. In order to determine a facility's TAP concentration at their ambient air boundary, and as noted similarly for PM_{10} emissions, DEQ must assess air impacts using maximum

potential emissions as limited by either the capacity of the unit/operation or as limited by enforceable permit provisions. *See* IDAPA 58.01.01.006.88.

D. Arsenic Pollution from the SGP & Flaws in the PTC

47. There are numerous arsenic sources at the SGP, including drilling, blasting, excavating, hauling, silos, rock dumps, and storage and tailing piles. Table 3 in the SGP TAPs Addendum indicates that the maximum arsenic Potential Total Emissions ("PTE") is 0.544 lbs/hr at the maximum mine production rate of 180,000 tons/day. The largest source of arsenic emissions are haul roads estimated at 0.464 lbs/yr (Table B1-W3 in SOB). PTE estimates for arsenic are calculated using the same formulas and Emission Factors as total particulate and PM_{10} emission rates. As such, like the PM and PM_{10} emission estimates discussed already, the arsenic emission estimates are similarly underestimated and equally unreliable.

48. During the permitting process, DEQ determined that the SGP's estimated arsenic emissions and concentrations at the ambient air boundary were excessive and would not meet the AACC for arsenic. To get around this problem, Perpetua chose to employ a process known as T-RACT. T-RACT is a demonstration that allows a permittee to analyze and employ reasonably available control technologies ("RACT") that could be applied to a source of TAPs. If RACT does not sufficiently reduce toxic emissions to below the AACC, then the permittee is allowed a 10-fold increase in the AACC and can employ production limitations to ensure compliance with the now 10-times-bigger AACC. These production limitations should then be incorporated as enforceable permit conditions. *See* IDAPA 58.01.01.210.13–14.

49. As part of the T-RACT determination process, the applicant must supply, and DEQ must consider, information on a variety of factors relevant to determining a "reasonable"

control technology including, but not limited to, control effectiveness, economic costs, operational feasibility, and associated environmental impact. IDAPA 58.01.01.210.14a–d.

50. Perpetua submitted to DEQ a T-RACT demonstration for arsenic emissions from open-pit drilling and ore haul roads. Perpetua determined that the most effective RACT for open-pit drilling was dry drilling with dust collectors and that the most effective RACT for ore haul roads was water sprays and chemical suppressants. In its T-RACT demonstration, Perpetua included limited qualitative discussion, and no quantitative support, regarding economic considerations. Perpetua failed to provide any discussion of environmental impacts.

51. DEQ approved Perpetua's T-RACT demonstration and granted Perpetua a 10-fold increase in allowable arsenic pollution, subject to operational limitations to reduce PTE. And as modeled by DEQ, arsenic pollution from the SGP would comply with this larger AACC.

52. DEQ's approval of Perpetua's T-RACT demonstration for arsenic, and its analysis determining the SGP will not exceed the AACC and thus will not injure or unreasonably affect human or animal life or vegetation, is flawed.

53. First, the T-RACT demonstration contained no persuasive economic information and no discussion at all regarding associated environmental impacts, despite the requirements to do so in IDAPA 58.01.01.210.14. There will be water quality and biological impacts associated with Perpetua's use of substantial amounts of chemical dust suppressants and water that have not been considered in the PTC. For example, the use of chemical dust suppressants like magnesium chloride can cause toxicity in trees and can lead to tree death. Magnesium chloride is also known to adversely affect aquatic ecosystems. Moreover, the proposed water source for dust control is primarily water collected in runoff ponds (captured rain or snowfall that has become contaminated through the contact of mine facilities), groundwater, and surface water from the

East Fork of the South Fork of the Salmon River. USGS sampling indicates elevated arsenic in these waters. The environmental impact of using magnesium chloride or arsenic-polluted water as dust suppression methods was never considered as part of the T-RACT demonstration. Likewise, the T-RACT demonstration did not provide sufficient economic support for Perpetua's decision to use water and chemical dust suppressants as compared to paving the haul roads, even though paving was shown to achieve the highest reasonable dust control efficiency.

54. Second, because the underlying particulate and PM_{10} emissions estimates and particulate control assumptions are unreliable in numerous respects, as already discussed above, so too are the estimated arsenic emissions. The SGP's estimated arsenic emissions were based on its PM_{10} emissions. PM_{10} emissions from the SGP may be higher, and their control effectiveness may be lower, than DEQ assumed, in which case arsenic emissions would also be higher and might exceed the AACC.

55. Third, Perpetua's and DEQ's TAPs analyses substantially reduce the SGP's purported arsenic emissions using three improper averaging tactics: (1) averaging emissions over a 5-year period for the T-RACT input to ambient toxics modeling; (2) averaging the estimated annual ambient modeling impacts across two multi-year scenarios; and (3) averaging the resultant 16-year total emissions over the 70-year human lifetime to assert compliance. Nothing in the Idaho Air Rules allows for multi-year emissions averaging and ambient air concentration adjustments. Rather, the arsenic AACC is an annual average. *See* IDAPA 58.01.01.586). DEQ's T-RACT regulations require comparing the estimated maximum annual ambient air arsenic concentration to 10 times the listed annual AACC. IDAPA 58.01.01.12.b. Therefore, to determine compliance with the AACC requires that DEQ estimate the SGP's maximum 1-year annual arsenic emissions and compare it to the annual arsenic AACC.

56. By relying on these improper averaging tactics, DEQ fails to show the SGP will satisfy the arsenic AACC and the resulting analysis masks potentially severe human health and environmental impacts of SGP's potential arsenic emissions. The underlying analyses supporting the TAPs requirements allows for a 1-in-1,000,000 excess cancer risk factor. The T-RACT approval increases that risk 10-fold to a 1-in-100,000 excess cancer risk factor. IDAPA 58.01.01.12.b. Perpetua's multi-year averaging of emission rates combined with DEQ's decision to allow the full lifetime exposure (70 years) to be imposed on receptors during the 16-year estimated life of mine increases the cancer risk by another order of magnitude to the 1-in-10,000 range or higher. Combined with uncertainties associated with the underlying particulate emissions calculations noted above, the SGP may result in extremely dangerous arsenic exposures.

57. Excacerbating this cancer risk is the fact that under DEQ's incremental TAPs regulations (*see* IDAPA 58.01.01.585), when DEQ considers permitting any additional sources of arsenic in the area over the next 70 years (such as an extension of the life of the SGP, expansion of the facility itself, and/or any adjacent facilities seeking a similar permit, like the potential Horse Heaven project), DEQ will not have to consider the arsenic emissions authorized by this PTC.

E. DEQ's Ambient Air Boundary for the SGP

58. The Clean Air Act and Idaho Air Rules require meeting various air standards, including the NAAQS and TAPs, in ambient air. *See*, *e.g.*, IDAPA 58.01.01.006.11 (NAAQS), 58.01.01.006.125 (TAPs). EPA defines "ambient air" as "that portion of the atmosphere, external to buildings, to which the general public has access." 40 C.F.R. § 50.1(e). In defining an ambient air boundary, the EPA has long followed a policy that exempts "the atmosphere over land owned

or controlled by the source and to which public access is precluded . . .” from ambient air. EPA’s Revised Policy on Exclusions from “Ambient Air” (Nov. 2018) states that “it is appropriate to exclude the atmosphere over land owned or controlled by the stationary source, where the owner or operator of the source employs measures, which may include physical barriers, that are effective in deterring or precluding access to the land by the general public.”

59. The Idaho Air Rules define “ambient air” as “[t]hat portion of the atmosphere, external to building, to which the general public has access.” IDAPA 58.01.01.005.09. To exclude areas from consideration as ambient air, the following conditions must be met: (1) the permittee must have the legal authority to exclude the general public from the area; (2) the boundary to ambient air must be clearly discernible to the general public; (3) the general public must be effectively precluded from assessing the facility; and (4) the general public is not considered employees of the facility; those having official business with the facility; guests of the facility, including participants in facility routes and those seeking access for a specific purpose.

60. Perpetua established an operations boundary (the active industrial site where mining activities and heavy equipment operation will occur) for the purposes of excluding this area from ambient air analysis, and for excluding public access. The area includes the current Stibnite Road point of entry and proposed site access via the Burntlog Route. According to Perpetua, access inside the operations boundary will be restricted for the life of the mine by physical barriers at points of potential access, as well as natural features of the landscape that prevent public access.

61. DEQ’s determination to exclude the access route from ambient air protections is flawed.

62. Perpetua has indicated that it intends to allow access to the general public through the mine site between Stibnite Road at Sugar Creek and Thunder Mountain Road at Meadow Creek. Furthermore, this roadway is currently accessible to and has been regularly used by the general public. And while Perpetua claims that it has "legal and practical ability to enforce its control over roadway access," the Forest Service has not yet completed its NEPA analysis and approval of the SGP, which would include a decision on whether it will require or will not permit general public access through the mine site.

63. DEQ states that the route would be managed in accordance with the Stibnite Road Access Management Plan ("AMP"). DEQ, however, relied on an ambiguous description of measures and requirements to preclude public access and ensure that those traveling over the road can be classified as "guests" of the mine.

64. PTC condition 2.7 requires the development of an AMP to address whether the NAAQS apply to the mine's access road through the Perpetua site given the extent of public access allowed. PTC condition 2.8 allows the AMP to be developed later, after the PTC was issued and without public comment, and it does not require the AMP to be enforceable. For the AMP to preclude the applicability of the NAAQS along the access road, the AMP must be reviewed and approved by DEQ, it must be reviewed through public comment, and it must be enforceable under the PTC.

65. Without full disclosure and knowledge of the exact measures and requirements in the AMP and enforceable permit limits, DEQ cannot make a determination of whether exclusion of the access road from ambient air protections complies with EPA's ambient air policy and the Idaho Air Rules, nor can DEQ determine whether the SGP will comply with the NAAQS and TAPs.

F. DEQ's Failure to Require Ambient Air Monitoring for the SGP

66. DEQ has the authority to require ambient air monitoring to determine the effect emissions from the stationary source or facility may have on the air quality of the area potentially impacted by the source. IDAPA 58.01.01.211.01(d).

67. DEQ received comments from the Nez Perce Tribe, EPA Region 10, ICL, and SSFS urging the PTC to require ambient air monitoring to verify the SGP's compliance with the NAAQS and TAPs increments. But DEQ declined, stating in the Response to Comments (pg. 16): "DEQ disagrees that a PM/PM_{10} ambient monitoring network is necessary to make the PTC practically enforceable." DEQ states in the Response to Comments that any violation of the permit would be processed in accordance with DEQ's enforcement procedures manual.

68. However, without ambient air monitoring, it will be impossible for DEQ to assess whether the SGP's operation is in compliance with NAAQS and TAPs increments at any given time. Ambient air monitoring is necessary because of the large uncertainty surrounding dust control efficiency and emissions factors associated with the SGP for PM_{10} and arsenic, as well as the lack of enforceable permit conditions for many important variables, as already described in this Petition.

RELIEF REQUESTED

69. An agency action, like DEQ's issuance of the PTC, may be reversed if it is in violation of constitutional or statutory provisions, is in excess of statutory authority, is made on unlawful procedure, or is arbitrary, capricious or an abuse of discretion. I.C. § 67-5279. When an agency action is not affirmed, it shall be set aside, in whole or in part, and remanded for further proceedings as necessary. *Id.*

70. As stated above, under the Idaho Air Rules, DEQ must not issue a PTC unless it determines: (1) "the stationary source or modification would comply with all applicable local, state or federal emission standards"; (2) "the stationary source would not cause or significantly contribute to a violation of any ambient air quality standard"; and (3) "the emissions of toxic air pollutants from the stationary source or modification would not injure or unreasonably affect human or animal life or vegetation as required by Section 161." IDAPA 58.01.01.203. Based on the flaws in DEQ's issuance of the PTC described above, DEQ's action is in violation of these provisions of the Idaho Air Rules and is otherwise arbitrary, capricious, and an abuse of discretion and must be reversed.

71. By issuing the PTC in its current form, DEQ failed to adequately protect the public and environment from harmful air pollution causing injury to the Nez Perce Tribe, ICL, SSFS, and their members and supporters. To redress these injuries, Petitioners respectfully request the Board set aside and remand the PTC and direct DEQ to correct the following errors prior to issuing any new or revised PTC:

Ore Haul Road PM_{10} & Arsenic Emissions

A. DEQ must develop and include in the PTC enforceable permit conditions for the maximum average empty weight of ore haul trucks, the maximum average loaded weight of ore haul trucks, the maximum total number vehicle miles traveled annually by ore haul trucks, the silt content of the roadbed, the arsenic content of the silt in the roadbed, and any other important variables affecting the SGP's fugitive emissions of PM_{10} and arsenic from vehicle traffic on mine haul roads. To develop such permit conditions and ensure compliance with the NAAQS and TAP limits, DEQ must reevaluate and recalculate fugitive emissions of PM_{10} and arsenic.

B. Silt and arsenic levels should be included as permit conditions and monitored regularly *in situ,* rather than from stockpiles as applied to the roadbed.

C. Instead of assuming 120 days of recordable precipitation at the SGP as a variable within ore haul road fugitive PM emission calculations, as done by the applicant based off general geographic guidance from AP-42 chapter 13.2.2-1, DEQ must recalculate all fugitive emissions after analyzing local meteorological data sources to determine a more accurate and representative number of days with recordable precipitation.

FDCP, AMP, O&M Manual, & HRCP

D. DEQ must require Perpetua to submit the FDCP, AMP, O&M Manual, and HRCP (collectively, "Plans"), must provide for public comment on the Plans, must review and revise Plans to ensure the SGP's emissions comply with IDAPA 58.01.01.203, and must incorporate the Plans as enforceable PTC conditions.

Arsenic Averaging

E. DEQ must remove the 5-year averaging for arsenic emissions, the averaging of estimated annual ambient modeling impacts across two multi-year scenarios, and the 16/70 life of mine versus lifetime exposure adjustment for the SGP's maximum arsenic ambient concentration it used to assess arsenic TAPs compliance. DEQ must use the SGP's highest 1-year arsenic emission rates for each scenario evaluated and repeat the modeling analyses using these rates. DEQ must use the maximum annual ambient arsenic concentration from the single emission scenario producing the highest annual concentration for any 1-year as the point of compliance. *See* IDAPA 58.01.01.210.03b ("The point of compliance is the receptor site that is estimated to have the highest ambient concentration of the toxic air pollutant of all the receptor sites that are located either at or beyond the facility property boundary or at a point of public

access . . . ."). DEQ must assess the impact of the SGP's maximum 1-year annual emissions from the single emission configuration by comparing to the T-RACT AACC for arsenic (10 times the AACC value published in IDAPA 58.01.01.586), without averaging over multiple years, and without adjusting for the alleged 16-year life of the mine or the 70-year lifetime exposure.

Ambient Air Boundary Monitoring

F. As part of any PTC for the SGP, DEQ must require ambient air boundary monitoring, as provided for by IDAPA 58.01.01.211.01(d), to ensure compliance with the NAAQS and the TAPs increments. DEQ must require Perpetua to submit an ambient air boundary monitoring plan ("AABMP"), must take public comment on the AABMP, must review and revise the AABMP, and must incorporate the AABMP as enforceable PTC conditions. At a minimum, the AABMP must provide a strategy for monitoring the ambient air concentrations of PM_{total}, PM_{10}, $PM_{2.5}$ and arsenic at the SGP's ambient air boundary. The AABMP must be developed according to best industry and regulatory practices, consulting contemporary sources (e.g., DEQ or EPA guidance, similarly established plans for other state permits, etc.). At a minimum, monitoring stations must be required for areas of the ambient air boundary in which DEQ ambient air modeling results (specifically results using operating scenario W3 and BULKRN meteorological data) show receptors with 24-hour PM_{10} or arsenic concentrations within 70% of the applicable NAAQS or AACC (without consideration to multi-year emissions averaging and 16/70 adjustment).

Environmental & Economic Impacts of Arsenic Control Technology

G. DEQ must require Perpetua to update their T-RACT analysis to include analysis of "environmental impacts caused by the control technology that cannot be mitigated, including, but not limited to, water pollution and the production of solid wastes," including the use of

magnesium chloride and its aquatic life and tree toxicity effects, as well as using arsenic-contaminated water sources for dust suppression. IDAPA 58.01.01.210.14.c.ii. DEQ must also require the updated T-RACT to adequately address the "economic feasibility of a control technology or other requirement, including the costs of necessary mitigation measures, for a particular source," including detailed consideration of the economic feasibility of paving haul roads to better control fugitive dust emissions. IDAPA 58.01.01.210.14.d. DEQ must provide the updated T-RACT demonstration for public comment, must review and revise the T-RACT demonstration, and must incorporate enforceable PTC conditions from the T-RACT demonstration in the PTC.

CONCLUSION

72. When it issued the PTC for the SGP, DEQ failed to comply with critical requirements of the federal Clean Air Act, the Idaho Air Rules, and related regulations and guidance. Accordingly, the Board should vacate and withdraw the PTC and remanded to DEQ to correct all errors.

Dated: July 22, 2022

Respectfully submitted,

/s/ Bryan Hurlbutt

Attorneys for Respondent

BEFORE THE DEPARTMENT OF ENVIRONMENTAL QUALITY
STATE OF IDAHO

NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON Petitioners, v. IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent.	Case Docket No. 0101-22-01 RESPONSE TO PETITION TO INITIATE CONTESTED CASE: AIR PERMIT TO CONSTRUCT P-2019.0047 (JUN. 17, 2022)

COMES NOW, Respondent, the Idaho Department of Environmental Quality (Department), by and through the Office of the Attorney General, and hereby submits this Response to Petition to Initiate Contested Case in accordance with the Contested Case Rules & Rules for Protection & Disclosure of Records, IDAPA 58.01.23.161, in response

to the Petition to Initiate Contested Case filed by Petitioners Nez Perce Tribe, Idaho Conservation League, and Save the South Fork Salmon on July 22, 2022 ("Petition").

FACTUAL AVERMENTS

The Department cannot separately admit or deny each fact alleged in the Petition because the factual averments were not made separately. Moreover, the Petition is written in the style of a legal brief, which intermingles the Petitioners' alleged facts with their arguments. Therefore, it difficult to discern whether a statement is a factual averment, argument, a conclusion of law or a combination of any of these. For this reason, any statements of fact set forth in the Petition that are not explicitly admitted or agreed upon, are hereby denied. Without waiving this objection, the Department responds as follows:

A. "INTRODUCTION" Section

The Department agrees with the facts alleged in Paragraph One. The Department admits that the Stibnite Gold Project ("SGP") is located approximately ten miles east of the town of Yellow Pine, Idaho, but has insufficient information to admit or deny the claim that the SGP is located with the Nez Perce Tribe's aboriginal homeland, as stated in Paragraph Two. The Department generally agrees with the statements in Paragraph Three but does not agree with the characterization of dust emissions, which are described as "massive." The Department denies the statements in Paragraph Four.

The Department will abide by the request for service in Paragraph Five and admits the statement of jurisdiction in Paragraph Six. Paragraphs Seven and Eight contain no facts which can be admitted or denied. The Department has insufficient information regarding the Nez Perce Tribe to admit or deny the factual averments in Paragraphs Nine through Thirteen. However, whether the Nez Perce Tribe has standing, a conclusion of

law asserted within Paragraph Ten, is disputed, and therefore denied. The Department denies the claim in Paragraph Twelve that the Nez Perce Tribe will suffer injuries from permitted dust emissions at the SGP.

Similarly, the Department can neither admit nor deny the assortment of factual averments scattered throughout Paragraphs Fourteen through Nineteen, which generally describe the constituencies, goals, and activities of the Petitioners, Idaho Conservation League and Save the South Fork Salmon. Again, whether Idaho Conservation League and Save the South Fork Salmon have standing, a conclusion of law asserted within Paragraphs Fifteen and Eighteen, is disputed, and therefore denied. The Department admits that all the Petitioners submitted multiple comments to the Department regarding the Department's Permit to Construct ("PTC"). However, the Department denies the statements claiming that these entities will suffer injuries from permitted dust emissions. The Department admits the statements in Paragraphs Twenty and Twenty-One.

B. **Section I "Overview of SGP & Chronology of DEQ's Issuing the PTC"**

The Department agrees with the course of events as set forth in Paragraphs Twenty-Two through Twenty-Six. However, the Department avers that the permittee, Perpetua Resources Idaho, Inc. ("Perpetua"), followed the Department's process of submitting a draft permit and then responding to requests for further information from the Department.

C. **Section II A, "PM_{10} Pollution and Regulation"**

The Department generally agrees with the statements of fact and the directly cited materials provided in Paragraphs Twenty-Eight through Thirty-Two.

D. **Section II B, "PM_{10} Pollution from the SGP & Flaws in the PTC"**

The Department largely agrees with the statements in Paragraph Thirty-Three, except that the generation of dust from trucks traveling along haul roads is estimated to be approximately 55% of all *fugitive mining* emissions, or 53% of all modeled PM_{10} emissions. The statements in Paragraph Thirty-Four appear to be correct.

Paragraphs Thirty-Five through Forty-One contain mixed statements of fact and argument, which must be denied. Generally, the Department agrees that the Fugitive Dust Control Plan and Haul Road Capping Plan will be important for ensuring compliance with air quality standards. Those plans are subject to the Department's approval, and individual provisions within each plan will be enforceable through the PTC. Thus, the Department denies the assertions that those plans are not directly enforceable.

E. **Section II C, "Arsenic Pollution & Regulation"**

The Department agrees with the Petitioners' description of arsenic as a toxic air pollutant in Paragraphs Forty-Two through Forty-Five. The Department neither admits nor denies the statement in Paragraph Forty-Six, which references the definition of "Potential to Emit/Potential Emissions" at IDAPA 58.01.01.006.88.

F. **Section II D, "Arsenic Pollution from the SGP & Flaws in the PTC**"

The Department largely agrees with the substance of Paragraphs Forty-Seven through Forty-Nine. Regarding Paragraph Fifty, the Department agrees that Perpetua submitted to the Department a T-RACT demonstration. The Department agrees with the statements in Paragraph Fifty-One but denies the allegations in Fifty-Two through Fifty-Seven.

G. **Section II E, "DEQ's Ambient Air Boundary for the SGP"**

The Department agrees with the averments in Paragraphs Fifty-Eight, Fifty-Nine, and Sixty; however, the definition of "ambient air" is found at IDAPA 58.01.01.006.10. The Department disagrees with the arguments contained in Sixty-One through Sixty-Five.

H. **Section II F, "DEQ's Failure to Require Ambient Air Monitoring for the SGP"**

The Department agrees with the statements in Paragraphs Sixty-Six and Sixty-Seven but disagrees with the arguments in Paragraph Sixty-Eight.

LEGAL AUTHORITY

As indicated in the Petition, the permit at issue in this contested case was issued pursuant to Title 39 Idaho Code and the Rules for the Control of Air Pollution in Idaho, IDAPA 58.01.01 *et. seq*.

ADDITIONAL FACTS

The Department's Air Quality Permitting Response to Public Comments (June 17, 2022) contains the factual underpinnings supporting the issuance of the PTC as well as the Department's positions on fugitive dust control efficiency (Third Response to Comments 1-4), monitoring, recordkeeping, and reporting (Third Response to Comments 5-9), operational plans (Third Response to Comments 10-18), estimation of potential emissions (Third Response to Comments 19-30), the applicability of "ambient air" standards (Comments 35-36), and the T-RACT process (Comment 39-41). The Response to Public Comments is located on the Department's website at https://www2.deq.idaho.gov/admin/LEIA/api/document/download/16969.

The Department's PTC issued to Perpetua is located on the Department's website at https://www2.deq.idaho.gov/admin/LEIA/api/document/download/16954.

The Statement of Basis is located on the Department's website at https://www2.deq.idaho.gov/admin/LEIA/api/document/download/16956.

These documents contain the additional facts relied upon by the Department.

RELIEF SOUGHT

The Department requests the Board issue an order affirming the Department's action in issuing the PTC.

DATED: August 12, 2022, FOR RESPONDENT:

Attorneys for Perpetua Resources, Inc.

BEFORE THE BOARD OF ENVIRONMENTAL QUALITY
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047 NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGE, and SAVE THE SOUTH FORK SALMON, Petitioners, v. IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent.	Case Docket No. 0101-22-01 **PETITION TO INTERVENE**

I. INTRODUCTION

Perpetua Resources Idaho, Inc. ("Perpetua"), hereby petitions to intervene as a party in the above-entitled matter pursuant to IDAPA 58.01.23.352 and .353. A Petition to Initiate Contested Case ("Petition"), filed by the Nez Perce Tribe, Idaho Conservation League, and Save the South Fork Salmon (collectively "Protestants"), challenges the Permit to Construct, Permit No. P-2019.0047 ("Permit") issued to Perpetua on June 17, 2022 by the Idaho Department of Environmental Quality ("IDEQ"). The Permit authorizes Perpetua to begin development of the

Stibnite Gold Project ("SGP"), consisting of conventional open-pit mining, ore preparation, and gold extraction operations. Protestants challenge of the Permit is legally and factually unsupported. Perpetua seeks to intervene in this proceeding to fully respond to Protestants' allegations and defend the Permit.

II. LISTING OF REPRESENTATIVES

Pursuant to IDAPA 58.01.23.040, copies of all pleadings, correspondence, and official documents shall be served on Perpetua's counsel listed below:

Krista K. McIntyre
Stoel Rives LLP
101 S. Capitol Boulevard

III. BACKGROUND

Perpetua is an Idaho corporation authorized to conduct business in the State of Idaho. Perpetua's corporate office is located at 405 South 8th Street, Suite 201, Boise Idaho 83702.

In August 2019, Perpetua applied to IDEQ for a permit to construct the SGP pursuant to the *Rules for the Control of Air Pollution in Idaho*, IDAPA 58.01.01. IDEQ thoroughly reviewed Perpetua's application for nearly three years. During that time, and as part of IDEQ's review, Perpetua submitted additional information as requested by IDEQ in support of its application. IDEQ provided three public comment periods on drafts of the permit, including an extended sixty-day public comment period for interested parties that began on December 9, 2021. When IDEQ issued the final Permit on June 17, 2022, IDEQ prepared a detailed Statement of Basis supporting the Permit, and a thorough and complete Response to Comments. The Permit was issued in compliance with the *Rules for the Control of Air Pollution in Idaho*. IDAPA 58.01.01.

On July 22, 2022, IDEQ served Perpetua with the Notice of Filing and Service of Petition and a copy of the Petition.

IV. ARGUMENT

Petitions to intervene filed by the permit applicant or permit holder must be filed within twenty-one (21) days after service of the initiating petition. IDAPA 58.01.23.352.02. A permit applicant or permit holder may intervene as a matter of right in any contested case in which the permit is contested. IDAPA 58.01.23.353.01.

The Notice of Filing and Service of Petition was served on Perpetua on July 22, 2022. Perpetua files this petition to intervene on August 12, 2022. Therefore, this petition to intervene is timely as it is filed within twenty-one days of service of the Petition. Further, Perpetua, as the holder of the Permit contested in this proceeding, is entitled to intervene as a matter of right. Finally, Perpetua has a direct and substantial interest in this proceeding as Protestants challenge the Permit authorizing Perpetua to begin development of the SGP.

V. CONCLUSION

Perpetua as the holder of the Permit contested in this proceeding is entitled to intervene as a matter of right, to participate in these proceedings fully, respond to the allegations in Protestants' Petition and, if a contested case hearing is held, to provide any relevant evidence concerning the Permit and the legality of the Permit.

DATED: August 12, 2022.

PERPETUA RESOURCES IDAHO, INC., Intervenor.	)	

Pursuant to IDAPA 58.01.23.300; IDAPA 04.11.01.510 - 514, NOTICE IS HEREBY GIVEN that Dylan Lawrence, the designated presiding officer, will convene a prehearing conference on September 21, 2022, beginning at 10 a.m. MDT in Conference Rooms A and B of the Department of Environmental Quality state office building,1410 N. Hilton, Boise, Idaho. Those who are unable to attend in person may join via Microsoft Teams. The Teams link is in the attached email.

The conference facility meets the accessibility requirements of the Americans with Disabilities Act. To request assistance with accommodations, contact the undersigned by September 12, 2022.

As listed in IDAPA 04.11.01.510, a prehearing conference is held for the following purposes:

1. Formulating or simplifying the issues;
2. Obtaining concessions of fact or identification of documents to avoid unnecessary proof;
3. Scheduling discovery when discovery is authorized before the agency;
4. Arranging for the exchange of proposed exhibits or prepared testimony;
5. Limiting witnesses;
6. Discussing settlement offers or making settlement offers;
7. Scheduling hearings;
8. Establishing procedure at hearings; and
9. Addressing other matters that may expedite orderly conduct and disposition of the proceeding or its settlement.

The prehearing conference will not be recorded.

Dated this 23rd day of August, 2022.

BEFORE THE BOARD OF ENVIRONMENTAL QUALITY
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047 _____ NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGE, and SAVE THE SOUTH FORK SALMON, Petitioner, v. IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent, and PERPETUA RESOURCES IDAHO, INC., Intervenor.	Case Docket No. 0101-22-01 **PERPETUA RESOURCES IDAHO'S MOTION TO DISMISS AND SUPPORTING BRIEF**

Pursuant to IDAPA 58.01.23.161.02 and .162, Perpetua Resources Idaho, Inc. ("Perpetua") respectfully moves to dismiss the Petition to Initiate Contested Case (the "Petition") filed by the Nez Perce Tribe, Idaho Conservation League, and Save the South Fork Salmon ("Petitioners"). Perpetua moves to dismiss the Petition because Petitioners have failed to comply

with the pleading standards of IDAPA 58.01.23.160.01 and otherwise failed to state a claim upon which relief can be granted.

I. INTRODUCTION

In August 2019, Perpetua applied to the Idaho Department of Environmental Quality (the "Department") for a permit to construct for the Stibnite Gold Project (the "SGP"). Nearly three years later, and after numerous Department requests for supplemental information and multiple opportunities for public input and engagement, the Department issued Perpetua a preconstruction permit, Permit to Construct No. 2019.0047 (the "Final Permit"). Petitioners ask the Board of Environmental Quality to set aside and remand the Final Permit on the grounds that the Department's issuance of the permit "failed to comply with" and "is in violation of" the federal Clean Air Act ("CAA"), 42 U.S.C. § 7401, *et seq.*, and "Idaho rules regulations, and guidance for [CAA] permitting." Petition ¶¶ 4, 70, 72.

But nowhere does the Petition cite the governing regulations that the Department allegedly violated. Nowhere does the Petition set forth any claim that would entitle Petitioners to relief. Instead, the Petition is filled with conditions that Petitioners wish the Department would have included in the Final Permit. The Petition is deficient in that it fails to connect Petitioners' wishes to binding regulatory provisions, fails to state facts or identify legal grounds supporting the requested relief, and fails to satisfy the heightened pleading standard of IDAPA 58.01.23.160.01. Accordingly, the Petition must be dismissed.

II. BACKGROUND

The SGP is designed to develop gold and antimony in Valley County, Idaho approximately 10 miles east of Yellow Pine. *See* Petition ¶ 22 (quoting Statement of Basis

("SOB")).[1] Perpetua has three distinct purposes for the SGP: (1) to responsibly produce precious metals as well as critical minerals necessary for the country's energy transformation; (2) to remediate and restore the legacy Stibnite mine site that was abandoned in 2012 by the federal government after decades of mining; and (3) to maintain a strong partnership with the local community.

On August 20, 2019, Perpetua applied to the Department for a Permit to Construct. Petition ¶ 23. The Department's review of Perpetua's application was thorough and comprehensive. It included four requests for additional information to supplement the application, three extended public comment opportunities to solicit feedback from the public and other stakeholders, two informational meetings requested by the public, and three iterations of draft permits. SOB at 9-11. This multi-year, comprehensive process culminated in the issuance of the Final Permit on June 17, 2022. *See* Petition ¶¶ 23-26; SOB at 9-11.

Petitioners fully participated in every public comment opportunity and informational meeting hosted by the Department, repeating critiques of the Department's evaluations and proposed controls of particulate matter ("PM") and toxic air pollutant ("TAP") emissions. *See* Petition ¶¶ 24-26. In response to those critiques, the Department requested, and Perpetua provided, additional information such as hazardous air pollutant ("HAP") and TAP emission inventories and modeling files. *See* SOB at 9-11. The Department also conducted additional modeling evaluations of PM emissions, additional analyses of TAP emissions, and enhanced enforceable permit requirements. *See id*. at 10-11.

[1] The Petition repeatedly references and incorporates information from the Permit and SOB. The Final Permit is attached as Exhibit A. The SOB is available on the Department's website at https://www2.deq.idaho.gov/admin/LEIA/api/document/download/16956.

The Petition repeats the same critiques and comments pressed during the public review periods, seeks more review and work by the Department, and alleges that the Department's actions and the Final Permit are "flawed." *See* Petition ¶¶ 35, 52, 61; *see also id*. ¶ 70. Notwithstanding their active participation in its development, Petitioners are dissatisfied with the Final Permit issued by the Department, but the Petition fails to state facts or identify law sufficient to support allegations that the Department "failed to comply with" or "is in violation of" an applicable law.

III. STANDARD OF REVIEW

A. An agency action may only be reversed if it is contrary to law, arbitrary, capricious, or an abuse of discretion.

An agency action may only be reversed if it is in violation of constitutional or statutory provisions, is in excess of statutory authority, is made on unlawful procedure, or is arbitrary, capricious, or an abuse of discretion. I.C. § 67-5279. The party challenging the agency decision must demonstrate that the agency erred in a manner specified in Idaho Code § 67-5279. *Wheeler v. Idaho Dep't of Health & Welfare*, 147 Idaho 257, 260, 207 P.3d 988, 991 (2009). As shown below, the Petition fails to present the requisite arbitrary and capricious action, an abuse of discretion, or a violation of law to reverse the Final Permit issued by the Department.

B. A petition for a contested case may be dismissed if defective or if it fails to allege facts that, if true, entitle petitioners to the relief requested.

The Board of Environmental Quality's Contested Case Rules, IDAPA 58.01.23, expressly permit a case to be disposed of through a motion to dismiss. IDAPA 58.01.23.162.01; IDAPA 58.01.23.161.02; IDAPA 04.11.01.304 (incorporated by IDAPA 58.01.23.003.04). The

Contested Case Rules also allow all motions recognized under the Idaho Rules of Civil Procedure ("I.R.C.P").[2] IDAPA 58.01.23.162.01.

Unlike I.R.C.P 8(a)(2), which requires "a short and plain statement of the claim showing that the pleader is entitled to relief," the Board's rules require a heightened pleading standard. The Contested Case Rules require a petition for a contested case to: (a) "[f]ully state the facts upon which it is based" and (b) "[r]efer to the particular provisions of statute, rule, order or other controlling law upon which it is based. Legal assertions will be accompanied by citations of cases and statutory provisions[.]" IDAPA 58.01.23.160.01. Thus, the pleading standard under IDAPA 58.01.23.160.01 is akin to the heightened pleading standards of I.R.C.P 9.

I.R.C.P. 12(b)(6) permits the dismissal of a claim if the plaintiffs, or here the petitioners, "fail[] to state a claim upon which relief can be granted." A motion to dismiss under Rule 12(b)(6) tests the legal sufficiency of a complaint. *See Hoffer v. City of Boise*, 151 Idaho 400, 402, 257 P.3d 1226, 1228 (2011). Where a petition fails to meet the heightened pleading standard set forth in the Contested Case Rules, dismissal is appropriate. IDAPA 04.011.01.304 (incorporated by IDAPA 58.01.23.003.04); *see also Jenkins v. Boise Cascade Corp.*, 141 Idaho 233, 239, 108 P.3d 380, 386 (2005) (upholding dismissal of fraud claim because plaintiff failed to plead claim with specificity as required by I.R.C.P. 9); *Fields v. State*, 155 Idaho 532, 534, 314 P.3d 587, 589 (2013) (dismissal appropriate where petition for post-conviction relief failed to meet heightened pleading standards required by statute).

Under I.R.C.P. 12(b)(6), the Board must also determine if the facts alleged in the complaint, if true, are sufficient to entitle the petitioners to the relief requested. *See Hoffer*, 151

[2] This includes motions to dismiss under I.R.C.P. 12(b)(6). *In the Matter of Petition for Review of HWMA/RCRA Hazardous Waste Treatment and Storage Permit Renewal for the AMWTP*, Docket No. 0105-19-01, Amended Order at 3-4 (Sept. 24, 2019).

Idaho at 402, 257 P.3d at 1228. In doing so, the Board must view all the facts and inferences in favor of the petitioners and ask if a claim for relief has been stated. *See id*. "The issue is not whether the plaintiff will ultimately prevail, but whether the party is entitled to offer evidence to support the claims." *Orthman v. Idaho Power Co.*, 126 Idaho 960, 962, 895 P.2d 561, 563 (1995) (internal quotation marks and citation omitted).

To survive an I.R.C.P. 12(b)(6) motion to dismiss, it is not enough for the complaint to make conclusory allegations. *See Owsley v. Idaho Indus. Comm'n*, 141 Idaho 129, 136, 106 P.3d 455, 462 (2005). "Although the non-movant is entitled to have his factual assertions treated as true, this privilege does not extend to the conclusions of law the non-movant hopes the court to draw from those facts." *Id*. (citation omitted). Where all factual allegations in the pleadings, if true, still fail to meet the elements of a claim showing a plaintiff is entitled to relief, dismissal is appropriate. *Orrock v. Appleton*, 147 Idaho 613, 618, 213 P.3d 398, 403 (2009).

When deciding a motion to dismiss under I.R.C.P. 12(b)(6), a court, or the Board, may consider documents incorporated by reference in a pleading without converting the motion to a motion for summary judgment. *Taylor v. McNichols*, 149 Idaho 826, 833, 243 P.3d 642, 649 (2010) (distinguishing between documents referenced in complaint and documents entirely outside the complaint); *Paslay v. A&B Irrigation Dist.*, 162 Idaho 866, 873, 406 P.3d 878, 885 (2017) (Burdick, C.J., concurring in part and dissenting in part) (explaining the Idaho Supreme Court's standard for considering documents referenced in the pleadings on a motion to dismiss).

IV. ANALYSIS

A. The Petition fails to plead a legal basis for remand of the Final Permit.

Perpetua was required to obtain a permit to construct for the SGP by the CAA and Idaho's State Implementation Plan ("SIP"), which is codified at IDAPA 58.01.01 ("Idaho Air

Rules").[3] Petitioners acknowledge that "EPA has delegated to [the Department] authority to issue air quality permits in Idaho." Petition ¶ 32. Although the Petition generally alleges that the Department failed to comply with the CAA, *id.* ¶¶ 4, 72, the Petition does not identify or allege any provision of the CAA that was violated; therefore, Perpetua focuses on the alleged violations of the Idaho Air Rules.

The Petition generally alleges that the Department's action violated statutory and regulatory provisions. *Id.* ¶¶ 4, 72. Petitioners also suggest that the Department's action was otherwise arbitrary, capricious, and an abuse of discretion.[4] *Id.* ¶ 70. While Petitioners generally cite Idaho Code § 67-5279 and suggest that some action of the Department was contrary to law, the Petition never specifically identifies which provisions of the Final Permit are contrary to law. Instead, Petitioners repeatedly allege that the Department's issuance of the Final Permit was "flawed" or "deficient" or contained "shortcomings." Petition ¶¶ 24, 25, 35, 52, 61, 70. But "flawed," "deficient," or containing "shortcomings" are not grounds for relief. *See* I.C. § 67-5279.

As observed by the Department's Response to the Petition (filed Aug. 12, 2022), the Petition is informally presented in the style of a legal brief, intermingling alleged facts, arguments, opinions, suggestions for permit content, and conclusory statements. Consequently, identifying any specifically pled basis for remand in the Petition is very difficult. The Petition contains no "short and plain statement of the claim showing that the pleader is entitled to relief."

---

[3] Idaho's SIP was adopted pursuant to Section 110 of the CAA, 40 U.S.C. § 7410, and approved by the U.S. Environmental Protection Agency. 40 C.F.R. § 52.670. Idaho's SIP has been amended multiple times to remain consistent with federal regulations. *See* 68 Fed. Reg. 2217 (Jan. 16, 2003); 87 Fed. Reg. 31,429 (May 24, 2022).

[4] Petitioners do not allege that the Department acted in excess of its statutory authority. *See* Petition ¶¶ 4, 70, 72.

I.R.C.P. 8(a)(2). And although styled as a legal brief, the Petition fails to plead with any specificity the particular legal bases that would entitle Petitioners to relief and therefore fails to meet the heightened pleading standard of IDAPA 58.01.23.160.01.

Petitioners do not like the Final Permit, and Petitioners oppose the SGP. But dislike of a project or permit is an insufficient basis to remand the Final Permit. Petitioners prefer a different permit, or no permit authorizing the SGP. The Petition is filled with Petitioner's wish list of conditions and speculation about the possible harm from the construction and operation of the SGP. But differences of opinion and speculation of hypothetical harm are insufficient bases to remand the Final Permit. *See Friends of the Columbia Gorge, Inc. v. Schafer*, 624 F. Supp. 2d 1253, 1271 (D. Or. 2008) (a difference of opinion between petitioners and the agency does not provide grounds to remand the agency action).

B. The Petition does not allege any violations of IDAPA 58.01.01.203.

The Petition does not allege that Perpetua failed to demonstrate each of the elements of IDAPA 58.01.01.203 to the satisfaction of the Department. The Petition does not allege that the SGP will violate any of the provisions of IDAPA 58.01.01.203. To be sure, Petitioners acknowledge that Perpetua demonstrated compliance with the elements of IDAPA 58.01.01.203 to the Department's satisfaction. Petition ¶¶ 34, 51. Instead, the Petition generally hypothesizes that Perpetua "could" exceed ambient air quality standards or TAP increments based on speculation and what-if scenarios. Even when liberally construed in favor of Petitioners, the Petition fails to state a claim, or sufficient facts supporting a claim, that the Final Permit is contrary to law.

Under IDAPA 58.01.01.203, to obtain a preconstruction permit for a new stationary source, the applicant must show "to the satisfaction of the Department all of the following:"

01. Emission Standards. The stationary source or modification would comply with all applicable local, state or federal emission standards.

02. NAAQS. The stationary source or modification would not cause or significantly contribute to a violation of any ambient air quality standard.

03. Toxic Air Pollutants. Using the methods provided in Section 210, the emissions of toxic air pollutants from the stationary source or modification would not injure or unreasonably affect human or animal life or vegetation as required by Section 161. Compliance with all applicable toxic air pollutant carcinogenic increments and toxic air pollutant non-carcinogenic increments will also demonstrate preconstruction compliance with Section 161 with regards to the pollutants listed in Sections 585 and 586.

In issuing the Final Permit, the Department found

> [t]he applicant has *demonstrated preconstruction compliance to DEQ's satisfaction* that emissions from this facility will not cause nor significantly contribute to a violation of any ambient air quality standard. The applicant has also *demonstrated preconstruction compliance to DEQ's satisfaction* that the emissions increase due to this permitting action will not exceed any acceptable ambient concentration (AAC) or acceptable ambient concentration for carcinogens (AACC) for toxic air pollutants (TAP).

SOB at 26 (emphasis added). Specific elements of IDAPA 58.01.01.203 are discussed below.

1. In accordance with IDAPA 58.01.01.203.02, Perpetua demonstrated to the satisfaction of the Department that the SGP would not cause or contribute to a violation of the NAAQS, and the Petition fails to state a factual or legal basis for remand of the Final Permit.

In Section II.B of the Petition ("PM_{10} Pollution from the SGP & Flaws in the PTC"), Petitioners critique the Department's determination under IDAPA 58.01.01.203.02 that the SGP will not cause or contribute to a violation of the PM_{10} NAAQS. Petitioners claim that the Department's determination is "flawed," Petition ¶ 35, and then suggest various enforceable requirements that they prefer to those imposed by the Department in the Final Permit, *id.* ¶¶ 36-41. Ultimately Petitioners speculate that under the Department's approach emissions "could" exceed the NAAQS. *Id.* ¶¶ 37, 39, 41.

Petitioners' opinions regarding the Department's work and their preferences for permit content – after three public comment periods and the development of a robust administrative record – do not support a claim that the Department's action and issuance of the Final Permit were unlawful. Under the governing regulations the applicant must show "*to the satisfaction of the Department*" that "[t]he stationary source or modification would not cause or significantly contribute to a violation of any ambient air quality standard." IDAPA 58.01.01.203.02 (emphasis added). Petitioners admit that

> DEQ modeled receptors at various locations along the SGP's ambient air boundary and *determined that the maximum potential emissions will be below (and thus comply with) the 24-hour PM10 NAAQS. DEQ found the maximum 24-hour PM_{10} pollution from the SGP would be 123.5 ug/m3, which is 82.3% of the NAAQS.*

Petition ¶ 34 (emphasis added). The Petition provides a commentary on the Final Permit, but there is no requisite factual or legal allegation in the Petition that the Department's work violated the applicable law.

Next, Petitioners second guess the Department's choices for enforceable requirements to ensure NAAQS compliance, alleging that the Department: (1) failed to establish enforceable permit conditions on ore haul trucks (*id.* ¶¶ 36, 39); (2) failed to require that the Fugitive Dust Control Plan ("FDCP"), Haul Road Capping Plan ("HRCP"), and Operations and Maintenance Manual ("O&M Manual") be developed prior to issuance of the permit and submitted to public comment (*id.* ¶¶ 37, 39, 40); (3) failed to require sufficient monitoring and recordkeeping (*id.* ¶ 40); and (4) allowed Perpetua to use precipitation data that was not the most representative data (*id.* ¶ 41). Critically, however, the Petition fails to identify any violations of the Idaho Air Rules.

Enforceable permit conditions on ore haul trucks. Petitioners admit that the Department required enforceable permit conditions for control of PM_{10} emissions in the Final Permit: silt

content of the haul roads (Petition ¶ 36 and Condition 3.13), total ore haulage per day (Petition ¶ 37 and Condition 3.5), enforceable work practice plans (Petition ¶¶ 37, 39, 40 and Conditions 2.4, 2.5, 2.6, 2.7, 2.8, 2.20, 3.10, 3.13), and application of water spray and chemical dust suppressants (Petition ¶ 38 and Condition 2.6). Petitioners entirely ignore Condition 2.5, which requires fugitive dust control measures on haul roads sufficient to ensure that visible emissions do not exceed 10% opacity. Instead, they suggest the Department should have included alternative or additional conditions. Still, the Petition fails to point to any regulations requiring such alternatives – because there are no such requirements.

Instead, the Idaho Air Rules provide the Department with discretion to impose "any reasonable conditions upon an approval [a permit to construct]." IDAPA 58.01.01.211.01. As the Department explained in the SOB, "Permit Conditions 2.1-2.8 incorporate fugitive dust emission limits and control requirements as required by IDAPA 58.01.01.650-51." SOB at 47. IDAPA 58.01.01.651 states:

> All reasonable precautions shall be taken to prevent particulate matter from becoming airborne. In determining what is reasonable, consideration will be given to factors such as the proximity of dust emitting operations to human habitations and/or activities, the proximity to mandatory Class I Federal Areas and atmospheric conditions which might affect the movement of particulate matter. Some of the reasonable precautions may include, but are not limited to….
>
> ... [u]se, where practical, of water or chemicals for control of dust ….
>
> ... [a]pplication, where practical, of asphalt, oil, water or suitable chemicals to, or covering of dirt roads…."

These are exactly the conditions that Petitioners admit the Department included in the Final Permit. Petition ¶ 38.

The submission of work practice plans for public comment. Petitioners acknowledge that the Department required work practice plans for control of PM_{10} emissions in the Final Permit.

Petitioners repeatedly allege, however, that the work practice plans – the FDCP, HRCP, and O&M Manual – should have been developed prior to issuance of the Final Permit and submitted for public comment. *Id.* ¶¶ 37, 39, 40. The regulations do not require that these work practice plans be developed, much less that they be prepared before construction of the SGP commences or be available for public comment. *See* IDAPA 58.01.01.211.01 (Department may impose reasonable conditions). Consistent with the Idaho Air Rules, the Department required that Perpetua develop these work practice plans, include specific provisions in the plans, and submit them to the Department *for approval* at least 30 days prior to startup. Condition 2.8 (FDCP), 2.21 (O&M Manual), 3.13 (HRCP). Once approved the requirements specified in these work practice plans become enforceable conditions of the PTC. Condition 2.6 (FDCP), 2.20 (O&M Manual), 3.13 (HRCP).

Sufficient monitoring and recordkeeping. Petitioners next object that the Final Permit "itself does not include all monitoring, recordkeeping, and reporting necessary to assure compliance with the permit emission limitations and applicable requirements." Petition ¶ 40. First, this is a conclusory statement without any associated factual support and should be dismissed on that basis. Second, Petitioners ignore the recordkeeping requirements included as conditions throughout the Final Permit. *See, e.g.,* Condition 2.2 (records of fugitive dust control required to be updated once every 12 hours), 2.3 (records of fugitive dust complaints), 2.4 (records of daily inspections), 2.11 (visible emission inspections).

Also, Condition 7.10 requires Perpetua to maintain "sufficient records to ensure compliance with all of the terms and conditions of this permit," including monitoring records and supporting information, such as calibration and maintenance records. These conditions were included in the Final Permit to comply with IDAPA 58.01.01.211. SOB at 50. IDAPA

58.01.01.211 does not contain specific recordkeeping requirements; instead, it gives the Department discretion to impose "reasonable conditions" necessary to ensure compliance with the Final Permit. Petitioners have identified no legal obligations for the Department to require additional recordkeeping, reporting, or monitoring requirements.

The use of representative precipitation data. Finally, Petitioners speculate that the precipitation data used to model fugitive PM emissions from the ore haul roads is not representative of actual precipitation at the SGP. Petition ¶ 41. Failing to meet their burden, Petitioners offer no facts alleging that the precipitation data used was not representative, nor do they identify any data that should have been used instead. *See id.* Rather, they make a conclusory allegation that the data was not representative without any supporting facts. This conclusory allegation is insufficient. *Orrock*, 147 Idaho at 618, 213 P.3d at 403 ("[F]actual allegations will be accepted as true, unless they are purely conclusory.").

Further, Petitioners' only support for their assertion that the Department erred by using unrepresentative precipitation data is the Department's *Guideline for Performing Air Quality Impact Analysis* ("Modeling Guideline"). The Modeling Guideline is "provided as general guidance" for permit applicants and "does not alter the discretionary authority of DEQ to protect public health." Modeling Guideline at 1. Nothing in the Idaho Air Rules or the Modeling Guideline requires Perpetua to provide, or the Department to require, "local meteorological data." Petition ¶ 41.

Section II.B of the Petition should be dismissed. In Section II.B of the Petition, Petitioners reaffirm that the Department complied with the Idaho Air Rules, IDAPA 58.01.01.203.02. While Petitioners dislike the Final Permit and question the Department's analyses of NAAQS compliance, none of the opinions presented in the Petition state a claim that

the Department *violated* the Idaho Air Rules or the CAA in issuing the Final Permit. Petitioners also do not satisfy their burden to allege any omission from the Final Permit that is required by law. Petitioners fail to comply with IDAPA 58.01.23.160.01 and fail to state a claim that the Department's issuance of the Final Permit is contrary to law. Accordingly, Perpetua requests that the allegations in Section II.B of the Petition be dismissed.

2. In accordance with IDAPA 58.01.01.203.03, Perpetua demonstrated to the satisfaction of the Department that TAP emissions would not injure or unreasonably affect human or animal life or vegetation, and the Petition fails to state a factual or legal basis for remand of the Final Permit.

In Section II.D of the Petition ("Arsenic Pollution from the SGP & Flaws in the PTC"), Petitioners attempt to pick apart the Department's work to select reasonably available control technology for TAPs ("T-RACT"), the Department's determination of compliance with the Acceptable Ambient Concentrations of Carcinogens ("AACC"), and the Department's conclusion that emissions of arsenic will not injure or unreasonably affect human or animal life or vegetation.

As before, Petitioners assert the Department's approval and analysis are "flawed." Petition ¶ 52. Then, Petitioners attack the Department's interpretation and application of the Idaho Air Rules that govern TAP emissions analyses (IDAPA 58.01.01.210). Petition ¶¶ 53-57. Ultimately Petitioners hypothesize that under the Department's approach emissions "could" exceed the AACC without supporting factual statements. *Id.* ¶¶ 54, 56. Petitioners' conjecture regarding the Department's work and Petitioners' preferences for different analytical approaches fail to support a claim that the Department's issuance of the Final Permit was unlawful. *See id.* ¶¶ 52-57.

Under IDAPA 58.01.01.203.03, the applicant must show "*to the satisfaction of the Department*" that

> [u]sing the methods provided in Section 210, the emissions of toxic air pollutants from the stationary source or modification would not injure or unreasonably affect human or animal life or vegetation as required by Section 161. Compliance with all applicable toxic air pollutant carcinogenic increments and toxic air pollutant non-carcinogenic increments will also demonstrate preconstruction compliance with Section 161 with regards to the pollutants listed in Sections 585 and 586.

(Emphasis added.) Although in the opinion of Petitioners the Department's work was flawed, Petitioners concede throughout Section II.D that the Department used the methods provided in Section 210 to evaluate T-RACT and AACC compliance. *See* Petition ¶¶ 47-51. Petitioners fail to allege and support with facts an allegation that the Department's work violated the requirements of the Idaho Air Rules, IDAPA 58.01.01.203.03 and 210.

T-RACT review complied with applicable analyses. Petitioners misconstrue IDAPA 58.01.01.210.14 and then attempt to argue that the Department was required to discuss environmental and economic impacts for the T-RACT Perpetua proposed and the Department selected, specifically, chemical dust suppressants. Petition ¶ 53. To understand why Petitioners fail to state a claim, it is helpful to begin with the regulatory definition of T-RACT:

> An emission standard based on the lowest emission of toxic air pollutants that a particular source is capable of meeting by the application of control technology that is reasonably available, as determined by the Department, considering technological and economic feasibility. If control technology is not feasible, the emission standard may be based on the application of a design, equipment, work practice or operational requirement, or combination thereof.

IDAPA 58.01.01.007.12. Petitioners wrongfully allege that the T-RACT demonstration failed to provide sufficient environmental and economic information. Petition ¶ 53.

The Idaho Air Rules only require the applicant to submit environmental and economic information to assist the Department in determining if the proposed control technology is reasonably available. *See* IDAPA 58.01.01.007.12; *id.* 210.14.a. ("The applicant shall submit information to the Department identifying and documenting which control technologies or other

requirements the applicant *believes to be* T-RACT." (emphasis added)); *id.* 210.14.b ("The Department shall review the information submitted by the applicant and determine whether the applicant has proposed T-RACT."); *id.* 210.14.e ("If the Department determines the applicant has proposed T-RACT, the Department shall determine which of the options, or combination of options, will result in the lowest emission of toxic air pollutants….").

The Department, applying its agency expertise, considered three dust control technologies for controlling fugitive dust from haul roads: paving, application of chemical dust suppressants, and watering. SOB, Appendix G, T-RACT Analysis, at 30. The Department then determined that paving was technologically infeasible because the weight of the haul trucks would significantly exceed the weight limits of paved roads. *Id.* at 32. The remaining control technologies were then ranked by control effectiveness and the most efficient control technology – chemical dust suppressants – was selected, along with supplemental frequent watering. *Id.* at 33.

As written into IDAPA 58.01.01.210.14, consideration of environmental and economic impacts is only necessary if the Department is required to evaluate whether a control technology is reasonably available. Use of chemical dust suppressants and watering are well recognized both in practice, and by the Idaho Air Rules, as reasonably available control technologies for fugitive dust.[5] *See, e.g.,* IDAPA 58.01.01.651 (prescribing use of water or suitable chemical suppressants to control fugitive dust from dirt roads). Therefore, no additional evaluation of the economic or environmental impacts of the chosen control technologies was required.

[5] The Department relied on well-recognized control technologies in the EPA RACT/BACT/LAER Clearinghouse database, to assist in its determination that (1) Perpetua had proposed T-RACT and (2) the level of control effectiveness of each of the alternatives. SOB, Appendix G, T-RACT Analysis, at 31.

The Petition also alleges that Perpetua submitted insufficient economic information for Perpetua's decision to use water and chemical dust suppressants instead of paving haul roads. Petition ¶ 53. The Department, applying agency expertise, determined that paving was technologically infeasible due to the weight of the haul trucks traveling on the roads. SOB, Appendix G, T-RACT Analysis, at 32. Therefore, no economic analysis of paving was required. IDAPA 58.01.01.210.14. Because chemical dust suppressant was selected as T-RACT and is well recognized as "reasonably available" no additional consideration of economic information was triggered. Again, the Petition fails to identify any violation of the Idaho Air Rules.

Emissions estimations did not violate the Idaho Air Rules. Petitioners allege that, because the Department's work on PM_{10} emissions estimates and controls was "flawed," so too was its estimates of arsenic emissions. Petition ¶ 54. For the same reasons described in Section IV.B.1, *supra*, the Petition fails to allege a claim that the Department violated any specific provision of the Idaho Air Rules.

Arsenic analysis complied with the Idaho Air Rules. Petitioners critique the Department's work on implementing T-RACT and using averages to establish a representative AACC, Petition ¶¶ 55-56, and assert that "[n]othing in the Idaho Air Rules allows for multi-year emissions averaging and ambient air concentration adjustments," *id.* ¶ 55. Critically, the Petition fails to identify any provision of the Idaho Air Rules that prohibits the approach taken by Perpetua in quantifying arsenic emissions or that invalidates the Department's approval of such approach. Instead, the applicant must show to the "satisfaction of the Department" that

> [u]sing the methods provided in Section 210, the emissions of toxic air pollutants from the stationary source or modification would not injure or unreasonably affect human or animal lie or vegetation as required by Section 161. Compliance with all applicable toxic air pollutant carcinogenic increments and toxic air pollutant non-carcinogenic increments *will also* demonstrate preconstruction compliance with Section 161 with regards to the pollutants listed in Sections 585 and 586.

IDAPA 58.01.01.203.03 (emphasis added). Section 161 provides: "Any contaminant which is by its nature is toxic … shall not be emitted in such quantities or concentrations as to … injure or unreasonably affect human or animal life or vegetation." IDAPA 58.01.01.161. Section 210 requires "the applicant … demonstrate preconstruction compliance with Section 161 *to the satisfaction of the Department*. The accuracy, completeness, execution and results of the demonstration *are all subject to review and approval by the Department*." IDAPA 58.01.01.210 (emphasis added).

As relevant here, Section 210.12 sets out the methods for calculating compliance with Section 161.

> Compare the source's or modification's approved T-RACT ambient concentration at the point of compliance for the toxic air pollutant to the amount of the toxic air pollutant that would contribute an ambient air cancer risk probability of less than one to one hundred thousand (1:100,000) (which amount is equivalent to ten (10) times the applicable acceptable ambient concentration listed in Section 586).

IDAPA 58.01.01.210.12.b.

> If the source's or modifications approved T-RACT ambient concentration at the point of compliance is less than or equal to the amount of the toxic air pollutant that would contribute to an ambient air cancer risk probability of less than one to one hundred thousand (1:100,000), no further procedures for demonstrating preconstruction compliance will be required for that toxic air pollutant as part of the application process.

IDAPA 58.01.01.210.12.c. As described by the regulations, and contrary to Petitioners' assertions, the applicant is required to demonstrate to the Department's satisfaction that the ambient concentration of the TAP at the point of compliance is equal to or less than the amount of TAP that would contribute to a cancer risk of one to 100,000. The Idaho Air Rules do not require annual averaging as Petitioners suggest.

As described fully in the SOB, the Department complied with the Idaho Air Rules in determining that the permitted arsenic emissions would not injure or unreasonably affect human or animal life or vegetation. SOB at 26 ("The applicant has … demonstrated preconstruction compliance to DEQ's satisfaction that the emissions increase due to this permitting action will not exceed any … acceptable ambient concentration for carcinogens (AACC) for toxic air pollutants (TAP)"); *id.* ("adjusted arsenic HAP TAP emissions at 0.544 pounds per hour (lb/hr) did not exceed 42% of the applicable AACC"); TAPS Addendum Modeling Review Attachment, SOB. While the AACCs in Section 586 are stated in annual averages, nothing in the Idaho Air Rules require the applicant to utilize annual averages in demonstrating compliance with Section 161. Instead, the regulations require that the applicant demonstrate the ambient air concentration of TAPs creates a cancer risk probability of less than one to 100,000. IDAPA 58.01.01.210.12.b.

Petitioners' critiques and opinions of the interpretation, application, and determination made by the Department in support of the requirement at IDAPA 58.01.01.203.03 do not support a claim that the Department's action and issuance of the Final Permit were unlawful.

Paragraph 57 of the Petition is irrelevant. The allegations in Paragraph 57 of the Petition, regarding the incremental nature of the Department's TAPs regulations, is irrelevant to whether the Final Permit is lawful and must be dismissed. *See In Re: Permit Applicant Garnet Energy LLC (Permit No. 0027-00081)*, No. 0101-01-10, Order Granting Motion for Summary Judgement at 11 (Feb. 22, 2002) (dismissing claim premised on irrelevant regulatory requirements).

Section II.D of the Petition should be dismissed. In Section II.D of the Petition, Petitioners reaffirm that the Department complied with the Idaho Air Rules, IDAPA 58.01.01.203.03 and 210. While Petitioners dislike the Final Permit and question the

Department's analyses of T-RACT and AACC for the SGP, none of the opinions presented in the Petition state facts supporting a claim that the Department violated the Idaho Air Rules in issuing the Final Permit. Section II.D does not identify a violation of applicable law for air quality permit issuance nor identify an action by the Department contrary to applicable law for air quality permit issuance. Accordingly, Perpetua requests that the allegations contained in Section II.D of the Petition be dismissed.

C. The Petition does not allege a violation of any law governing the ambient air boundary.

In Section II.E of the Petition ("DEQ's Ambient Air Boundary for the SGP"), Petitioners critique the Department's decision to exclude from ambient air the access route between Stibnite Road at Sugar Creek and Thunder Mountain Road at Meadow Creek (the "North Access Route"), claiming that the Department's determination is "flawed." Petition ¶ 61.

Petitioners attack the Department's interpretation and application of the Idaho Air Rules and policy that govern ambient air boundary assessments, demanding that the access management plan ("AMP") required by the Final Permit be reviewed by the public and enforceable. *Id.* ¶¶ 62-65. Petitioners' opinions and suggestions regarding the Department's work and Petitioners' preference for public review of the AMP do not support a claim that the Department's action and issuance of the Final Permit were unlawful. *Id.* ¶¶ 61-65. The Petition does not identify a violation of law for air quality permit issuance nor identify an action by the Department contrary to law for air quality permit issuance.

Under IDAPA 58.01.01.203.02, the applicant must show "*to the satisfaction of the Department*" that "[t]he stationary source or modification would not cause or significantly contribute to a violation of any ambient air quality standard." (Emphasis added.) "Ambient air" is defined at IDAPA 58.01.01.006.10 as "[t]hat portion of the atmosphere, external to buildings,

to which the general public has access." Although in the opinions of Petitioners the Department's exclusion of the North Access Route is flawed, Petitioners fail to allege a violation of the Idaho Air Rules.

Contrary to Petitioners' critique of the Department's AMP requirements in the Final Permit, the measures required for the AMP are not "ambiguous." Petition ¶¶ 63-65. Condition 2.7 of the Final Permit requires the AMP to include concrete and unambiguous measures to exclude the general public from the SGP, like locked gates and barriers for the two primary access points, plus posted warning signs, plus registration by users seeking access, and more. Contrary to the assertions in the Petition, "[t]he measures specified in the AMP shall be incorporated by reference to this permit and *shall be enforceable permit conditions*." Condition 2.7 (emphasis added). The AMP must be submitted to the Department for review and approval prior to startup. Condition 2.8. There is no legal requirement in the Idaho Air Rule for the AMP to be reviewed by the public.

Petitioners also allege that without "disclosure and knowledge" of the AMP contents, the Department cannot comply with policy, the Idaho Air Rules, the NAAQS, or TAPs. Petition ¶ 65. But Petitioners do not identify any specific violation of law. Petitioners' opinion overlooks the details of substance and process imposed by the Department for the AMP in Conditions 2.7 and 2.8 of the Final Permit. Petitioners are dissatisfied with the AMP requirements as imposed by the Department, but the Petition fails to allege any violation of law with respect to the ambient air boundary. Perpetua requests that the allegations contained in Section II.E of the Petition be dismissed.

D. The Petition does not allege a violation of any law governing ambient air monitoring.

In Section II.F of the Petition ("DEQ's Failure to Require Ambient Air Monitoring for the SGP"), Petitioners demand ambient air monitoring to verify compliance with NAAQS and TAPs. Petition ¶¶ 66-68. Although the Department has authority to require monitoring under IDAPA 58.01.01.211.01(d), ambient air monitoring is not a legal requirement for lawful issuance of an air quality permit. Petitioners are dissatisfied with the Department's decision not to require ambient air monitoring for the SGP, but do not identify any regulatory provision compelling the Department to require such monitoring because there is none. The Petition fails to state a claim in Section II.F that the Department acted contrary to law in issuing the Final Permit. Perpetua requests that the allegations contained in Section II.F of the Petition be dismissed.

E. Petitioners requested relief is not required by law.

Petitioners include a laundry list of requested relief, including:

(1) additional permit conditions to limit PM_{10} and arsenic emissions;

(2) analysis of local meteorological data to calculate fugitive emissions;

(3) submission of the FDCP, HRCP, O&M Manual, and AMP for public comment;

(4) analysis of an annual average concentration of arsenic emissions;

(5) required ambient air boundary monitoring; and

(6) additional environmental and economic analyses of T-RACT.

Petitioners have entirely failed to state any facts or identify any provision of the Idaho Air Rules that would legally entitle them to the relief they request. To the contrary, and as explained at length above, the Idaho Air Rules do not provide any legal requirement that a permit to construct contain any of the conditions Petitioners request; nor do the Idaho Air Rules compel the Department to require the applicant to model emissions in the way Petitioners suggest. The Idaho

Air Rules require the applicant to show "to the satisfaction of the Department" that the permitted project will not cause a violation of an ambient air quality standard, and that TAP emissions will not injure or unreasonably affect human or animal life or vegetation. IDAPA 58.01.01.203.

The Idaho Air Rules then vest the Department with discretion to "impose any reasonable conditions" in granting the final permit. IDAPA 58.01.01.211.01. The Idaho Air Rules simply contain no provision entitling Petitioners to the relief they request. Therefore, Petitioners have failed to allege that they are entitled to any of the relief they seek in the Petition.

F. The Petition fails to comply with IDAPA 58.01.23.160.01, is defective, and should be dismissed because it fails to allege a legally sufficient claim that the Department's action was arbitrary, capricious, or an abuse of discretion.

Petitioners dislike the Final Permit and oppose the SGP and wish it were permitted differently or not at all. But dislike of a project or a permit does not provide a legal basis to remand the agency action and reverse the issuance of the Final Permit. The Petition is rich with Petitioner's wish list of conditions for the Final Permit and speculation about the possible harm from the construction and operation of the SGP. But the Petition fails to satisfy the basic requirements of IDAPA 58.01.23.160.01, and as such it is defective and must be returned or dismissed. *See* IDAPA 04.11.01.304.

Specifically, the Petition fails to fully state facts and identify the particular statute or rule under which the Department allegedly erred. Further, to the extent Petitioners believe that the Department's action was arbitrary and capricious and an abuse of discretion they have failed to sufficiently allege facts or law supporting such a claim. An arbitrary and capricious decision occurs where the decision was reached in an unreasonable manner or based on clearly erroneous findings. *Floyd v. Bd. of Ada Cnty. Comm'rs*, 164 Idaho 659, 668, 434 P.3d 1265, 1274 (2019). An abuse of discretion standard examines whether the agency acted within the boundaries of its

discretionary decision and applicable legal standards and reached a decision by exercising reason. *Id.*

Nowhere in the Petition do Petitioners identify with specificity how the Department's issuance of the Final Permit was arbitrary, capricious, or an abuse of discretion. Nor does the Petition use words such as "unreasonable" or "clearly erroneous," which would at least alert the reader that Petitioners were attempting to raise a claim that the action was arbitrary or capricious. In fact, the Petition uses the terms "arbitrary," "capricious," and "abuse of discretion" only three times, none of which are in reference to a specific allegation, and two of which simply restate Idaho Code § 67-5279. Petition ¶¶ 7, 69, 70. The Petition fails to provide factual allegations or citations to legal authority to allude to, let alone support, claims of any arbitrary and capricious decision or any abuse of discretion.

Rather, Petitioners allege that the Department's determination was "flawed" or "deficient" or contained "shortcomings." *Id.* ¶¶ 24, 25, 35, 52, 61, 70. However, "flawed," "deficient," and containing "shortcomings" are not the grounds identified in Idaho Code § 67-5279, on which the permit may be remanded. The Petition is insufficient to apprise the Department and Perpetua of Petitioners' claims of violations of law, arbitrary and capricious decision making, or any abuse of discretion. *Vendelin v. Costco Wholesale Corp.*, 140 Idaho 416, 427, 95 P.3d 34, 45 (2004) ("The key issue in determining the validity of a complaint is whether the adverse party is put on notice of the claims brought against it."). Judged under the standard of I.R.C.P 12(b)(6) and the heightened pleading standard of IDAPA 58.01.23.160.01, the Petition is wholly deficient and must be dismissed. IDAPA 04.11.01.304.

V. CONCLUSION

The Petition challenging the Final Permit is abundant on speculation and hypotheticals but devoid of factual or legal foundation. Petitioners completely fail to allege and to support

factually any claim that the Final Permit is contrary to law. Indeed, each of the regulatory provisions that Petitioners contend were violated afford the Department ample discretion to rely on the information submitted by Perpetua and to assemble the Final Permit as issued. Ultimately, Petitioners' so-called "flaws" are differences of opinion between themselves and the permitting authority.

Further, the Petition fails to meet the heightened pleading standard set out in IDAPA 58.01.23.160.01 that requires Petitioners to apprise the Department or Perpetua of both the facts and the law underlying the specific claims allegedly entitling them to relief. The Petition fails to put Perpetua and the Department on notice of Petitioners' theory of their claims. Instead, they offer a smorgasbord of legally ungrounded "flaws." Absent facts alleging that the Final Permit is contrary to the Idaho Air Rules, or that the Department's issuance of the Final Permit was arbitrary, capricious, or an abuse of discretion, Petitioners fail to state a claim upon relief can be granted. Accordingly, Perpetua respectfully requests that the Petition be dismissed.

DATED: September 6, 2022.

Air Quality

PERMIT TO CONSTRUCT

Permittee	Perpetua Resources Idaho, Inc.
Permit Number	P-2019.0047
Project ID	62288
Facility ID	085-00011
Facility Location	Forest Service Roads NF-374 and NF-412 Stibnite, Idaho 83611

Permit Authority

This permit (a) is issued according to the "Rules for the Control of Air Pollution in Idaho" (Rules), IDAPA 58.01.01.200–228; (b) pertains only to emissions of air contaminants regulated by the State of Idaho and to the sources specifically allowed to be constructed or modified by this permit; (c) has been granted on the basis of design information presented with the application; (d) does not affect the title of the premises upon which the equipment is to be located; (e) does not release the permittee from any liability for any loss due to damage to person or property caused by, resulting from, or arising out of the design, installation, maintenance, or operation of the proposed equipment; (f) does not release the permittee from compliance with other applicable federal, state, tribal, or local laws, regulations, or ordinances; and (g) in no manner implies or suggests that the Idaho Department of Environmental Quality (DEQ) or its officers, agents, or employees assume any liability, directly or indirectly, for any loss due to damage to person or property caused by, resulting from, or arising out of design, installation, maintenance, or operation of the proposed equipment. Changes in design, equipment, or operations may be considered a modification subject to DEQ review in accordance with IDAPA 58.01.01.200–228.

Date Issued June 17, 2022

3 Mining and Ore Processing 17
4 Ore Concentration and Refining 22
5 Lime, Aggregate, and Concrete Production 30
6 Engines 36
7 General Provisions 39

1 Permit Scope

Purpose

1.1 This is an initial permit to construct (PTC) for ore processing, ore concentration and refining, and ancillary equipment at the Stibnite Gold Project (SGP).

Regulated Sources

1.2 Table 1.1 lists all sources of regulated emissions in this permit.

Source ID No.	Source	Control Equipment
Mining		
	Drilling activities	Reasonable control and Fugitive Dust Control Plan (FDCP) Dust collection systems on drilling rigs Control efficiency: 90%
	Blasting activities	Reasonable control & FDCP
	Excavating and hauling activities	Reasonable control & FDCP – Chemical suppression and water sprays Control efficiency: 93.3% for PM/PM_{10} (haul roads) Haul road capping with low-arsenic (90 ppm or less) quartzite
	Rock dumps and storage piles	Reasonable control & FDCP
PS1–2-L/U	(2) Prill Silos #1-2 Maximum capacity: 100 T (each)	Loading – None Unloading – None
Ore Processing		
OC1	Loader Transfer of Ore to Grizzly	Reasonable control & FDCP – Water sprays and moisture carryover
OC2	Grizzly to Apron Feeder	
OC3	Conveyor – Apron Feeder to Dribble	
OC4	Conveyor – Apron Feeder to Grizzly	
OC5	Conveyor – Dribble to Grizzly	
OC6	Grizzly to Primary Crusher or Coarse Ore Stockpile Feed	
OC7	Primary Crusher	Reasonable control & FDCP – Water sprays and moisture carryover
OC8	Conveyor – Coarse Ore Stockpile Feed Transfer to Stockpile	
OC9	Stockpile Transfer to Reclaim Conveyors	Reasonable control & FDCP – Below-grade of storage piles Control efficiency: 80% for PM/PM_{10}
OC10	Conveyor – Reclaim Conveyors to SAG Mill Feed Conveyor	
OC11	Conveyor – SAG Mill Feed Transfer to SAG Mill	Reasonable control & FDCP – Enclosure Control efficiency: 80% for PM/PM_{10}
OC12	Pebble Crusher	Reasonable control & FDCP – Water sprays and moisture carryover
OC13	Pebble Discharge to SAG Mill Feed	
Ore Concentration and Refining		
CN Tanks	Cyanide Leach Tanks and Cyanide Detox Tanks	Chemical treatment (lime, caustic soda, hydrogen peroxide, copper sulfate, etc.)
Float Tanks	Floatation Tanks	None

Source ID No.	Source	Control Equipment
AC	Autoclave (AC)	Venturi Scrubber (VS1) Vent Gas Cleaning Tower (ST1) Vent Gas Steam Condensation Tower (CT1) Carbon Filter (CA5) Type: sulfur-impregnated activated carbon Form: granulated
EW	Electrowinning Cells and Pregnant Solution Tank	Shared Carbon Filter (CA2) Type: sulfur-impregnated activated carbon Form: granulated
MR	Mercury Retort	Condenser Carbon Filter (CA3) Type: sulfur-impregnated activated carbon Form: granulated
MF	Induction Melting Furnace	Baghouse (BH2) Carbon Filter (CA4) Type: sulfur-impregnated activated carbon Form: granulated
CKD	Carbon Regeneration Kiln (Drum)	Wet Scrubber (WS2) Carbon Filter (CA1) Type: sulfur-impregnated activated carbon Form: granulated
Tailings and Maintenance Pond activities		Chemical treatment, reasonable control & FDCP
Process Heating		
ACB	POX Boiler (for AC) Maximum capacity: 17 MMBtu/hr Fuel: propane	None
HS	Strip Circuit Solution Heater Maximum capacity: 5 MMBtu/hr Fuel: propane	None
CKB	Carbon Regeneration Kiln Burners Maximum capacity: 2.255 MMBtu/hr Fuel: propane	None
PV	Propane Vaporizer Maximum capacity: 0.1 MMBtu/hr Fuel: propane	None
LKC	PFR Shaft Lime Kiln Combustion Maximum capacity: 22.0 MMBtu/hr Fuel: propane	None

Source ID No.	Source	Control Equipment
Lime Production		
LS1	Limestone transfer to Primary Crusher Hopper	Reasonable control & FDCP
LS2	Primary Crusher Maximum capacity: 1,130 T/day	
LS3	Primary Screen	
LS4	Secondary Crusher	
LS5	Secondary Screen	
LS6	Conveyor – Limestone to Ball Mill Feed Bin	
LS7	Conveyor – Limestone to Ball Mill Feed	
LS8	Conveyor – Ball Mill Feed to Ball Mill	
LSBM	Limestone Ball Mill	Reasonable control & FDCP Baghouse (BH3)
LS9	Conveyor – Limestone to Kiln Feed Bin	Reasonable control & FDCP
LS10	Conveyor – Limestone to Lime Kiln Feed	
LS11	Fines Screen	
LS12	Conveyor – Kiln Feed to PFR Shaft Lime Kiln	
LK	Parallel Flow Regenerative (PFR) Shaft Kiln	Reasonable control & FDCP Baghouse (BH4)
LCR	Lime Mill Crusher	Reasonable control & FDCP Baghouse (BH5)
LS-L/U	Bucket Elevator – Pebble Lime Silo Loading	Loading – Bin Vent Filter
	Pebble Lime Silo discharge to Lime Slaker	Unloading – Wet Scrubber (WS3)
LS1-L/U	SAG Mill Lime Silo #1 Maximum capacity: 250 T/day	Loading – Bin Vent Filter Unloading – None
MillS2-L/U	SAG Mill Lime Silo #2 Maximum capacity: 250 T/day	Loading – Bin Vent Filter Unloading – None
ACS1	AC Lime Silo #1 Maximum capacity: 1,000 T/day	Loading – Bin Vent Filter Unloading – None
ACS2	AC Lime Silo #2 Maximum capacity: 1,000 T/day	Loading – Bin Vent Filter Unloading – None
ACS3	AC Lime Silo #3 Maximum capacity: 1,000 T/day	Loading – Bin Vent Filter Unloading – None
ACS4	AC Lime Silo #4 Maximum capacity: 500 T/day	Loading – Bin Vent Filter Unloading – None
Aggregate Production		
PCSP1	Portable Crushing and Screening Plant 1 Crushers, screens, and conveyors	Reasonable control & FDCP – water sprays and moisture carryover
PCSP2	Portable Crushing and Screening Plant 2 Crushers, screens, and conveyors	Reasonable control & FDCP – water sprays and moisture carryover
Concrete Production		
CM	Central Mixer Loading Maximum capacity: 120 T/hr	Reasonable control & FDCP – Controls may include water sprays, enclosures, hoods, curtains, shrouds, movable and telescoping chutes, and central duct collection systems.
CS1-L/U	Cement/Shotcrete Silo #1 Maximum capacity: 80 T	Loading – Bin Vent Filter Unloading – None
CS2-L/U	Cement/Shotcrete Silo #2 Maximum capacity: 80 T	Loading – Bin Vent Filter Unloading – None
CA-L/U	Aggregate Bin Maximum capacity: 2,400 T	Loading – None Unloading – None

Source ID No.	Source	Control Equipment
Heating, Ventilation, and Air Conditioning (HVAC)		
H1M	Mine Air Heater #1 Maximum capacity: 4 MMBtu/hr Fuel: propane	None
H2M	Mine Air Heater #2 Maximum capacity: 4 MMBtu/hr Fuel: propane	None
HM	(4) Mill HVAC Heaters #1-4 Maximum capacity: 1.0 MMBtu/hr (each) Fuel: propane	None
HAC	Autoclave HVAC Heater Maximum capacity: 0.25 MMBtu/hr Fuel: propane	None
HR	Refinery HVAC Heater Maximum capacity: 0.25 MMBtu/hr Fuel: propane	None
HA	Admin HVAC Heater Maximum capacity: 0.25 MMBtu/hr Fuel: propane	None
HMO	(2) Mine Ops. HVAC Heaters Maximum capacity: 0.25 MMBtu/hr (each) Fuel: propane	None
HTS	(2) Truck Shop HVAC Heaters Maximum capacity: 1.0 MMBtu/hr (each) Fuel: propane	None
HW	(3) Warehouse HVAC Heaters Maximum capacity: 1.0 MMBtu/hr (each) Fuel: propane	None

Source ID No.	Source	Control Equipment
Emergency Power Generation and Fire Suppression		
EDG1	Camp Emergency Generator Date of construction: 2007 or later Maximum capacity: 1,000 bkW Maximum operation: 100 hr/yr (non-emergency) Fuel: ultra-low sulfur diesel (ULSD) Displacement: <10 L/cyl	EPA Tier 2 certified or better
EDG2	Plant Emergency Generator #1 Date of construction: 2007 or later Maximum capacity: 1,000 bkW Maximum operation: 100 hr/yr (non-emergency) Fuel: ULSD Displacement: <10 L/cyl	EPA Tier 2 certified or better
EDG3	Plant Emergency Generator #2 Date of construction: 2007 or later Maximum capacity: 1,000 bkW Maximum operation: 100 hr/yr (non-emergency) Fuel: ULSD Displacement: <10 L/cyl	EPA Tier 2 certified or better
EDFP	Mill Fire Pump Date of construction: 2009 or later Maximum capacity: 200 bkW Maximum operation: 100 hr/yr (non-emergency) Fuel: ULSD Displacement: <10 L/cyl	None
Fuel Storage		
TG1–TG2	Mine Site Gasoline Tanks (#1 through #2) Maximum capacity: 5,000 gal each	Lids or other appropriate closure with gasketed seal and submerged filling
TD3–TD10	Mine Site Diesel Tanks (#3 through #10)	Lids or other appropriate closure

2 Facility-Wide

Fugitive Dust

2.1 All reasonable precautions shall be taken to prevent particulate matter from becoming airborne in accordance with IDAPA 58.01.01.650-651. In determining what is reasonable, consideration will be given to factors such as the proximity of dust-emitting operations to human habitations and/or activities and atmospheric conditions which might affect the movement of PM. Some of the reasonable precautions include, but are not limited to, the following:

- Use, where practical, of water or chemicals for control of dust in the demolition of existing buildings or structures, construction operations, the grading of roads, or the clearing of land.
- Application, where practical, of asphalt, oil, water, or suitable chemicals to, or covering of dirt roads, material stockpiles, and other surfaces which can create dust.
- Installation and use, where practical, of hoods, fans, and fabric filters or equivalent systems to enclose and vent the handling of dusty materials. Adequate containment methods should be employed during sandblasting or other operations.
- Covering, when practical, open-bodied trucks transporting materials likely to give rise to airborne dusts.
- Paving of roadways and their maintenance in a clean condition, where practical.
- Prompt removal of earth or other stored material from streets, where practical.

2.2 At least once every 12 hours, the permittee shall monitor and maintain records of the frequency and the methods used (e.g., water, chemical dust suppressants) to reasonably control fugitive dust emissions.

2.3 The permittee shall maintain records of all fugitive dust complaints received. The permittee shall take appropriate corrective action as expeditiously as practicable after receipt of a valid complaint. The records shall include, at a minimum, the date that each complaint was received and a description of the following: the complaint, the permittee's assessment of the validity of the complaint, any corrective action taken, and the date the corrective action was taken.

2.4 Each day during daylight hours and under normal operating conditions, the permittee shall conduct a facility-wide inspection of potential sources of fugitive emissions from the following equipment: drilling activities, blasting activities, excavating and hauling activities, rock dumps and storage piles, ore processing, aggregate production, and central mixer loading. These sources are identified in the Fugitive Dust Control Plan to ensure that the methods used to reasonably control fugitive dust emissions are effective. If emissions are not being reasonably controlled the permittee shall take corrective action as expeditiously as practicable. The permittee shall maintain records of the results of each fugitive dust emissions inspection. The records shall include, at a minimum, the date of each inspection and a description of the following: the permittee's assessment of the conditions existing at the time fugitive emissions were present (if observed), any corrective action taken in response to the fugitive dust emissions, and the date the corrective action was taken.

2.5 Fugitive dust control measures shall be applied to haul roads on a frequency such that visible emissions from vehicle traffic on a haul road do not exceed 10% opacity. When emissions are observed at any time to exceed this control trigger level, an appropriate control measure such as those defined in the Fugitive Dust Control Plan (FDCP) shall be used to reasonably control the emissions of fugitive dust. If the control measure chosen does not adequately control fugitive dust emissions, the permittee shall employ additional control measures until fugitive dust control is achieved.

2.6 The permittee shall develop and maintain a FDCP to ensure compliance with fugitive dust requirements (Permit Conditions 2.1–2.5) and also fugitive dust best management practices at the lime production, aggregate production, and concrete plants in accordance with IDAPA 58.01.01.799. The permittee shall comply with the FDCP at all times. The requirements specified in the FDCP shall be incorporated by reference to this permit and shall be enforceable permit conditions. At a minimum, the FDCP shall contain a list of all potential sources of fugitive dust emissions and the following reasonable precautions to minimize fugitive dust emissions (Permit Condition 2.1):

- Post and limit the maximum speed of haul trucks in accordance with the FDCP. Signs shall be posted along the haul route and placed so they are visible to vehicles entering and leaving the site of operations.
- Apply water or suitable dust suppressant chemicals (e.g., magnesium chloride, calcium chloride) to disturbed areas, haul roads, equipment staging areas, parking areas, and storage piles during the dry season and at other times as necessary to control fugitive dust.
- Prior to onset of winter conditions each year, the condition of haul and access roads should be assessed before freeze-up and required maintenance needed to maintain the roads through the winter months should be performed, and any preventative dust suppression activities should be completed before the roads are frozen and liquid application of suppressants or water are unrealistic.
- Apply water or suitable dust suppressant chemicals to transfer points, screening operations, and crushing operations identified in the FDCP as necessary to control fugitive dust. Transfer points include points where material (e.g., ore and development rock (DR), lime, aggregate, cement, etc.) is transferred to or from a belt conveyor, conveying system, bucket elevator, screening operation, or stockpile. Controls shall include manual water spray capability or installing, operating, and maintaining water spray bars at transfer points to wet the material and to provide moisture carryover for downstream control. Controls shall also include limiting drop heights in truck loading, front-end loader dumping, and conveying operations to ensure a homogeneous flow of material.
- Apply water or suitable dust suppressant chemicals to storage piles as necessary to control fugitive dust. Water may need to be applied to storage piles before and during truck loading, and when stockpiled ore and waste rock is not processed promptly in order to avoid drying and becoming airborne. Stockpile height should be limited to limit disturbance.
- Apply appropriate dust control at the initial point of material handling to suppress dust throughout the material handling process.
- Apply crushed gravel to haul roads, equipment staging areas, and other areas as necessary to limit migration of fine sediment.
- Install wind fences or barriers around, place below grade, or enclose all storage piles, parking areas, and equipment staging areas as necessary to control fugitive dust. This is required for

the Stockpile Transfer to Reclaim Conveyors (OC9), Reclaim Conveyors to SAG Mill Feed Conveyor (OC10), and SAG Mill Feed Transfer to SAG Mill conveyor (OC11).

- Develop specific criteria to determine what frequency and type (water and/or chemical) of dust suppressant must be applied, and appropriate suppressant application rates. Chemical dust suppressants shall be applied consistent with manufacturer's instructions and recommendations.
- Develop and implement precautionary measures to address high-wind events, such as when average (sustained) wind speed is forecast to exceed 25 miles per hour.
- Provide training/orientation to all relevant employees regarding FDCP requirements, including the necessity of restricting public access as specified in the Access Management Plan (AMP). Visible emissions evaluations shall be conducted by the permittee's employees who are certified visible emission observers.
- At least once each year, evaluate FDCP requirements to identify additional requirements and evaluate effectiveness of practices, including dust suppressant application rates, as appropriate.

2.7 The permittee shall develop and maintain an AMP that identifies the facility boundary and all primary and secondary access points, and clearly specifies measures used to discourage public access to the facility. The permittee shall comply with the measures identified in the AMP at all times. The measures specified in the AMP shall be incorporated by reference to this permit and shall be enforceable permit conditions. At a minimum, the AMP shall include requirements to:

- Observe all primary access points to preclude unauthorized public access. Onsite personnel shall be available for this purpose during active mining and mineral processing operations. Public access to the facility may be monitored by the use of security escort vehicles or manned guardhouses, or sufficiently precluded by the use of locked gates, barriers, or equivalent measures. Primary access points include the North and South Security Gates.
- Post warning signs and periodically patrol secondary access points to the facility to preclude public access. Onsite personnel shall be available for this purpose. Plans shall be described in the AMP, including identifying the access points monitored, the frequency of patrol, and measures employed to discourage access (e.g., locked gates, barriers, natural features, etc.). Secondary access points include secondary roadways and trails traversing the facility.
- Only registered guests of the facility will be allowed access to or through the facility. Those seeking to be a guest for the sole purpose of passing through the facility to another destination shall be provided a registration sheet that explains Perpetua's requirements for accessing the site and identifies potential hazards of the site.

2.8 Copies of the FDCP and AMP shall be submitted to DEQ for approval 30 days prior to startup at the address provided (Permit Condition 2.26), and shall remain onsite at all times. Any changes to the FDCP or the AMP shall be submitted to DEQ for review, comment, and approval 30 days prior to the change.

Visible Emissions

2.9 The permittee shall not discharge any air pollutant to the atmosphere from any point of emission for a period or periods aggregating more than three minutes in any 60-minute period which is greater than 20% opacity as determined by the test methods and procedures contained in IDAPA 58.01.01.625. These provisions shall not apply when the presence of uncombined water, nitrogen oxides, and/or chlorine gas is the only reason for the failure of the emission to comply with this permit condition.

2.10 Each day during daylight hours and under normal operating conditions, the permittee shall conduct a facility-wide inspection of potential point sources of visible emissions including stacks, vents, and functionally equivalent openings. Sources that are monitored using a continuous opacity monitoring system (COMS) are not required to comply with this permit condition. The inspection shall consist of a see/no see evaluation for each potential source of visible emissions. If any visible emissions are present from any point of emission, the permittee shall either:

- Take appropriate corrective action as expeditiously as practicable to eliminate the visible emissions. Within 24 hours of the initial see/no see evaluation and after the corrective action, the permittee shall conduct a see/no see evaluation of the emissions point in question. If the visible emissions are not eliminated, the permittee shall comply with the following; or
- Perform a Method 9 opacity test in accordance with the procedures outlined in IDAPA 58.01.01.625. A minimum of 30 observations shall be recorded when conducting the opacity test. If opacity is greater than 20% for a period or periods aggregating more than three minutes in any 60-minute period, the permittee shall take all necessary corrective action and report the exceedance in the annual compliance certification and in accordance with IDAPA 58.01.01.130-136.

2.11 The permittee shall maintain records of the results of each visible emission inspection and each opacity test when conducted. The records shall include, at a minimum, the date and results of each inspection and test and a description of the following: the permittee's assessment of the conditions existing at the time visible emissions are present (if observed), any corrective action taken in response to the visible emissions, and the date corrective action was taken.

2.12 The permittee shall have a certified opacity reader onsite at all times during operation of any regulated sources (in Table 1.1). The reader shall be certified in using the test methods and procedures of EPA Reference Methods 9 and knowledgeable of Method 22 procedures.

2.13 Reserved.

Odor

2.14 The permittee shall not allow, suffer, cause, or permit the emission of odorous gases, liquids, or solids into the atmosphere in such quantities as to cause air pollution in accordance with IDAPA 58.01.01.776.01.

2.15 The permittee shall maintain records of all odor complaints received. If the complaint has merit, the permittee shall take appropriate corrective action as expeditiously as practicable. The records shall include, at a minimum, the date that each complaint was received and a description of the following: the complaint, the permittee's assessment of the validity of the complaint, any corrective action taken, and the date the corrective action was taken.

Fuels

2.16 The permittee shall not sell, distribute, use, or make available for use any distillate fuel oil containing more than the following percentages of sulfur, in accordance with IDAPA 58.01.01.725:

- ASTM Grade 1 fuel oil - 0.3% by weight.
- ASTM Grade 2 fuel oil - 0.5% by weight.

2.17 The permittee shall maintain documentation of supplier verification of fuel oil sulfur content on an as-received basis to ensure compliance with fuel specifications (Permit Condition 2.16).

2.18 The maximum throughput of gasoline to the Gasoline Tanks (TG1, TG2) shall not exceed 100,000 gallons per month (gal/mo).

2.19 After startup, each month the permittee shall maintain records demonstrating compliance with gasoline throughput limits, by tracking either amounts loaded or amounts dispensed from each Gasoline Tank.

O&M Manual

2.20 Thirty days prior to startup of any process equipment (Permit Condition 2.13), the permittee shall develop and maintain an Operation and Maintenance (O&M) manual to ensure compliance with emission limits (Permit Conditions 2.9, 2.13, 4.3, and 5.3) and the control equipment maintenance and operation general provision (Permit Condition 7.2). The O&M manual shall be a permittee-developed document based upon, but independent from, manufacturer-supplied operating manuals. The permittee shall operate control equipment in accordance with the O&M manual at all times. The requirements in the O&M manual shall be incorporated by reference to this permit and shall be enforceable permit conditions. At a minimum, the O&M manual shall include the following for all (Table 1.1):

- Identify the manufacturer, model, date of manufacture, and maximum capacity (as-built) for each regulated emission source assigned a source ID, and for each control device in the service of ore concentration and refining, lime production, and concrete production (in Table 1.1). For each wet scrubber, vent gas cleaning tower, venturi scrubber, carbon filter, baghouse and bin vent filter cartridge control device, a copy of the vendor-supplied performance guarantee shall be included. For each engine, a copy of the EPA tier certification shall be included. For each cyanide leach tank and for each cyanide detox tank, the tank dimensions (e.g., diameter) shall be included.
- Establish operating ranges for control equipment, based on manufacturer specifications and conditions measured during performance testing.
    - Minimum pressure drop across each wet scrubber, vent gas cleaning tower, and venturi scrubber;
    - Minimum circulation flow rate for each wet scrubber, vent gas cleaning tower, venturi scrubber;
    - Maximum inlet gas stream temperature to each carbon filter;
    - Maximum pressure drop across each carbon filter;
    - Minimum pressure drop across each baghouse; and
    - Minimum coolant flow rate in the mercury retort (MR) condenser and vent gas steam condensation tower;

- Describe the procedures for proper operation, startup, and shutdown of control equipment, based on manufacturer specifications.
- Describe the schedule and procedures for routine inspection (Permit Condition 2.10), maintenance, repair, and replacement of control equipment.
    - See-no-see visible emissions inspection of each wet scrubber, carbon filter, baghouse, and bin vent shall be conducted at least once per day.
    - At least once every six months, the drum lining of the carbon regeneration kiln shall be visually inspected for structural damage and cracks.
    - The dates, times, and results from each inspection (as required by Permit Condition 2.11), corrective action, maintenance, repair, and replacement of control equipment shall be recorded at least once per month.
    - The replacement dates for each baghouse and bin vent filter cartridge and for each activated carbon filter medium shall be recorded at the time of each replacement. For cartridges, records shall include the manufacturer and model. For carbon filters, records shall include the manufacturer, type, and form of medium added. Records shall also include any changes in supplier and other relevant information.
    - All carbon filter beds shall be disposed of in an acceptable manner in compliance with all applicable state rules and federal regulations.
- Describe the schedule and procedures for corrective action that will be taken if visible emissions are present from wet scrubber (WS2, WS3), carbon filter (CA1, CA2, CA3, CA4, CA5), baghouse (BH2, BH3, BH4, BH5), or bin vent filter (LS, LS1, MillS2, ACS1, ACS2, ACS3, ACS4, CS1, CS2) control equipment at any time. Procedures should include how to determine whether filter cartridges are ruptured or are not appropriately secured in place, and how to determine whether the wet scrubber, condenser, and carbon filters are operating properly.
- Describe each monitoring device and methodology used to measure weight rates of materials to demonstrate compliance with each material throughput limit (Permit Conditions 3.5–3.9, 4.8–4.11, and 5.4–5.8). Procedures for proper installation, calibration, and maintenance shall be included.
- Describe each monitoring device and methodology used to measure the volumetric rates of materials to demonstrate compliance with the electrowinning cells and pregnant solution tank throughput limit (Permit Condition 4.12). Procedures for proper installation, calibration, and maintenance shall be included.
- Describe each monitoring device and methodology used to monitor pH, temperature, and free cyanide in each cyanide leach tank, each cyanide detox tank, and each tailings reclaim stream to comply with Cyanide Emissions Limit Compliance Monitoring (Permit Condition 4.18). Procedures for proper installation, calibration, and maintenance shall be included.
- Describe the methodology and sample calculations used to estimate monthly and rolling 12-month facility-wide cyanide emissions to assess compliance with the Cyanide Emissions Limit (Permit Condition 4.4). Calculations shall be based on the pH, temperature, and free cyanide concentrations that are measured each day, and the methodology used shall be consistent with the permittee's application as addended December 18, 2020 and shall be based on the following equation:

    $$r_v = k_g \alpha_0 C_l H A F_a F_w$$

where,

r_v = hydrogen cyanide emissions from surface (g/s)

k_g = gas phase mass transfer coefficient (m/s)

α_0 = non-ionized cyanide fraction determined from pH and pK_a (ionization coefficient)

C_l = total liquid phase free cyanide concentration (g/m^3)

H = Henrys Law Coefficient (g/m^3 per g/m^3)

A = process surface area (m^2)

F_a = area factor

F_w = wind factor

- Describe the monitoring methodology used to monitor xanthates usage (Permit Condition 4.19).

2.21 The O&M manual shall be submitted for approval to DEQ 30 days prior to startup of any ore processing, ore concentration and refining, lime production, or aggregate production emission source regulated by this permit (as identified in Table 1.1) at the address provided (Permit Condition 2.26), and shall remain onsite at all times. Any changes to the O&M manual shall be submitted to DEQ for review, comment, and approval 30 days prior to the change.

Incorporation of Federal Requirements

2.22 Unless expressly provided otherwise, any reference in this permit to any document identified in IDAPA 58.01.01.107.03 shall constitute the full incorporation into this permit of that document for the purposes of the reference, including any notes and appendices therein. Documents include, but are not limited to:

- Standards of Performance for New Stationary Sources (NSPS) 40 CFR 60, Subpart A – General Provisions.
- NSPS 40 CFR 60, Subpart LL – Standards of Performance for Metallic Mineral Processing Plants. Each crusher (OC7, OC12), conveyor belt transfer point (OC2–OC6, OC9–OC11, OC13), and truck unloading station (OC1) is an affected facility.
- NSPS 40 CFR 60, Subpart OOO – Standards of Performance for Nonmetallic Mineral Processing Plants. Each crusher (LS2, LS4), grinding mill (LSBM), screening operation (LS3, LS5, LS11), belt conveyor (LS6–LS10, LS12), and storage bin (LS1) is an affected facility.
- NSPS 40 CFR 60, Subpart IIII – Standards of Performance for Stationary Compression Ignition Internal Combustion Engines. Each emergency generator engine and fire pump (EDG1, EDG2, EDG3, and EDFP) is an affected facility.
- National Emission Standards for Hazardous Air Pollutants for Source Categories (NESHAP) 40 CFR 63, Subpart A – General Provisions.
- NESHAP 40 CFR 63, Subpart EEEEEEE – National Emission Standards for Hazardous Air Pollutants: Gold Mine Ore Processing and Production Area Source Category. The collection of ore pretreatment processes including the autoclave (AC) and the carbon process including the carbon regeneration kiln (CKD), the electrowinning cells and pregnant solution tank (EW), the mercury retort (MR), and the induction melting furnace (MF) are affected facilities.

- NESHAP 40 CFR 63, Subpart ZZZZ – National Emission Standards for Hazardous Air Pollutants for Stationary Reciprocating Internal Combustion Engines (RICE). Each emergency generator engine and fire pump (EDG1, EDG2, EDG3, and EDFP) is an affected facility.
- NESHAP 40 CFR 63, Subpart CCCCCC – National Emission Standards for Hazardous Air Pollutants for Source Category: Gasoline Dispensing Facilities. Each gasoline fuel storage tank (TG1, TG2) is an affected facility.

The permittee shall comply with all applicable NSPS and NESHAP requirements. For permit conditions referencing or cited in accordance with any document incorporated by reference (including permit conditions identified as NSPS or NESHAP), should there be any conflict between the requirements of the permit condition and the requirements of the document, the requirements of the document shall govern, including any amendments to that regulation.

2.23 In accordance with IDAPA 58.01.01.314.06, the permittee shall notify DEQ in writing the date upon which the Tier I source (e.g., gold ore concentration and refining process equipment) commences operation. The notification shall be titled, "TIER I SOURCE NOTIFICATION OF COMMENCING OPERATION," and shall include the name of the permittee, the permit and project numbers, the date the permit was issued, and the date the Tier I source commences operation. The notification shall be submitted to DEQ within five (5) days of commencing operation and shall be sent to:

Air Quality Permitting
Idaho Department of Environmental Quality
1410 N. Hilton
Boise, ID 83706-1255

2.24 In accordance with IDAPA 58.01.01.313.01.b., the permittee shall submit a complete application to DEQ at the address provided (Permit Condition 2.26) for an initial Tier I operating permit within 12 months of becoming a Tier I source or commencing operation.

REC 0093

Test Methods

2.25 Except as otherwise specified in this permit and in IDAPA 58.01.01.157.02, when testing is required the following test methods shall be used to measure pollutant emissions.

Table 2.1 Test Methods

Pollutant		Test Method	Additional Requirements
H_2SO_4		EPA Method 8	
$PM_{2.5}$ or PM_{10}		EPA Methods 5 and 202, or 201A and 202	Particulate matter (PM), including condensable PM as defined in IDAPA 58.01.01.006 with an aerodynamic diameter less than or equal to a nominal 10 micrometers for PM_{10}, and less than or equal to a nominal 2.5 micrometers for $PM_{2.5}$.
Opacity	point	EPA Method 9	For NSPS and NESHAP sources, use IDAPA 58.01.01.625 and Method 9. For other sources, use IDAPA 58.01.01.625 only.
	fugitive	EPA Method 22	Visible fugitive PM.

Notifications

2.26 All requests, reports, applications, submittals, certifications, and other communications required by this permit shall be submitted to:

3 Mining and Ore Processing

3.1 Process Description

Conventional open-pit mining methods including drilling, blasting, excavating, and hauling will be used to extract ore and waste rock, termed development rock (DR). Hydraulic shovels and front-end loaders will be used to load ore and DR into haul trucks. DR will be used for construction, restoration, and backfilling, or hauled to dedicated development rock storage facilities (DRSF). Approximately 340 million tons of DR will be handled over the life of the mine.

The SGP will include three years of pre-mining development and construction activities, followed by an operating mine life of approximately 12 years. Mining will occur in three open pits: Yellow Pine Pit (YPP), Hangar Flats pit (HFP), and West End pit (WEP). Legacy tailings from the Meadow Creek valley (Bradley Tailings [BT]) will also be reclaimed and reprocessed. Surface exploration drilling will occur within the pits and underground within the Scout Prospect decline.

Ore will be hauled to the primary crusher area, where it will be fed directly into the crusher dump pocket or stockpiled. The ore crushing plant will be designed to operate at a maximum rate of 25,000 tons per calendar day (T/day). Approximately 100 million tons of ore will be mined from the three pits over the life of the project.

The metal-recovery process from ore will include conventional crushing and grinding, followed by froth-flotation circuits that will generate separate gold-silver and antimony-silver concentrates. The antimony-silver concentrate will be shipped offsite for refining, whereas additional onsite processing of the gold-silver concentrate will include pressure oxidation, carbon-in-leach circuits, and refining processes to recover gold and minor amounts of silver. The finely ground leftover ore material from the mineral-recovery process, termed tailings, will be neutralized, thickened, and transported via a pipeline to the tailings storage facility.

3.2 Control Device Descriptions

Table 3.1 contains a description of control equipment used to control emissions from mining and ore processing activities.

Table 3.1 Mining and Ore Processing Control Device Descriptions

Emission Sources	Control Devices
Mining	
Drilling activities	Reasonable control and Fugitive Dust Control Plan (FDCP) Dust collection systems on drilling rigs Control efficiency: 90%
Blasting activities	Reasonable control & FDCP
Excavating and hauling activities	Reasonable control & FDCP Chemical suppression and water sprays Control efficiency: 93.3% for PM/PM_{10} (haul roads) Haul road capping with low-arsenic quartzite
Rock dumps and storage piles	Reasonable control & FDCP
(2) Prill Silos #1-2 Maximum capacity: 100 T (each)	None
Ore Processing	
Loader Transfer of Ore to Grizzly	Reasonable control & FDCP Water sprays and moisture carryover
Grizzly to Apron Feeder	
Apron Feeder to Dribble	
Apron Feeder to Grizzly	
Dribble to Grizzly	
Grizzly to Primary Crusher or Coarse Ore Stockpile Feed	
Primary Crusher	Reasonable control & FDCP Water sprays and moisture carryover
Coarse Ore Stockpile Feed Transfer to Stockpile	
Stockpile Transfer to Reclaim Conveyors	Reasonable control & FDCP Below-grade of storage piles Control efficiency: 80% for PM/PM_{10}
Reclaim Conveyors to SAG Mill Feed Conveyor	
SAG Mill Feed Transfer to SAG Mill	Reasonable control & FDCP Enclosure Control efficiency: 80% for PM/PM_{10}
Pebble Crusher	Reasonable control & FDCP Water sprays and moisture carryover
Pebble Discharge to SAG Mill Feed	

Operating Limits

3.3 Drilling Limits

The permittee shall drill no more than 1,200 blast holes per day.

3.4 Blasting Limits

The permittee shall complete no more than two blasting operations per day.

3.5 Daily Hauling and Excavating Limits

The permittee shall haul no more than 180,000 tons per day (T/day) of ore and DR.

The permittee shall haul no more than 135,000 T/day of ore and DR, based on a 5-year rolling average.

3.6 Life of Mine Hauling and Excavating Limits

The permittee shall haul no more than 788.4 million tons (MT) of ore and DR from all deposits over the life of the mine and no more than 394.2 MT of ore and DR from the West End deposit over the life of the mine.

3.7 Primary Crusher Limit

The permittee shall process ore as the raw material in the primary crusher, and the maximum input to the primary crusher shall not exceed 25,000 T/day.

3.8 Pebble Crusher Limit

The permittee shall process ore as the raw material, and the maximum input to the pebble crusher shall not exceed 27,600 T/day.

3.9 Prill Loading Limit

The permittee shall not load in excess of 200 T/day and 9,000 tons per any consecutive 12-month period of prill (ammonium nitrate) to the prill silos.

3.10 Mining and Ore Processing Dust Control

The permittee shall control emissions from mining and ore processing emission sources (Table 3.1) in accordance with the Fugitive Dust Control Plan.

3.11 Drilling Rigs Dust Control System

The permittee shall install and operate dust collection systems with a minimum control efficiency of 90% on all drilling rigs in accordance with the O&M manual (Permit Condition 2.20). The dust collection systems shall be in operation at all times when the drilling rigs are operated.

3.12 Ore Processing Equipment Water Sprays

The permittee shall install, operate, and maintain water sprays in accordance with the O&M manual (Permit Condition 2.20) to control PM emissions from each ore processing crusher and conveyor. Water sprays shall operate according to the FDCP when this equipment is operated to ensure compliance with Fugitive Dust requirements (Permit Conditions 2.1–2.6).

3.13 Haul Road Capping

The permittee shall cap haul roads that are outside of the Yellow Pine Pit (YPP), Hangar Flats Pit (HFP), and West End Pit (WEP) and development rock storage facilities (DRSF) including the Yellow Pine DRSF, Fiddle DRSF, and Hangar Flats DRSF with low-arsenic material.

The permittee shall use low-arsenic quartzite rock deposits from the WEP, or other material with equal or lower arsenic concentration, as capping material. Low-arsenic quartzite rock is defined as material with a median arsenic concentration of 90 parts per million (ppm) or less.

The permittee shall use capping material with a maximum of 4.0% silt content.

The permittee shall develop and maintain a Haul Road Capping Plan (HRCP) that identifies the low-arsenic quartzite rock deposits in the West End pit based on core sample analyses. The permittee shall comply with the measures identified in the HRCP at all times. The measures specified in the HRCP shall be incorporated by reference to this permit and shall be enforceable permit conditions. At a minimum, the HRCP shall include:

- The low-arsenic quartzite rock sampling plan including standard operational procedure for sampling, frequency of sampling, and ASTM (or equivalent) method of analysis for arsenic concentration.
- The frequency of inspection of the haul roads and maintenance procedures.
- The silt content sampling plan including standard operational procedure for sampling, frequency of sampling, and ASTM (or equivalent) method of analysis for silt content.

A copy of the HRCP shall be submitted to DEQ for approval 30 days prior to startup at the address provided (Permit Condition 2.26), and shall remain onsite at all times. Any changes to the HRCP shall be submitted to DEQ for review, comment, and approval 30 days prior to the change.

Monitoring and Recordkeeping Requirements

3.14 Drilling Limits Monitoring

Each day, the permittee shall monitor and record the number of blast holes drilled.

3.15 Blasting Limits Monitoring

Each day, the permittee shall monitor and record the number of blasting operations completed.

3.16 Daily Hauling and Excavating Monitoring

Each day, the permittee shall monitor and record the amount of ore and DR transported on haul trucks (T/day). The devices and methodologies used to measure weights shall be identified in the O&M Manual.

Each calendar month, the permittee shall monitor and record the amount of ore and DR transported on haul trucks in tons per month (T/mo) and in tons per year (T/yr). Annual amounts of ore and DR transported shall be determined by summing the monthly amount over the previous consecutive 12-month period. The annual amounts of ore and DR transported shall be used to calculate the 5-year rolling average in T/day.

3.17 Life of Mine Hauling and Excavating Limit Monitoring

Each day, the permittee shall monitor and record the amount of ore and DR transported on haul trucks from all deposits (T/day) and the amount of ore and DR transported on haul trucks (T/day) from the West End deposit. The devices and methodologies used to measure weights shall be identified in the O&M Manual.

Each calendar month, the permittee shall monitor and record the amount of ore and DR transported on haul trucks in tons per month (T/mo) and in tons per year (T/yr) from all deposits and the West End deposit. Annual amounts of ore and DR transported shall be determined by summing the monthly amount over the previous consecutive 12-month period. The annual amounts of ore and DR transported shall be used to calculate the life of mine total (MT) for all deposits and the West End deposit.

3.18 Primary Crusher Limit Monitoring

Each day, the permittee shall monitor and record the tons of ore input to the crusher (T/day). The devices and methodologies used to measure weights shall be identified in the O&M Manual.

3.19 Pebble Crusher Limit Monitoring

Each day, the permittee shall monitor and record the tons of ore input to the pebble crusher (T/day). The devices and methodologies used to measure weights shall be identified in the O&M Manual.

3.20 Prill Loading Limit Monitoring

Each day, the permittee shall monitor and record the amount of prill loaded to all of the prill silos combined in tons (T/day). The devices and methodologies used to measure weights shall be identified in the O&M Manual.

Each month, the permittee shall monitor and record the amount of prill loaded to all of the prill silos combined in tons per month (T/mo) and in tons per year (T/yr) to demonstrate compliance with the annual prill silos limit. Annual prill loaded shall be determined by summing the monthly input over the previous consecutive 12-month period.

4 Ore Concentration and Refining

4.1 Process Description

The autoclave is a pressure oxidation (POX) vessel used to oxidize gold gold-silver concentrate at elevated temperature and pressure in the presence of oxygen. Upon exiting the autoclave, the slurry is cooled in flash vessels and neutralized using lime and caustic soda prior to being sent to the vat leaching circuit for gold and silver recovery. A dilute sodium cyanide solution is added to the leach tanks to dissolve the gold and silver from the ore. Leached "pulp" is sent to multistage carbon-in-pulp (CIP) and/or carbon-in-leach (CIL) tanks, where gold is recovered onto activated carbon. The autoclave is located in the POX Building and the exhaust from the autoclave passes through a venturi scrubber, vent gas cleaning tower, vent gas steam condensation tower, and carbon filter.

Carbon loaded with gold is removed and washed with acid, then stripped with a caustic solution. This mineral-bearing solution is sent to the electrowinning cells and pregnant solution tank (EW). The EW cells remove the gold from the solution by plating it onto cathodes consisting of stainless-steel plates with steel wool. The EW cell exhaust passes through a carbon adsorption column (CA2), where remaining mercury vapor is adsorbed onto sulfur-impregnated activated carbon (SIAC). The stripped carbon must be periodically regenerated in the carbon regeneration kiln. Exhaust from the carbon regeneration kiln passes through a carbon adsorption bed (CA1), where mercury is adsorbed onto SIAC.

Gold concentrate is loaded into the mercury retort (MR), where it is heated under vacuum to drive off mercury. The MR exhaust passes through a shell-and-tube condenser to cool the exhaust and condense the mercury vapor into a liquid, which is collected by the mercury trap. The exhaust passes through a carbon adsorption column (CA3), where remaining vapor mercury is adsorbed onto SIAC.

After retorting, the gold concentrate is transferred to the electric induction melting furnace. Only retorted concentrate is melted in the furnace. The exhaust passes through a carbon adsorption column (CA4), where remaining mercury vapor is adsorbed onto SIAC. The electrowinning cells and pregnant solution tank, carbon regeneration kiln, MR, and induction melting furnace are located in the Refinery Building.

4.2 Control Device Descriptions

Table 4.1 Ore Concentration and Refining Control Device Descriptions

Emissions Unit / Processes	Control Devices	Emission Points
Cyanide Leach Tanks and Cyanide Detox Tanks	Chemical treatment (lime, caustic soda, hydrogen peroxide, copper sulfate, etc.)	Various
Flotation Tanks	None	
Autoclave	Venturi Scrubber (VS1) Minimum pressure drop and Minimum circulation flow rate in O&M	Autoclave Carbon Filter Stack
	Vent Gas Cleaning Tower (ST1) Minimum pressure drop and Minimum circulation flow rate in O&M	
	Vent Gas Steam Condensation Tower (CT1) Minimum coolant flow rate in O&M	
	Carbon Filter (CA5) Maximum pressure drop established in O&M Maximum inlet gas stream temperature established in O&M and by Subpart EEEEEEE	
POX Boiler	None	POX Boiler Stack
Electrowinning Cells and Pregnant Solution Tank	Shared Carbon Filter (CA2) Maximum pressure drop established in O&M Maximum inlet gas stream temperature established in O&M and by Subpart EEEEEEE in O&M	Electrowinning Cells and Pregnant Solution Tank Shared Carbon Filter Stack
Strip Circuit Solution Heater	None	Strip Circuit Solution Heater Stack
Mercury Retort	Condenser Minimum coolant flow rate established in O&M	Mercury Retort Carbon Filter Stack
	Carbon Filter (CA3) Maximum pressure drop established in O&M Maximum inlet gas stream temperature established in O&M and by Subpart EEEEEEE	
Induction Melting Furnace	Baghouse (BH2) Minimum pressure drop established in O&M	Induction Melting Furnace Carbon Filter Stack
	Carbon Filter (CA4) Maximum pressure drop established in O&M Maximum inlet gas stream temperature established in O&M and by Subpart EEEEEEE	
Carbon Regeneration Kiln	Wet Scrubber (WS2) Minimum pressure drop and Minimum circulation flow rate established in O&M	Carbon Regeneration Kiln Carbon Filter Stack
	Carbon Filter (CA1) Maximum pressure drop established in O&M Maximum inlet gas stream temperature established in O&M and by Subpart EEEEEEE	
Carbon Regeneration Kiln Burners	None	Carbon Regeneration Kiln Burners Stack
Propane Vaporizer	None	Propane Vaporizer Stack
Tailings and Maintenance Pond	None	Various

Emission Limits

4.3 Ore Concentration and Refining Equipment Emissions Limits

Emissions from ore concentration and refining equipment stacks shall not exceed any corresponding emission rate limits (Table 4.2).

Table 4.2 Ore Concentration and Refining Emissions Limits [a]

Source Description	PM / PM_{10} / $PM_{2.5}$ [b]	NO_x	CO	VOC	SO_2	H_2SO_4
	lb/hr [c]	lb/hr [c]	lb/hr [c]	lb/hr [c]	lb/hr [c]	lb/hr [c]
Autoclave (AC)	5.08				0.65	2.03
Carbon regeneration kiln (CKD)	0.42	0.01	0.12	0.11		
Electrowinning cells and pregnant solution tank (EW)	0.07					
Mercury retort (MR)	0.01 [d]					
Induction melting furnace (MF)	2.84					

a) In absence of any other credible evidence, compliance is ensured by complying with permit operating, monitoring, and recordkeeping requirements.
b) Particulate matter (PM) including condensable PM as defined in IDAPA 58.01.01.006, with an aerodynamic diameter less than or equal to a nominal 10 micrometers for PM_{10}, and less than or equal to a nominal 2.5 micrometers for $PM_{2.5}$.
c) Pounds per hour, as determined by a test method prescribed by IDAPA 58.01.01.157, EPA reference test method, continuous emission monitoring system (CEMS) data, or DEQ-approved alternative.
d) For this emission limit, compliance may be demonstrated as measurement below detection limits, when addressed as part of a performance test protocol that is approved by DEQ.

4.4 Cyanide Emissions Limit

Facility-wide emissions shall not exceed 1.99 tons per any consecutive 12-month period of cyanide compounds.

4.5 Carbon Disulfide Emissions Limit

Facility-wide emissions shall not exceed 0.063 tons per any consecutive 12-month period of carbon disulfide.

Operating Limits

4.6 Xanthates Usage

The permittee shall use potassium amyl xanthate (PAX) for flotation treatment. Total xanthate usage shall not exceed 1,700 tons per any consecutive 12-month period.

4.7 POX Boiler Operation

Operation of the POX Boiler shall be limited to the autoclave start-up operation only.

4.8 Autoclave Input

The permittee shall process ore concentrate as the raw material in the autoclave, and the maximum input to the autoclave shall not exceed 6,960 T/day.

4.9 Mercury Retort Input

The permittee shall process precious metal concentrate as the raw material in the mercury retort, and the maximum input to the mercury retort shall not exceed 1,000 pounds per batch (lb/batch) and 21 tons per any consecutive 12-month period.

Precious metal concentrate includes material loaded with precious metals produced by electrowinning, flotation and gravity separation, and other gold concentration or precipitation processes; and material collected from the wash-down of equipment and surfaces contacted with precious metals that have been concentrated through these concentration methods.

4.10 Induction Melting Furnace Input

The permittee shall process retorted concentrate as the raw material in the induction melting furnace, and the input to the induction melting furnace shall not exceed 1,000 lb/batch, and 21 tons per any consecutive 12-month period. Retorted concentrate includes precious metal

concentrate that has been retorted and dust collected from the baghouse and fume hood of the induction melting furnace.

4.11 Carbon Regeneration Kiln Input

The permittee shall process carbon filters as the raw material in the carbon regeneration kiln, and the maximum input to the carbon regeneration kiln shall not exceed 7.2 T/day.

4.12 Electrowinning Cells and Pregnant Solution Tank Throughput

The permittee shall process mineral-bearing solution as the raw materials in the electrowinning cells and pregnant solution tank, and the maximum throughput for the electrowinning cells and pregnant solution tank shall not exceed 100 gallons per minute (gpm).

4.13 Autoclave Venturi Scrubber, Vent Gas Cleaning Tower, Vent Gas Steam Condensation Tower, and Carbon Filter

The permittee shall install, operate, and maintain venturi scrubber (VS1), vent gas cleaning tower (ST1), vent gas steam condensation tower (CT1), and carbon filter (CA5) systems in accordance with the O&M manual (Permit Condition 2.20) and consistent with manufacturer's recommendations. All emissions from the autoclave shall be ducted to these control devices at all times to ensure compliance with autoclave emission limits (Table 4.2).

4.14 Electrowinning Cells and Pregnant Solution Tank Shared Carbon Filter

The permittee shall install, operate, and maintain a carbon filter (CA2) in accordance with the O&M manual (Permit Condition 2.20) and consistent with manufacturer's recommendations. All emissions from the electrowinning cells and pregnant solution tank shall be ducted to a carbon filter at all times to ensure compliance with electrowinning cells and pregnant solution tank emission limits (Table 4.2).

4.15 Mercury Retort Condenser and Carbon Filter

The permittee shall install, operate, and maintain a condenser and carbon filter (CA3) in series in accordance with the O&M manual (Permit Condition 2.20) and manufacturer's recommendations. All emissions from the mercury retort (MR) shall be ducted to the condenser and activated carbon filter at all times to ensure compliance with mercury retort emission limits (Table 4.2).

- The MR shall be fully enclosed in the refinery building.
- The air pressure within the MR shall be maintained lower than the room air pressure such that air flows into the MR at all times when the MR is operating. The MR door shall be kept closed at all times during operation.
- The permittee shall not operate the MR unless the chilled water condenser is operating, carbon filter in place, and the condenser coolant flow rate is maintained within the range specified in the O&M manual.
- The condenser and carbon filter shall be maintained and operated in accordance with the O&M manual.
- All liquid mercury captured from the MR shall be stored in closed containers.

4.16 Induction Melting Furnace Baghouse and Carbon Filter

The permittee shall install, operate, and maintain a baghouse (BH2) and carbon filter (CA4) in series in accordance with the O&M manual (Permit Condition 2.20) and manufacturer's recommendations. All emissions from the induction melting furnace shall be ducted to the

baghouse and carbon filter at all times during operation to ensure compliance with induction melting furnace emission limits (Table 4.2).

4.17 Carbon Regeneration Kiln Wet Scrubber and Carbon Filter

The permittee shall install, operate, and maintain a wet scrubber (WS2) and carbon filter (CA1) in series in accordance with the O&M manual (Permit Condition 2.20) and consistent with manufacturer's recommendations. All emissions from the carbon regeneration kiln shall be ducted to the wet scrubber and a carbon filter at all times to ensure compliance with carbon regeneration kiln drum emission limits (Table 4.2).

Monitoring and Recordkeeping

4.18 Cyanide Emissions Limit Compliance Monitoring

On at least a daily basis, the permittee shall monitor and record the pH, temperature, and free cyanide concentration levels in grams per cubic meter (g/m^3) of each cyanide leach tank, detox tank, and tailings reclaim stream, and use this information to estimate monthly facility-wide cyanide emissions using the equation and calculation methodology in the O&M Manual (Permit Condition 2.20).

Each month, the permittee shall estimate the monthly and rolling 12-month facility-wide cyanide emissions. Monthly facility-wide cyanide emissions shall be estimated from all emission sources including cyanide leach tanks, detox tanks, electrowinning cells and pregnant solution tank, and barren tanks. Rolling 12-month facility-wide cyanide emissions shall be estimated by summing the monthly emissions from all sources over the previous consecutive 12-month period. The rolling 12-month facility-wide cyanide emissions shall be used to assess compliance with the Cyanide Emissions Limit (Permit Condition 4.4).

4.19 Xanthates Usage Monitoring

Each month, the permittee shall monitor and record the xanthates delivered to the facility and the xanthates used by the facility in tons per month (T/mo) and in tons per 12-month period to demonstrate compliance with the xanthates usage limit. Annual delivery and usage shall be determined by summing the respective monthly amounts over the previous consecutive 12-month period. The methodologies used to measure xanthates usage shall be identified in the O&M Manual.

4.20 POX Boiler Operation Monitoring

Each month, the permittee shall monitor and record the operating hours of the POX Boiler, in hours (hr/mo) and in hours per 12-month period (hr/yr). Annual hours shall be determined by summing the monthly hours over the previous consecutive 12-month period.

4.21 Autoclave Input Monitoring

Each day, the permittee shall monitor and record the material input to the autoclave in tons (T/day) to demonstrate compliance with the autoclave input limit. The devices and methodologies used to measure weights shall be identified in the O&M Manual, and the devices shall be installed in accordance with the requirements of NESHAP Subpart EEEEEEE.

4.22 Mercury Retort Input Monitoring

Each day, the permittee shall monitor and record the material input to the mercury retort in pounds (lb/day) to demonstrate compliance with the daily mercury retort input limit. The devices and methodologies used to measure weights shall be in accordance with the requirements of NESHAP Subpart EEEEEEE.

Each month, the permittee shall monitor and record the material input to the mercury retort in T/mo and T/yr to demonstrate compliance with the annual mercury retort input limit. Annual material input shall be determined by summing the monthly input over the previous consecutive 12-month period.

4.23 Induction Melting Furnace Input Monitoring

Each day, the permittee shall monitor and record the material input to the induction melting furnace in pounds (lb/day) to demonstrate compliance with the daily induction melting furnace input limit. The devices and methodologies used to measure weights shall be identified in the O&M Manual.

Each month, the permittee shall monitor and record the material input to the induction melting furnace in T/mo and in T/yr to demonstrate compliance with the annual induction melting furnace input limit. Annual material input shall be determined by summing the monthly input over the previous consecutive 12-month period.

4.24 Carbon Regeneration Kiln Input Monitoring

Each day, the permittee shall monitor and record the material input to the carbon regeneration kiln in tons (T/day) to demonstrate compliance with the carbon regeneration kiln input limit. The devices and methodologies used to measure weights shall be identified in the O&M Manual.

4.25 Electrowinning Cells and Pregnant Solution Tank Throughput Monitoring

Each day, the permittee shall monitor and record the material throughput in the electrowinning cells and pregnant solution tank in gallons per minute (gpm) to demonstrate compliance with the Electrowinning Cells and Pregnant Solution Tank Throughput limit. The devices and methodologies used to measure weights shall be identified in the O&M Manual.

4.26 Autoclave Venturi Scrubber and Vent Gas Cleaning Tower Monitoring

The permittee shall install, calibrate, operate, and maintain devices for monitoring the circulation flow rate in the venturi scrubber, the circulation flow rate in the vent gas cleaning tower, the pressure drop across the venturi scrubber, and the pressure drop across the vent gas cleaning tower for the autoclave.

At least once per shift, the permittee shall monitor and record the circulation flow rate in the venturi scrubber, the circulation flow rate in the vent gas cleaning tower, the pressure drop across the venturi scrubber, and the pressure drop across the vent gas cleaning tower to ensure compliance with O&M specifications.

4.27 Autoclave Vent Gas Steam Condensation Tower Monitoring

The permittee shall install, calibrate, operate, and maintain devices for monitoring the coolant flow rate to the vent gas steam condensation tower for the autoclave.

At least once per shift, the permittee shall monitor and record the coolant flow rate to the vent gas steam condensation tower to ensure compliance with O&M specifications.

4.28 Autoclave Carbon Filter Monitoring

The permittee shall install, calibrate, operate, and maintain devices for monitoring the inlet gas stream temperature to the carbon filter, and the pressure drop across the carbon filter for the autoclave.

At least once per shift, the permittee shall monitor and record the inlet gas stream temperature and pressure drop across the carbon filter to ensure compliance with O&M specifications.

4.29 Electrowinning Cells and Pregnant Solution Tank Shared Carbon Filter Monitoring

The permittee install, calibrate, operate, and maintain devices for monitoring the inlet gas stream temperature to the carbon filter, and the pressure drop across the carbon filter for the electrowinning cells and pregnant solution tank.

At least once per shift, the permittee shall monitor and record the inlet gas stream temperature and pressure drop across the carbon filter to ensure compliance with O&M specifications.

4.30 Mercury Retort Condenser and Carbon Filter Monitoring

The permittee shall install, calibrate, operate, and maintain devices for monitoring the coolant flow rate in the condenser, the inlet gas temperature to the carbon filter, the pressure drop across the carbon filter, and the difference between the pressure inside the MR and the air pressure in the room.

At least once per shift, the permittee shall monitor and record the coolant flow rate to the condenser, the inlet gas stream temperature, the pressure drop across the carbon filter, and the difference between the pressure inside the MR and the air pressure in the room to ensure compliance with O&M specifications.

4.31 Induction Melting Furnace Baghouse and Carbon Filter Monitoring

The permittee shall install, calibrate, operate, and maintain devices for monitoring the pressure drop across the baghouse, the inlet gas stream temperature to the carbon filter, and the pressure drop across the carbon filter for the induction melting furnace.

At least once per shift, the permittee shall monitor and record the pressure drop across the induction melting furnace baghouse, the inlet gas stream temperature to the carbon filter, and pressure drop across the carbon filter to ensure compliance with O&M specifications.

4.32 Carbon Regeneration Kiln Wet Scrubber and Carbon Filter Monitoring

The permittee shall install, calibrate, operate, and maintain a device for monitoring the circulation flow rate in the wet scrubber, the pressure drop across the wet scrubber, the inlet gas stream temperature to the carbon filter, and the pressure drop across the carbon filter for the carbon regeneration kiln.

At least once per shift, the permittee shall monitor and record the circulation flow rate, the pressure drop across the carbon regeneration kiln wet scrubber, the inlet gas stream temperature to the carbon filter, and the pressure drop across the carbon filter to ensure compliance with O&M specifications.

Testing

4.33 Ore Concentration and Refining Equipment Performance Tests

Within 180 days after initial startup, performance testing shall be conducted to demonstrate compliance with the following Ore Concentration and Refining Equipment Emissions Limits. The permittee shall conduct three separate test runs for each performance test using the appropriate test method (Permit Condition 2.25). The source test shall be conducted under "worst-case normal" conditions as required by IDAPA 58.01.01.157 and the General Provisions of this permit, and the source test report shall contain documentation that the test was conducted under these conditions.

- $PM_{10}/PM_{2.5}$ and H_2SO_4 in lb/hr from the Autoclave Wet Scrubber Stack
- $PM_{10}/PM_{2.5}$ in lb/hr from the Carbon Regeneration Kiln Carbon Filter Stack

- $PM_{10}/PM_{2.5}$ in lb/hr from the Electrowinning Cells and Pregnant Solution Tank Shared Carbon Filter Stack
- $PM_{10}/PM_{2.5}$ in lb/hr from the Mercury Retort Carbon Filter Stack
- $PM_{10}/PM_{2.5}$ in lb/hr from the Induction Melting Furnace Carbon Filter Stack

4.34 Ore Concentration and Refining Equipment Performance Tests Monitoring

The permittee shall monitor and record the following during each performance test:

- Material input rates for all ore concentration and refining process equipment (Permit Conditions 4.21 through 4.25) during each test run.
- Control equipment monitoring relevant to the stack tested (Permit Condition 4.26 through 4.32), measured at least once during each test run.
- The visible emissions observed for the stack tested during each test, using the methods specified in IDAPA 58.01.01.625 (Permit Condition 2.9).

5 Lime, Aggregate, and Concrete Production

5.1 Process Description

The lime, aggregate, and cement batch plants produce raw materials necessary for mining and ore concentration and refining operations. Lime is used in ore processing for pH control. Aggregate and cement are used in concrete production, with aggregate also used in road construction.

Lime production consists of a limestone crushing, screening, and grinding plant and lime storage silos. The limestone grinding process utilizes a baghouse to reduce emissions during processing. Each storage silo has a bin vent filter used to reduce PM emissions during silo loading.

Aggregate production consists of two portable crushing and screening plants and aggregate and cement storage silos. Each portable crushing and screening plant utilizes water sprays and moisture carryover to reduce emissions during processing. Each storage silo has a bin vent filter used to reduce PM emissions during silo loading.

Concrete production consists of a central mix batch plant and cement storage silos. The central mix batch plant utilizes controls that may include water sprays, enclosures, hoods, curtains, shrouds, movable and telescoping chutes, and central duct collection systems to reduce PM emissions during processing. Each storage silo has a bin vent filter used to reduce PM emissions during silo loading.

5.2 Control Device Descriptions

Emission Limits

5.3 Lime, Aggregate, and Concrete Production Emission Limits

Emissions from the lime production plant stacks shall not exceed any emission rate limit in the following table.

Table 5.2 Lime, Aggregate, and Concrete Production Plant Emission Limits [a]

Source Description	PM [b]	PM_{10} [b]	$PM_{2.5}$ [b]	NO_x	CO	VOC	SO_2
	lb/hr [c]	lb/hr [c]	lb/hr [c]	lb/hr [c]	lb/hr [c]	lb/hr [c]	lb/hr [c]
Lime Production							
Parallel Flow Regenerative Shaft Kiln (LK, LKC)	1.08	1.08	1.08	4.82	4.98	0.19	0.39
Limestone Ball Mill (LSBM)	1.90	1.60	0.57				
Lime Mill Crusher (LCR)	0.28	0.24	0.09				
Lime Mill screens and conveyors (LS2, LS4, LS3, LS5, LS11, LS1, LS6–LS10, LS12)	3.66	1.34	0.20				
Mill Lime Silo loading (each) (LS1L, MillS2L)	0.06	0.02	0.01				
Mill Lime Silo unloading (each) (LS1U, MillS2U)	0.10	0.06	0.01				
AC Lime Silo loading (each) (ACS1L, ACS2L, ACS3L, ACS4L)	0.12	0.04	0.01				
AC Lime Silo loading (each) (ACS1U, ACS2U, ACS3U, ACS4U)	0.10	0.06	0.01				
Pebble Lime Silo loading (LS-L)	0.01	0.01	0.01				
Pebble Lime Silo unloading (LS-U)	0.001	0.001	0.001				
Crushers, screens, conveyors, silo unloading (LSBM, LCR, LS1– LS12)	6.00	3.22	0.87				
Aggregate Production							
Portable Crushing and Screening Plant 1	0.63	0.23	0.03				
Portable Crushing and Screening Plant 2	0.63	0.23	0.03				
Concrete Production							
Central Mix Plant (CM, CS1, CS2, CA)	2.10	0.94	0.14				

a) In absence of any other credible evidence, compliance is ensured by complying with permit operating, monitoring, and recordkeeping requirements.

b) Particulate matter (PM) including condensable PM as defined in IDAPA 58.01.01.006, with an aerodynamic diameter less than or equal to a nominal 10 micrometers for PM_{10}, and less than or equal to a nominal 2.5 micrometers for $PM_{2.5}$.

c) Pounds per hour, as determined by a test method prescribed by IDAPA 58.01.01.157, EPA reference test method, continuous emission monitoring system (CEMS) data, or DEQ-approved alternative.

Operating Requirements

5.4 Primary Crusher Limit

The permittee shall process limestone as the raw material, and the maximum input to the primary crusher shall not exceed 1,130 T/day.

5.5 Parallel Flow Regenerative Kiln Limit

The permittee shall process lime as the raw material in the Parallel Flow Regenerative Kiln. The maximum output from the kiln shall not exceed 169 T/day and 52,377 tons per any consecutive 12-month period.

5.6 Portable Crushing and Screening Plant 1 Input Limit

The permittee shall process aggregate as the raw material, and the maximum input to the Portable Crushing and Screening Plant 1 shall not exceed 2,000 T/day.

5.7 Portable Crushing and Screening Plant 2 Input Limit

The permittee shall process aggregate as the raw material, and the maximum input to the Portable Crushing and Screening Plant 2 shall not exceed 2,000 T/day.

5.8 Central Mix Input Limit

The permittee shall process cement and aggregate as the raw materials, and the maximum input to the central mix plant shall not exceed 2,480 T/day and 560,000 tons per any consecutive 12-month period.

5.9 Lime Silos Input Limit

The permittee shall load lime as the raw material, and the maximum input to the Mill Lime Silos and the AC Lime Silos shall not exceed 4,000 T/day and 70,000 tons per any consecutive 12-month period combined.

5.10 Lime, Aggregate, and Concrete Production Dust Control

The permittee shall control emissions from lime production, aggregate production, and concrete production emission sources (Table 5.1) in accordance with the Fugitive Dust Control Plan.

5.11 Portable Crushing and Screening Plant Water Sprays

The permittee shall install, operate, and maintain water sprays in accordance with the O&M manual (Permit Condition 2.20) to control PM emissions from each portable crushing and screening plant. Water sprays shall operate at all times, except as specified in the O&M manual during winter conditions, when this equipment is operated to ensure compliance with Fugitive Dust requirements (Permit Conditions 2.1–2.6).

5.12 Parallel Flow Regenerative Kiln Baghouse

The permittee shall install, operate, and maintain a baghouse system (BH4) in accordance with the O&M manual (Permit Condition 2.20) and consistent with manufacturer's recommendations. All emissions from the parallel flow regenerative kiln shall be ducted to the baghouse at all times to ensure compliance with parallel flow regenerative emission limits.

5.13 Limestone Ball Mill Baghouse

The permittee shall install, operate, and maintain a baghouse system (BH3) in accordance with the O&M manual (Permit Condition 2.20) and consistent with manufacturer's recommendations. All emissions from the limestone ball mill shall be ducted to the baghouse at all times to ensure compliance with limestone ball mill emission limits.

5.14 Lime Mill Crusher Baghouse

The permittee shall install, operate, and maintain a baghouse (BH5) in accordance with the O&M manual (Permit Condition 2.20) and consistent with manufacturer's recommendations.
All emissions from the lime mill crusher shall be ducted to the baghouse at all times to ensure compliance with limestone ball mill emission limits.

5.15 Pebble Lime Silo Wet Scrubber

The permittee shall install, operate, and maintain a wet scrubber on the Pebble Lime Silo discharge (LS) in accordance with the O&M manual (Permit Condition 2.20) and consistent with manufacturer's recommendations. All emissions during discharge from the Pebble Lime Silo shall be ducted to the wet scrubber to ensure compliance with pebble lime silo emission limits (Table 5.2).

5.16 Silo Bin Vent Filters

The permittee shall install, operate, and maintain a bin vent filter on each silo (LS1, MillS2, ACS1, ACS2, ACS3, ACS4, LS, CS1, CS2) in accordance with the O&M manual (Permit Condition 2.20) and consistent with manufacturer's recommendations. All emissions during loading of each silo shall be ducted to the corresponding bin vent filter to ensure compliance with corresponding silo emission limits (Table 5.2).

Monitoring and Recordkeeping Requirements

5.17 Primary Crusher Monitoring

Each day, the permittee shall monitor and record the material input to the Primary Crusher in tons (T/day) to demonstrate compliance with the daily Primary Crusher Limit. The devices and methodologies used to measure weights shall be identified in the O&M Manual.

5.18 Parallel Flow Regenerative Kiln Limit Monitoring

Each day, the permittee shall monitor and record the material output from the Parallel Flow Regenerative Kiln in tons (T/day) to demonstrate compliance with the daily Parallel Flow Regenerative Kiln Limits. The devices and methodologies used to measure weights shall be identified in the O&M Manual.

Each month, the permittee shall calculate and record the material output from the Parallel Flow Regenerative Kiln in T/mo and in T/yr to demonstrate compliance with the annual Parallel Flow Regenerative Kiln Limit. Annual material output shall be determined by summing the monthly output over the previous consecutive 12-month period.

5.19 Portable Crushing and Screening Plant 1 Input Limit Monitoring

Each day, the permittee shall monitor and record the material input to the Portable Crushing and Screening Plant 1 plant in tons (T/day) to demonstrate compliance with the daily Portable Crushing and Screening Plant 1 Input Limit. The devices and methodologies used to measure weights shall be identified in the O&M Manual.

5.20 Portable Crushing and Screening Plant 2 Input Limit Monitoring

Each day, the permittee shall monitor and record the material input to the Portable Crushing and Screening Plant 2 plant in tons (T/day) to demonstrate compliance with the daily Portable Crushing and Screening Plant 2 Input Limit. The devices and methodologies used to measure weights shall be identified in the O&M Manual.

5.21 Central Mix Input Limit Monitoring

Each day, the permittee shall monitor and record the material input to the Central Mix Plant in tons (T/day) to demonstrate compliance with the daily Central Mix Input Limit. The devices and methodologies used to measure weights shall be identified in the O&M Manual.

Each month, the permittee shall calculate and record the material input to the central mix plant in T/mo and in T/yr to demonstrate compliance with the annual Central Mix Input Limit. Annual

material input shall be determined by summing the monthly input over the previous consecutive 12-month period.

5.22 Lime Silos Input Limit Monitoring

Each day, the permittee shall monitor and record the material input to the Mill Lime Silos and the AC Lime Silos in tons (T/day) to demonstrate compliance with the daily Lime Silos Input Limit. The devices and methodologies used to measure weights shall be identified in the O&M Manual.

Each month, the permittee shall calculate and record the material input to the Mill Lime Silos and the AC Lime Silos in T/mo and in T/yr to demonstrate compliance with the annual Lime Silos Input Limit. Annual material input shall be determined by summing the monthly input over the previous consecutive 12-month period.

5.23 Parallel Flow Regenerative Kiln Baghouse Monitoring

The permittee shall install, calibrate, operate, and maintain a device for monitoring the pressure drop across the parallel flow regenerative kiln baghouse. At least once per shift, the permittee shall monitor and record the pressure drop across the parallel flow regenerative kiln baghouse to demonstrate compliance with O&M specifications.

5.24 Limestone Ball Mill Baghouse Monitoring

The permittee shall install, calibrate, operate, and maintain a device for monitoring the pressure drop across the limestone ball mill baghouse. At least once per shift, the permittee shall monitor and record the pressure drop across the limestone ball mill kiln baghouse to demonstrate compliance with O&M specifications.

5.25 Lime Mill Crusher Baghouse Monitoring

The permittee shall install, calibrate, operate, and maintain a device for monitoring the pressure drop across the lime mill crusher baghouse. At least once per shift, the permittee shall monitor and record the pressure drop across the lime mill crusher kiln baghouse to demonstrate compliance with O&M specifications.

5.26 Pebble Lime Silo Wet Scrubber Monitoring

The permittee shall install, calibrate, operate, and maintain a device for monitoring the circulation flow rate in the pebble lime silo wet scrubber, and the pressure drop across the pebble lime silo wet scrubber. At least once per shift, the permittee shall monitor and record the circulation flow rate and the pressure drop across the pebble lime silo wet scrubber to demonstrate compliance with O&M specifications.

6 Engines

6.1 Process Description

Stationary internal combustion engines (ICE) for emergency power generation and fire suppression are essential to ensure safety and uninterrupted essential operations in case of unforeseen power failures or emergency situations. Portable diesel-fired light plant engines provide supplemental lighting as needed; these are not regulated by this permit and will be operated as nonroad engines defined in 40 CFR 1068.30.

6.2 Emission Standards for Emergency Generators and Fire Pump Engines

In accordance with 40 CFR 60.4205(b) and 40 CFR 60.4206, EDG1, EDG2, and EDG3 shall be EPA Tier II Certified engines and must comply with the emission standards for new nonroad CI engines in § 60.4202, for all pollutants, for the same model year and maximum engine power and must be operated and maintained so that they achieve the emission standards as required in §§60.4204 and 60.4205 over the entire life of the engine.

In accordance with 40 CFR 60.4205(c), EDFP must comply with the emission standards in Table 4 to the Subpart for all pollutants.

6.3 Emergency Generator and Fire Pump Engine Operation

Operation of each emergency generator engine (EDG1, EDG2, EDG3) and each fire pump engine (EDFP) shall not exceed 1 hour per day (hr/day) and 100 hr/yr for non-emergency purposes.

6.4 Emergency Generator Monitoring Requirements

In accordance with 40 CFR 60.4209(a), EDG1, EDG2, and EDG3 shall have non-resettable hour meters installed prior to startup.

6.5 Emergency Generator Compliance Requirements

In accordance with 40 CFR 60.4211(f), EDG1, EDG2, and EDG3 must be operated according to the requirements in paragraphs (f)(1) through (3) of this section of the Subpart. In order for the engines to be considered emergency stationary ICE under this subpart, any operation other than emergency operation, maintenance and testing, emergency demand response, and operation in non-emergency situations for 50 hours per year, as described in paragraphs (f)(1) through (3) of this section, is prohibited. If you do not operate the engine according to the requirements in paragraphs (f)(1) through (3) of this section, the engine will not be considered an emergency engine under this subpart and must meet all requirements for non-emergency engines.

(1) There is no time limit on the use of emergency stationary ICE in emergency situations.

(2) You may operate your emergency stationary ICE for any combination of the purposes specified in paragraphs (f)(2)(i) through (iii) of this section for a maximum of 100 hours per calendar year. Any operation for non-emergency situations as allowed by paragraph (f)(3) of this section counts as part of the 100 hours per calendar year allowed by this paragraph (f)(2).

(i) Emergency stationary ICE may be operated for maintenance checks and readiness testing, provided that the tests are recommended by federal, state or local government, the manufacturer, the vendor, the regional transmission

organization or equivalent balancing authority and transmission operator, or the insurance company associated with the engine. The owner or operator may petition the Administrator for approval of additional hours to be used for maintenance checks and readiness testing, but a petition is not required if the owner or operator maintains records indicating that federal, state, or local standards require maintenance and testing of emergency ICE beyond 100 hours per calendar year.

(ii) Emergency stationary ICE may be operated for emergency demand response for periods in which the Reliability Coordinator under the North American Electric Reliability Corporation (NERC) Reliability Standard EOP-002-3, Capacity and Energy Emergencies (incorporated by reference, see § 60.17), or other authorized entity as determined by the Reliability Coordinator, has declared an Energy Emergency Alert Level 2 as defined in the NERC Reliability Standard EOP-002-3.

(iii) Emergency stationary ICE may be operated for periods where there is a deviation of voltage or frequency of 5 percent or greater below standard voltage or frequency.

(3) Emergency stationary ICE may be operated for up to 50 hours per calendar year in non-emergency situations. The 50 hours of operation in non-emergency situations are counted as part of the 100 hours per calendar year for maintenance and testing and emergency demand response provided in paragraph (f)(2) of this section. Except as provided in paragraph (f)(3)(i) of this section, the 50 hours per calendar year for non-emergency situations cannot be used for peak shaving or non-emergency demand response, or to generate income for a facility to an electric grid or otherwise supply power as part of a financial arrangement with another entity.

(i) The 50 hours per year for non-emergency situations can be used to supply power as part of a financial arrangement with another entity if all of the following conditions are met:

(A) The engine is dispatched by the local balancing authority or local transmission and distribution system operator.

(B) The dispatch is intended to mitigate local transmission and/or distribution limitations so as to avert potential voltage collapse or line overloads that could lead to the interruption of power supply in a local area or region.

(C) The dispatch follows reliability, emergency operation or similar protocols that follow specific NERC, regional, state, public utility commission or local standards or guidelines.

(D) The power is provided only to the facility itself or to support the local transmission and distribution system.

(E) The owner or operator identifies and records the entity that dispatches the engine and the specific NERC, regional, state, public utility commission or local standards or guidelines that are being followed for dispatching the engine. The local balancing authority or local transmission and distribution system operator may keep these records on behalf of the engine owner or operator.

6.6 Emergency Generator and Fire Pump Engine Operation Monitoring

Each month, the permittee shall monitor and record the emergency and non-emergency operating hours of each emergency generator and fire pump engine, in hr/mo and in hr/yr to demonstrate compliance with the emergency generator and fire pump engine operation limit. Annual operation shall be determined by summing the monthly hours over the previous consecutive 12-month period.

6.7 Engines Subject to Regulation Notification

With the exception of the emergency generator and fire pump engines (identified in Table 1.1) and engines used to propel vehicles, notification shall be provided to DEQ if an engine (including any previously operated as a nonroad engine) will be operated onsite at a specific location beyond 12 months, and no longer meets criteria for regulation as a nonroad engine. Notification shall be provided as soon as practicable in advance of exceeding 12 months of operation at a single location and within 30 days after the engine ceases to meet the definition of nonroad engine in 40 CFR 1068.30.

- A nonroad engine may include engines that are portable or transportable, meaning designed to be and capable of being carried or moved from one location to another (e.g., portable light plant engines). Indicia of transportability include, but are not limited to, wheels, skids, carrying handles, dolly, trailer, or platform.
- A portable or transportable internal combustion engine is not a nonroad engine if it remains or will remain at a location for more than 12 consecutive months, or a shorter period of time for an engine located at a seasonal source. A location is any single site at a building, structure, facility, or installation. Any engines (or engine) that replace(s) an engine at a location and is intended to perform the same or similar function as the engine(s) replaced are included in calculating the consecutive time period. Permitting requirements and emission standards may become applicable when an engine becomes a stationary source.

7 General Provisions

General Compliance

7.1 The permittee has a continuing duty to comply with all terms and conditions of this permit. All emissions authorized herein shall be consistent with the terms and conditions of this permit and the "Rules for the Control of Air Pollution in Idaho." The emissions of any pollutant in excess of the limitations specified herein, or noncompliance with any other condition or limitation contained in this permit, shall constitute a violation of this permit, the "Rules for the Control of Air Pollution in Idaho," and the Environmental Protection and Health Act (Idaho Code §39-101, et seq).

[Idaho Code §39-101, et seq.]

7.2 The permittee shall at all times (except as provided in the "Rules for the Control of Air Pollution in Idaho") maintain in good working order and operate as efficiently as practicable all treatment or control facilities or systems installed or used to achieve compliance with the terms and conditions of this permit and other applicable Idaho laws for the control of air pollution.

[IDAPA 58.01.01.211]

7.3 Nothing in this permit is intended to relieve or exempt the permittee from the responsibility to comply with all applicable local, state, or federal statutes, rules, and regulations.

[IDAPA 58.01.01.212.01]

Inspection and Entry

7.4 Upon presentation of credentials, the permittee shall allow DEQ or an authorized representative of DEQ to do the following:

- Enter upon the permittee's premises where an emissions source is located, emissions-related activity is conducted, or where records are kept under conditions of this permit;
- Have access to and copy, at reasonable times, any records that are kept under the conditions of this permit;
- Inspect at reasonable times any facilities, equipment (including monitoring and air pollution control equipment), practices, or operations regulated or required under this permit; and
- As authorized by the Idaho Environmental Protection and Health Act, sample or monitor, at reasonable times, substances or parameters for the purpose of determining or ensuring compliance with this permit or applicable requirements.

[Idaho Code §39-108]

Construction and Operation Notification

7.5 This permit shall expire if construction has not begun within two years of its issue date, or if construction is suspended for one year.

[IDAPA 58.01.01.211.02]

7.6 The permittee shall furnish DEQ written notifications as follows:

- A notification of the date of initiation of construction, within five working days after occurrence; except in the case where pre-permit construction approval has been granted then notification shall be made within five working days after occurrence or within five working days after permit issuance whichever is later;
- A notification of the date of any suspension of construction, if such suspension lasts for one year or more; and

- A notification of the initial date of achieving the maximum production rate, within five working days after occurrence - production rate and date.

[IDAPA 58.01.01.211.01]

- A notification of the anticipated date of initial start-up of the stationary source or facility not more than sixty days or less than thirty days prior to such date; and
- A notification of the actual date of initial start-up of the stationary source or facility within fifteen days after such date.

[IDAPA 58.01.01.211.03]

Performance Testing

7.7 If performance testing (air emissions source test) is required by this permit, the permittee shall provide notice of intent to test to DEQ at least 15 days prior to the scheduled test date or shorter time period as approved by DEQ. DEQ may, at its option, have an observer present at any emissions tests conducted on a source. DEQ requests that such testing not be performed on weekends or state holidays.

7.8 All performance testing shall be conducted in accordance with the procedures in IDAPA 58.01.01.157. Without prior DEQ approval, any alternative testing is conducted solely at the permittee's risk. If the permittee fails to obtain prior written approval by DEQ for any testing deviations, DEQ may determine that the testing does not satisfy the testing requirements. Therefore, at least 30 days prior to conducting any performance test, the permittee is encouraged to submit a performance test protocol to DEQ for approval. The written protocol shall include a description of the test method(s) to be used, an explanation of any or unusual circumstances regarding the proposed test, and the proposed test schedule for conducting and reporting the test.

7.9 Within 60 days following the date in which a performance test required by this permit is concluded, the permittee shall submit to DEQ a performance test report. The report shall include a description of the process, identification of the test method(s) used, equipment used, all process operating data collected during the test period, and test results, as well as raw test data and associated documentation, including any approved test protocol.

[IDAPA 58.01.01.157]

Monitoring and Recordkeeping

7.10 The permittee shall maintain sufficient records to ensure compliance with all of the terms and conditions of this permit. Monitoring records shall include, but not be limited to, the following: (a) the date, place, and times of sampling or measurements; (b) the date analyses were performed; (c) the company or entity that performed the analyses; (d) the analytical techniques or methods used; (e) the results of such analyses; and (f) the operating conditions existing at the time of sampling or measurement. All monitoring records and support information shall be retained for a period of at least five years from the date of the monitoring sample, measurement, report, or application. Supporting information includes, but is not limited to, all calibration and maintenance records, all original strip-chart recordings for continuous monitoring instrumentation, and copies of all reports required by this permit. All records required to be maintained by this permit shall be made available in either hard copy or electronic format to DEQ representatives upon request.

[IDAPA 58.01.01.211]

Excess Emissions

7.11 The permittee shall comply with the procedures and requirements of IDAPA 58.01.01.130-136 for excess emissions. The provisions of IDAPA 58.01.01.130-136 shall govern in the event of conflicts between the excess emissions general provisions and the regulations of IDAPA 58.01.01.130-136.

During an excess emissions event, the permittee shall, with all practicable speed, initiate and complete appropriate and reasonable action to correct the conditions causing the excess emissions event; to reduce the frequency of occurrence of such events; to minimize the amount by which the emission standard is exceeded; and shall, as provided below or upon request of DEQ, submit a full report of such occurrence, including a statement of all known causes, and of the scheduling and nature of the actions to be taken.

[IDAPA 58.01.01.132]

7.12 In all cases where startup, shutdown, or scheduled maintenance of any equipment or emission unit is expected to result or results in an excess emissions event, the permittee shall demonstrate compliance with IDAPA 58.01.01.133.01(a) through (d), including, but not limited to, the following:

- Prohibiting any scheduled startup, shutdown, or maintenance resulting in excess emissions shall occur during any period in which an Atmospheric Stagnation Advisory or a Wood Stove Curtailment Advisory has been declared by DEQ.
- Notifying DEQ of the excess emissions event as soon as reasonably possible, but no later than two hours prior to, the start of the event, unless the permittee demonstrates to DEQ's satisfaction that a shorter advance notice was necessary.
- Reporting and recording the information required pursuant to the excess emissions reporting and recordkeeping requirements and IDAPA 58.01.01.135 and 136 for each excess emissions event due to startup, shutdown, or scheduled maintenance.

[IDAPA 58.01.01.133]

7.13 In all cases where upset or breakdown of equipment or an emissions unit, or the initiation of safety measures, results or may result in an excess emissions event, the permittee shall demonstrate compliance with IDAPA 58.01.01.134.01(a) and (b) and the following:

- Immediately undertake all appropriate measures to reduce and, to the extent possible, eliminate excess emissions resulting from the event and to minimize the impact of such excess emissions on the ambient air quality and public health.
- Notify DEQ of any upset, breakdown, or safety event that results in excess emissions. Such notification shall identify the time, specific location, equipment or emissions unit involved, and (to the extent known) the cause(s) of the occurrence. The notification shall be given as soon as reasonably possible, but no later than 24 hours after the event, unless the permittee demonstrates to DEQ's satisfaction that the longer reporting period was necessary.
- Report and record the information required pursuant to the excess emissions reporting and recordkeeping facility wide conditions and IDAPA 58.01.01.135 and 136 for each excess emissions event caused by an upset, breakdown, or safety measure.

- During any period of excess emissions caused by upset, breakdown, or operation under facility safety measures, DEQ may require the permittee to immediately reduce or cease operation of the equipment or emissions unit causing the period until such time as the condition causing the excess has been corrected or brought under control. Such action by DEQ shall be taken upon consideration of the factors listed in IDAPA 58.01.01.134.03 and after consultation with the permittee.

[IDAPA 58.01.01.134]

7.14 The permittee shall submit a written report to DEQ for each excess emissions event, no later than 15 days after the beginning of such an event. Each report shall contain the information specified in IDAPA 58.01.01.135.02.

[IDAPA 58.01.01.135]

7.15 The permittee shall maintain excess emissions records at the facility for the most recent five calendar-year period. The excess emissions records shall be made available to DEQ upon request and shall include the information requested by IDAPA 58.01.01.136.03(a) and (b) as summarized in the following:

- An excess emissions log book for each emissions unit or piece of equipment containing copies of all reports that have been submitted to DEQ pursuant to IDAPA 58.01.01.135 for the particular emissions unit or equipment; and
- Copies of all startup, shutdown, and scheduled maintenance procedures and upset, breakdown, or safety preventative maintenance plans that have been developed by the permittee in accordance with IDAPA 58.01.01.133 and 134, and facility records as necessary to demonstrate compliance with such procedures and plans.

[IDAPA 58.01.01.136]

Certification

7.16 All documents submitted to DEQ—including, but not limited to, records, monitoring data, supporting information, requests for confidential treatment, testing reports, or compliance certification—shall contain a certification by a responsible official. The certification shall state that, based on information and belief formed after reasonable inquiry, the statements and information in the document(s) are true, accurate, and complete.

[IDAPA 58.01.01.123]

False Statements

7.17 No person shall knowingly make any false statement, representation, or certification in any form, notice, or report required under this permit or any applicable rule or order in force pursuant thereto.

[IDAPA 58.01.01.125]

Tampering

7.18 No person shall knowingly render inaccurate any monitoring device or method required under this permit or any applicable rule or order in force pursuant thereto.

[IDAPA 58.01.01.126]

Transferability

7.19 This permit is transferable in accordance with procedures listed in IDAPA 58.01.01.209.06.

[IDAPA 58.01.01.209.06]

Severability

7.20 The provisions of this permit are severable, and if any provision of this permit to any circumstance is held invalid, the application of such provision to other circumstances, and the remainder of this permit, shall not be affected thereby.

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047	Case Docket No. 0101-22-01
NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON Petitioners, v. IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent, and PERPETUA RESOURCES IDAHO, INC., Intervenor.	NOTICE OF JOINDER

COMES NOW, Respondent, the Idaho Department of Environmental Quality (Department), by and through its attorney of record, the Office of the Attorney General,

and pursuant to IDAPA 58.01.03.162.02, to join the Motion to Dismiss filed by Intervenor, Perpetua Resources. The Department does not intend to file a supplementary memorandum in support of the Motion to Dismiss and does not request a hearing on the motion.

DATED: September 12, 2022, FOR RESPONDENT:

STATE OF IDAHO, DEPARTMENT OF ENVIRONMENTAL QUALITY

By: /s/ *John R. Shackelford*
John R. Shackelford
Attorney for Respondent

CERTIFICATE OF SERVICE

I HEREBY CERTIFY that on this 12th day of September, 2022, a true and correct copy of the foregoing NOTICE OF JOINDER was served on the following via electronic mail to the indicated address:

BEFORE THE BOARD OF ENVIRONMENTAL QUALITY
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047	)	CASE DOCKET NO. 0101-22-01
NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON *Petitioners*,	)	**PETITIONERS' OPPOSITION TO PERPETUA'S MOTION TO DISMISS**
v.	)	
IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY, *Respondent*,	)	
and	)	
PERPETUA RESOURCES IDAHO, INC., *Intervenor.*	)	

INTRODUCTION

The Motion to Dismiss ("MTD") filed by Perpetua Resources Idaho ("Perpetua") applies the wrong legal standards, while disregarding the detailed facts and law recited in the Petition to Initiate Contested Case Hearing challenging the Idaho Department of Environmental Quality's ("DEQ") Air Quality Permit to Construct ("Final Permit") for the Stibnite Gold Project ("SGP"). Perpetua's attempt to deprive Petitioners Nez Perce Tribe *et al.* of their right to challenge the Final Permit through contested case procedures must be rejected.

As explained below, Perpetua wrongly invokes standards for pleading fraud or similar claims with particularity under the Idaho Rules of Civil Procedure—which are inapplicable here—while disregarding Petitioners' detailed allegations of how the Final Permit violates specific requirements and/or was arbitrary, capricious, or an abuse of discretion under the Idaho Administrative Procedure Act (APA) and DEQ regulations. Petitioners did not merely allege the Final Permit was "flawed," "deficient," or "contained shortcomings," as Perpetua claims—their Petition documented those flaws, deficiencies, and shortcomings in detailed allegations, which the Hearing Officer must accept as true in considering the motion to dismiss.

Moreover, rather than accept as true all facts alleged in the Petition, Perpetua repeatedly cites to the Final Permit and its supporting Statement of Basis ("SOB") to argue the merits of its position that DEQ acted correctly. But that is a determination that can only be made by the Hearing Officer through the contested case hearing procedures, not through the kind of summary judgment determination that Perpetua is seeking under the guise of its motion to dismiss.

Neither is Perpetua right as a matter of law in invoking the "to the satisfaction of the Department" language from the Idaho Air Rules, to argue that Petitioners have no right to challenge those determinations. *See* Perpetua MTD at 10, 14, 17. Contrary to Perpetua's reading,

this language provides no "free pass" that insulates DEQ's determinations from challenges under the Idaho APA and Idaho Air Rules. The whole point of contested proceedings is to allow interested parties to establish facts and legal principles that DEQ may have misconstrued, ignored, or misapplied in making the Final Permit decision—including whether adequate basis exists to support determinations that air quality requirements would be met under the permit.

As detailed below, the Petition clearly states the factual and legal grounds supporting Petitioners' arguments that DEQ violated the Air Rules and the APA by issuing the Final Permit without complying with all applicable rules, by acting arbitrarily or capriciously, and by abusing its discretion. The Hearing Officer should, therefore, deny Perpetua's Motion to Dismiss.

STANDARD OF REVIEW

On a motion to dismiss for failure to state a claim, the Hearing Officer can look "only at the pleadings, and all inferences are viewed in favor of the non-moving party." *Burghart v. Carlin*, 151 Idaho 730, 731, 264 P.3d 71, 72 (Idaho App. 2011) (citation omitted). "[T]he non-moving party is entitled to have all inferences from the record viewed in his favor and only then may the question be asked whether a claim for relief has been stated". *Miles v. Idaho Power Co.*, 116 Idaho 635, 637, 778 P.2d 757, 759 (1989). "[T]he question is whether the non-movant has alleged sufficient facts in support of his claim which, if true, would entitle him to relief." *Rincover v. State, Dep't of Finance, Securities Bureau*, 128 Idaho 653, 656, 917 P.2d 1293, 1296 (1996). A motion to dismiss for failure to state a claim "will not be granted unless it appears beyond doubt that the [plaintiff] could prove no set of facts in support of his claim which would entitle him to relief." *Orthman v. Idaho Power Co.*, 126 Idaho 960, 962, 895 P.2d 561, 563 (1995)). "The issue is not whether the plaintiff will ultimately prevail, but whether the party is entitled to offer evidence to support the claims." *Young*, 137 Idaho at 104, 44 P.3d at 1159.

ARGUMENT

I. CONTESTED CASE PLEADING RULES REQUIRE LIBERAL CONSTRUCTION, ALLOW AMENDMENT, AND DISFAVOR DISMISSAL.

Perpetua points to "heightened" pleading standards under the Idaho Rules of Civil Procedure (IRCP) for "special matters," including fraud, to contend that such heightened pleading standards apply here. MTD at 5. But the IRCP do not apply to this contested case, and the rules that do apply require liberal construction of pleadings and frown against dismissal.

DEQ's Contested Case Rules and Rules for the Protection and Disclosure of Records ("Contested Case Rules"), IDAPA 58.01.23, govern contested cases, such as this one. The Contested Case Rules incorporate Rules 52 and 305 (among others) of the Idaho Rules of Administrative Procedure of the Attorney General ("Idaho Rules of Administrative Procedure"). IDAPA 58.01.23.003.01, .05. Rule 52 states:

> The rules in this chapter will be liberally construed to secure just, speedy and economical determination of all issues presented to the agency. Unless prohibited by statute, the agency may permit deviation from these rules when it finds that compliance with them is impracticable, unnecessary or not in the public interest.

IDAPA 04.11.01.052. Similarly, Rule 305 favors liberal construction of the pleadings and amendment if necessary:

> The presiding officer may allow any pleading to be amended or corrected or any omission to be supplied. Pleadings will be liberally construed, and defects that do not affect substantial rights of the parties will be disregarded. . . .

IDAPA 04.11.01.305

Notably, Rule 52 further provides: "Unless required by statute, the Idaho Rules of Civil Procedure and the Idaho Rules of Evidence do not apply to contested case proceedings." *Id.* (emphasis added). Perpetua's Motion to Dismiss ignores Rule 52 and fails to point to any statute requiring the IRCP to apply to contested cases like this one before the Board. The IRCP do not

apply here;[1] and the rules that do apply—DEQ's Contested Case Rules and the Idaho Rules of Administrative Procedure—are to be liberally construed, defects in pleadings can be disregarded, and amendments are to be liberally granted.[2]

As set forth below, the Petition complies with all pleading requirements, and Perpetua's Motion to Dismiss must be denied. However, even if the Hearing Officer finds any defects in the Petition, Rules 52 and 305 do not support dismissal. Perpetua has not even argued, let alone demonstrated, that any of the supposed defects in the Petition affect Perpetua's substantial rights, as required under Rule 305. *See* IDAPA 04.11.01.305. Nor could Perpetua show any substantial rights are affected. Perpetua's own Motion to Dismiss shows it clearly has been put on notice of the challenged decision and of the alleged errors DEQ made in making that decision, and shows that Perpetua is prepared to defend against them.

Thus, even if there are any defects in the Petition—which there are not, as explained further below—the Hearing Officer should, consistent with Rule 305, disregard them and deny Perpetua's Motion to Dismiss, or alternatively direct Petitioners to file an amended petition. *See* IDAPA 04.11.01.305. Dismissing the Petition, as Perpetua seeks, runs counter to the applicable rules, would be extreme, would impose overly-burdensome and unforgiving requirements on anyone seeking to challenge an agency's decision through contested case proceedings before the Board, and would thus be in contravention of the public interest.

---

[1]Nothing in the Idaho APA requires application of the IRCP to contested cases either. *See* Idaho Code § 67-5206(2) (directing attorney general to create Idaho Rules of Administrative Procedure); I.C. §§ 67-5240–5253 (provisions on contested cases).

[2] In freely allowing amended pleadings, Rule 305 is consistent with IRCP 15(a)(2), which likewise allows liberal amendments to ensure claims are "determined on the merits rather than on technicalities, and to make pleadings serve the limited role of providing notice of the nature of the claim and the facts at issue." *Hayward v. Valley Vista Care Corp.*, 136 Idaho 342, 33 P.3d 816, 819 (2001) (quotation omitted).

II. THE PETITION COMPLIES WITH ALL PLEADING REQUIREMENTS IN DEQ'S CONTESTED CASE RULES.

Perpetua contends that the Petition does not comply with the pleading requirements in Rule 160.01 of DEQ's Contested Case Rules. *See* MTD at 4–5, 7–8. Rule 160.01 provides that a contested case petition must include the following contents:

> a. Fully state the facts upon which it is based, including the specific alleged action or inaction of the Department;
> b. Refer to the particular provisions of statute, rule, order or other controlling law upon which it is based. Legal assertions will be accompanied by citations of cases and statutory provisions;
> c. State the relief sought; and
> d. State the basis for the petitioner's legal standing to initiate the contested case.

IDAPA 58.01.23.160.01. As discussed below, the Petition complies with all these pleading requirements, and Perpetua's Motion to Dismiss should be denied.

First, the Petition fully states the facts upon which it is based, satisfying Rule 160.01.a. The section of the Petition titled "FACTUAL SUPPORT FOR PETITION" includes seventeen pages of detailed factual allegations about DEQ's challenged action in issuing the Final Permit. *See* Petition ¶¶ 22–68. This section of the Petition states facts describing the Stibnite Gold Project and the action being challenged in this contested case, *i.e.*, DEQ's issuance of the Final Permit. *Id.* ¶¶ 22–26. Next, after stating background facts on PM_{10} pollution and regulation, *id.* ¶¶ 27–32, the Petition states detailed facts surrounding the alleged flaws in the way DEQ addressed PM_{10} permitting requirements when it issued the Final Permit. *Id.* ¶¶ 33–41. Third, after stating background facts on arsenic pollution and regulation, *id.* ¶¶ 42–46, the Petition states detailed facts surrounding the alleged flaws in the way DEQ addressed arsenic permitting requirements when it issued the Final Permit. *Id.* ¶¶ 47–57. Then, the Petition states detailed facts about DEQ's establishment of the ambient air boundary for the Stibnite Gold Project and the alleged flaws in the way DEQ did this. *Id.* ¶¶ 58–65. Finally, the Petition states detailed facts

about DEQ's failure to require ambient air monitoring in the Final Permit. *Id.* ¶¶ 66–68. The Petition thus amply meets the requirements of Rule 160.01.a to "[f]ully state the facts upon which it is based . . ." IDAPA 58.01.23.160.01.a.

Second, the Petition satisfies the requirement under Rule 160.01.b to "refer" to the controlling law. The Petition has a section entitled "JURISDICTION, STANDARD OF REVIEW, PARTIES and STANDING," plus a "RELIEF REQUESTED" section, which both refer to provisions of controlling law upon which the Petition is based, including I.C. § 67-5279 and Rule 203 of the Idaho Air Rules. *See* Petition ¶¶ 6–8, 69–70. Additionally, throughout the sections on "FACTUAL SUPPORT FOR THE PETITION," the Petition refers to Rule 203 of the Idaho Air Rules, other provisions of the Idaho Air Rules, and to the federal Clean Air Act and Clean Air Act Regulations when applicable for every set of issues raised in the Petition. *Id.* ¶¶ 30–32 (PM_{10} issues); 44–46, 48–49, 55–57 (arsenic issues); 58–59 (ambient air boundary issues); 66 (ambient monitoring issues). Furthermore, the "RELIEF REQUESTED" section of the Petition restates many of the controlling provisions of the Idaho Air Rules. *Id.* ¶¶ D–G. The Petition thus complies with the requirements of Rule 160.01.b to "[r]efer to the particular provisions of statute, rule, order or other controlling law upon which it is based." IDAPA 58.01.23.160.01.b.

Third, the Petition satisfies the requirement under Rule 160.01.c to "state the relief sought." The section of the Petition titled "RELIEF REQUESTED" does exactly that. *See* Petition ¶¶ 69–71, A–G. There, the Petition requests that the "Board set aside and remand the [Final Permit] and direct DEQ to correct the following errors prior to issuing any new or revised [Final Permit]." Petition ¶ 71. The Petition then states specifically what DEQ should be directed to do on remand to correct each alleged error. Petition ¶¶ A–C (stating relief to correct errors on

remand regarding PM_{10} and arsenic emissions from ore haul), D (stating relief to correct errors on remand regarding various plans and manuals), E (stating relief to correct errors on remand regarding arsenic averaging), F (stating relief to correct errors on remand regarding ambient air boundary monitoring), G (stating relief on remand to correct errors regarding environmental and economic impacts of arsenic control technology). The Petition is thus consistent with the requirement to "state the relief sought." IDAPA 58.01.23.160.01.d.

Finally, the Petition "states the basis" for each Petitioner's standing, satisfying Rule 160.01.d. *See* Petition ¶¶ 9–13 (Nez Perce Tribe), 14–16 (Idaho Conservation League), 17–19 (Save the South Fork Salmon).

In short, the Petition fully meets the pleading requirements of Rule 160 of DEQ's Contested Case Rules. Perpetua's Motion to Dismiss should therefore be denied.

III. THE PETITION SUFFICIENTLY PLEADS NUMEROUS BASES FOR REVIEWING DEQ'S ACTION IN ISSUING THE FINAL PERMIT.

Perpetua argues that the "Petition fails to plead a legal basis for remand of the Final Permit" and that it "never specifically identifies which provisions of the Final Permit are contrary to law." MTD at 6, 7. Perpetua similarly contends the Petition fails to fully state facts and identify statutes or rules under which DEQ erred, and it fails to sufficiently allege facts or law supporting a claim that DEQ's action was arbitrary, capricious, or an abuse of discretion. MTD at 23–24. Perpetua specifically criticizes the Petition for stating DEQ's action in issuing the permit contained various "flaws," "deficiencies," and "shortcomings," arguing that the Petition failed to use the words "unreasonable" or "clearly erroneous" instead and that this provides grounds for dismissal. *Id.*

Perpetua's contentions are patently wrong. As discussed further below, the Petition clearly identifies numerous errors DEQ made and connects those errors to specific provisions in

the Idaho Air Rules that, based on the facts alleged, were violated by DEQ's issuance of the Final Permit, or otherwise asserts that those errors were arbitrary, capricious, and an abuse of discretion in violation of the Idaho APA. Perpetua's Motion should therefore be denied.

A. DEQ Rules and the Idaho APA Provide for Review of Agency Actions Like This One.

Pursuant to I.C. § 39-107(5), IDAPA 58.01.23 (Contested Case Rules), and IDAPA 58.01.01 (Idaho Air Rules), the Board has jurisdiction over this contested case challenging DEQ's action issuing the Final Permit. IDAPA 58.01.23.002.02 provides that "[a]ny person aggrieved by an action or inaction of the Department may file a petition to initiate a contested case pursuant to Chapter 52, Title 67, Idaho Code." *See also* I.C. § 39-107(5). Under the Idaho APA, an agency action—such as DEQ's issuance of the Final Permit being challenged here—must be reversed if it is in violation of constitutional or statutory provisions, is in excess of statutory authority, is made on unlawful procedure, is not supported by substantial evidence on the record as a whole, or is arbitrary, capricious, or an abuse of discretion. I.C. § 67-5279(3). "If the agency action is not affirmed, it shall be set aside, in whole or in part, and remanded for further proceedings as necessary." *Id.*

The Petition clearly states that it is being brought pursuant to the above-referenced codes, and that Petitioners seek review of DEQ's issuance of the Final Permit under the Idaho APA, which provides for the relief Petitioners requested. Petition ¶¶ 6–8, 72.

The Board has considered similar challenges to this one and reached decisions on the merits in its precedential orders. *See*, *e.g.*, *In re: Permit Applicant Garnet Energy LLC*, Docket No. 0101-01-10 (challenged to air quality permit to construct); *Rickards v. Idaho Dep't of Health & Welfare*, Docket No. 0101-92-12 (same). *See also In re Section 401 Water Quality Certification for Relicensing of the C.J. Strike Hydroelectric Facility*, Docket No. 0102-01-06; *In*

re IDEQ Report - The Upper Snake Rock TMDL Modification, Docket No. 0102-05-02; *In re Section 401 Water Quality Certification, Wetland Fill and Boat Dock Along Lake Cascade*, Docket No. 0102-07-04. For example, in the precedential order from *In re Sunnyside Park Utilities*, Docket No. 0103-07-02, the Board explained:

> Under [IDAPA], the Board must determine whether DEQ has acted reasonably and in accordance with law. *See* I.C. §§ 67-5248(a) and 67-5279. These requirements provide parties subject to regulation with a reasoned explanation for agency action and furnish a basis for effective administrative and judicial review. For the reasons set forth below, the Board concludes that the record before us is inadequate to determine whether DEQ acted reasonably and in accordance with law in denying Sunnyside's permit application.

Id., Final Order at 10.

The Board has thus considered challenges to DEQ's decisions to issue permits to construct, such as is at issue in this case, and on the same or similar grounds as alleged here. Perpetua's argument that the Petition fails to articulate any legal basis for challenging the Final Permit is flatly wrong, and its Motion to Dismiss again must be denied.

B. The Petition Sufficiently Alleges Flaws, Deficiencies, and Shortcomings in DEQ's Action Entitling Petitioners to Relief.

Perpetua argues that the "flaws," "deficiencies," and "shortcomings" identified in the Petition are not grounds for relief, because Petitioners supposedly did not connect the dots clearly enough or use the right magic words to convey the precise legal violations associated with each flaw, deficiency, or shortcoming. *See* MTD at 23–24. To the contrary, the Petition sufficiently sets forth the alleged flaws, deficiencies, and shortcomings DEQ committed[3] and the alleged legal violations associated with each, and thus Perpetua's Motion should be denied.

[3] Perpetua also contends that the Petition "does not allege that Perpetua failed to demonstrate each of the elements of IDAPA 58.01.01.203," or "that the [Stibnite Gold Project] will violate any of the provisions" of the Idaho Air Rules. MTD at 8. The Petition does not challenge actions taken by Perpetua; it challenges DEQ's actions approving the Final Permit, and DEQ's actions must comply with applicable provisions of the Idaho Air Rules and the Idaho APA.

1. PM_{10}

At the outset, the Petition states: "An agency action, such as DEQ's issuance of the PTC being challenged here, may be reversed if it is in violation of constitutional or statutory provisions, is in excess of statutory authority, is made on unlawful procedure, or is arbitrary, capricious, or an abuse of discretion." Petition ¶ 7 (citing I.C. § 67-5279). In sections on PM_{10}, the Petition states that PM_{10} is a criteria pollutant for which National Ambient Air Quality Standards ("NAAQS") have been established. *Id.* ¶ 31. It then states in the PM_{10} section:

> DEQ is required to ensure that no [Final Permit] shall be granted for a new or modified stationary source unless the applicant shows to the satisfaction of DEQ that the source would not cause or significantly contribute to a violation of any NAAQS. IDAPA 58.01.01.203.02. To satisfy these requirements, DEQ must assess air impacts using maximum potential emissions as limited by either the capacity of the unit/operation or as limited by enforceable permit provisions. *See* IDAPA 58.01.01.006.88.

Id. ¶ 32. The Petition then states a couple paragraphs later: "DEQ's determination that the SGP will not cause or contribute to a violation of the PM_{10} NAAQS is flawed." *Id.* ¶ 35. Immediately after, the Petition alleges, flaw by flaw and in detail, four ways DEQ failed to include enforceable permit limitations and other ways the agency acted unreasonably or improperly in making its determination that the Stibnite Gold Project will not cause or contribute to an exceedance of the NAAQS. *See id.* ¶¶ 36-42.

These allegations are more than adequate to establish Petitioners' challenges relating to PM_{10} emissions—as Perpetua recognizes, since its MTD argues at length that DEQ's issuance of the Final Permit complied with all of the PM_{10} requirements discussed in the Petition. *See* MTD at 9–14. In truth, Perpetua's substantive arguments go to the merits of Petitioners' contested case and are not properly decided at the outset in a motion to dismiss. Perpetua's arguments can be properly decided by the Hearing Officer only by denying the Motion to Dismiss and by continuing with this contested case.

2. Arsenic

In its sections on arsenic, the Petition identifies arsenic as a Toxic Air Pollutant (TAP) regulated by DEQ, and properly alleges that DEQ is required to ensure that no permit to construct shall be granted for a new or modified stationary source unless DEQ determines emissions of TAPS from the constructed source would not injure or unreasonably affect human or animal life or vegetation as required by Section 161 of the Air Quality Rules. *See* Petition ¶¶ 42–57. The Petition states that Section 161 requires that "any contaminant which is by its nature toxic to human or animal life or vegetation shall not be emitted in such quantities or concentrations as to alone, or in combination with other contaminants, injure or unreasonably affect human or animal life or vegetation." *Id.* ¶ 44, citing IDAPA 58.01.01.161.

The next two paragraphs in the Petition cite other requirements of the Idaho Air Rules relevant to complying with TAPs regulations. *See* Petition ¶¶ 45–46 (describing and citing IDAPA 58.01.01.586, 006.125, 210.12, 006.88). Additional paragraphs then explain the related T-RACT process and its relevant requirements, again describing and citing the specific Idaho Air Rules at issue. *Id.* ¶¶ 48–49 (citing IDAPA 58.01.01.210.13–14). A couple paragraphs later, the Petition states: "DEQ's approval of Perpetua's T-RACT demonstration for arsenic, and its analysis determining the SGP will not exceed the AACC and thus will not injure or unreasonably affect human or animal life or vegetation, is flawed." *Id.* ¶ 52. The Petition then alleges, flaw by flaw and in detail, the ways DEQ failed to comply with the cited provisions of the Idaho Air Rules and otherwise acted arbitrarily and capriciously. *Id.* ¶¶ 53–57.

These allegations are more than sufficient to identify Petitioners' challenges regarding arsenic. Again, Perpetua might dispute on the merits whether these flaws occurred in the arsenic TAPs analysis and T-RACT approval, or whether they rise to the level of arbitrary and

capricious decision-making. In fact, much of Perpetua's brief is devoted to such arguments. *See* MTD at 14–20. But such disputes go to the merits of Petitioner's contested case and are not properly decided at the outset in a motion to dismiss.

3. Ambient Air Boundary

In the section on the ambient air boundary, the Petition cites to the provision of the Air Rules and EPA regulations explaining what counts as "ambient air", and to EPA policy on determining ambient air boundaries. Petition, ¶¶ 58–59. Then, after a paragraph describing the air boundary DEQ approved for the SGP, the Petition states: "DEQ's determination to exclude the access route from ambient air protections is flawed." *Id.*, ¶ 61. The Petition then explains, including by alleging in factual detail, the bases for why this determination was flawed under the previously cited rules, regulations, and policies. *Id.* ¶¶ 62–65.

These allegations are more than sufficient to put DEQ and Perpetua on notice of Petitioners' challenges related to the air boundary, and these challenges should not be dismissed.

4. Ambient Air Monitoring

In the section on ambient air monitoring, the Petition cites to the provision of the Air Rules granting DEQ authority to require ambient air monitoring. Petition, ¶ 66 (citing IDAPA 58.01.01.211.01(d). Then, identifying comments submitted to DEQ urging the agency to require ambient air monitoring, the Petition states that DEQ responded by saying monitoring was not necessary. *Id.* ¶ 67. The Petition then alleges, and explains how, DEQ was incorrect and why monitoring is necessary. *Id.* ¶ 68. These allegations—which must be accepted as true at this stage—are more than adequate to lay out Petitioners' challenges, and Perpetua's defense of the Final Permit regarding ambient air monitoring must be addressed on the merits, not through a motion to dismiss.

D. Perpetua's Reliance on the "To the Satisfaction of" DEQ Language of Section 203 of the Air Rules Is Misplaced.

Throughout its Motion, Perpetua wrongly implies that the "to the satisfaction of the Department" language in Section 203 of the Idaho Air Rules provides DEQ with unlimited discretion in applying the rules and approving permits, thus requiring dismissal of the Petition. *See*, *e.g.*, MTD at 10, 14, 17. Under Section 203, DEQ cannot issue a permit to construct unless it determines that the applicant has shown "to the satisfaction of the Department" that three conditions are satisfied: (1) the facility will comply with applicable emissions standards; (2) the facility not cause or contribute to an exceedance of the NAAQS; and (3) the emissions of toxic air pollutants from the stationary source or modification would not injure or unreasonably affect human or animal life or vegetation. IDAPA 58.01.01.203.

Contrary to Perpetua's incorrect reading, this "satisfaction" language does not render DEQ's determinations that these three conditions were met when it approved the Final Permit immune from challenge and review. DEQ's actions issuing the Final Permit are subject to review and shall be "set aside, in whole or in part, and remanded for further proceedings" if DEQ's decision to issue the Final Permit violated constitutional or statutory provisions, is in excess of statutory authority, was made on unlawful procedure, is not supported by substantial evidence on the record as a whole, or was arbitrary, capricious, or an abuse of discretion. I.C. § 67-5279(3).

As a matter of law, the Air Quality Rules cannot somehow limit or immunize a DEQ decision from challenge under the Idaho APA and the DEQ contested case regulations, as Perpetua seems to believe. Rather, the Idaho APA broadly provides that "[a] proceeding by an agency . . . which may result in the issuance of an order[ ] is a contested case and is governed by the provisions of" Title 67, Chapter 52 (Idaho Administrative Procedure Act) of the Idaho Code. *See* I.C. § 67-5240.

Review of agency action under the Idaho APA is limited or prohibited only if "provided by other provisions of law." I.C. § 67-5240. Perpetua has not cited any law that prohibits the review of DEQ's decision to approve a permit to construct under the Idaho Air Quality Rules under the provisions of the Idaho APA, and no such law exists to Petitioners knowledge. Proceedings in front of DEQ, such as contesting the approval of the Final Permit in this case, therefore are unequivocally subject to the Idaho APA.

DEQ's determination that it is "satisfied" the requirements would be met can obviously be arbitrary, capricious, an abuse of discretion, or contrary to law, just as any other agency determination or decision can be. For example, in determining whether a facility "would not cause or significantly contribute to a violation of any ambient air quality standard," as required by Idaho Air Rule 58.01.01.203.02, the fact that DEQ was "satisfied" there would be no such violation does not somehow exempt that aspect of the Final Permit immune from challenge and review to show that DEQ erred, either factually or legally.

Thus, whether DEQ acted in an arbitrary and capricious manner, abused its discretion, or violated legal requirements of Section 203 of the Air Rules when it issued the Final Permit is properly challenged by Petitioners, regardless of whether DEQ found "to its satisfaction" that the Section 203 requirements would be met. Petitioners are entitled to develop and present the full record, through contested case proceedings, for the Hearing Officer to fully evaluate their challenges, including whether DEQ was arbitrary and capricious in concluding it was "satisfied" all requirements in Section 203 were met.

IV. PETITIONERS' REQUESTED RELIEF IS PROPER.

Finally, Perpetua argues that Petitioners are not entitled to any of the relief requested in the Petition. *See* MTD at 22–23. This argument is wrong, and must be rejected.

Petitioners requested that the Final Permit be set aside and remanded for any of the flaws, deficiencies, or shortcomings identified in the Petition. *See* Petition ¶ 71 ("Petitioners respectfully request that the Board set aside and remand the PTC and direct DEQ to correct the following errors prior to issuing any new or revised PTC"). This is not only appropriate, but it is the very relief the Idaho APA requires for a successful challenge to an agency decision: "If the agency action is not affirmed, it shall be set aside, in whole or in part, and remanded for further proceedings as necessary." I.C. § 67-5279(3) (emphasis added). *See, e.g., In re Variance ZV2011-2*, 156 Idaho 491, 496 (Idaho 2014) (vacating and remanding arbitrary approval of subdivision); *In re Sunnyside Park Utilities*, Docket No. 0103-07-0, p. 11 (Apr. 7, 2009) (Final Order, stating: "Since we cannot determine that DEQ's reasoning and conclusion were rational, the permit denial must be set aside."). Upon prevailing on the merits of any of their claims, Petitioners will thus be entitled to have the Final Permit set aside and remanded.

Petitioners also request that DEQ be directed to take specific steps to rectify the various deficiencies in the Final Permit during remand. Again, I.C. § 67-5279(2) provides for remand "for further proceedings as necessary." *See, e.g., In re Variance ZV2011-2*, 156 Idaho at 496–97 (providing guidance to agency on remand); *In re Sunnyside Park Utilities*, Docket No. 0103-07-0, p. 12 (providing direction to DEQ for reviewing permit application on remand). DEQ has the duty or authority to take each action Petitioners have requested in order to issue a lawful permit. *See* IDAPA 58.01.01.202.03 (authorizing DEQ to obtain from permit applicant "[a]ny additional information, plans, specifications, evidence or documents the Department may require to make the determinations required under [the PTC sections of the Air Rules]"); IDAPA 58.01.01.211 (authorizing DEQ to "impose any reasonable conditions upon an approval" of a PTC); IDAPA 58.01.01.121 (authorizing DEQ to require schedules, reports, records, monitoring, and plans to

ensure compliance with Air Rules); IDAPA 58.01.01.122.03.g (authorizing DEQ to issue an information order to provide any "information the Department may require").

Perpetua might argue that such relief is not warranted under the specific circumstances of this case, but that is not a proper basis for dismissing the Petition at outset. After discovery, briefing, and hearing, the Hearing Office can decide these issues.

CONCLUSION

For the foregoing reasons, Petitioners respectfully request that Perpetua's Motion to Dismiss be denied. Alternatively, if the Hearing Officer finds any defects in the Petition that cannot be disregarded under Idaho Rule of Administrative Procedure 305, he should grant Petitioners leave to amend the Petition to correct such defects.

Dated: September 20, 2022

Respectfully submitted,

/s/ Bryan Hurlbutt

BEFORE THE BOARD OF ENVIRONMENTAL QUALITY
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047	)	
NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON, Petitioners, v.	)	Case Docket No. 0101-22-01
	)	PREHEARING ORDER
DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent,	)	
and	)	
PERPETUA RESOURCES IDAHO, INC., Intervenor.	)	

On September 21, 2022, a prehearing conference was held at the Department of Environmental Quality state office in Boise, Idaho, with the option of joining via Microsoft Teams. Bryan Hurlbutt and Laird Lucas appeared for Petitioners Nez Perce Tribe and Idaho Conservation League, and Julia Thrower appeared for Petitioner Save the South Fork Salmon. John Shackelford, Deputy Attorney General, appeared for Respondent. W. Christopher Pooser and Wade Foster appeared for Intervenor.

Pending before the hearing officer was Intervenor's Motion to Dismiss and Supporting Brief and the scheduling of proceedings related thereto. As discussed, the hearing officer previously participated in a contested case before the Board of Environmental Quality in which the standards

governing dispositive motions in contested air permit matters were at issue. That matter ultimately settled and did not result in the issuance of a precedential order. However, it is possible that the transcribed deliberations of Board members could have some relevance to this matter. Given the passage of time and out of an abundance of caution, prior to hearing and ruling on the Intervenor's Motion to Dismiss, the hearing officer would like to give the parties an opportunity to review those materials and express their opinions as to how those deliberations affect this matter, if at all.

Rule 003 of the Board's Contested Case Rules, IDAPA 58.01.23, adopt the Idaho Rules of Administrative Procedure of the Attorney General, IDAPA 04.11.01, to the extent they are not inconsistent with the Board's Rules. Rule 602 of the AG's rules provides in pertinent part that, "official notice may be taken of any facts that could be judicially noticed in the courts of Idaho…." If one were to substitute "agency" for "court" and "administrative" for "judicial," Idaho Rule of Evidence 201 would read in pertinent part:

> The [agency] may [administratively] notice a fact that is not subject to reasonable dispute because it: (1) is generally known within the [agency's] territorial jurisdiction; or (2) can be accurately and readily determined from sources whose accuracy cannot reasonably be questioned.
>
> ***
>
> The [agency]: (1) may take [administrative] notice on its own….
>
> ***
>
> When a[n] [agency] takes [administrative] notice of records, exhibits, or transcripts from the [agency] file in the same or a separate case, the [agency] must identify the specific documents or items so noticed.

Upon discussion with the parties, and based upon the foregoing, IT IS HEREBY ORDERED that administrative notice is taken of the following documents, all of which are from the Board's Docket No. 0101-14-01, which the parties may access at https://cloud.deq.idaho.gov/s/c5f5SZLBR87nxJE :

1. Motion to Dismiss or in the Alternative Motion for Summary Judgment, Idaho Dept. of Environmental Quality, June 18, 2014;

2. Memorandum in Support of Motion to Dismiss or in the Alternative Motion for Summary Judgment, Idaho Dept. of Environmental Quality, June 18, 2014;

3. Magnida's Motion to Dismiss, Magnolia Nitrogen Idaho LLC, June 25, 2014;

4. Interlocutory Order Denying Intervenor's Motion to Dismiss, Presiding Officer Michael J. Kane, August 8, 2014;

5. Recommended Order Granting Motion for Summary Judgment, Presiding Officer Michael J. Kane, September 15, 2014;

6. Reporter's Transcript of Proceedings before the Board of November 20, 2014; and

7. Reporter's Transcript of Proceedings before the Board of December 4, 2014.

Further, upon service of this Order, Hearing Coordinator Paula Wilson will coordinate with the parties to schedule a virtual status conference to discuss whether any further briefing on the Motion to Dismiss is warranted, the scheduling of a hearing on the Motion to Dismiss, and any other procedural issues the parties would like to discuss.

Dated this 23rd day of September, 2022.

BEFORE THE BOARD OF ENVIRONMENTAL QUALITY
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047	)	
NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON,	)	Case Docket No. 0101-22-01
Petitioners,	)	ORDER ON STATUS CONFERENCE; NOTICE OF STATUS CONFERENCE
v.	)	
DEPARTMENT OF ENVIRONMENTAL QUALITY,	)	
Respondent,	)	
and	)	
PERPETUA RESOURCES IDAHO, INC.,	)	
Intervenor.	)	

On October 11, 2022, a status conference was held virtually via Microsoft Teams. Bryan Hurlbutt and Laird Lucas appeared for Petitioners Nez Perce Tribe and Idaho Conservation League, and Julia Thrower appeared for Petitioner Save the South Fork Salmon. John Shackelford, Deputy Attorney General, appeared for Respondent. W. Christopher Pooser and Wade Foster appeared for Intervenor. The parties and hearing officer discussed the following matters:

Motion to Dismiss: Perpetua Resources filed a combined motion to dismiss the petition in this matter and supporting legal brief on September 6, 2022. The Petitioners filed a brief in opposition to that motion on September 20, 2022. The hearing officer issued an order taking official

notice of filings and hearing transcripts from a prior Board of Environmental Quality (BEQ) matter on September 23, 2022. At the status conference, the parties and hearing officer agreed that as long as the hearing officer accepts the Petition's factual allegations as true and confines his consideration of factual issues to the "four corners" of the pleadings, those officially noticed documents are of limited relevance to the pending motion to dismiss. Therefore, additional briefing referencing the noticed documents is not necessary.

In addition, Perpetua Resources stated it does not request to file a reply brief or hold oral argument on its motion pursuant to BEQ Rule of Procedure 162.02. Therefore, Perpetua's motion to dismiss has been fully submitted for decision by the hearing officer.

Scheduling Order: The parties agreed to coordinate among themselves regarding a potential stipulated scheduling order to present to the hearing officer. The parties may wish to consider the following items in connection with this effort:

The number of days needed for a hearing on the merits. Ideally, the parties would also present at least three sets of dates that are mutually agreeable to the parties for the hearing officer's consideration and to confirm facility availability at DEQ's offices.

Whether the hearing on the merits will include direct testimony or, alternatively, whether written direct testimony will be provided in advance of the hearing on the merits, in which case deadlines for the filing of written direct testimony and objections thereto should also be considered.

Potential dates for a final pre-hearing conference to discuss procedural issues related to the hearing on the merits and the resolution of any remaining pre-trial motions, objections, or other filings.

Deadlines for final witness and exhibit lists and the filing of any pre-hearing briefs.

Deadlines for the filing of additional dispositive motions, motions in limine, and other pre-

hearing motions.

Deadlines for the filing of expert reports.

Dates for the opening and completion of written discovery and depositions.

Office of Administrative Hearings: During the initial September 21 prehearing conference, the parties and hearing officer acknowledged the possibility that the newly-formed Office of Administrative Hearings (OAH) could impact this proceeding. At the time, the parties and hearing officer generally agreed to continue with this proceeding under existing, applicable procedural rules until they receive formal notice from the BEQ of any changes to the proceeding. However, at the October 11 status conference, counsel for DEQ brought to the attention of the parties and hearing officer the specific language of newly enacted Idaho Code Section 67-5286.

In particular, subsection (1) of that statute suggests that if a hearing on the merits is not scheduled to be completed before January 1, 2023, the hearing is to be conducted by OAH. The parties and hearing officer agreed that it is infeasible to complete a hearing on the merits in this matter by that time, and also that the transition of this matter to OAH could result in substantial delay directly impacting any scheduling order. Based on that, the hearing officer committed to coordinate with BEQ staff to find out any additional information regarding this issue.

Establishing Administrative Record for Hearing: The parties and hearing officer also discussed in general terms potential approaches to establishing a written record of documents for the parties, hearing officer, and BEQ to refer to during the course of these proceedings. The BEQ Rules of Procedure do not contain a specific rule regarding the compilation of an agency record. Historically, such records were created through the discovery process, though that does not appear to be the parties' first choice here.

While not specifically discussed during the status conference, the hearing officer notes that

BEQ has recently amended its Rules of Procedure to incorporate some of the AG's Rule of Procedure, specifically including Rule 650, which enumerates items that "shall" be included in the agency record. *See* BEQ RULE OF PROCEDURE 003.15; AG RULE OF PROCEDURE 650.02. While Rule 650.02 may be somewhat helpful, it does not appear to specifically resolve the issue of how to select specific documents out of a voluminous DEQ permitting record that likely contains several hundreds of pages of documents not relevant to the Petition in this matter. AG Rule of Procedure 650.02(h) mandates that the record for a contested case include "[a]ll staff memoranda or data submitted in connection with the consideration of the proceeding." Perhaps one approach would be for DEQ to issue a staff memorandum with the documents it believes are relevant, and then the other parties could use discovery and motion practice to supplement the record as necessary. This seems consistent with the discussions at the October 11 status conference. In any event, the parties agreed to further evaluate this issue for discussion at the next status conference.

Based on the foregoing, NOTICE IS HEREBY GIVEN that the hearing officer will hold a follow-up status conference on Thursday, October 27, 2022, at 9:30 a.m. MDT via Microsoft Teams. Due to difficulties accessing the Microsoft Teams link for the October 11 status conference, the hearing coordinator is sending an electronic calendar appointment to the participants, a hard copy of which is attached hereto. During the status conference, the hearing officer intends to 1) update the parties regarding issues related to the OAH; 2) inquire with the parties regarding efforts to coordinate regarding a stipulated scheduling order and/or administrative record; and 3) discuss any additional issues the parties wish to discuss.

Dated this 14th day of October, 2022.

BEFORE THE BOARD OF ENVIRONMENTAL QUALITY
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047	)	
NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON, Petitioners, v.	)	Case Docket No. 0101-22-01
	)	ORDER ON STATUS CONFERENCE; NOTICE OF STATUS CONFERENCE
DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent, and PERPETUA RESOURCES IDAHO, INC., Intervenor.	)	

On October 27, 2022, a status conference was held virtually via Microsoft Teams. Bryan Hurlbutt and Laird Lucas appeared for Petitioners Nez Perce Tribe and Idaho Conservation League, and Julia Thrower appeared for Petitioner Save the South Fork Salmon. John Shackelford, Deputy Attorney General, appeared for Respondent. Krista McIntyre, W. Christopher Pooser, and Wade Foster appeared for Intervenor. The parties and hearing officer discussed the following matters:

Office of Administrative Hearings (OAH): Based upon recently adopted Idaho Code Section 67-5286 and recent discussions with Board representatives, the hearing officer reported his understandings to the parties as follows:

1) If the hearing-on-the-merits in this proceeding has not been scheduled to commence prior to January 1, 2023, OAH intends to assume responsibility for this proceeding from the Board and hearing officer.

2) OAH plans to contact Board representatives on or about December 1, 2022, to inquire regarding the status of the proceeding and a potential transition plan.

3) The hearing officer may apply to OAH by December 15, 2022, to be re-appointed as the hearing officer in this matter.

Motion to dismiss: The hearing officer reported that he still intends to issue a decision on Perpetua's motion to dismiss in mid-November.

Scheduling order: Perpetua reported that it has developed a proposed framework for a scheduling order in this matter, which can be completed and circulated for consideration once a decision is issued on the motion to dismiss.

Administrative record: The parties reported that DEQ has made its project file available to the other parties, which will be helpful in finalizing an administrative record once a decision on the motion to dismiss has been issued.

Status conference: Based on the above, the parties and hearing officer agreed to schedule the next status conference in this proceeding for mid- to late-November.

Therefore, based on the foregoing, NOTICE IS HEREBY GIVEN that the hearing officer and parties will hold a follow-up status conference on Monday, November 28, 2022, at 2:00 p.m. mountain time, via Microsoft Teams. At the status conference, the participants will discuss the status of, and any updates to, the above matters. The hearing coordinator has sent an electronic calendar appointment to the participants, a hard copy of which is attached hereto.

Dated this 28th day of October, 2022.

NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON, Petitioners, v.	)	Case Docket No. 0101-22-01
	)	ORDER ON MOTION TO DISMISS
DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent,	)	
and	)	
PERPETUA RESOURCES IDAHO, INC., Intervenor.	)	

I. FACTUAL AND PROCEDURAL HISTORY

Perpetua Resources Idaho, Inc. is in the process of applying for a variety of permits for its proposed Stibnite Gold Project ("SGP") in Valley County, Idaho. The SGP would consist of conventional open-pit mining, ore preparation, and gold extraction operations. In August 2019, Perpetua applied to the Idaho Department of Environmental Quality ("DEQ") for an air quality permit for the construction and operation of the SGP, pursuant to the Rules for the Control of Air Pollution in Idaho in IDAPA 58.01.01 (the "Air Rules"). DEQ issued the final version of air quality permit-to-construct P-2019.0047 (the "Permit") on June 17, 2022.

On July 22, 2022, the Nez Perce Tribe, Idaho Conservation League, and Save the South Fork Salmon ("Petitioners") filed a joint petition to initiate a contested case (the "Petition") regarding the Permit. The Petition alleges that DEQ committed several errors in its development of the Permit and requests that the Board of Environmental Quality ("Board" or "BEQ") vacate and withdraw the Permit and remand it to DEQ to correct such errors.

DEQ filed its response to the Petition on August 12, 2022, denying that its development of the Permit was in error and requesting that the Board affirm the Permit. DEQ's response consists primarily of general admissions or denials. For denied allegations, the DEQ response contains virtually no explanation or elaboration. That same day, Perpetua filed a petition to intervene in the contested case proceeding pursuant to Rule 353.01 of the Board's Contested Case Rules in IDAPA 58.01.23 (the "BEQ Procedural Rules"), which the hearing officer granted on August 22, 2022.

On September 6, 2022, Perpetua filed a motion to dismiss the Petition in its entirety and a supporting legal brief (collectively, the "Motion"). DEQ filed a notice of joinder in the Motion on September 12, 2022, without further explanation. At a status conference held October 11, 2022, Perpetua waived filing a reply brief and holding oral argument on its Motion pursuant to BEQ Procedure Rule 162.02. Therefore, the Motion has been fully submitted for decision.

II. RELEVANT LEGAL STANDARDS

A. Standards on Motion to Dismiss

The BEQ Procedural Rules specifically contemplate motions to dismiss but do not articulate applicable standards. *See* BEQ PROCEDURAL RULE 161.02. The Board has typically applied the standards for such motions in judicial proceedings under Idaho Rule of Civil Procedure 12(b)(6).

"In reviewing an I.R.C.P. 12(b)(6) motion to dismiss for failure to state a claim upon which relief must be granted, the question is whether the non-movant has alleged sufficient facts in support

of his claim, which if true, would entitle him to relief." *Canyon County v. Idaho Dept. of Envr. Quality*, FINAL ORDER ON REVIEW OF RECOMMENDED ORDER, at p. 14 (BEQ Dkt. No. 0101-11-02, Dec. 28, 2011) (*citing Orrock v. Appleton*, 147 Idaho 613, 618, 213 P.3d 398, 403 (2009)). As Perpetua acknowledges, "[t]he issue [on a motion to dismiss] is not whether the plaintiff will ultimately prevail, but whether the party is entitled to offer evidence to support the claims." (Mot., p. 6 (*quoting Orthman v. Idaho Power Co*., 126 Idaho 960, 962, 895 P.2d 561, 563 (1995)).

In *Freeman v. Idaho Dept. of Envr. Quality*, the petitioner argued his vehicle was exempt from DEQ's emissions testing program. FINAL ORDER ON REVIEW OF AMENDED ORDER, at pp. 9-10 (BEQ Dkt. No. 0101-11-04, Apr. 11, 2012). However, the relevant statute and rule did not provide DEQ with authority to exempt his vehicle. *Id*. In essence, he was asking DEQ to do something it was not authorized to do. Even assuming all factual allegations to be true, there was no legal avenue available to obtain the requested relief. Therefore, granting a motion to dismiss was appropriate. *Id*.

While it may be necessary to consult applicable law to determine if a valid claim exists, when evaluating the sufficiency of the factual allegations, "[a] 12(b)(6) motion looks only at the pleadings to determine whether a claim for relief has been stated." *Thatcher v. Idaho Dept. of Envr. Quality*, AMENDED ORDER ON IDAHO DEPT. OF ENVR. QUALITY'S MOT. TO DISMISS at pp. 3-4 (BEQ Dkt. No. 0105-19-01; Sept. 24, 2019) (*citing Young v. City of Ketchum*, 137 Idaho 102, 104, 44 P.3d 1157, 1159 (2002)). And, when reviewing the pleadings, one must "draw[] all inferences in the non-moving party's favor" and grant the motion to dismiss only if "it appears beyond doubt that the [plaintiff] could prove no set of facts in support of his claim which would entitle him to relief." *Orthman*, 126 Idaho at 962, 895 P.2d at 562 (citations omitted).

Perpetua asserts that, "[w]hen deciding a motion to dismiss under I.R.C.P. 12(b)(6), a court, or the Board, may consider documents incorporated by reference in a pleading without converting

the motion to a motion for summary judgment. (Mot., p. 6 (citations omitted)). However, in both of the cited cases, the Idaho Supreme Court held the district court erred by considering matters outside the pleadings. Also, at the October 11 status conference, the parties and hearing officer agreed he would confine his consideration of factual matters to the "four corners" of the pleadings. (*See generally* Order of 10/14/22, p. 2).

Clearly, reference to the Permit itself is necessary to resolve the Motion; to not consider the relevant provisions in the Permit would be akin to ignoring the relevant agreement in a breach of contract case. However, on several occasions, Perpetua argues for dismissal of claims based upon DEQ's Statement of Basis ("SOB"). The hearing officer finds justifications documented in the SOB to be outside the scope of the pleadings. Consideration of the SOB may be appropriate on a motion for summary judgment, but not on a motion to dismiss.

B. Standards Applicable to Pleadings

Perpetua argues the BEQ Rules of Procedure contain "heightened" pleading standards. (Mot., pp. 5, 8, 24-25). Perpetua further argues Petitioners' use of terms such as "flawed," "deficient," and "shortcomings," instead of the specific language of Idaho Code Section 67-5279, fails to meet these "heightened" pleading standards, and that "the Petition is wholly efficient and must be dismissed." (Mot., pp. 23-24). Therefore, a brief discussion of the standards appliable to pleadings in BEQ proceedings is warranted.

For civil judicial actions, the Idaho Rules of Civil Procedure contain a "relaxed notice pleading standard" that simply requires that the "adverse party is put on notice of the claims brought against it." *Raymond v. Idaho State Police*, 165 Idaho 682, 689, 451 P.3d 17, 24 (Idaho 2019). By contrast, BEQ Procedural Rule 160.01 requires the Petition to "[f]ully state the facts upon which it is based, including the specific alleged action or inaction of the Department," and to "[r]efer to the

particular provisions of statute, rule, order or other controlling law upon which it is based," including "citations of cases and statutory provisions." Therefore, as a general matter, the hearing officer agrees with Perpetua that, when compared to the Idaho Rules of Civil Procedure, the BEQ Procedural Rules contain a "heightened" pleading standard.

However, satisfying the pleading standards in a judicial action is a low threshold to meet. Also, BEQ Procedural Rule 003.01 adopts AG Procedural Rule 052, which states that the procedural rules "will be ***liberally construed*** to secure just, speedy and economical determination of ***all issues presented to the agency***." Similarly, BEQ Procedural Rule 003.05 adopts AG Procedural Rule 305, which states that "[p]leadings will be liberally construed…." Focusing only on the pleading standard in BEQ Procedural Rule 160.01 to the exclusion of AG Procedural Rules 052 and 350 would render BEQ Procedural Rule 003 a nullity—a result to be avoided. *See generally Hillside Landscape Constr., Inc. v. City of Lewiston*, 151 Idaho 749, 753, 264 P.3d 388, 392 (Idaho 2011) ("[i]n determining the ordinary meaning of a statute 'effect must be given to all the words of the statute if possible, so that none will be void, superfluous, or redundant'").

C. Idaho APA Judicial Standards of Review

Perpetua's Motion invokes Idaho Code Section 67-5279 multiple times. (*See* Mot., pp. 4, 7, 24). That statute contains the standards of review that apply when a petition for judicial review of an agency decision has been filed pursuant to the Idaho Administrative Procedure Act, Idaho Code Sections 67-5201 – 67-5292 (the "APA"). After the Board has rendered a final decision in this matter, if one or more of the parties appeals to the judicial system, Section 67-5279 contains the standards that govern the court's evaluation of the Board's decision.

Even though those standards are not directly applicable to the Motion, it is still important to understand the standards that will ultimately govern judicial review of the Board's decision. As the

Board itself has recognized, in a contested case proceeding, "the Board must determine whether DEQ has acted reasonably and in accordance with law." *In the Matter of Sunnyside Park Utilities' Application for Sewage Disposal Permit*, Final Order on Petition for Review of Preliminary Order, at p. 10 (BEQ Dkt. 0103-07-02, Apr. 7, 2009).[1]

Pursuant to DEQ Procedural Rule 003.18 and AG Procedural Rule 740, the Board will render a decision in this matter by issuing a final order. Therefore, subsection (3) of Section 67-5279 would apply to judicial review, and the court would affirm the Board's decision unless it finds:

- DEQ or the Board acted in violation of constitutional or statutory provisions;
- DEQ or the Board acted in excess of their statutory authority;
- DEQ's approval of the Permit or the Board's decision were made upon unlawful procedure;
- The Board's decision was not supported by substantial evidence on the record as a whole; or
- DEQ or the Board otherwise acted in a manner that qualifies as arbitrary, capricious, or an abuse of discretion.

IDAHO CODE § 67-5279(3)

The Petition does not raise constitutional questions or assert DEQ followed an unlawful procedure in issuing the Permit. In addition, the record for judicial appeal has not yet been created; that is the purpose of the contested case hearing process. Taking into consideration the standards governing pleadings, the standards governing motions to dismiss, and the standards that will govern

[1] The hearing officer is aware that Board members have previously expressed concern regarding application of Section 67-5279 standards too early in an administrative hearing process. (*See generally* Order of 9/23/22, *taking administrative notice of* Tr. of 12/4/14, 47:5-9 (BEQ Dkt. No. 0101-14-01)). To be clear, the hearing officer is not applying those standards directly here in ruling on Perpetua's Motion. The phrase "motion to dismiss" is shorthand for a "motion to dismiss [a petition] for failure to state a claim upon which relief must [or could] be granted." It is practically impossible to apply this standard without an understanding of the "relief" that is possible and how it could be obtained. Section 67-5279 is the ultimate basis for any such "relief." That is why its standards are relevant generally, even though they are not being applied

judicial review, the following questions govern review of the Petition and the pending Motion:

- Taking all of the factual allegations in the Petition as true, could the Petitioners demonstrate that DEQ violated a statute when it issued the Permit?
- Taking all of the factual allegations in the Petition as true, even if DEQ did not overtly violate a statute, could the Petitioners demonstrate that DEQ exceeded the scope of its statutory authority when it issued the permit?
- Taking all of the factual allegations in the Petition as true, even if DEQ did not overtly violate a statute or exceed its statutory authority, could the Petitioners demonstrate that DEQ took some action that could be described as "arbitrary" or "capricious" when it issued the Permit?
- Taking all of the factual allegations in the Petition as true, if DEQ has been provided with discretion regarding the development of a particular Permit provision, could the Petitioners demonstrate that DEQ abused that discretion?

III. ANALYSIS

A. The Petition Overall

As previously referenced, Perpetua's Motion asserts the entire Petition should be dismissed for failure to satisfy the "heightened" pleading standard of BEQ Procedural Rule 160.01. (*See* Mot., pp. 2, 23-24). The Motion further asserts "the Petition is informally presented in the style of a legal brief, intermingling alleged facts, arguments, opinions, suggestions for permit content, and conclusory statements," and that it "contains no 'short and plain statement of the claim showing that the pleader is entitled to relief.'" (Mot., p. 7; *see also* DEQ Resp. of 8/12/22, p. 2).

Again, the "heightened" pleading standard of Rule 160.01 requires the Petition to "[f]ully state the facts" and to "[r]efer to the particular provisions of….controlling law." The Petition contains detailed factual allegations and several references to Idaho Code, IDAPA provisions, and the Code of Federal Regulations. Also relevant is the relatively short 35-day deadline to file the Petition, *see* BEQ PROCEDURAL RULE 060, a document to be "liberally construed."

Under these circumstances, dismissing the Petition outright would impose a pleading

---

specifically to the Motion.

standard nearly impossible to satisfy. Despite Perpetua's criticism of the format of the Petition, in a typical civil judicial action, a plaintiff asserts discrete, well-known causes of action, such as "breach of contract," "trespass," and "negligence." An administrative proceeding challenging an air quality permit does not necessarily lend itself to this pleading style. Taken as a whole, the Petition is adequately pled, and the hearing officer declines to dismiss the Petition in its entirety. Instead, given the pleading requirements of BEQ Procedural Rule 160.01, the hearing officer believes it is appropriate to evaluate the Petition and the Motion on a claim-by-claim basis.

B. Summary of Claims Asserted in Petition

As previously discussed, an administrative proceeding involving air quality permitting does not involve discrete, recognized causes of action. Before discussing whether particular claims should be dismissed, it is necessary to identify the individual alleged errors. The Petition is 26 pages long, with more than 70 separately numbered allegations, many of which are long and detailed. The sooner the Petition is reduced to discrete, identifiable claims, the better.

The hearing officer believes the following table fairly summarizes the individual errors alleged in the Petition:

Claim No.	Petition ¶ No.	Pollutant/Source/Issue	Summary of Alleged Error
1	36-37	PM_{10} from haul trucks/road	Variables relied upon not adopted as enforceable limitations; instead, relied on plans that have not yet been developed
2	38	PM_{10} from haul trucks/road	Assumed control of 93.3% of emissions without related enforceable limitations
3	40	PM_{10} from haul trucks/road	Based monitoring and recordkeeping requirements on O&M Plan not yet developed
4	40	PM_{10} from haul trucks/road	Permit does not include adequate monitoring, recordkeeping, and reporting requirements
5	41	PM_{10} from haul trucks/road	Assumed 120 days of recordable precipitation rather than using local weather data
6	53	Arsenic from various sources	T-RACT demonstration did not contain persuasive economic information re suppressants vs. paving

Claim No.	Petition ¶ No.	Pollutant/Source/Issue	Summary of Alleged Error
7	53	Arsenic from various sources	T-RACT demonstration did not evaluate environmental impacts
8	54	Arsenic from various sources	Estimated As emissions based on PM_{10} emissions, so same flawed assumptions above apply
9	55-56	Arsenic from various sources	Multi-year averaging of arsenic emissions not authorized by Air Rules
10	57	Arsenic from various sources	Impacts on future permitting actions
11	62	Ambient air boundary	Insufficient legal authority to exclude general public
12	65	Ambient air boundary	Whether Permit effectively precludes access by general public
13	68	Ambient air monitoring	Lack of ambient air monitoring makes it impossible to assess compliance

C. Alleged Errors Related to PM_{10} Emissions From Haul Trucks and Roads

For all of the allegations in the Petition related to PM_{10} emissions from haul trucks and roads, Perpetua's Motion argues:

> While Petitioners dislike the Final Permit and question the Department's analyses of NAAQS compliance, none of the opinions presented in the Petition state a claim that the Department ***violated the Idaho Air Rules or the CAA*** in issuing the Final Permit. Petitioners also do not satisfy their burden to allege any omission from the Final Permit ***that is required by law***.

(Mot., pp. 13-14 (emphasis added)).

As previously discussed, the Petitioners could ultimately obtain relief by demonstrating that DEQ (1) violated a statute, (2) exceeded its statutory authority, (3) took action that could be characterized as "arbitrary" or "capricious," or (4) abused its discretion.

1. Claim No. 1: Reliance on Variables Not Adopted as Enforceable Conditions

The Petition asserts error occurred because "important variables affecting the quantity of PM_{10} generated by the ore haul trucks are not directly limited and enforceable as PTC permit conditions." (Pet., ¶ 36). More specifically, even though Perpetua used multiple "[c]ritical

variables…as inputs to PM emission calculations," the Petition argues DEQ erred by "rel[ying] on a surrogate limit in the PTC," "[i]nstead of developing PTC conditions for these other critical variables." (Pet., ¶¶ 36-37). According to the Petition, the three "critical variables" lacking relevant Permit conditions are the average empty weight of ore haul trucks, the average loaded weight of ore haul trucks, and the total number of vehicle miles traveled by ore haul trucks.[2] (*See* Pet., ¶ 36).

As Perpetua's Motion notes, it does not appear the Petition asserts DEQ's decision not to adopt certain variables as enforceable permit conditions constitutes a statutory violation or an exceedance of statutory authority. However, Perpetua has not cited to legal authority precluding DEQ from adopting such enforceable conditions, either. To the contrary, Perpetua acknowledges "the Idaho Air Rules provide [DEQ] with discretion to impose 'any reasonable conditions upon an approval [of a permit to construct].'" (Mot., p. 11 (*citing* AIR RULE 211.01)).

If DEQ had discretion to adopt certain variables as enforceable permit conditions and declined to do so, it is possible for Petitioners to demonstrate DEQ abused that discretion. Therefore, Perpetua's Motion as to Claim No. 1 is hereby denied. However, due to the heightened pleading requirements of Procedural Rule 160.01, the Petitioners will be limited to the three variables specifically raised in the Petition: the average empty weight of ore haul trucks, the average loaded weight of ore haul trucks, and the total number of vehicle miles traveled by ore haul trucks.

2. Claim No. 2: Assumption of 93.3% Emissions Control

The Petition asserts error occurred because "DEQ assumed 93.3% of all haul road PM_{10} emissions from the SGP can be controlled by using an unspecified combination, volume, and frequency of water sprays and chemical dust suppressants" without also including "specific and enforceable permit conditions within the PT to ensure a 93.3% control efficiency." (Pet., ¶¶ 38-39).

[2] The Petition acknowledges that an enforceable Permit condition was included for silt content of

According to the Petition, "[a] lesser control efficiency, even just slightly lesser, could result in large enough PM_{10} emissions to violate the NAAQS." (Pet., ¶ 39).

Perpetua's arguments as to this claim are essentially identical as they are for Claim No. 1. (*See* Mot., pp. 10-11). If DEQ had discretion to include permit conditions that would help ensure a 93.3% control efficiency, it is possible for Petitioners to demonstrate DEQ abused that discretion by declining to do so. Therefore, Perpetua's Motion as to Claim No. 2 is denied.

3. Claim No. 3: Basing Monitoring and Recordkeeping Requirements on Undeveloped O&M Plan

Section 3.5 of the Permit contains daily limits on the amount of ore and development rock Perpetua may haul, expressed in tons per day. In order to help ensure compliance with these daily weight limits, Section 3.16 of the Permit provides:

> Each day, the permittee shall monitor and record the amount of ore and DR [development rock] transported on haul trucks (T/day). ***The devices and methodologies used to measure weights shall be identified in the O&M [Operation and Maintenance] Manual***.

(Mot., Ex. A, p. 20 (emphasis added)).

Section 2.20 of the Permit governs development of the O&M Manual. It states:

> Thirty days prior to startup of any process equipment (Permit Condition 2.13), the permittee shall develop and maintain an Operation and Maintenance (O&M) manual to ensure compliance with emission limits (Permit Conditions 2.9, 2.13, 4.3, and 5.3) and the control equipment maintenance and operation general provisions (Permit Condition 7.2). The O&M manual shall be a permittee-developed document based upon, but independent from, manufacturer-supplied operating manuals. The permittee shall operate control equipment in accordance with the O&M manual at all times. The requirements in the O&M manual shall be incorporated by reference to this permit and shall be enforceable permit conditions.

(Mot., Ex. A, p. 12).

---

haul roads.

Section 2.20 then proceeds to enumerate a full page-and-a-half of very detailed requirements that the O&M Manual must satisfy, followed by requirements in Section 2.21 for the O&M Manual to be submitted to DEQ at least 30 days prior to startup and to obtain DEQ approval prior to changing the Manual. (Mot., Ex. A, pp. 12-14).

The Petition alleges error occurred because "DEQ relied on monitoring and record keeping (permit condition 3.16) using ***devices and methodologies*** in the [O&M Manual]" even though "the O&M Manual has not yet been developed." (Pet., ¶ 40 (emphasis added)). The Petition is ***not*** challenging the numeric daily hauling limitations adopted in Section 3.5 of the Permit. Instead, it alleges DEQ erred by allowing Perpetua to identify the "devices and methodologies" for weighing haulage in a plan that has not yet been developed.

The Petition does not cite any specific legal provision that has arguably been violated, and it does otherwise articulate how identification of the "devices and methodologies" for weighing haulage later might qualify as arbitrary, capricious, or an abuse of discretion. The closest the Petitioners get to addressing this allegation in their response brief is to cite authorities in the Air Rules authorizing DEQ to require "plans" as a general matter. (*See* Resp. Br. of 9/20/22, pp. 15-16 (citing Air Rules 121, 122.03(g), 202.03, 211)).

Even though AG Procedural Rule 052 requires the rules of procedure to be "liberally construed," DEQ Procedural Rule 160.01 must be given ***some*** effect. The hearing officer finds this allegation of error does not satisfy the requirements in Rule 160.01 to "[f]ully state the facts" and to "[r]efer to the particular provisions of statute, rule, order or other controlling law…." Therefore, as to Claim No. 3, Perpetua's Motion is granted, and Claim No. 3 is dismissed.

4. Claim No. 4: The Permit Does Not Contain Monitoring, Recordkeeping, and Reporting Requirements Necessary to Assure Compliance

The Permit contains several monitoring and recordkeeping requirements. Generally applicable requirements to the SGP appear in Section 7.10, which states:

> The permittee shall maintain sufficient records to ensure compliance with all of the terms and conditions of this permit. Monitoring records shall include, but not be limited to, the following: (a) the date, place, and times of sampling or measurements; (b) the date analyses were performed; (c) the company or entity that performed the analyses; (d) the analytical techniques or methods used; (e) the results of such analyses; and (f) the operating conditions existing at the time of sampling or measurement. All monitoring records and support information shall be retained for a period of at least five years from the date of the monitoring sample, measurement, report, or application. Supporting information includes, but is not limited to, all calibration and maintenance records, all original strip-chart recordings for continuous monitoring instrumentation, and copies of all reports required by this permit. All records required to be maintained by this permit shall be made available in either hard copy or electronic format to DEQ representatives upon request.

(Mot., Ex. A, p. 40).

The same "General Provisions" portion of the Permit contains multiple reporting requirements. (*See* Mot., Ex. A, pp. 41-42 (§§ 7.11, 7.12, 7.13, 7.14)). In addition, the portion of the Permit applicable to fugitive dust contains several monitoring and recordkeeping requirements. (*See* Mot., Ex. A, pp. 8 (§ 2.2), 11 (§ 2.10), 12-14 (§ 2.20)). Moreover, the Permit incorporates several portions of the Code of Federal Regulations, including 40 C.F.R. Part 60, Subpart A (General Provisions), which includes requirements related to recordkeeping (40 C.F.R. § 60.7), monitoring (40 C.F.R. § 60.13), and reporting (40 C.F.R. § 60.19). (*See* Mot., Ex. A, p. 14, § 2.22)).

The Petition alleges "the PTC itself does not include all monitoring, recordkeeping, and reporting necessary to assure compliance…." (Pet., ¶ 40). Neither the Petition nor the Petitioners' response brief further elaborate on this allegation.

Because the Permit contains detailed monitoring, recordkeeping, and reporting requirements, the Petition should have explained how those requirements could be inadequate. The hearing officer finds this alleged error does not satisfy the pleading standards in BEQ Procedural Rule 160.01. Stated in terms of the standards governing a motion to dismiss, even assuming these factual allegations to be true, they are too conclusory to benefit from that standard. Without more than a bald allegation of inadequacy, the Petitioners could not obtain relief on this issue. Therefore, as to Claim No. 4, Perpetua's Motion is granted, and Claim No. 4 is dismissed.

5. Claim No. 5: Assumption of 120 Days of Recordable Precipitation Without Using Local Weather Data

The Petition alleges that (1) "[d]ays of recordable precipitation is an important variable affecting the SGP's emissions of PM_{10} from ore haul roads;" (2) "DEQ assumed there would be 120 days of recordable precipitation at the SGP" based on "general geographic guidance" instead of "local meteorological data;" and (3) "DEQ's failure to use the most representative site data…increases the risk of miscalculation of ore haul road emissions." (Pet., ¶ 41). On a motion to dismiss, these allegations are taken as true.

DEQ's responsive pleading states generally that Paragraph 41 of the Petition "contain[s] mixed statements of fact and argument, which must be denied," then proceeds to discuss the various work plans. (Resp. of 8/12/22, p. 4). Perpetua's Motion argues the Petition's factual allegations on this issue are conclusory and that neither the Air Rules nor the referenced DEQ "Modeling Guideline" require DEQ to utilize "local meteorological data." (Mot, p. 13).

While the Petition does not allege an outright statutory violation, its allegations can fairly be read to allege DEQ's action was arbitrary, capricious, or an abuse of discretion. It is conceivable that if local precipitation data was available but not utilized, resulting in an underestimation of

emissions, disregarding such data could be arbitrary, capricious, or an abuse of discretion.[3] While Petitioners would have the burden to demonstrate error at hearing, the hearing officer finds the factual allegations in the Petition to be adequately pled for the purposes of Rule 160.01 and withstanding a motion to dismiss. Therefore, as to Claim No. 5, Perpetua's Motion is denied.

D. Alleged Errors Related to Arsenic Emissions

Section 2 of the Permit contains several requirements related to control of fugitive dust. These include: (1) "[u]se, where practical, of water or chemicals for control of dust" in a variety of activities (Mot., Ex. A, p. 8, § 2.1); (2) "[a]pplication, where practical, of asphalt, oil, water, or suitable chemicals to…surfaces which can create dust" (*id.*); and (3) application of "water or suitable dust suppressant chemicals (*e.g.*, magnesium chloride, calcium chloride)" to a variety of facilities "as necessary to control fugitive dust." (*Id*. at p. 9, § 2.6).

1. Claim No. 6: T-RACT Determination Lacked Persuasive Economic Information Regarding Suppressants vs. Paving

The Petition alleges DEQ's evaluation of "reasonably available control technologies" ("RACT") for the toxic air pollutant arsenic ("T-RACT") "contained no persuasive economic information" regarding "Perpetua's decision to use water and chemical dust suppressants as compared to paving the haul roads, even though paving was shown to achieve the highest reasonable dust control efficiency." (Pet., ¶¶ 48, 53). According to the Petition, this violated Air Rule 210.14.

T-RACT is defined in the Air Rules as:

> An emission standard based on the lowest emission of toxic air pollutants that a particular source is capable of meeting by the application of control technology that is reasonably available, as determined by the Department, considering technological and ***economic feasibility***. If control technology is not feasible, the

[3] While there are references in the SOB suggesting some use of local precipitation data, that is a factual issue not relevant on a motion to dismiss. (*See generally* SOB of 6/17/22, pp. 9, 44, 46-47, 64).

> emission standard may be based on the application of a design, equipment, work practice or operational requirement, or combination thereof.

AIR RULE 007.12 (emphasis added).

The first step in the T-RACT process established by the Air Rules is for the applicant to "submit information to [DEQ] identifying and documenting which control technologies or other requirements the applicant believes to be T-RACT." AIR RULE 210.14(a). DEQ must determine T-RACT "on a case-by-case basis" considering separate factors for technological feasibility and economic feasibility. AIR RULE 210.14. For economic feasibility, DEQ must consider a non-exclusive list of factors, including costs of necessary mitigation measures, capital costs, cost effectiveness, and the difference in costs between the particular source and other sources, if any, that have implemented emissions reductions. AIR RULE 210.14(d).

The Motion responds to these allegations in two ways. First, it argues DEQ complied with the Air Rules. More specifically, the Motion argues that pursuant to Air Rules 007.12 and 210.14(a), Perpetua was only required "to submit environmental and economic information to assist [DEQ] in determining if the proposed technology is reasonably available." (Mot., p. 15).

The hearing officer does not read these rules so narrowly. Both rules require DEQ to consider economic feasibility when evaluating T-RACT. Perpetua's argument appears to be that there can be no error because "[u]se of chemical and dust suppressants and watering are well recognized…as reasonably available control technologies for fugitive dust." (Mot, p. 16). However, the hearing officer does not read the Petition to allege the T-RACT adopted by DEQ is infeasible. Instead, the hearing officer reads the Petition to allege DEQ erred in its evaluation of whether another technology that would have achieved a higher level of control was economically feasible.

These arguments are highly technical, and it is possible the hearing officer is missing some nuance. However, without oral argument, there was no ability to discuss nuance. Taking the

Petition's factual allegations as true, it is conceivable the Petitioners could demonstrate DEQ's evaluation of economic feasibility qualified as arbitrary, capricious, or an abuse of discretion.

Second, Perpetua also references the SOB to support DEQ's action. (*See* Mot., p. 16). While reference to the SOB may be appropriate on a motion for summary judgment or at hearing, it exceeds the inquiry on a motion to dismiss. As to Claim No. 6, Perpetua's Motion is denied.

2. Claim No. 7: T-RACT Determination Did Not Evaluate Other Environmental Impacts

The Petition alleges DEQ's T-RACT determination failed to evaluate impacts to water quality potentially caused by chemical dust suppressants. (Pet., ¶ 53). The Petition further alleges use of chemical dust suppressants can cause toxicity to trees and impact water quality and aquatic ecosystems, and that "[t]he environmental impact of using magnesium chloride or arsenic-polluted water as dust suppression methods was never considered as part of the T-RACT demonstration." In its Motion, Perpetua relies upon references within the SOB to argue that DEQ did, in fact, appropriately evaluate T-RACT. (Mot., pp. 15-17).

As previously referenced, DEQ's T-RACT determination involves analysis of both economic feasibility and technological feasibility. *See* AIR RULE 210.14(c), (d). The Air Rules specifically require DEQ's evaluation of technological feasibility to include consideration of "[t]he environmental impacts caused by the control technology that cannot be mitigated, including, but not limited to, water pollution and the production of solid wastes." AIR RULE 210.14(c)(ii).

In short, DEQ is required by the Air Rules to consider "environmental impacts" in its T-RACT determination, and the Petition alleges DEQ did not consider certain environmental impacts. Taking all of the factual allegations in Paragraph 53 as true, it would be inappropriate to dismiss Claim No. 7. To evaluate this claim by reference to deliberations by DEQ described in the SOB is resolution of a factual issue outside the pleadings, which is not appropriate on a motion to

dismiss. Therefore, as to Claim No. 7, Perpetua's Motion is denied.

3. Claim No. 8: Arsenic Emissions Estimates Are Based on PM_{10} Emissions Estimates, So Are Subject to Same Flawed Assumptions

Paragraph 54 of the Petition alleges:

> Second, because the underlying particulate and PM_{10} emissions estimates and particulate control assumptions are unreliable in numerous respects, as already discussed above, so too are the estimated arsenic emissions. The SGP's estimated arsenic emissions were based on its PM_{10} emissions. PM_{10} emissions from the SGP may be higher, and their control effectiveness may be lower, than DEQ assumed, in which case arsenic emissions would also be higher and might exceed the AACC [Acceptable Concentrations of Carcinogens].

(Pet., ¶ 54).

Similar to the Petition's approach to this allegation, Perpetua's Motion refers back to counter-arguments lodged earlier in the Motion. (*See* Motion, p. 17). DEQ's response generally denies these allegations. (See Resp., p. 4).

The hearing officer finds Paragraph 54 to flirt with non-compliance with Rule 160.01's requirements to "[f]ully state the facts" and to "[r]efer to the particular provisions" of law upon which it is based. However, given AG Procedural Rule's directive to "liberally construe[]" the procedural rules, and because Claim Nos. 1, 2, and 5 have been adequately pled, outright dismissal of Paragraph 54 in its entirety does not seem appropriate.

Therefore, to the extent Claim No. 8 incorporates by reference the allegations comprising Claim Nos. 1, 2, and 5 (which survive the Motion), Perpetua's Motion is denied. To the extent Claim No. 8 incorporates by reference the allegations comprising Claim Nos. 3 and 4 (which are dismissed), Perpetua's Motion is granted, and that portion of Claim No. 8 is dismissed.

4. Claim No. 9: DEQ Improperly Averaged Arsenic Emissions

The Petition alleges DEQ improperly averaged arsenic emissions over multi-year periods.

(Pet., ¶ 55). According to the Petition, this resulted in "substantially reduc[ing] the SGP's purported arsenic emissions…." (*Id*.) The Petition also alleges it is inappropriate to compare the AAC for arsenic, which is an annual standard, to multi-year averages. (*Id*.)

It is worth noting the Petition identifies three multi-year averaging "tactics" as inappropriate. (*See* Pet., ¶ 55). At some point, it may be appropriate to treat them as separate claims. For the purposes of the Motion, all three "tactics" are within the umbrella of "multi-year averaging."

DEQ denies the allegations in Paragraph 55 without explanation. (Resp., p. 4). The Motion addresses Paragraph 55 in three ways. First, it argues "the Petition fails to identify any provision of the Idaho Air Rules that prohibits the approach taken by Perpetua in quantifying arsenic emissions or that invalidates the Department's approval of such approach." (Mot., p. 17). Second, the Motion engages in detailed analysis of the language of the Air Rules to argue that "[t]he Idaho Air Rules do not require annual averaging as Petitioners suggest." (Mot., p. 18). Third, the Motion references DEQ's SOB to argue DEQ complied with the Air Rules. (Mot., p 19).

Even if the Air Rules do not prohibit multi-year averaging, it is still theoretically possible for the Petitioners to demonstrate DEQ's approval of multi-year averaging was arbitrary, capricious, or an abuse of discretion. At this stage of the proceedings, it would be appropriate to dismiss this claim only if the averaging techniques employed by Perpetua and approved by DEQ were mandatory, in which case it would be arbitrary, capricious, or an abuse of discretion ***not*** to use them. However, this is not the Motion's argument. Therefore, as to Claim No. 9, the Motion is denied.

5. Claim No. 10: Consideration of Arsenic Emissions in Future Permitting Decisions

Paragraph 57 of the Petition alleges:

> Excacerbating [*sic*] this cancer risk [from arsenic emissions] is the fact that under DEQ's incremental TAPs regulations (*see* IDAPA 58.01.01.585), when DEQ considers permitting any additional

> sources of arsenic in the area over the next 70 years (such as an extension of the life of the SGP, expansion of the facility itself, and/or any adjacent facilities seeking a similar permit, like the potential Horse Heaven project), DEQ will not have to consider the arsenic emissions authorized by this PTC.

(Pet., ¶ 57).

DEQ generally denies this allegation without explanation. (DEQ Resp. of 8/12/22, p. 4). Perpetua argues Paragraph 57 "is irrelevant to whether the Final Permit is lawful and must be dismissed." (Mot., p. 19). It is unclear to the hearing officer if the Petitioners intend Paragraph 57 to allege a reversible error. However, Perpetua reads it as a claim and has requested its dismissal.

After having read Paragraph 57 and Air Rule 585, the hearing officer does not find any discernable basis for reversible error based upon implications for future permitting decisions. As to Claim No. 10, the Motion is granted, and the claim is dismissed.

E. Alleged Errors Related to Ambient Air Boundary and Monitoring

The Petition alleges multiple errors regarding ambient air boundaries and monitoring. Even though the phrase "ambient air" appears in the Permit one time, (*see* Permit, p. 41, § 7.13), it is an important concept behind many Permit conditions. Therefore, before addressing each individual error alleged regarding ambient air, it will be helpful to briefly discuss the concept of ambient air within the context of air quality regulation.

Under the federal Clean Air Act, EPA is required to establish national ambient air quality standards for a handful of "criteria" air pollutants, including PM_{10}. *See generally* 42 U.S.C. § 7602(t); 40 C.F.R. § 50.6. When DEQ evaluates an application for a permit to construct for a new or modified source of air pollutants, it must determine that "[t]he stationary source or modification would not cause or significantly contribute to a violation of any ambient air quality standard." AIR RULE § 203.02. Ambient air can also be relevant to DEQ's determination of T-RACT for toxic air

pollutants such as arsenic. *See* AIR RULE §§ 006.125, 210.12(b), (c).

Based on the federal definition, the Air Rules define "ambient air" as "[t]hat portion of the atmosphere, external to buildings, to which the general public has access." AIR RULES § 006.10. The Petition alleges—and DEQ agrees—that to exclude areas from ambient air, the following must be true: (1) the permittee must have the ***legal authority to exclude the general public*** from the area; (2) the boundary to ambient air must be clearly discernable to the general public; (3) the general public must be ***effectively precluded*** from assessing the facility; and (4) the general public is not considered (a) employees of the facility; (b) those having official business with the facility; or (c) guests of the facility, including participants in facility routes and those seeking access for a specific purpose. (Pet., ¶ 59; DEQ Resp., p. 5 (emphasis added)).

As the hearing officer understands, the Petition alleges the ambient air boundary was established by Perpetua and DEQ to coincide with the boundaries of the SGP. However, there is an existing road bisecting the SGP through which members of the public will have some level of access. Therefore, according to the Petition, that access road should have been treated as ambient air, not excluded from it. (*See generally* Petition, ¶¶ 60, 62).

Section 2.7 of the Permit contains the following minimum requirements for access management at the SGP:

- Perpetua must "observe" all primary access points to preclude unauthorized public access. The Permit does not specifically define the phrase "primary access point," but states that it includes the North and South Security Gates.

- Perpetua must post warning signs and periodically patrol secondary access points to the facility to preclude public access. Secondary access points include secondary roadways and trails traversing the SGP.

- Only registered guests will be allowed access to or through the SGP. For those seeking to pass through the SGP to another destination, Perpetua will provide them with a "registration sheet" explaining Perpetua's requirements for accessing the SGP and identifying potential hazards.

(*See generally* Permit, p. 10, § 2.7).

1. Claim No. 11: Whether Perpetua Has Sufficient Legal Authority to Exclude the General Public From the Access Route

As previously discussed, one of the requirements to exclude an area from ambient air is that the permittee must have "the legal authority to exclude the general public from the area." The Petition alleges the access road "is currently accessible to and has been regularly used by the general public" and that the Forest Service has not yet decided "whether it will require or will not permit general public access through the mine site." (Pet., ¶ 62).

These allegations must be taken as true on a motion to dismiss, and they are directly relevant to the "legal authority" requirement for exclusion from ambient air. If the Petitioners demonstrate Perpetua does not have legal authority to exclude the general public from the access road, it is possible they could demonstrate it was error to exclude the access road from ambient air. As to Claim No. 10, the Motion is denied.

2. Claim No. 12: Whether the Existing Permit Conditions "Effectively Preclude" Access by the General Public

Sections 2.6 and 2.7 of the Permit require Perpetua to develop and implement an "Access Management Plan" ("AMP"). Some requirements related to the AMP include:

- Identifying the SGP facility boundary and all primary and secondary access points;
- Specifying measures used to discourage public access to the facility;
- "Observ[ing]" all primary access points to preclude unauthorized public access;
- Posting warning signs;
- Requiring onsite personnel to be available to preclude unauthorized public access;
- Periodically patrolling secondary access points to preclude public access;
- Identifying the access points monitored, the frequency of patrol, and measures employed to discourage access;

- Limiting access to the SGP to "registered guests of the facility;"
- Providing guests whose sole purpose is to pass through the SGP with a "registration sheet that explains Perpetua's requirements for accessing the site and identifies potential hazards of the site;" and
- Providing training to employees regarding the need to restrict public access.

(Permit, pp. 9-10, §§ 2.6-2.7).

Also, "[t]he measures specified in the AMP shall be incorporated by reference to [the Permit] and shall be enforceable [P]ermit conditions." (*Id*., p. 10, § 2.7).

The Petition alleges that, "[w]ithout full disclosure and knowledge of the exact measures and requirements in the AMP and enforceable permit limits, DEQ cannot make a determination of whether exclusion of the access road from ambient air protections complies with EPA's ambient air policy and the Idaho Air Rules, nor can DEQ determine whether the SGP will comply with the NAAQS and TAPs." (Pet., ¶¶ 58, 59, 62, 65).

In response, DEQ agrees with some of these allegations and disagrees with others. (Resp., p. 5). Paraphrasing, Perpetua responds that (1) the Petition does not identify any violations of law or the Air Rules, and (2) even though the AMP has not been fully developed, the provisions in the Permit are sufficiently concrete and enforceable to preclude public access to the road excluded from ambient air. (*See* Mot., pp. 20-21).

As to the first argument, even if DEQ has not overtly violated the law or exceeded the scope of its authority, it is theoretically possible its actions were arbitrary, capricious, or an abuse of discretion. Therefore, dismissal of the claim on this basis is not appropriate.

As to the second argument, it is unclear how this claim could be dismissed without exceeding the scope of a motion to dismiss. While the Permit contains minimum requirements the AMP must satisfy, the hearing officer is not equipped at this stage to evaluate the adequacy of those requirements. Therefore, as to Claim No. 11, Perpetua's Motion is denied.

3. Claim No. 13: Lack of Ambient Air Monitoring

The Permit contains several "monitoring" requirements, but it does not require monitoring of the quality of the ambient air. The Petition alleges that "without ambient air monitoring, it will be impossible for DEQ to assess whether the SGP's operation is in compliance with NAAQS and TAPs increments at any given time." (Pet., ¶ 68). Air Rule 211.01(d) expressly authorizes DEQ to include reasonable ambient air monitoring requirements in a permit-to-construct, and neither DEQ nor Perpetua dispute this. (*See* Resp. of 8/12/22, p. 5; Mot., p. 22). Instead, Perpetua argues this claim should be dismissed because "ambient air monitoring is not a legal requirement for lawful issuance of an air quality permit." (Mot., p. 22).

If DEQ had discretion to require ambient air monitoring, it is possible there are circumstances under which not including such requirements is an abuse of discretion. Because demonstrating abuse of discretion is one of the ways Petitioners could obtain relief, the Petition states a claim on which relief could be granted. Therefore, as to Claim No. 12, the Motion is denied.

IV. SUMMARY, CONCLUSION, AND ORDER

Based on the foregoing, it is hereby ordered that:

- As to Claim Nos. 3 and 4, the Motion is granted, and those claims are dismissed;
- As to Claim Nos. 1, 2, 5, 6, 7, 9, 10, 11, 12, and 13,the Motion is denied, and those claims survive the Motion, though Claim No. 1 is limited to the three variables specifically referenced in the Petition; and
- As to Claim No. 8, the Motion is granted in part and denied in part. To the extent Claim No. 8 incorporates by reference the allegations comprising Claim Nos. 1, 2, and 5, Perpetua's Motion is denied, and that portion of Claim 8 survives the Motion. To the extent Claim No. 8 incorporates by reference the allegations comprising Claim Nos. 3 and 4, Perpetua's Motion is granted, and that portion of Claim No. 8 is dismissed.

The following table summarizes the results of this Order:

Claim No.	Pollutant/Source/Issue	Summary of Alleged Error	Motion	Claim
1	PM_{10} from haul trucks/road	Variables relied upon not adopted as enforceable limitations; instead, relied on plans that have not yet been developed	Denied	Survives, but limited to 3 variables described in Petition
2	PM_{10} from haul trucks/road	Assumed control of 93.3% of emissions without related enforceable limitations	Denied	Survives
3	PM_{10} from haul trucks/road	Based monitoring and recordkeeping requirements on O&M Plan not yet developed	Granted	Dismissed
4	PM_{10} from haul trucks/road	Permit does not include adequate monitoring, recordkeeping, and reporting requirements	Granted	Dismissed
5	PM_{10} from haul trucks/road	Assumed 120 days of recordable precipitation rather than using local weather data	Denied	Survives
6	Arsenic from various sources	T-RACT demonstration did not contain persuasive economic information re suppressants vs. paving	Denied	Survives
7	Arsenic from various sources	T-RACT demonstration did not evaluate environmental impacts	Denied	Survives
8	Arsenic from various sources	Estimated As emissions based on PM10 emissions, so same flawed assumptions above apply	Denied (1,2,5); granted (3,4)	Survives (1,2,5); dismissed (3,4)
9	Arsenic from various sources	Multi-year averaging of arsenic emissions not authorized by Air Rules	Denied	Survives
10	Arsenic from various sources	Impacts on future permitting actions	Granted	Dismissed
11	Ambient air boundary	Insufficient legal authority to exclude general public	Denied	Survives
12	Ambient air boundary	Whether Permit effectively precludes access by general public	Denied	Survives

Claim No.	Pollutant/Source/Issue	Summary of Alleged Error	Motion	Claim
13	Ambient air monitoring	Lack of ambient air monitoring makes it impossible to assess compliance	Denied	Survives

Finally, while most of Petitioners' claims survive Perpetua's Motion, four have been fully or partially dismissed. In their response to the Motion, the Petitioners suggest that instead of dismissing claims, they should be allowed to file an amended petition pursuant to the language in AG Procedural Rule 305 stating that "[t]he presiding officer ***may*** allow any pleading to be amended or corrected or any omission to be supplied." (Opp. Br. of 9/20/22, p. 4, n. 2 (emphasis added)). The hearing officer declines to exercise that discretion unless and until Petitioners file a formal motion to amend their Petition.

Pursuant to DEQ Procedural Rule 003.17 and AG Procedural Rule 710, this order is an interlocutory order because it does not decide all previously undecided issues in this matter.

Dated this 15th day of November 2022.

BEFORE THE BOARD OF ENVIRONMENTAL QUALITY
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047	)	
NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON,	)	Case Docket No. 0101-22-01
Petitioners,	)	ORDER ON STATUS CONFERENCE
v.	)	
DEPARTMENT OF ENVIRONMENTAL QUALITY,	)	
Respondent,	)	
and	)	
PERPETUA RESOURCES IDAHO, INC.,	)	
Intervenor.	)	

On November 28, 2022, a status conference was held virtually via Microsoft Teams. Bryan Hurlbutt and Laird Lucas appeared for Petitioners Nez Perce Tribe and Idaho Conservation League, and Julia Thrower appeared for Petitioner Save the South Fork Salmon. John Shackelford, Deputy Attorney General, appeared for Respondent. W. Christopher Pooser, and Wade Foster appeared for Intervenor.

At the status conference, the Petitioners expressed an intent to file a motion to amend their Petition pursuant to Board of Environmental Quality (BEQ) Procedural Rules 003.05 and 162.01 and AG Procedural Rule 305, based upon the November 15 Order on Motion to Dismiss. The parties

and hearing officer agreed that 21 days after the Order, *i.e.*, December 6, is a reasonable deadline for motions to amend pleadings.

The parties also reported progress on a stipulated scheduling order. However, the scheduling order cannot be finalized until there is more clarity regarding the impacts of the motion to amend on the proceedings. Therefore, the parties agreed to schedule a call shortly after the December 6 deadline to attempt to finalize the scheduling order at that time.

Finally, the parties and hearing officer discussed the status of establishing an administrative record. Intervenor suggested it is appropriate to open discovery at this time to allow for supplementation of the DEQ project file, while Petitioners expressed concern that doing so before resolution of their motion to amend would be premature. As a result, the hearing officer has not yet formally authorized discovery pursuant to BEQ Procedural Rule 003.11 and AG Procedural Rules 413.01(b) and 521, though any party desiring discovery at this time is free to file a motion to that effect.

Based on the foregoing, it is hereby ordered that any motions to amend pleadings in this matter shall be filed no later than Tuesday, December 6, 2022.

Dated this 30th day of November, 2022.

Attorney for Save the South Fork Salmon

BEFORE THE BOARD OF ENVIRONMENTAL QUALITY
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047	)	
	)	CASE DOCKET NO. 0101-22-01
NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON	)	**MOTION TO FILE FIRST AMENDED PETITION**
Petitioners,	)	
v.	)	
IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY,	)	
Respondent,	)	
and	)	
PERPETUA RESOURCES IDAHO, INC.	)	
Intervenor.	)	

Petitioners Nez Perce Tribe, Idaho Conservation League ("ICL"), and Save the South Fork Salmon ("SSFS") hereby move to file the First Amended Petition to Initiate Contested Case (attached), as invited by the Hearing Officer in his November 15, 2022, Order on Motion to Dismiss, and under AG Procedural Rule 305 and Idaho Rule of Civil Procedure 15(a)(2).

BEQ Procedural Rule 003.01 adopts AG Procedural Rule 305, which states: "The presiding officer may allow any pleading to be amended or corrected or any omission to be supplied." IDAPA 04.11.01.350.

Similarly, after a responsive pleading has been filed, the Idaho Rules of Civil Procedure allow the pre-trial amendment of a pleading either with the opposing party's written consent or with the court's leave, and states that "[t]he court should freely give leave when justice so requires." IRCP 15(a)(2). "The twin purposes behind the rule are to allow claims to be determined on the merits rather than on technicalities, and to make pleadings serve the limited role of providing notice of the nature of the claim and the facts at issue." *Carl H. Christensen Family Trust v. Christensen*, 133 Idaho 866, 871 (Idaho 1999) (citation omitted). Thus, "motions for leave to amend pleadings are to be liberally granted." *Taylor v. McNichols*, 149 Idaho 826, 847 (Idaho 2010).

"In considering whether to grant a motion for leave to amend, a trial court may consider whether the amended pleading sets out a valid claim, whether the opposing party would be prejudiced by any undue delay, or whether the opposing party has an avialable defense to the newly added claim." *Spur Products Corp v. Stoel Rives LLP*, 142 Idaho 41, 44 (Idaho 2005) (citation omitted). "Timeliness of a motion for leave to amend is not decisive, but it is important in view of factors such as undue delay, bad faith, and prejudice to the opponent." *Id.* (quotation and citation omitted).

Petitioners Motion to Amend should be granted. Granting the Motion furthers the two purposes behind the rule that leave to amend should be freely given: (1) it will allow Petitioners' claims to be determined on the merits rather than on technicalities; and (2) it will ensure the pleadings serve the limited role of providing notice of the nature of the claims and the facts at issue.

Neither DEQ nor Perpetua faces any undue delay or prejudice. Petitioners merely seek to correct deficiencies the Hearing Officer found with respect to some claims and to provide additional detail and clarity regarding each claim being pursued in this contested case, each of which was already raised in the original Petition. The First Amended Petition does not add new claims or otherwise expand the scope of the contested case. This Motion is promptly filed within 21 days of the Order on Motion to Dismiss. No hearing date or contested case schedule has been set yet, and granting this motion will not result in any delay.

Dated: December 6, 2022

Respectfully submitted,

/s/ Bryan Hurlbutt
Bryan Hurlbutt
Attorney for the Nez Perce Tribe and the Idaho Conservation League

/s/ Julia S. Thrower

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047	CASE DOCKET NO. 0101-22-01
NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON Petitioners, v. IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent, and PERPETUA RESOURCES IDAHO, INC. Intervenor.	**<u>FIRST AMENDED</u> PETITION TO INITIATE CONTESTED CASE: AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047 (JUN. 17, 2022)***

** This First Amended Petition uses <u>underscoring to highlight the additions made to the original Petition,</u> ~~and strikeouts to show redactions from the original Petition~~, <u>as illustrated here</u>. Where text underscoring was used in the original Petition, *it has been replaced with italics as illustrated here.*

INTRODUCTION

1. Petitioners Nez Perce Tribe, Idaho Conservation League ("ICL"), and Save the South Fork Salmon ("SSFS"), by and through their attorneys of record, file this Petition to Initiate Contested Case ("Petition") before the Idaho Board of Environmental Quality ("Board") pursuant to Idaho Code § 39-107(5) and IDAPA 58.01.23. This Petition challenges the Air Quality Permit to Construct P-2019.0047 ("PTC") issued by the Idaho Department of Environmental Quality ("DEQ") on June 17, 2022, to mining company Perpetua Resources Idaho, Inc. ("Perpetua") for its proposed Stibnite Gold Project ("SGP").

2. The SGP is in the headwaters of the East Fork of the South Fork of the Salmon River approximately ten miles east of the town of Yellow Pine, Idaho. The SGP is geographically located within the Nez Perce Tribe's aboriginal homeland and within the area over which the Nez Perce Tribe has Treaty-reserved rights and resources. As proposed, Perpetua would use conventional mining techniques to extract ore from three open pits, process gold, and dispose of mine waste at the SGP site.

3. The PTC being challenged here authorizes emissions of air pollutants from the SGP that will occur over the mine's anticipated 16-year life span. These emissions include massive quantities of dust generated by mining, hauling, and processing. The dust includes particulate matter and arsenic—pollutants which can cause serious harm to human health and the environment.

4. When it issued the PTC, DEQ failed to comply with the federal Clean Air Act and with Idaho rules, regulations, and guidance for Clean Air Act permitting, and DEQ acted arbitrarily and capriciously, acted on unlawful procedure, and abused its discretion, under the Idaho Administrative Procedure Act, Idaho Code § 67-5279, in multiple ways set forth below.

Petitioners respectfully request that the Board reverse and set aside the PTC and remand to DEQ to correct these errors.

LISTING OF REPRESENTATIVES

5. Copies of all pleadings, correspondence, and official documents shall be served on the Petitioners' counsel listed below:

For the Nez Perce Tribe and the Idaho Conservation League:

Bryan Hurlbutt
Advocates for the West
P.O. Box 1612
Boise, ID 83701
bhurlbutt@advocateswest.org

For Save the South Fork Salmon:

Julia Thrower
Mountain Top Law PLLC
614 Thompson Ave.
McCall, ID 83638
jthrower@mtntoplaw.com

JURISDICTION, STANDARD OF REVIEW, PARTIES, AND STANDING

6. Pursuant to Idaho Code § 39-107(5), IDAPA 58.01.23, and IDAPA 58.01.01 (the "Idaho Air Rules"), the Board has jurisdiction over this contested case challenging DEQ's action issuing PTC P-2019.0047 for the SGP on June 17, 2022. Th~~is~~e original Petition ~~is~~was timely filed on July 22, 2022, within thirty-five (35) days of the date of DEQ's June 17, 2022 decision. *See* IDAPA 58.01.23.060. This Amended Petition is proper under IDAPA 58.01.23.003.01, IDAPA 04.11.01.305, and Idaho Rule of Civil Procedure 15(a)(2).

7. An agency action, such as DEQ's issuance of the PTC being challenged here, may be reversed if it is in violation of constitutional or statutory provisions, is in excess of statutory authority, is made on unlawful procedure, or is arbitrary, capricious, or an abuse of discretion.

Idaho Code ("I.C.") § 67-5279. When an agency action is not affirmed, it shall be set aside, in whole or in part, and remanded for further proceedings as necessary. *Id.*

8. Pursuant to IDAPA 58.01.23.002.02: "Any person aggrieved by an action or inaction of the Department may file a petition to initiate a contested case pursuant to Chapter 52, Title 67, Idaho Code." An aggrieved person is defined as "any person or entity with legal standing to challenge an action or inaction of the Department, including but not limited to permit holders and applicants for permits challenging Department permitting actions." IDAPA 58.01.23.005.01.

9. PETITIONER NEZ PERCE TRIBE is a federally-recognized Indian tribe with headquarters on the Nez Perce Reservation in Lapwai, Idaho; and with offices in Orofino, McCall, and Powell, Idaho, and Joseph, Oregon.

10. The Nez Perce Tribe has standing to bring this contested case. The Nez Perce people, the *Nimiipuu*, exclusively occupied, since time immemorial, over thirteen million acres encompassing a large part of what is today Idaho, Oregon, and Washington—stretching from the Bitterroot Mountains to the Blue Mountains. Nez Perce also traveled far beyond this homeland to fish, hunt, gather, and pasture—frequently going east to buffalo country, in what is today the state of Montana, and west along the Snake and Columbia rivers to the Pacific Ocean. The Nez Perce actively maintain their connection to the land, water, and resources of their vast homeland. The Nez Perce's intimate knowledge and continuous use of their homeland over millennia have created a unique and reverential bond between people and place that defines Nez Perce culture and identity.

11. When the Nez Perce Tribe entered into a treaty with the United States in 1855, it sought to reserve the rights central to maintaining its culture and way of life. The 1855 Treaty

reserved to the Tribe, for its "exclusive use and benefit," 7.5 million acres of its more than thirteen-million- acre homeland, including an area spanning present-day north-central Idaho, southeast Washington, and northeast Oregon as well as:

> [T]he right of taking fish at all usual and accustomed places in common with citizens of the Territory; and of erecting temporary buildings for curing, together with the privilege of hunting, gathering roots and berries, and pasturing their horses and cattle upon open and unclaimed land.

Treaty with the Nez Perces, art. 3, June 11, 1855, 12 Stat. 957. Nez Perce Tribal members, pursuant to the Nez Perce Tribe's Treaty-reserved rights, continue to fish, hunt, gather, and pasture across the Nez Perce Tribe's vast aboriginal homeland and at traditional places, including areas within and surrounding the SGP. The Nez Perce Tribe, as a co-manager of its treaty-reserved resources, also plays a leading role in the restoration of the East Fork South Fork Salmon River and South Fork Salmon River fisheries, expending approximately $2.5 million annually to restore Chinook salmon runs in both rivers through hatchery supplementation, fishery research, and watershed restoration.

12. The Nez Perce Tribe will suffer physical, cultural, spiritual, and economic injury caused by excessive air pollutants resulting from DEQ's issuance of the PTC. Clean, clear air is a critical component to ensuring the health and resiliency of the Nez Perce Tribe's Treaty-reserved rights and resources. Air pollution reduces visibility, which impairs cultural and ceremonial practices for Tribal members and reduces enjoyment of these special places. Air pollution causes a host of environmental and human health problems, including damage to culturally important plants, sensitive forests, and fish habitat, acidification of lakes and streams, depletion of soil nutrients, aggravated asthma, heart attacks, and premature death. Impacts can be especially harmful to at-risk ecosystems and especially harmful for sensitive human populations such as asthmatics, children, the elderly, people with diabetes, and people with heart or lung disease.

13. To safeguard its rights and interests, the Nez Perce Tribe has participated extensively in DEQ's review process, including submitting comments on October 12 and November 10, 2020, March 8, 2021, and March 14, 2022. A favorable decision in the Contested Case will redress these injuries suffered by the Tribe.

14. PETITIONER IDAHO CONSERVATION LEAGUE is an Idaho non-profit conservation organization. Its main office is located in Boise, Idaho, and it has three field offices in Sandpoint, Ketchum, and McCall. ICL represents approximately 50,000 supporters dedicated to protecting and conserving Idaho's clean water, air, public lands, and wildlife.

15. ICL has standing to bring this contested case. ICL supporters, staff, and board members ("ICL members") regularly visit the SGP and/or nearby areas where air quality would be affected by the SGP for professional, recreational, aesthetic, and other purposes. ICL members will suffer health, environmental, and aesthetic injuries from the particulate matter and arsenic air pollution emitted by the SGP and authorized by DEQ's issuance of the PTC. A favorable decision in the Contested Case will redress ICL's injuries. Neither the claim asserted, nor the relief requested, requires participation of these individual ICL members in the lawsuit. The interests ICL seeks to protect are germane to the organization's purpose in protecting Idaho's clean water, clean air, wildlife, and public lands.

16. In furtherance of its mission, ICL participated extensively in the public processes for the PTC, including by submitting formal public comments to DEQ on October 12 and November 11, 2020, March 19, 2021, and March 16, 2022.

17. PETITIONER SAVE THE SOUTH FORK SALMON is a community-based, non-profit conservation organization headquartered in McCall, Idaho. SSFS represents members and supporters dedicated to preserving the South Fork Salmon River watershed and ecosystem.

18. SSFS has standing to bring this contested case. SSFS members, supporters, and members of the Board of Directors ("SSFS members") regularly visit the South Fork Salmon River watershed and the SGP site, where the emission of excessive air pollutants due to DEQ's issuance of the PTC would impact professional, economic, recreational, aesthetic, environmental, and human health interests. SSFS members would suffer injury from DEQ's issuance of the PTC from environmental, health, and aesthetic harms caused by the emission of harmful air pollutants, including particulate matter and arsenic. A favorable decision in the Contested Case will redress these injuries suffered by SSFS members. Neither the claims asserted, nor the relief requested, requires participation of these individual supporters in the lawsuit. The interests SSFS seeks to protect are germane to the organization's mission of protecting and preserving the South Fork Salmon River watershed and ecosystem, and protecting public health, the river, the fish, and recreational opportunities in the area.

19. In furtherance of this mission, SSFS participated extensively in the public process for the PTC, including submitting formal public comments to DEQ on October 12 and November 11, 2020, March 19, 2021, and March 16, 2022.

20. RESPONDENT IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY is an executive department and administrative agency organized under the laws of the State of Idaho, pursuant to the Idaho Constitution (Article IV, Section 20) and Idaho Code section 39-104(1). Its principal offices are located at 1410 N. Hilton, Boise, Idaho 83706. DEQ, through its Director, and subject to Board oversight, is responsible for issuing air quality PTCs under the Idaho Air Rules, IDAPA 58.01.01.

21. On June 17, 2022, DEQ issued PTC P-2019.0047, which is the subject of this contested case. On July 22, 2022, Petitioners timely filed the original Petition to Initiate

Contested Case. On July 28, 2022, the Hearing Officer Dylan Lawrence was assigned to preside over this matter. On August 12, 2022, Perpetua filed a Petition to Intervene. On August 22, 2022, Perpetua's Petition to Intervene was granted. On September 6, 2022, Perpetua filed a Motion to Dismiss. On November 15, 2022, the Hearing Officer issued the Order on Motion to Dismiss, denying the motion with respect to the majority of Petitioners' claims, dismissing or partially dismissing four claims, and declining to allow the pleadings to be amended unless Petitioners file for consideration a formal motion to amend the Petition.

FACTUAL SUPPORT FOR PETITION

I. OVERVIEW OF SGP & CHRONOLOGY OF DEQ'S ISSUING THE PTC

22. Perpetua is currently in the process of seeking multiple permits and other approvals from multiple agencies and other authorities for the proposed SGP. As described by DEQ in the Statement of Basis ("SOB") document prepared with the PTC:

> Perpetua proposes to construct and operate the SGP, consisting of conventional open-pit mining, ore preparation, and gold extraction operations. The SGP is to be located in Valley County at the intersection Forest Service roads NF-374 and NF-412 (Stibnite Road), approximately 10 miles east of Yellow Pine. The project will be located on a combination of public national forest and private lands. The mining operations boundary within which public access will be excluded is defined in Figure 1. This operations boundary also defines the ambient air boundary that was used in all ambient air quality impact analyses as part of the development process of the PTC.
>
> The SGP will require the construction of significant infrastructure, including a power transmission line, a primary mine site access road, onsite haul roads, an ore processing facility, onsite workspaces, employee housing and recreation, water storage and distribution facilities, and sewage disposal facilities.
>
> Conventional open-pit mining methods including drilling, blasting, excavating, and hauling will be used to extract ore and waste rock, termed development rock (DR). Hydraulic shovels and front-end loaders will be used to load ore and DR into haul trucks. DR will be used for construction, restoration, and backfilling, or hauled to the dedicated development rock storage facilities (DRSF). Approximately 340 million tons of DR will be handled over the life of the mine.

> The SGP will include three years of pre-mining development and construction activities, followed by an operating mine life of approximately 12 years. Mining will occur in three open pits: Yellow Pine Pit (YPP), Hangar Flats pit (HFP), and West End pit (WEP). Although there will be overlap in mine development, construction and operations, the general sequence of mining will be the YPP deposit, followed by the HFP and WEP deposits. Legacy tailings from the Meadow Creek valley (Bradley Tailings [BT]) will also be reclaimed and reprocessed during the initial project schedule. Surface exploration drilling will occur within the pits and within the Scout Prospect decline (underground exploration) throughout the mine operation period. Restoration and reclamation of other legacy mining features will occur prior to mining, throughout the life of the mine, and as part of the mine closure.
>
> Ore will be hauled to the primary crusher area, where it will be fed directly into the crusher dump pocket or stockpiled. The ore crushing plant will be designed to operate at a maximum rate of 25,000 tons per calendar day (T/day). Approximately 100 million tons of ore will be mined from the three pits over the life of the project. The metal-recovery process from ore will include conventional crushing and grinding, followed by froth-flotation circuits that will generate separate gold-silver and antimony-silver concentrates. The antimony-silver concentrate will be shipped offsite for refining, whereas additional onsite processing of the gold-silver concentrate will include pressure oxidation, carbon-in-leach circuits, and refining processes to recover gold and minor amounts of silver. The finely ground leftover ore material from the mineral recovery process, termed tailings, will be neutralized, thickened, and transported via a pipeline to the tailings storage facility. A diagram of ore processing and ore concentration and refining process flows is provided in Figure 2.

23. Perpetua (previously Midas Gold) submitted a PTC application for the SGP to DEQ on August 20, 2019. As shown in the "Application Chronology" section of the SOB, between that date and March 6, 2020, DEQ determined that the application was incomplete, requested additional information, and received supplementary materials from Perpetua no fewer than four times. On May 15, 2020, DEQ deemed Perpetua's application complete.

24. Between May 15, 2020, and March 16, 2022, DEQ developed three versions of the draft PTC and released them for public comment. As noted in comments submitted by the Nez Perce Tribe, ICL, and SSFS, the first two draft versions of the PTC (herein referred to the September 2020 and February 2021 draft PTCs) contained significant shortcomings. As a result, the September 2020 draft PTC was considered deficient and required updated information from

Perpetua, including updated hazardous air pollutants ("HAP") and toxic air pollutants ("TAP") emissions estimates, a HAP/TAP addendum to the application, updated TAP modeling analyses, supporting references, and updated modeling files with corrections for formaldehyde and sulfuric acid.

25. DEQ subsequently updated the draft PTC and in February 2021, provided a revised draft PTC for public comment. Following additional comments, DEQ again determined that the February 2021 draft PTC was deficient and required additional information from Perpetua, including Prevention of Significant Deterioration emissions estimates and regulatory applicability for the lime manufacturing plant, as well as an updated TAP/HAP addendum including an updated emission inventory and modeling files.

26. DEQ revised theFebruary 2021 draft PTC and released it for public comment on January 13, 2022. Comments were submitted by the Nez Perce Tribe, ICL, SSFS, the U.S. Environmental Protection Agency ("EPA") Region 10, and Ian von Lindern of Terragraphics International Foundation. Commenters raised numerous concerns with the draft PTC and urged DEQ to gather additional information, to perform additional modeling and analysis, and to develop additional enforceable permit conditions and limits prior to issuing a final PTC. On June 17, 2022, DEQ issued the final PTC, along with responses to comments and the SOB. While DEQ made limited updates to the PTC, it rejected most of the issues raised by the commenters.

II. PM_{10} & ARSENIC EMISSIONS FROM THE SGP

27. While the SGP will emit numerous air pollutants, PM_{10} and arsenic are the air pollutants of greatest concern and are the pollutants at issue in this contested case.

A. PM_{10} Pollution and Regulation

28. Particulate matter ("PM") contains microscopic solids or liquid droplets that are so small that they can be inhaled and cause serious health problems. Some particles less than 10 micrometers in diameter can get deep into a person's lungs, and some may even get into the person's bloodstream. Numerous scientific studies have linked particle pollution exposure to a variety of problems, including premature death in people with heart or lung disease; nonfatal heart attacks; irregular heartbeat; aggravated asthma; decreased lung function; and increased respiratory symptoms, such as irritation of the airways, coughing or difficulty breathing. People with heart or lung diseases, children, and older adults are the most likely to be affected by particle pollution exposure.

29. In addition to causing human health problems, PM causes environmental damage. Particles can be carried over long distances by wind and then settle on ground or water. Depending on their chemical composition, the effects of settling may include making lakes and streams acidic; changing the nutrient balance in river basins; depleting nutrients in soil; damaging sensitive forests and crops; affecting diversity of ecosystems; and contributing to acid rain.

30. Under Sections 108 and 109 of the federal Clean Air Act, EPA is required to establish National Ambient Air Quality Standards ("NAAQS") for each "criteria air pollutant" to protect the nation's public health and welfare. "[E]ffects on welfare include[ ], but [are] not limited to, effects on soils, water, crops, vegetation, manmade materials, animals, wildlife, weather, visibility, and climate, damage to and deterioration of property, and hazards to transportation, as well as effects on economic values and on personal comfort and well-being, whether caused by transformation, conversion, or combination with other air pollutants." 42 U.S.C. § 7602(h).

31. PM is a criteria air pollutant. EPA has established primary and secondary NAAQS for coarse particulate matter, or "PM_{10}," 40 C.F.R. § 50.6, and for fine particulate matter, or "$PM_{2.5}$," *id.* at § 50.7. PM_{10} consists of inhalable particles with diameters that are generally ten micrometers and smaller. 42. U.S.C. § 7602(t). $PM_{2.5}$ consists of inhalable particles that are 2.5 micrometers and smaller. The NAAQS specify a maximum amount of PM to be present in the outdoor air. *See* 40 C.F.R. §§ 50.6, 50.7.

32. EPA has delegated to DEQ authority to issue air quality permits in Idaho. Under the Clean Air Act, State air rules like DEQ's "shall" include "enforceable emission limitations" and other control measures, means, or techniques as necessary or appropriate to meet Clean Air Act requirements. 42 U.S.C. § 7410(a)(2)(A). State plans "shall" include a "program to provide for the enforcement" of the limitations and measures described in subparagraph (A), and for the "regulation of the modification and construction of any stationary source . . . to assure that [NAAQS] are achieved." *Id.* § 7410(a)(2)(C). EPA's Clean Air Act regulations require each State plan to "set forth legally enforceable procedures" that enable the State to determine whether the construction of a facility will result in a violation of its air pollution control strategies or interfere with attaining or maintaining the NAAQS. 40 C.F.R. § 51.160(a). These legally enforceable procedures: must icnlude means by which the State will prevent construction if the facility will violate air pollution control strategies or will interfere with attaining or maintaining the NAAQS; and must provide for the applicant to submit information on the "location, design, construction, and operation of such facility . . . as may be necessary" to permit the state to "to make the determination" that the facility will comply with its air pollution control strategies and the NAAQS. *Id.* § 51.160(b)–(c). "The legally enforceable procedures in § 51.160(b) must also require" the State to provide opportunity for public comment on information

submitted by the applicant and on the State's analysis of the effects on ambient air quality. *Id.* § 51.161(a). Under the Rules for the Control of Air Pollution in Idaho, DEQ is required to ensure that no PTC shall be granted for a new or modified stationary source unless the applicant shows to the satisfaction of DEQ that the source would not cause or significantly contribute to a violation of any NAAQS. IDAPA 58.01.01.203.02. To satisfy these requirements, DEQ must assess air impacts using maximum potential emissions as limited by either the capacity of the unit/operation or as limited by enforceable permit provisions. *See* IDAPA 58.01.01.006.88. Prior to issuing a permit to contruct, DEQ must provide an opportunity for public comment by making available DEQ's proposed action together with information provided by the applicant and with DEQ's analysis of air quality impacts. IDAPA 58.01.01.209.c.

B. PM_{10} Pollution from the SGP & Flaws in the PTC

33. According to DEQ's Statement of Basis for the SGP, the SGP has the potential to emit 55.7 tons per year of PM_{10} from a variety of sources. The generation of dust from ore haul trucks traveling along haul roads is the most significant source, estimated to be approximately 55% of all modeled PM_{10} emissions. The next most significant source is open pit drilling fugitive emissions, estimated by DEQ to account for approximately 24% of all modeled emissions.

34. DEQ modeled receptors at various locations along the SGP's ambient air boundary and determined that the maximum potential emissions will be below (and thus comply with) the 24-hour PM_{10} NAAQS. DEQ found the maximum 24-hour PM_{10} pollution from the SGP would be 123.5 ug/m^3, which is 82.3% of the NAAQS.

35. For each of the reasons below, DEQ's determination that the SGP will not cause or contribute to a violation of the PM_{10} NAAQS and its action approving the PTC ~~is flawed~~violates the Clean Air Act, violates EPA's Clean Air Act regulations, violates the Idaho

Air Rules, and is otherwise arbitrary, capricious, made on unlawful procedure, and an abuse of discretion and must be set aside under I.C. § 67-5279.

36. First, important variables affecting the quantity of PM_{10} generated by the ore haul trucks are not directly limited and enforceable as PTC permit conditions. Perpetua estimated the quantity of PM_{10} that would be emitted by the ore haul trucks based on EPAs compilation of air emissions factors (AP-42 Chapter 13.2.2) and their subsequent analysis of sources used by the EPA to develop Chapter 13.2.2. Critical variables that Perpetua used as inputs to PM emission calculations include: the average empty weight of ore haul trucks; the average loaded weight of ore haul trucks; the total number of larger versus smaller ore haul trucks (CAT 789D versus CAT 740B); the silt content of the haul road being traveled; the number of days per year with precipitation greater than or equal to 0.01 inches per day; and the total number vehicle miles traveled by ore haul trucks. However, only one of these critical variables is directly limited and enforceable as a condition in the PTC: the silt content of the haul roads. *See* PTC condition 3.13.

37. Instead of developing PTC conditions for these other critical variables, DEQ relied on a surrogate limit in the PTC (total ore haulage per day, *see* PTC conditions 3.5) and on plans that have not yet been developed and have not been subject to public comment,—a Fugitive Dust Control Plan ("FDCP") and a Haul Road Capping Plan ("HRCP")—to claim the PTC ensures enforceable compliance with 24-hour PM_{10} NAAQS. Without developing the FDCP and HRCP first, without taking public comment on them, and without including important variables as enforceable permit conditions, there is no assurance the SGP will comply with the 24-hour PM_{10} NAAQS, even with the total ore haulage per day limit. Perpetua used a very specific combination of these variables to arrive at a quantity of ore haul truck generated PM_{10} that they contend ensures compliance with the NAAQS. Changing these variables in any number

of ways (ways which are not precluded by any conditions in the PTC) can result in higher PM_{10} levels—levels so high that they exceed the NAAQS. As just one example, merely changing the ratio of large to small ore haul trucks used by Perpetua (to include more ~~large~~ small trucks) could cause a violation of the NAAQS.

38. Second, DEQ assumed 93.3% of all haul road PM_{10} emissions from the SGP can be controlled by using an unspecified combination, volume, and frequency of water sprays and chemical dust suppressants. This extremely high level of control which DEQ assumed Perpetua can achieve is based on Perpetua's interpretation of AP-42 Chapter 13.2.2. AP-42 Chapter 13.2.2 discusses the critically important variables surrounding control efficiencies (in particular to chemical suppressants, some of which can reasonably be assumed to apply to water too):

> The control effectiveness of chemical dust suppressants appears to depend on (a) the dilution rate used in the mixture; (b) the application rate (volume of solution per unit road surface area); (c) the time between applications; (d) the size, speed and amount of traffic during the period between applications; and (e) meteorological conditions (rainfall, freeze/thaw cycles, etc.) during the period. Other factors that affect the performance of dust suppressants include other traffic characteristics (e. g., cornering, track-on from unpaved areas) and road characteristics (e. g., bearing strength, grade). The variabilities in the above factors and differences between individual dust control products make the control efficiencies of chemical dust suppressants difficult to estimate. Past field testing of emissions from controlled unpaved roads has shown that chemical dust suppressants provide a PM-10 control efficiency of **about 80 percent when applied at regular intervals of 2 weeks to 1 month (**emphasis added**).**

39. None of the above variables, however, have any specific and enforceable permit conditions within the PTC to ensure a 93.3% control efficiency. Instead, the PTC has a permit condition (permit condition 2.6) only requiring the permittee to develop and submit the FCDP and HRCP, which merely describe how these variables will be addressed 30 days before start-up of the SGP. Permit condition 2.6 details what variables contributing to PM_{10} control effectiveness must be detailed in the FCDP, but the specific details that are so important to

control efficiency (e.g., the amount of water or chemical suppressants applied and the frequency of application) are undetermined at present, have not been subject to public comment, and are left to Perpetua to decide at a later date. A lesser control efficiency, even just slightly lesser, could result in large enough PM_{10} emissions to violate the NAAQS. In fact, if the SGP were to instead achieve 80% control (as EPA found through past field testing of chemical dust suppressants), then the SGP's PM_{10} emissions could exceed the NAAQS.

40. Third, DEQ relied on monitoring and record keeping (permit condition 3.16) using devices and methodologies in the Operation and Maintenance ("O&M") Manual for the potential to emit limit associated with the 180,000 tons per day hauling in permit condition 3.5. However, the O&M Manual has not yet been developed, submitted to the public for comment, ~~or~~ reviewed and revised by DEQ, or incorporated into and made enforceable under the Permit. The O&M Manual is critical to ensuring the 180,000 tons per day hauling condition is satisfied, and the 180,000 tons per day is critical to DEQ's determination under IDAPA 58.01.01.203.02 that the SGP will not exceed the NAAQS. Additionally, DEQ is authorized to require plans and to impose any reasonable conditions on permits, but instead of doing so here, it is letting Perpetua do this later, outside of the permit process. *See* IDAPA 58.01.01.202.03 (authorizing DEQ to obtain from permit applicant "[a]ny additional information, plans, specifications, evidence or documents the Department may require to make the determinations required under [the PTC sections of the Air Rules]"); IDAPA 58.01.01.211 (authorizing DEQ to "impose any reasonable conditions upon an approval" of a PTC); IDAPA 58.01.01.121 (authorizing DEQ to require schedules, reports, records, monitoring, and plans to ensure compliance with Air Rules); IDAPA 58.01.01.122.03.g (authorizing DEQ to issue an information order to provide any "information the Department may require"). ~~Further, the PTC itself does not include all monitoring,~~

~~recordkeeping, and reporting necessary to assure compliance with the permit emission limitations and applicable requirements.~~

41. Fourth, DEQ assumed there would be 120 days of recordable precipitation at the SGP (defined as recording precipitation of 0.01 inch or greater) as a variable in its ore haul road fugitive PM emission calculations. This 120 days comes from general geographic guidance from AP-42 Chapter 13.2.2-1. DEQ, however, should have used local meteorological data. Section 6.8 (Meteorological Data) of DEQ's *Guideline for Performing Air Quality Impact Analyses* states: "The meteorological data used in the modeling analysis should be representative of the meteorological conditions at the particular site of the proposed construction or modification." Days of recordable precipitation is an important variable affecting the SGP's emissions of PM_{10} from ore haul roads. DEQ's failure to use the most representative site data is counter to this guidance and increases the risk of miscalculation of ore haul road emissions. As a result, DEQ failed to ensure PM_{10} emissions from the SGP will comply with the NAAQS.

C. Arsenic Pollution & Regulation

42. Arsenic is a naturally occurring element in soils and minerals. When soil or rock containing arsenic is disturbed, arsenic may enter the air, water, and land from wind-blown dust and from run-off and leaching. The EPA classifies inorganic arsenic as a "human carcinogen," based on evidence in human studies of links to lung, bladder, kidney, skin, and liver cancers.

43. Arsenic released from the soil and rock as airborne dust causes environmental damage. Airborne arsenic pollutes soil, plants, and water resources when it is removed from the air by rain, snow, or gradually settling. Studies have shown that there is a strong correlation between arsenic concentrations in water and in the tissues of fish collected from arsenic-polluted waters. Plants may also absorb arsenic in their leaves and root system from arsenic-polluted soil.

The health effects of long-term ingestion of arsenic include developmental effects, diabetes, pulmonary disease, cardiovascular disease, and skin, bladder, or lung cancer.

44. Arsenic is a Toxic Air Pollutant regulated by DEQ. DEQ is required to ensure that no permit to construct shall be granted for a new or modified stationary source unless emissions of TAPs from the constructed source would not injure or unreasonably affect human or animal life or vegetation as required by Section 161. IDAPA 58.01.01.203.03. Section 161 states, "any contaminant which is by its nature toxic to human or animal life or vegetation shall not be emitted in such quantities or concentrations as to alone, or in combination with other contaminants, injure or unreasonably affect human or animal life or vegetation." IDAPA 58.01.01.161.

45. To comply with these TAPs regulations, emissions from a facility must not exceed the Acceptable Ambient Concentrations of Carcinogens ("AACC") at the ambient air boundary. For each carcinogenic TAP, IDAPA 58.01.01.586 lists the applicable TAP and its AACC in ug/m^3 as an annual average. The AACC can practically be defined as the concentration of a TAP that, if an individual was exposed to yearly over a 70-year lifetime, would equate to a cancer development probability risk of 1 in 1,000,000. *See* IDAPA 58.01.01.006.125 & 58.01.01.210.12.

46. In order to determine a facility's TAP concentration at their ambient air boundary, and as noted similarly for PM_{10} emissions, DEQ must assess air impacts using maximum potential emissions as limited by either the capacity of the unit/operation or as limited by enforceable permit provisions. *See* IDAPA 58.01.01.006.88.

D. Arsenic Pollution from the SGP & Flaws in the PTC

47. There are numerous arsenic sources at the SGP, including drilling, blasting, excavating, hauling, silos, rock dumps, and storage and tailing piles. Table 3 in the SGP TAPs Addendum indicates that the maximum arsenic Potential Total Emissions ("PTE") is 0.544 lbs/hr at the maximum mine production rate of 180,000 tons/day. The largest source of arsenic emissions are haul roads estimated at 0.464 lbs/yr (Table B1-W3 in SOB). PTE estimates for arsenic are calculated using the same formulas and Emission Factors as total particulate and PM_{10} emission rates. As such, like the PM and PM_{10} emission estimates discussed already, the arsenic emission estimates are similarly underestimated and equally unreliable.

48. During the permitting process, DEQ determined that the SGP's estimated arsenic emissions and concentrations at the ambient air boundary were excessive and would not meet the AACC for arsenic. To get around this problem, Perpetua chose to employ a process known as T-RACT. T-RACT is a demonstration that allows a permittee to analyze and employ reasonably available control technologies ("RACT") that could be applied to a source of TAPs. If RACT does not sufficiently reduce toxic emissions to below the AACC, then the permittee is allowed a 10-fold increase in the AACC and can employ production limitations to ensure compliance with the now 10-times-bigger AACC. These production limitations should then be incorporated as enforceable permit conditions. *See* IDAPA 58.01.01.210.13–14.

49. As part of the T-RACT determination process, the applicant must supply, and DEQ must consider, information on a variety of factors relevant to determining a "reasonable" control technology including, but not limited to, control effectiveness, economic costs, operational feasibility, and associated environmental impact. IDAPA 58.01.01.210.14a–d.

50. Perpetua submitted to DEQ a T-RACT demonstration for arsenic emissions from open-pit drilling and ore haul roads. Perpetua determined that the most effective RACT for open-

pit drilling was dry drilling with dust collectors and that the most effective RACT for ore haul roads was water sprays and chemical suppressants. In its T-RACT demonstration, Perpetua included limited qualitative discussion, and no quantitative support, regarding economic considerations. Perpetua failed to provide any discussion of environmental impacts.

51. DEQ approved Perpetua's T-RACT demonstration and granted Perpetua a 10-fold increase in allowable arsenic pollution, subject to operational limitations to reduce PTE. And as modeled by DEQ, arsenic pollution from the SGP would comply with this larger AACC.

52. For each of the reasons below, DEQ's approval of Perpetua's T-RACT demonstration for arsenic, ~~and~~ its analysis determining the SGP will not exceed the AACC and thus will not injure or unreasonably affect human or animal life or vegetation, and its action approving the PTC ~~is flawed~~violates the Clean Air Act, violates EPA's Clean Air Act regulations, violates the Idaho Air Rules, and is otherwise arbitrary, capricious, made on unlawful procedure, and an abuse of discretion and must be set aside under I.C. § 67-5279.

53. First, the T-RACT demonstration contained no persuasive economic information and no discussion at all regarding associated environmental impacts, despite the requirements to do so in IDAPA 58.01.01.210.14. There will be water quality and biological impacts associated with Perpetua's use of substantial amounts of chemical dust suppressants and water that have not been considered in the PTC. For example, the use of chemical dust suppressants like magnesium chloride can cause toxicity in trees and can lead to tree death. Magnesium chloride is also known to adversely affect aquatic ecosystems. Moreover, the proposed water source for dust control is primarily water collected in runoff ponds (captured rain or snowfall that has become contaminated through the contact of mine facilities), groundwater, and surface water from the East Fork of the South Fork of the Salmon River. USGS sampling indicates elevated arsenic in

these waters. The environmental impact of using magnesium chloride or arsenic-polluted water as dust suppression methods was never considered as part of the T-RACT demonstration. Likewise, the T-RACT demonstration did not provide sufficient economic support for Perpetua's decision to use water and chemical dust suppressants as compared to paving the haul roads, even though paving was shown to achieve the highest reasonable dust control efficiency.

54. Second, because the underlying particulate and PM_{10} emissions estimates and particulate control assumptions are unreliable in numerous respects, as already discussed above, so too are the estimated arsenic emissions. The SGP's estimated arsenic emissions were based on its PM_{10} emissions. PM_{10} emissions from the SGP may be higher, and their control effectiveness may be lower, than DEQ assumed, in which case arsenic emissions would also be higher and might exceed the AACC.

55. Third, Perpetua's and DEQ's TAPs analyses substantially reduce the SGP's purported arsenic emissions using three improper averaging tactics: (1) averaging emissions over a 5-year period for the T-RACT input to ambient toxics modeling; (2) averaging the estimated annual ambient modeling impacts across two multi-year scenarios; and (3) averaging the resultant 16-year total emissions over the 70-year human lifetime to assert compliance. Nothing in the Idaho Air Rules allows for multi-year emissions averaging and ambient air concentration adjustments. Rather, the arsenic AACC is an annual average. *See* IDAPA 58.01.01.586). DEQ's T-RACT regulations require comparing the estimated maximum annual ambient air arsenic concentration to 10 times the listed annual AACC. IDAPA 58.01.01.12.b. Therefore, to determine compliance with the AACC requires that DEQ estimate the SGP's maximum 1-year annual arsenic emissions and compare it to the annual arsenic AACC.

56. By relying on these improper averaging tactics, DEQ fails to show the SGP will satisfy the arsenic AACC and the resulting analysis masks potentially severe human health and environmental impacts of SGP's potential arsenic emissions. The underlying analyses supporting the TAPs requirements allows for a 1-in-1,000,000 excess cancer risk factor. The T-RACT approval increases that risk 10-fold to a 1-in-100,000 excess cancer risk factor. IDAPA 58.01.01.12.b. Perpetua's multi-year averaging of emission rates combined with DEQ's decision to allow the full lifetime exposure (70 years) to be imposed on receptors during the 16-year estimated life of mine increases the cancer risk by another order of magnitude to the 1-in-10,000 range or higher. Combined with uncertainties associated with the underlying particulate emissions calculations noted above, the SGP may result in extremely dangerous arsenic exposures.

57. While not the basis for a separate claim for relief, Petitioners note that excacerbating this cancer risk is the fact that under DEQ's incremental TAPs regulations (*see* IDAPA 58.01.01.585), when DEQ considers permitting any additional sources of arsenic in the area over the next 70 years (such as an extension of the life of the SGP, expansion of the facility itself, and/or any adjacent facilities seeking a similar permit, like the potential Horse Heaven project), DEQ will not have to consider the arsenic emissions authorized by this PTC.

E. DEQ's Ambient Air Boundary for the SGP

58. The Clean Air Act and Idaho Air Rules require meeting various air standards, including the NAAQS and TAPs, in ambient air. *See*, *e.g.*, IDAPA 58.01.01.006.11 (NAAQS), 58.01.01.006.125 (TAPs). EPA defines "ambient air" as "that portion of the atmosphere, external to buildings, to which the general public has access." 40 C.F.R. § 50.1(e). In defining an ambient air boundary, the EPA has long followed a policy that exempts "the atmosphere over land owned

or controlled by the source and to which public access is precluded . . .” from ambient air. EPA’s Revised Policy on Exclusions from “Ambient Air” (Nov. 2018) states that “it is appropriate to exclude the atmosphere over land owned or controlled by the stationary source, where the owner or operator of the source employs measures, which may include physical barriers, that are effective in deterring or precluding access to the land by the general public.”

59. The Idaho Air Rules define “ambient air” as “[t]hat portion of the atmosphere, external to building, to which the general public has access.” IDAPA 58.01.01.005.09. To exclude areas from consideration as ambient air, the following conditions must be met: (1) the permittee must have the legal authority to exclude the general public from the area; (2) the boundary to ambient air must be clearly discernible to the general public; (3) the general public must be effectively precluded from assessing the facility; and (4) the general public is not considered employees of the facility; those having official business with the facility; guests of the facility, including participants in facility routes and those seeking access for a specific purpose.

60. Perpetua established an operations boundary (the active industrial site where mining activities and heavy equipment operation will occur) for the purposes of excluding this area from ambient air analysis, and for excluding public access. The area includes the current Stibnite Road point of entry and proposed site access via the Burntlog Route. According to Perpetua, access inside the operations boundary will be restricted for the life of the mine by physical barriers at points of potential access, as well as natural features of the landscape that prevent public access.

61. DEQ’s determination to exclude the access route from ambient air protections, and its action approving the PTC ~~is flawed~~violates the Clean Air Act, violates EPA’s Clean Air

Act regulations, violates the Idaho Air Rules, and is otherwise arbitrary, capricious, made on unlawful procedure, and an abuse of discretion and must be set aside under I.C. § 67-5279.

62. Perpetua has indicated that it intends to allow access to the general public through the mine site between Stibnite Road at Sugar Creek and Thunder Mountain Road at Meadow Creek. Furthermore, this roadway is currently accessible to and has been regularly used by the general public. And while Perpetua claims that it has "legal and practical ability to enforce its control over roadway access," the Forest Service has not yet completed its NEPA analysis and approval of the SGP, which would include a decision on whether it will require or will not permit general public access through the mine site.

63. DEQ states that the route would be managed in accordance with the Stibnite Road Access Management Plan ("AMP"). DEQ, however, relied on an ambiguous description of measures and requirements to preclude public access and ensure that those traveling over the road can be classified as "guests" of the mine.

64. PTC condition 2.7 requires the development of an AMP to address whether the NAAQS apply to the mine's access road through the Perpetua site given the extent of public access allowed. PTC condition 2.8 allows the AMP to be developed later, after the PTC was issued and without public comment, and it does not require the AMP to be enforceable. For the AMP to preclude the applicability of the NAAQS along the access road, the AMP must be reviewed and approved by DEQ, it must be reviewed through public comment, and it must be enforceable under the PTC.

65. Without full disclosure and knowledge of the exact measures and requirements in the AMP and enforceable permit limits, DEQ cannot make a determination of whether exclusion of the access road from ambient air protections complies with EPA's ambient air policy and the

Idaho Air Rules, nor can DEQ determine whether the SGP will comply with the NAAQS and TAPs.

F. DEQ's Failure to Require Ambient Air Monitoring for the SGP

66. DEQ has the authority to require ambient air monitoring to determine the effect emissions from the stationary source or facility may have on the air quality of the area potentially impacted by the source. IDAPA 58.01.01.211.01(d).

67. DEQ received comments from the Nez Perce Tribe, EPA Region 10, ICL, and SSFS urging the PTC to require ambient air monitoring to verify the SGP's compliance with the NAAQS and TAPs increments. But DEQ declined, stating in the Response to Comments (pg. 16): "DEQ disagrees that a PM/PM_{10} ambient monitoring network is necessary to make the PTC practically enforceable." DEQ states in the Response to Comments that any violation of the permit would be processed in accordance with DEQ's enforcement procedures manual.

68. However, without ambient air monitoring, it will be impossible for DEQ to assess whether the SGP's operation is in compliance with NAAQS and TAPs increments at any given time. Ambient air monitoring is necessary because of the large uncertainty surrounding dust control efficiency and emissions factors associated with the SGP for PM_{10} and arsenic, as well as the lack of enforceable permit conditions for many important variables, as already described in this Petition.

RELIEF REQUESTED

69. An agency action, like DEQ's issuance of the PTC, may be reversed if it is in violation of constitutional or statutory provisions, is in excess of statutory authority, is made on unlawful procedure, or is arbitrary, capricious or an abuse of discretion. I.C. § 67-5279. When an

agency action is not affirmed, it shall be set aside, in whole or in part, and remanded for further proceedings as necessary. *Id.*

70. As stated above, under the Idaho Air Rules, DEQ must not issue a PTC unless it determines: (1) "the stationary source or modification would comply with all applicable local, state or federal emission standards"; (2) "the stationary source would not cause or significantly contribute to a violation of any ambient air quality standard"; and (3) "the emissions of toxic air pollutants from the stationary source or modification would not injure or unreasonably affect human or animal life or vegetation as required by Section 161." IDAPA 58.01.01.203. Prior to issuing a permit to contruct, DEQ must provide an opportunity for public comment by making available DEQ's proposed action together with the information provided by the applicant and with DEQ's analysis. IDAPA 58.01.01.209.c. To ensure compliance with the NAAQS and other air pollution control strategies, the Clean Air Act and EPA's Clean Air Act regulations require state air rules like DEQ's: to include "enforceable emission limitations" and other measures, 42 U.S.C. § 7410(a)(2)(A); to include a "program to provide for the enforcement" of such measures, and to regulate the construction of any stationary source, *id.* § 7410(a)(2)(C); to "set forth legally enforceable procedures" for determining whether the construction of a facility will comply with control strategies and NAAQS, 40 C.F.R. § 51.160(a); to require sufficient information needed "to make the determination" whether the facility will comply with air pollution control strategies and the NAAQS, i*d.* § 51.160(c); and to provide opportunity for public comment on information submitted by the applicant and on the agency's analysis of the effects to air quality. *Id.* § 51.161(a). Based on the flaws in DEQ's issuance of the PTC described above, DEQ's action is in violation of these provisions of the Idaho Air Rules, the Clean Air Act, and EPA's Clean Air Act

regulations, and is otherwise arbitrary, capricious, made on unlawful procedure, and an abuse of discretion and must be reversed.

71. By issuing the PTC in its current form, DEQ failed to adequately protect the public and environment from harmful air pollution causing injury to the Nez Perce Tribe, ICL, SSFS, and their members and supporters. To redress these injuries, Petitioners respectfully request the Board set aside and remand the PTC and direct DEQ to correct the following errors prior to issuing any new or revised PTC:

Ore Haul Road PM_{10} & Arsenic Emissions

A. DEQ must develop and include in the PTC enforceable permit conditions for the maximum average empty weight of ore haul trucks, the maximum average loaded weight of ore haul trucks, the maximum total number vehicle miles traveled annually by ore haul trucks, the silt content of the roadbed, the arsenic content of the silt in the roadbed, and any other important variables affecting the SGP's fugitive emissions of PM_{10} and arsenic from vehicle traffic on mine haul roads. To develop such permit conditions and ensure compliance with the NAAQS and TAP limits, DEQ must reevaluate and recalculate fugitive emissions of PM_{10} and arsenic.

B. Silt and arsenic levels should be included as permit conditions and monitored regularly *in situ,* rather than from stockpiles as applied to the roadbed.

C. Instead of assuming 120 days of recordable precipitation at the SGP as a variable within ore haul road fugitive PM emission calculations, as done by the applicant based off general geographic guidance from AP-42 chapter 13.2.2-1, DEQ must recalculate all fugitive emissions after analyzing local meteorological data sources to determine a more accurate and representative number of days with recordable precipitation.

FDCP, AMP, O&M Manual, & HRCP

D. DEQ must require Perpetua to submit the FDCP, AMP, O&M Manual, and HRCP (collectively, "Plans"), must provide for public comment on the Plans, must review and revise Plans to ensure the SGP's emissions comply with IDAPA 58.01.01.203, and must incorporate the Plans as enforceable PTC conditions.

Arsenic Averaging

E. DEQ must remove the 5-year averaging for arsenic emissions, the averaging of estimated annual ambient modeling impacts across two multi-year scenarios, and the 16/70 life of mine versus lifetime exposure adjustment for the SGP's maximum arsenic ambient concentration it used to assess arsenic TAPs compliance. DEQ must use the SGP's highest 1-year arsenic emission rates for each scenario evaluated and repeat the modeling analyses using these rates. DEQ must use the maximum annual ambient arsenic concentration from the single emission scenario producing the highest annual concentration for any 1-year as the point of compliance. *See* IDAPA 58.01.01.210.03b ("The point of compliance is the receptor site that is estimated to have the highest ambient concentration of the toxic air pollutant of all the receptor sites that are located either at or beyond the facility property boundary or at a point of public access . . . ."). DEQ must assess the impact of the SGP's maximum 1-year annual emissions from the single emission configuration by comparing to the T-RACT AACC for arsenic (10 times the AACC value published in IDAPA 58.01.01.586), without averaging over multiple years, and without adjusting for the alleged 16-year life of the mine or the 70-year lifetime exposure.

Ambient Air Boundary Monitoring

F. As part of any PTC for the SGP, DEQ must require ambient air boundary monitoring, as provided for by IDAPA 58.01.01.211.01(d), to ensure compliance with the NAAQS and the TAPs increments. DEQ must require Perpetua to submit an ambient air

boundary monitoring plan ("AABMP"), must take public comment on the AABMP, must review and revise the AABMP, and must incorporate the AABMP as enforceable PTC conditions. At a minimum, the AABMP must provide a strategy for monitoring the ambient air concentrations of PM_{total}, PM_{10}, $PM_{2.5}$ and arsenic at the SGP's ambient air boundary. The AABMP must be developed according to best industry and regulatory practices, consulting contemporary sources (e.g., DEQ or EPA guidance, similarly established plans for other state permits, etc.). At a minimum, monitoring stations must be required for areas of the ambient air boundary in which DEQ ambient air modeling results (specifically results using operating scenario W3 and BULKRN meteorological data) show receptors with 24-hour PM_{10} or arsenic concentrations within 70% of the applicable NAAQS or AACC (without consideration to multi-year emissions averaging and 16/70 adjustment).

Environmental & Economic Impacts of Arsenic Control Technology

G. DEQ must require Perpetua to update their T-RACT analysis to include analysis of "environmental impacts caused by the control technology that cannot be mitigated, including, but not limited to, water pollution and the production of solid wastes," including the use of magnesium chloride and its aquatic life and tree toxicity effects, as well as using arsenic-contaminated water sources for dust suppression. IDAPA 58.01.01.210.14.c.ii. DEQ must also require the updated T-RACT to adequately address the "economic feasibility of a control technology or other requirement, including the costs of necessary mitigation measures, for a particular source," including detailed consideration of the economic feasibility of paving haul roads to better control fugitive dust emissions. IDAPA 58.01.01.210.14.d. DEQ must provide the updated T-RACT demonstration for public comment, must review and revise the T-RACT

demonstration, and must incorporate enforceable PTC conditions from the T-RACT demonstration in the PTC.

CONCLUSION

72. When it issued the PTC for the SGP, DEQ ~~failed to comply with critical requirements of~~violated the federal Clean Air Act, EPA's Clean Air Act regulations, and the Idaho Air Rules; and it acted arbitrarily, capriciously, and on unlawful procedure and abused its discretion under I.C. § 67-5279. Accordingly, the Board should vacate and withdraw the PTC and remanded to DEQ to correct all errors.

STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047 NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON, Petitioners, v. IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent, and PERPETUA RESOURCES IDAHO, INC. Intervenor-Respondent.	Case Docket No. 0101-22-01 **PERPETUA RESOURCES IDAHO, INC.'S RESPONSE TO FIRST AMENDED PETITION TO INITIATE CONTESTED CASE: AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047 (JUN. 17, 2022)**

Pursuant to IDAPA 58.01.23.161, Perpetua Resources Idaho, Inc. ("Perpetua"), through its undersigned counsel, hereby submits its response to Petitioners' First Amended Petition to Initiate Contested Case: Air Quality Permit to Construct P-2019.0047 (Jun. 17, 2022) ("FAP").

I. GENERAL RESPONSES

The FAP is informally presented in the style of a legal brief, intermingling alleged facts, arguments, opinions, suggestions for permit content, and conclusory statements. Almost every paragraph of the FAP contains multiple assertions of fact, law, and suggestions for how the Department of Environmental Quality ("Department") could have done better. These mixed pleadings make it difficult to separate factual allegations, to which a response is required, from legal assertions, to which no response is required. Therefore, Perpetua denies all allegations contained in the FAP that are not explicitly admitted below.

Petitioners repeatedly reference those portions of the Clean Air Act ("CAA") and 40 C.F.R. Part 51 ("Part 51 Regulations") setting forth the requirements for development and approval of a State Implementation Plan ("SIP"). *See* FAP ¶¶ 32, 70. Idaho's SIP was originally approved in 1972, and amendments thereto have been approved multiple times over the years. *See Safe Air for Everyone v. United States EPA*, 488 F.3d 1088, 1093 (9th Cir. 2007) (describing history of Idaho's SIP).[1] Idaho's SIP is codified in the Department's Rules for the Control of Air Pollution in Idaho, IDAPA 58.01.01 ("Air Rules"). It is unclear whether Petitioners seek to collaterally attack the Air Rules through this proceeding, or if they are attempting to import the requirements of the CAA provisions relating to SIP approval and the Part 51 Regulations as a governing legal standard for review of the Permit to Construct.

Under either scenario, Petitioners reliance on the CAA provisions relating to SIP approval and the Part 51 Regulations is improper. As explained by *NRDC v. S. Coast Air Quality Mgmt. Dist.*, a plaintiff cannot challenge a state agency action, such as issuance of a permit, for

[1] *See also* U.S. EPA, *EPA Approved Regulations in the Idaho SIP* (updated May 31, 2022), https://www.epa.gov/sips-id/epa-approved-regulations-idaho-sip.

failure to comply with the CAA provisions relating to SIP approval or the Part 51 Regulations because those provisions and regulations do not "establish enforceable emissions standards or limitations, but rather identify the types of emissions standards and limitations that must be set forth in a SIP." 694 F. Supp. 2d 1092, 1111 (C.D. Cal. 2010). And to the extent Petitioners seek to collaterally attack the Air Rules for failure to comply with the CAA or the Part 51 Regulations, the Board lacks jurisdiction over their claim. *See Cal. Dump Truck Owners Ass'n v. Nichols*, 784 F.3d 500, 502 (9th Cir. 2015) (the CAA vests federal circuit courts of appeals with exclusive jurisdiction over challenges to a SIP).

II. SPECIFIC RESPONSES

1. Perpetua admits that Petitioners filed a Petition to Initiate Contested Case on July 22, 2022, challenging the Permit to Construct P-2019.0047 ("PTC") issued by the Department on June 17, 2022 to Perpetua for the Stibnite Gold Project ("SGP").

2. Perpetua admits the allegations contained in the first and third sentence of Paragraph 2 of the FAP. Perpetua lacks knowledge or information sufficient to form a belief as to the truth of the allegations contained in the second sentence of Paragraph 2 of the FAP, and therefore denies those allegations.

3. In Paragraph 3 of the FAP, Perpetua admits that the PTC authorizes Perpetua to construct and begin operating the SGP. Perpetua admits that dust will be generated by normal mining activities, which were fully analyzed by the Department in reaching its decision to issue the PTC. Perpetua denies that the amount of dust emitted from operation of the SGP will be a "massive quantity," which is an entirely subjective term and has no legal relevance or meaning. Perpetua admits that the dust generated by operation of the SGP will contain particulate matter and may contain arsenic, both of which are recognized and regulated as air pollutants by the Department.

4. Perpetua denies the allegations contained in Paragraph 4 of the FAP. Perpetua affirmatively states that there are no grounds for the Board of Environmental Quality (the "Board") to reverse or set aside the PTC, nor to remand the PTC to the Department. Perpetua further states that Petitioners are entitled to no relief and respectfully requests that this case be dismissed.

5. Perpetua admits that the individuals listed in Paragraph 5 of the FAP have entered appearances as counsel for Petitioners.

6. Perpetua admits the allegations of Paragraph 6 of the FAP to the extent Petitioners seek to challenge the Department's action under the Air Rules of issuing the PTC. Perpetua denies that the Board has jurisdiction to the extent Petitioners raise claims that the Air Rules are deficient under the CAA or the Part 51 Regulations.

7. Perpetua admits that Idaho Code ("I.C.") § 67-5279 provides the applicable standard of review of this matter. Perpetua affirmatively states that I.C. § 67-5279 speaks for itself. Perpetua denies all allegations contained in Paragraph 7 of the FAP to the extent they are inconsistent with I.C. § 67-5279.

8. Perpetua admits that IDAPA 58.01.23 authorizes Petitioners to initiate a contested case and defines "aggrieved person." Perpetua affirmatively states that IDAPA 58.01.23 speaks for itself. Perpetua denies all allegations contained in Paragraph 8 of the FAP to the extent they are inconsistent with IDAPA 58.01.23.

9. Perpetua admits that the Nez Perce Tribe is a federally recognized Indian tribe. Perpetua lacks knowledge or information sufficient to form a belief as to the truth of the remaining allegations contained in Paragraph 9 of the FAP and, therefore, denies those allegations.

10. Perpetua denies that the Nez Perce Tribe has standing to bring this contested case. Perpetua lacks knowledge or information sufficient to form a belief as to the truth of the remaining allegations contained in Paragraph 10 of the FAP and, therefore, denies those allegations.

11. Perpetua admits that the Nez Perce Tribe entered into a treaty with the United States, which speaks for itself. To the extent the allegations contained in Paragraph 11 of the FAP are inconsistent with the treaty, Perpetua denies those allegations. Perpetua lacks knowledge or information sufficient to form a belief as to the truth of the remaining allegations contained in Paragraph 11 of the FAP and, therefore, denies those allegations.

12. Perpetua denies that issuance of the PTC will result in the emission of "excessive air pollutants," which is an entirely subjective term and has no legal relevance or meaning. Perpetua denies that the Nez Perce Tribe has suffered, or will suffer, a legally cognizable injury caused by the Department's issuance of the PTC. Perpetua admits that air pollution may cause environmental and human health impacts, but denies that the ecosystem surrounding the SGP or members of the Nez Perce Tribe will suffer any of the harms alleged in Paragraph 12 of the FAP.

13. Perpetua admits that the Nez Perce Tribe submitted comments on the draft versions of the PTC. Perpetua denies that the Nez Perce Tribe is entitled to any relief because neither the Nez Perce Tribe nor its members have suffered, or will suffer, a legally cognizable injury due to the Department's issuance of the PTC.

14. Perpetua lacks knowledge or information sufficient to form a belief as to the truth of the allegations contained in Paragraph 14 of the FAP and, therefore, denies those allegations.

15. Perpetua denies the allegations contained in Paragraph 15 of the FAP. Perpetua affirmatively states that neither Idaho Conservation League ("ICL") nor its members have

suffered, or will suffer, a legally cognizable injury caused by the Department's issuance of the PTC and ICL is therefore entitled to no relief.

16. Perpetua admits that ICL submitted comments on the various drafts of the PTC.

17. Perpetua lacks knowledge or information sufficient to form a belief as to the truth of the allegations contained in Paragraph 17 of the FAP, and therefore denies those allegations.

18. Perpetua denies the allegations contained in Paragraph 18 of the FAP. Perpetua affirmatively states that neither Save the South Fork Salmon ("SSFS") nor its members have suffered, or will suffer, a legally cognizable injury caused by the Department's issuance of the PTC and SSFS is, therefore, entitled to no relief.

19. Perpetua admits that SSFS submitted comments on the various drafts of the PTC.

20. Perpetua admits the allegations contained in Paragraph 20 of the FAP.

21. Perpetua admits the allegations contained in Paragraph 21 of the FAP.

22. Perpetua admits the allegations contained in Paragraph 22 of the FAP.

23. Perpetua admits the allegations contained in Paragraph 23 of the FAP.

24. In Paragraph 24, Perpetua admits that the Department developed, and issued for comment, three draft versions of the PTC. Perpetua admits that Petitioners commented on the draft versions of the PTC. Perpetua denies that any draft "contained significant shortcomings," which is a subjective term that has no legal meaning or relevance. Perpetua denies that the "draft PTC was considered deficient."

25. Perpetua admits that the Department issued a revised draft of the PTC for public comment in February 2021. Perpetua denies that the "February 2021 draft was deficient."

26. Perpetua admits that the Department issued a revised draft PTC on January 13, 2021, for which the Petitioners, the U.S. Environmental Protection Agency ("EPA"), and Mr. von

Lindern submitted comments. Perpetua admits that the Department appropriately rejected many of the issues raised by Petitioners' comments because they were either baseless or would not meaningfully improve compliance with the Air Rules.

27. Perpetua admits that construction and operation of the SGP has the potential to cause emissions of arsenic and particular matter ("PM") with diameters less than 10 micrometers ("PM_{10}"). Perpetua admits that the FAP only makes allegations relating to arsenic and PM_{10} and no other air pollutant.

28. Perpetua admits that certain types of PM may cause negative impacts to human health. Perpetua denies that PM emissions from the SGP will cause any of the health effects alleged in Paragraph 28 of the FAP.

29. Perpetua admits that certain types of PM may cause negative environmental impacts. Perpetua denies that PM emissions from the SGP will cause any of the environmental harms alleged in Paragraph 29 of the Petition. Perpetua further states that Petitioners have not alleged that the PM emissions potentially generated from the SGP are of the nature that would cause the environmental impacts alleged in Paragraph 29 of the FAP.

30. Perpetua admits that Sections 108 and 109 of the CAA govern the establishment of National Ambient Air Quality Standards ("NAAQS"). Perpetua affirmatively states that the statute speaks for itself, and denies all allegation contained in Paragraph 30 of the FAP to the extent they are inconsistent with the language of the CAA.

31. Perpetua admits that, consistent with the CAA, EPA has established NAAQS for PM_{10} and $PM_{2.5}$. Perpetua affirmatively states that 40 C.F.R. §§ 50.6 and 50.7 speak for themselves, and denies all allegations contained in Paragraph 31 of the FAP that are inconsistent with those regulations.

32. Perpetua admits that EPA has approved Idaho's SIP, which is codified in the Air Rules. *See Safe Air for Everyone v. United States EPA*, 488 F.3d 1088, 1093 (9th Cir. 2007). Perpetua admits that the Department has authority to issue air quality permits in Idaho. Perpetua denies that those sections of the CAA or the Part 51 Regulations cited in Paragraph 32 of the FAP have any relevance to this proceeding because they govern the creation and approval of SIPs, but do not govern the issuance of permits under an approved SIP. Perpetua affirmatively states that, to the extent Petitioners seek to challenge the Air Rules as failing to comply with the CAA or Part 51 Regulations, the Board lacks jurisdiction. Perpetua admits that IDAPA 58.01.01.203.02 sets forth permit requirements for new and modified stationary sources related to NAAQS. Perpetua admits that IDAPA 58.01.01.006.88 sets forth the definition of "Potential to Emit/Potential Emissions." Perpetua admits that IDAPA 58.01.01.209 sets forth procedures for issuing permits. Perpetua affirmatively states that the cited provisions of IDAPA 58.01.01 speak for themselves, and Perpetua denies all allegations contained in Paragraph 32 of the FAP to the extent they are inconsistent with IDAPA 58.01.01.

33. Perpetua admits the allegations contained in Paragraph 33 of the FAP.

34. Perpetua admits the allegations contained in Paragraph 34 of the FAP.

35. Perpetua denies the allegations contained in Paragraph 35 of the FAP.

36. Perpetua admits that it relied, in-part, on AP-42 Chapter 13.2.2 to model particulate matter emissions from ore hauling operations. Perpetua admits that the Department established an enforceable condition in the PTC for the silt content of the haul roads. Perpetua admits that the average loaded weight of ore haul trucks, the size of trucks used, the number of days of precipitation, and the total number of vehicle miles traveled by ore haul trucks, were not included as specific conditions in the PTC. Perpetua denies that it is necessary for these

additional variables to be limited by permit conditions to ensure compliance with the NAAQS. Perpetua affirmatively states that the variables used to model emissions were the most representative of proposed operations and most realistic for the proposed mining activities. Perpetua denies that it would be possible to set a permit condition limiting the number of days per year with precipitation greater than or equal to 0.01 inches per day. Perpetua affirmatively states that, in addition to the silt content of the haul roads, the Department established permit conditions that establish enforceable limits on multiple operating parameters of the SGP, including daily ore hauling limits, which will ensure compliance with the NAAQS. PTC Conditions 3.3 – 3.13.

37. Perpetua admits that PTC Condition 3.5 establishes enforceable maximum daily hauling limits of 180,000 tons per day, and 135,000 tons per day based on a 5-year rolling average, of ore and development rock. Perpetua admits that the PTC requires Perpetua to develop a Fugitive Dust Control Plan ("FDCP"), which must ensure compliance with the fugitive dust requirements of the PTC (Conditions 2.1 – 2.5). PTC Condition 2.6. Perpetua admits that the PTC requires Perpetua to develop a Haul Road Capping Plan ("HRCP"), consistent with the requirements of Condition 3.13. PTC Condition 3.13. Perpetua admits that it must submit the FDCP and HRCP to the Department for approval at least 30-days prior to startup, and once approved the provisions of those plans will become enforceable permit conditions. PTC Conditions 2.6, 3.13. Perpetua denies that the Department erred by requiring the FDCP and HRCP to be submitted for approval after issuance of the PTC. Perpetua denies that the PTC lacks enforceable permit conditions or lacks assurance that the SGP will comply with the NAAQS.

38. Perpetua admits that the Department analyzed emissions from the SGP using a 93.3% control factor from water sprays and chemical dust suppressants applied to haul roads. Perpetua admits that AP-42 is a reference source for control effectiveness.

39. Perpetua denies that the PTC omits specific and enforceable conditions to ensure a 93.3% control efficiency. Perpetua affirmatively states that the PTC contains multiple conditions for the control of fugitive dust. PTC Conditions 2.1 – 2.6, 2.8. Perpetua denies that the Department erred by not including the variables identified by Petitioners as conditions of the PTC. Perpetua admits that it will develop a FDCP and HRCP and submit those plans to the Department 30 days prior startup for approval. Perpetua affirmatively states that there is no requirement in the Air Rules that the Department provide these Plans for public comment.

40. Perpetua admits that the Air Rules, which speak for themselves, give the Department authority to require Perpetua to submit an Operations and Maintenance Manual ("O&M Manual"). Perpetua further admits that the PTC requires Perpetua to develop and submit an O&M Manual to the Department for approval. Perpetua denies that the Air Rules require the O&M Manual to be submitted for public comment.

41. Perpetua admits that the Department relied on emissions modeling, which assumed 120 days of recordable precipitation at the SGP. Perpetua denies that the *Guidelines for Performing Air Quality Impact Analyses* are binding on the Department. Perpetua denies that the Department erred by using 120 days of recordable precipitation at the SGP for purposes of modeling fugitive PM emissions.

42. Perpetua admits the allegations in Paragraph 42.

43. Perpetua admits the allegations of environmental transport and human health effects of arsenic contained in Paragraph 43 of the FAP.

44. Perpetua admits that the Air Rules, which speak for themselves, give the Department authority to regulate the emission of toxic air pollutants ("TAPs"), including arsenic. To the extent any allegations contained in Paragraph 44 of the FAP are inconsistent with the Air Rules, Perpetua denies those allegations.

45. Perpetua admits that the Air Rules give the Department authority to regulate emissions of TAPs and establish acceptable risk levels of TAPs. Perpetua affirmatively states that the Air Rules speak for themselves. Perpetua denies all allegations contained in Paragraph 45 to the extent they are inconsistent with the Air Rules.

46. Perpetua admits that the Air Rules require the Department to assess impacts of TAPs based on a facility's potential to emit. Perpetua affirmatively states that the Air Rules speak for themselves. Perpetua denies all allegations contained in Paragraph 46 of the FAP to the extent they are inconsistent with the Air Rules.

47. Perpetua admits that construction and operation of the SGP has the potential to cause arsenic emissions. Perpetua admits that the TAPS Addendum estimates arsenic emissions from the various potential sources at the SGP. Perpetua affirmatively states that the TAPS Addendum speaks for itself, and denies all allegations contained in Paragraph 47 of the FAP to the extent they are inconsistent with the TAPS Addendum. Perpetua denies that any portion of arsenic emission estimates relied on by the Department in granting the PTC are "underestimated" or "unreliable."

48. Perpetua admits that it selected T-RACT to control arsenic emissions from the SGP. Perpetua further admits that the Air Rules establish the requirements for T-RACT and give the Department authority to allow a permittee to utilize T-RACT to control emissions of TAPs, like arsenic. Perpetua affirmatively states that the Air Rules speak for themselves and denies all

allegations contained in Paragraph 48 of the FAP to the extent they are inconsistent with the Air Rules. Perpetua denies that the arsenic emissions from the SGP will be "excessive," which is an entirely subjective term and has no legal relevance or meaning.

49. Perpetua admits that the Air Rules set forth various factors for the Department to consider when determining whether a control technology is "reasonably available." Perpetua affirmatively states that the Air Rules speak for themselves and denies all allegations contained in Paragraph 49 of the FAP to the extent they are inconsistent with the Air Rules.

50. Perpetua admits that it submitted a T-RACT demonstration for arsenic to the Department, which included "reasonably available" control technologies, including using dry drilling with dust collectors for open pit drilling and the use of dust suppressant (water and chemical) for ore haul roads. Perpetua denies that its T-RACT analysis was deficient or that Perpetua was required to submit additional information.

51. Perpetua admits that the Department approved Perpetua's T-RACT demonstration and issued the PTC consistent with the Air Rules, which speak for themselves.

52. Perpetua denies the allegations contained in Paragraph 52 of the FAP.

53. Perpetua denies that its T-RACT demonstration submitted to the Department was deficient or that use of the selected reasonably available control technologies would result in adverse environmental impacts. Perpetua denies that additional economic analysis was required to justify its determination that paving was not "reasonably available."

54. Perpetua admits that the analysis of potential arsenic emissions from the SGP are based on the same underlying analysis as potential PM emissions. Perpetua denies that the analysis of potential arsenic emissions, or PM emissions, are "unreliable" or that arsenic emissions could exceed the limits established by the Air Rules.

55. Perpetua admits that it utilized source-specific TAPs emission rates that are representative of a 5-year averaging period in dispersion modeling for the T-RACT Analysis. Statement of Basis, TAPS Addendum Modeling Review Attachment at 2. Perpetua admits that it averaged estimated annual modeling impacts across two multi-year scenarios. Perpetua admits that it refined the life-time exposures to carcinogenic TAPs by multiplying the maximum modeled annual impact by a ratio of 16/70 to account for the life-of-mine emissions. *Id.* Perpetua denies that these were "improper averaging tactics," or contrary to the Air Rules. Perpetua affirmatively states that the Air Rules speak for themselves and denies all allegations contained in Paragraph 55 to the extent they are inconsistent with the Air Rules.

56. Perpetua admits that the Air Rules allow an increase in the cancer risk factor when T-RACT is utilized to control TAPs emissions. Perpetua affirmatively states that the Air Rules speak for themselves and denies all allegations contained in Paragraph 56 of the FAP to the extent they are inconsistent with the Air Rules. Perpetua denies that its TAPs analysis will result in cancer risk levels above those authorized by the Air Rules. Perpetua denies that construction or operation of the SGP will result in "extremely dangerous arsenic exposures," which is a subjective term and has no legal relevance or meaning. Perpetua denies that these were "improper averaging tactics," or are contrary to the Air Rules.

57. Perpetua admits that the Air Rules, which speak for themselves, do not require the Department to consider the emissions from the SGP when making permitting decisions on permit applications for new facilities. Perpetua affirmatively states that this paragraph is legally irrelevant as to whether the Department erred in issuing the PTC.

58. Perpetua admits that the Air Rules, which speak for themselves, require facilities operating under a PTC to meet various air standards. Perpetua admits that the Air Rules,

consistent with 40 C.F.R. § 50.1(e), define "ambient air." Perpetua admits that EPA has issued guidance to assist in determining what portions of a facility should be excluded from "ambient air." Perpetua affirmatively states that EPA's guidance speaks for itself and denies all allegations contained in Paragraph 58 of the FAP to the extent they are inconsistent with the guidance.

59. Perpetua admits that the Air Rules establish the definition of "ambient air" and set forth the factors that must be considered in determining whether an area can be excluded from "ambient air." Perpetua affirmatively states that the Air Rules speak for themselves and denies all allegations contained in Paragraph 59 of the FAP to the extent they are inconsistent with the Air Rules.

60. Perpetua admits that it established an operations boundary, the interior of which is excluded from "ambient air" as described in Perpetua's application and supplemental materials submitted to the Department. To the extent any allegations contained in Paragraph 60 are inconsistent with the application and supplemental materials, Perpetua denies those allegations.

61. Perpetua denies the allegations contained in Paragraph 61 of the FAP.

62. Perpetua denies that it will allow the "general public," as that term is used by the Air Rules, access within the operations boundary. Perpetua denies that it will lack effective legal authority to control access to areas within the operations boundary following the U.S. Forest Service's approval of Perpetua's operations plan.

63. Perpetua admits that the PTC requires it to prepare and submit an Access Management Plan ("AMP") to the Department at least 30 days prior to startup, which must be approved by the Department. Perpetua denies that the application or supplemental materials submitted to the Department contained "an ambiguous description" of the control measures used to preclude the "general public" from accessing the area within the operations boundary.

64. Perpetua admits that PTC Conditions 2.7 and 2.8 require preparation and submission of an AMP to the Department. Perpetua denies that for the AMP to be legally sufficient or ensure that the entire operations boundary be excluded from "ambient air" it must be submitted for public comment.

65. Perpetua denies the allegations contained in Paragraph 65 of the Petition.

66. Perpetua admits that the Air Rules, which speak for themselves, give the Department authority to require ambient air monitoring when issuing a PTC.

67. Perpetua admits that the various entities identified in Paragraph 67 commented on the various draft permits, and that the Department declined to require ambient air monitoring.

68. Perpetua denies the allegations contained in Paragraph 68 of the FAP.

69. Perpetua admits that I.C. § 67-5279 sets forth the applicable standard of review of an agency action and remedies if an agency action is not affirmed. Perpetua affirmatively states that I.C. § 67-5279 speaks for itself, and to the extent any allegations contained in Paragraph 69 of the FAP are inconsistent with I.C. § 67-5279, Perpetua denies those allegations.

70. Perpetua admits that the Air Rules set forth the applicable standard for the Department to consider in issuing a PTC. Perpetua affirmatively states that the Air Rules speak for themselves, and to the extent any allegations contained in Paragraph 70 are inconsistent with the Air Rules, Perpetua denies those allegations. Perpetua denies that the provisions of the CAA relating to SIP approval, or the Part 51 Regulations, provide a governing legal standard for review of the Department's action in issuing the PTC. Perpetua affirmatively states that to the extent the Petitioners seek to collaterally attack the Air Rules in this proceeding, the Board lacks jurisdiction to consider their claims. Perpetua denies that the Department's issuance of the PTC was in violation of the Air Rules, the CAA, EPA's CAA regulations, or is otherwise arbitrary,

capricious, made on unlawful procedure, or an abuse of discretion. Perpetua affirmatively states that there are no grounds for reversal of the Department's issuance of the PTC.

71. Perpetua denies the allegations contained in Paragraph 71, including subsections A through G, of the FAP. Perpetua affirmatively states that Petitioners are entitled to no relief.

72. Perpetua denies the allegations contained in Paragraph 72 of the FAP.

III. RELIEF REQUESTED

Perpetua respectfully requests that the Board affirm the Department's issuance of the PTC and dismiss the FAP with prejudice.

DATED: December 13, 2022.

SHORT STATEMENT OF THE NATURE OF THE CASE (e.g., "Suspension of license based on following grounds . . .") AND GOVERNING STATUTES

Short statement of the nature of the case
Petitioners are seeking Board review of Air Quality Permit to Construct P-2019.0047 issued by the Department of Environmental Quality on June 17, 2022, to Perpetua Resources Idaho, Inc. for its proposed Stibnite Gold Project.
Governing statutes and administrative rules
The Board of Environmental Quality has legal authority to hear this matter pursuant to the Environmental Protection and Health Act, Chapter 1, Title 39, Idaho Code. This proceeding is governed by the Administrative Procedure Act, Chapter 52, Title 67, Idaho Code; IDAPA 04.11.01, Idaho Rules of Administrative Procedure of the Attorney General; IDAPA 58.01.23, Contested Case Rules and Rules for Protection and Disclosure of Records; and IDAPA 58.01.01, Rules for the Control of Air Pollution in Idaho.

ARE THERE SPECIFIC STATUTORY/REGULATORY RULES ON THE TIME FOR HEARING OR DECISION?
YES: **NO:** X
[OAH typically sets hearings based on parties' availability and agreement with written decision no later than the end of the month following the month the hearing was held]
If yes:

Deadline for hearing		
Deadline for decision		
Statute(s)/Rule(s) citation		

HAS ANY PARTY TO THE CONTESTED CASE PROCEEDING REQUESTED INTERIM, EXPEDITED, OR EMERGENCY RELIEF?
YES: **NO: X**

If yes, briefly explain	

DO ANY HEARING PROCEDURAL RULES, OTHER THAN THE IDAHO RULES OF ADMINISTRATIVE PROCEDURE OF THE ATTORNEY GENERAL, APPLY TO THIS PROCEEDING?
YES: X **NO:**

If yes, statute(s)/rule(s) citation	IDAPA 58.01.23, Contested Case Rules and Rules for Protection and Disclosure of Records IDAPA 58.01.01, Rules for the Control of Air Pollution in Idaho

TO ALL PARTIES AND COUNSEL OF RECORD:

The Chief Administrative Hearing Officer of the Office of Administrative Hearings, pursuant to his authority under Idaho Code § 67-5282(1)(d), hereby appoints as the duly authorized Hearing Officer in this matter the following individual:

Dylan B. Lawrence
Varin Thomas, LLC
242 N. 8th St., Suite 220
Boise, ID 83702
(208) 345-6021
DYLAN@VARINTHOMAS.COM

The Hearing Officer is appointed to conduct a hearing in this matter in accord with all governing statutes and rules, and make appropriate findings of fact, conclusions of law, and

recommended orders to the Director of Idaho Department of Environmental Quality. The Hearing Officer is required to comply with the Office of Administrative Hearing's Code of Conduct.

AUTHORITY OF HEARING OFFICER

The Hearing Officer has the authority to:

1. Schedule and conduct motion hearings and enter the appropriate orders disposing of all pre-hearing motions, such as motions for notices of proposed default orders, motions on the admissibility of evidence, and motions for continuances.

2. Schedule and conduct any pre-hearing conference and enter the appropriate orders for any purpose recognized by IDAPA 04.11.01.510.

3. Perform other duties assigned by the Board and as authorized by the Idaho Administrative Procedure Act, promulgated at Idaho Code §§ 67-5201 *et seq.*, and the Idaho Rules of Administrative Procedure of the Attorney General, promulgated at IDAPA 04.11.01 *et seq*. The hearing officer may not engage in *ex parte* communications concerning the substance of this matter, except as provided in Idaho Code § 67-5253 and IDAPA 04.11.01.424.

FILING OF DOCUMENTS

All **original** documents must be filed directly with the Office of Administrative Hearings at the following address:

Office of Administrative Hearings
P.O. Box 83720
Boise, ID 83720-0104

Additionally, all documents filed in this matter must also be served upon or mailed to the Hearing Officer at the address listed above, **as well as** OAH at the following email:

filings@oah.idaho.gov

REQUIRED SERVICE OF DOCUMENTS ON OTHER PARTIES

Any document filed by either party in this matter must be served on the other party (or the other party's attorney, if represented). The contact information for each party is as follows:

BEFORE THE BOARD OF ADMINISTRATIVE HEARINGS
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047	Agency Case No. 0101-22-01
NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON, Petitioners, v. IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent, and PERPETUA RESOURCES IDAHO, INC., Intervenor.	OAH Case No. 23-245-01 ORDER GRANTING MOTION TO FILE FIRST AMENDED PETITION

On December 6, 2022, the Petitioners in this matter filed a Motion to File First Amended Petition, along with a proposed amended petition identifying proposed changes to their original petition filed July 22, 2022. On December 13, 2022, Intervenor Perpetua Resources Idaho, Inc. (Perpetua) filed its Notice of Non-Opposition to the Motion, along with its responsive pleading. Respondent Idaho Department of Environmental Quality (DEQ) has not formally responded to the Motion.

BEQ Procedural Rule 003.05 and AG Procedural Rule 305 provide that, "[t]he presiding officer may allow any pleading to be amended or corrected or any omission to be supplied." They also state that, "[p]leadings will be liberally construed, and defects that do not affect substantial

rights of the parties will be disregarded."

Neither DEQ nor Perpetua opposes the Motion. The hearing officer has reviewed the proposed amended petition and sees no reason it should not be granted. Therefore:

The Petitioners' Motion to File First Amended Petition is hereby granted;

The Petitioners shall file a formal version of the amended petition accompanying their Motion with changes accepted within seven days of service of this order; and

Respondent DEQ shall file a formal responsive pleading to the First Amended Petition within seven days of service of Petitioners' First Amended Petition.

Dated this 6th day of January, 2023.

BEFORE THE OFFICE OF ADMINISTRATIVE HEARINGS
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047	)	BEQ Case No. 0101-22-01
NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON, Petitioners, v.	)	OAH Case No. 23-245-01 NOTICE OF STATUS CONFERENCE
DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent,	)	
and	)	
PERPETUA RESOURCES IDAHO, INC., Intervenor.	)	

On December 19, 2022, the Director of the Environmental Quality, on behalf of BEQ, issued a notice reassigning this matter to OAH. At the time of that notice, the following were recently completed or currently pending items:

1. On November 15, 2022, the hearing officer issued a decision on the motion to dismiss filed by Perpetua Resources;
2. At the November 28, 2022 status conference, Petitioners expressed an intent to file a motion to amend its petition;
3. At the same status conference, Perpetua Resources reported substantial progress on a

stipulated scheduling order that could potentially be finalized after the disposition of any motions to amend pleadings;

4. At the same status conference, the parties and hearing officer discussed a potential approach to establishing an administrative record for this matter; and
5. On December 6, 2022, the Petitioners filed a motion to amend their petition in this matter.

On January 3, 2023, OAH issued a notice re-appointing the hearing officer in this matter. On January 6, 2023, the hearing officer issued an order granting the Petitioners' motion to amend their petition in this matter. Now that the transition of this matter from BEQ to OAH is complete and the scope of the claims in the Petition have been finalized, it is appropriate for the parties and hearing officer to hold a status conference to discuss the items enumerated above that are still pending or undecided.

Therefore, based on the foregoing, NOTICE IS HEREBY GIVEN that the hearing officer and parties will hold a follow-up status conference on Thursday, January 12, 2023, at 10:00 a.m. mountain time, via Zoom. The hearing officer has sent an electronic calendar appointment to the participants, a hard copy of which is attached hereto.

Dated this 10th day of January, 2023.

Attorney for Save the South Fork Salmon

BEFORE THE BOARD OF ENVIRONMENTAL QUALITY
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047	
	Agency Case No. 0101-22-01
NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON Petitioners, v. IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent, and PERPETUA RESOURCES IDAHO, INC. Intervenor.	OAH Case No. 23-245-01 **FIRST AMENDED PETITION TO INITIATE CONTESTED CASE: AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047 (JUN. 17, 2022)***

* As directed in the Order Granting Motion to File First Amended Petition First Amended Petition (Jan. 6, 2023), Petitioners file this formal version of the First Amended Petition.

INTRODUCTION

1. Petitioners Nez Perce Tribe, Idaho Conservation League ("ICL"), and Save the South Fork Salmon ("SSFS"), by and through their attorneys of record, file this Petition to Initiate Contested Case ("Petition") before the Idaho Board of Environmental Quality ("Board") pursuant to Idaho Code § 39-107(5) and IDAPA 58.01.23. This Petition challenges the Air Quality Permit to Construct P-2019.0047 ("PTC") issued by the Idaho Department of Environmental Quality ("DEQ") on June 17, 2022, to mining company Perpetua Resources Idaho, Inc. ("Perpetua") for its proposed Stibnite Gold Project ("SGP").

2. The SGP is in the headwaters of the East Fork of the South Fork of the Salmon River approximately ten miles east of the town of Yellow Pine, Idaho. The SGP is geographically located within the Nez Perce Tribe's aboriginal homeland and within the area over which the Nez Perce Tribe has Treaty-reserved rights and resources. As proposed, Perpetua would use conventional mining techniques to extract ore from three open pits, process gold, and dispose of mine waste at the SGP site.

3. The PTC being challenged here authorizes emissions of air pollutants from the SGP that will occur over the mine's anticipated 16-year life span. These emissions include massive quantities of dust generated by mining, hauling, and processing. The dust includes particulate matter and arsenic—pollutants which can cause serious harm to human health and the environment.

4. When it issued the PTC, DEQ failed to comply with the federal Clean Air Act and with Idaho rules, regulations, and guidance for Clean Air Act permitting, and DEQ acted arbitrarily and capriciously, acted on unlawful procedure, and abused its discretion, under the Idaho Administrative Procedure Act, Idaho Code § 67-5279, in multiple ways set forth below.

Petitioners respectfully request that the Board reverse and set aside the PTC and remand to DEQ to correct these errors.

LISTING OF REPRESENTATIVES

5. Copies of all pleadings, correspondence, and official documents shall be served on the Petitioners' counsel listed below:

For the Nez Perce Tribe and the Idaho Conservation League:

Bryan Hurlbutt
Advocates for the West
P.O. Box 1612
Boise, ID 83701
bhurlbutt@advocateswest.org

For Save the South Fork Salmon:

Julia Thrower
Mountain Top Law PLLC
614 Thompson Ave.
McCall, ID 83638
jthrower@mtntoplaw.com

JURISDICTION, STANDARD OF REVIEW, PARTIES, AND STANDING

6. Pursuant to Idaho Code § 39-107(5), IDAPA 58.01.23, and IDAPA 58.01.01 (the "Idaho Air Rules"), the Board has jurisdiction over this contested case challenging DEQ's action issuing PTC P-2019.0047 for the SGP on June 17, 2022. The original Petition was timely filed on July 22, 2022, within thirty-five (35) days of the date of DEQ's June 17, 2022 decision. *See* IDAPA 58.01.23.060. This Amended Petition is proper under IDAPA 58.01.23.003.01, IDAPA 04.11.01.305, and Idaho Rule of Civil Procedure 15(a)(2).

7. An agency action, such as DEQ's issuance of the PTC being challenged here, may be reversed if it is in violation of constitutional or statutory provisions, is in excess of statutory authority, is made on unlawful procedure, or is arbitrary, capricious, or an abuse of discretion.

Idaho Code ("I.C.") § 67-5279. When an agency action is not affirmed, it shall be set aside, in whole or in part, and remanded for further proceedings as necessary. *Id.*

8. Pursuant to IDAPA 58.01.23.002.02: "Any person aggrieved by an action or inaction of the Department may file a petition to initiate a contested case pursuant to Chapter 52, Title 67, Idaho Code." An aggrieved person is defined as "any person or entity with legal standing to challenge an action or inaction of the Department, including but not limited to permit holders and applicants for permits challenging Department permitting actions." IDAPA 58.01.23.005.01.

9. PETITIONER NEZ PERCE TRIBE is a federally-recognized Indian tribe with headquarters on the Nez Perce Reservation in Lapwai, Idaho; and with offices in Orofino, McCall, and Powell, Idaho, and Joseph, Oregon.

10. The Nez Perce Tribe has standing to bring this contested case. The Nez Perce people, the *Nimiipuu*, exclusively occupied, since time immemorial, over thirteen million acres encompassing a large part of what is today Idaho, Oregon, and Washington—stretching from the Bitterroot Mountains to the Blue Mountains. Nez Perce also traveled far beyond this homeland to fish, hunt, gather, and pasture—frequently going east to buffalo country, in what is today the state of Montana, and west along the Snake and Columbia rivers to the Pacific Ocean. The Nez Perce actively maintain their connection to the land, water, and resources of their vast homeland. The Nez Perce's intimate knowledge and continuous use of their homeland over millennia have created a unique and reverential bond between people and place that defines Nez Perce culture and identity.

11. When the Nez Perce Tribe entered into a treaty with the United States in 1855, it sought to reserve the rights central to maintaining its culture and way of life. The 1855 Treaty

reserved to the Tribe, for its "exclusive use and benefit," 7.5 million acres of its more than thirteen-million- acre homeland, including an area spanning present-day north-central Idaho, southeast Washington, and northeast Oregon as well as:

> [T]he right of taking fish at all usual and accustomed places in common with citizens of the Territory; and of erecting temporary buildings for curing, together with the privilege of hunting, gathering roots and berries, and pasturing their horses and cattle upon open and unclaimed land.

Treaty with the Nez Perces, art. 3, June 11, 1855, 12 Stat. 957. Nez Perce Tribal members, pursuant to the Nez Perce Tribe's Treaty-reserved rights, continue to fish, hunt, gather, and pasture across the Nez Perce Tribe's vast aboriginal homeland and at traditional places, including areas within and surrounding the SGP. The Nez Perce Tribe, as a co-manager of its treaty-reserved resources, also plays a leading role in the restoration of the East Fork South Fork Salmon River and South Fork Salmon River fisheries, expending approximately $2.5 million annually to restore Chinook salmon runs in both rivers through hatchery supplementation, fishery research, and watershed restoration.

12. The Nez Perce Tribe will suffer physical, cultural, spiritual, and economic injury caused by excessive air pollutants resulting from DEQ's issuance of the PTC. Clean, clear air is a critical component to ensuring the health and resiliency of the Nez Perce Tribe's Treaty-reserved rights and resources. Air pollution reduces visibility, which impairs cultural and ceremonial practices for Tribal members and reduces enjoyment of these special places. Air pollution causes a host of environmental and human health problems, including damage to culturally important plants, sensitive forests, and fish habitat, acidification of lakes and streams, depletion of soil nutrients, aggravated asthma, heart attacks, and premature death. Impacts can be especially harmful to at-risk ecosystems and especially harmful for sensitive human populations such as asthmatics, children, the elderly, people with diabetes, and people with heart or lung disease.

13. To safeguard its rights and interests, the Nez Perce Tribe has participated extensively in DEQ's review process, including submitting comments on October 12 and November 10, 2020, March 8, 2021, and March 14, 2022. A favorable decision in the Contested Case will redress these injuries suffered by the Tribe.

14. PETITIONER IDAHO CONSERVATION LEAGUE is an Idaho non-profit conservation organization. Its main office is located in Boise, Idaho, and it has three field offices in Sandpoint, Ketchum, and McCall. ICL represents approximately 50,000 supporters dedicated to protecting and conserving Idaho's clean water, air, public lands, and wildlife.

15. ICL has standing to bring this contested case. ICL supporters, staff, and board members ("ICL members") regularly visit the SGP and/or nearby areas where air quality would be affected by the SGP for professional, recreational, aesthetic, and other purposes. ICL members will suffer health, environmental, and aesthetic injuries from the particulate matter and arsenic air pollution emitted by the SGP and authorized by DEQ's issuance of the PTC. A favorable decision in the Contested Case will redress ICL's injuries. Neither the claim asserted, nor the relief requested, requires participation of these individual ICL members in the lawsuit. The interests ICL seeks to protect are germane to the organization's purpose in protecting Idaho's clean water, clean air, wildlife, and public lands.

16. In furtherance of its mission, ICL participated extensively in the public processes for the PTC, including by submitting formal public comments to DEQ on October 12 and November 11, 2020, March 19, 2021, and March 16, 2022.

17. PETITIONER SAVE THE SOUTH FORK SALMON is a community-based, non-profit conservation organization headquartered in McCall, Idaho. SSFS represents members and supporters dedicated to preserving the South Fork Salmon River watershed and ecosystem.

18. SSFS has standing to bring this contested case. SSFS members, supporters, and members of the Board of Directors ("SSFS members") regularly visit the South Fork Salmon River watershed and the SGP site, where the emission of excessive air pollutants due to DEQ's issuance of the PTC would impact professional, economic, recreational, aesthetic, environmental, and human health interests. SSFS members would suffer injury from DEQ's issuance of the PTC from environmental, health, and aesthetic harms caused by the emission of harmful air pollutants, including particulate matter and arsenic. A favorable decision in the Contested Case will redress these injuries suffered by SSFS members. Neither the claims asserted, nor the relief requested, requires participation of these individual supporters in the lawsuit. The interests SSFS seeks to protect are germane to the organization's mission of protecting and preserving the South Fork Salmon River watershed and ecosystem, and protecting public health, the river, the fish, and recreational opportunities in the area.

19. In furtherance of this mission, SSFS participated extensively in the public process for the PTC, including submitting formal public comments to DEQ on October 12 and November 11, 2020, March 19, 2021, and March 16, 2022.

20. RESPONDENT IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY is an executive department and administrative agency organized under the laws of the State of Idaho, pursuant to the Idaho Constitution (Article IV, Section 20) and Idaho Code section 39-104(1). Its principal offices are located at 1410 N. Hilton, Boise, Idaho 83706. DEQ, through its Director, and subject to Board oversight, is responsible for issuing air quality PTCs under the Idaho Air Rules, IDAPA 58.01.01.

21. On June 17, 2022, DEQ issued PTC P-2019.0047, which is the subject of this contested case. On July 22, 2022, Petitioners timely filed the original Petition to Initiate

Contested Case. On July 28, 2022, the Hearing Officer Dylan Lawrence was assigned to preside over this matter. On August 12, 2022, Perpetua filed a Petition to Intervene. On August 22, 2022, Perpetua's Petition to Intervene was granted. On September 6, 2022, Perpetua filed a Motion to Dismiss. On November 15, 2022, the Hearing Officer issued the Order on Motion to Dismiss, denying the motion with respect to the majority of Petitioners' claims, dismissing or partially dismissing four claims, and declining to allow the pleadings to be amended unless Petitioners file for consideration a formal motion to amend the Petition.

FACTUAL SUPPORT FOR PETITION

I. OVERVIEW OF SGP & CHRONOLOGY OF DEQ'S ISSUING THE PTC

22. Perpetua is currently in the process of seeking multiple permits and other approvals from multiple agencies and other authorities for the proposed SGP. As described by DEQ in the Statement of Basis ("SOB") document prepared with the PTC:

> Perpetua proposes to construct and operate the SGP, consisting of conventional open-pit mining, ore preparation, and gold extraction operations. The SGP is to be located in Valley County at the intersection Forest Service roads NF-374 and NF-412 (Stibnite Road), approximately 10 miles east of Yellow Pine. The project will be located on a combination of public national forest and private lands. The mining operations boundary within which public access will be excluded is defined in Figure 1. This operations boundary also defines the ambient air boundary that was used in all ambient air quality impact analyses as part of the development process of the PTC.
>
> The SGP will require the construction of significant infrastructure, including a power transmission line, a primary mine site access road, onsite haul roads, an ore processing facility, onsite workspaces, employee housing and recreation, water storage and distribution facilities, and sewage disposal facilities.
>
> Conventional open-pit mining methods including drilling, blasting, excavating, and hauling will be used to extract ore and waste rock, termed development rock (DR). Hydraulic shovels and front-end loaders will be used to load ore and DR into haul trucks. DR will be used for construction, restoration, and backfilling, or hauled to the dedicated development rock storage facilities (DRSF). Approximately 340 million tons of DR will be handled over the life of the mine.

> The SGP will include three years of pre-mining development and construction activities, followed by an operating mine life of approximately 12 years. Mining will occur in three open pits: Yellow Pine Pit (YPP), Hangar Flats pit (HFP), and West End pit (WEP). Although there will be overlap in mine development, construction and operations, the general sequence of mining will be the YPP deposit, followed by the HFP and WEP deposits. Legacy tailings from the Meadow Creek valley (Bradley Tailings [BT]) will also be reclaimed and reprocessed during the initial project schedule. Surface exploration drilling will occur within the pits and within the Scout Prospect decline (underground exploration) throughout the mine operation period. Restoration and reclamation of other legacy mining features will occur prior to mining, throughout the life of the mine, and as part of the mine closure.
>
> Ore will be hauled to the primary crusher area, where it will be fed directly into the crusher dump pocket or stockpiled. The ore crushing plant will be designed to operate at a maximum rate of 25,000 tons per calendar day (T/day). Approximately 100 million tons of ore will be mined from the three pits over the life of the project. The metal-recovery process from ore will include conventional crushing and grinding, followed by froth-flotation circuits that will generate separate gold-silver and antimony-silver concentrates. The antimony-silver concentrate will be shipped offsite for refining, whereas additional onsite processing of the gold-silver concentrate will include pressure oxidation, carbon-in-leach circuits, and refining processes to recover gold and minor amounts of silver. The finely ground leftover ore material from the mineral recovery process, termed tailings, will be neutralized, thickened, and transported via a pipeline to the tailings storage facility. A diagram of ore processing and ore concentration and refining process flows is provided in Figure 2.

23. Perpetua (previously Midas Gold) submitted a PTC application for the SGP to DEQ on August 20, 2019. As shown in the "Application Chronology" section of the SOB, between that date and March 6, 2020, DEQ determined that the application was incomplete, requested additional information, and received supplementary materials from Perpetua no fewer than four times. On May 15, 2020, DEQ deemed Perpetua's application complete.

24. Between May 15, 2020, and March 16, 2022, DEQ developed three versions of the draft PTC and released them for public comment. As noted in comments submitted by the Nez Perce Tribe, ICL, and SSFS, the first two draft versions of the PTC (herein referred to the September 2020 and February 2021 draft PTCs) contained significant shortcomings. As a result, the September 2020 draft PTC was considered deficient and required updated information from

Perpetua, including updated hazardous air pollutants ("HAP") and toxic air pollutants ("TAP") emissions estimates, a HAP/TAP addendum to the application, updated TAP modeling analyses, supporting references, and updated modeling files with corrections for formaldehyde and sulfuric acid.

25. DEQ subsequently updated the draft PTC and in February 2021, provided a revised draft PTC for public comment. Following additional comments, DEQ again determined that the February 2021 draft PTC was deficient and required additional information from Perpetua, including Prevention of Significant Deterioration emissions estimates and regulatory applicability for the lime manufacturing plant, as well as an updated TAP/HAP addendum including an updated emission inventory and modeling files.

26. DEQ revised theFebruary 2021 draft PTC and released it for public comment on January 13, 2022. Comments were submitted by the Nez Perce Tribe, ICL, SSFS, the U.S. Environmental Protection Agency ("EPA") Region 10, and Ian von Lindern of Terragraphics International Foundation. Commenters raised numerous concerns with the draft PTC and urged DEQ to gather additional information, to perform additional modeling and analysis, and to develop additional enforceable permit conditions and limits prior to issuing a final PTC. On June 17, 2022, DEQ issued the final PTC, along with responses to comments and the SOB. While DEQ made limited updates to the PTC, it rejected most of the issues raised by the commenters.

II. PM_{10} & ARSENIC EMISSIONS FROM THE SGP

27. While the SGP will emit numerous air pollutants, PM_{10} and arsenic are the air pollutants of greatest concern and are the pollutants at issue in this contested case.

A. PM_{10} Pollution and Regulation

28. Particulate matter ("PM") contains microscopic solids or liquid droplets that are so small that they can be inhaled and cause serious health problems. Some particles less than 10 micrometers in diameter can get deep into a person's lungs, and some may even get into the person's bloodstream. Numerous scientific studies have linked particle pollution exposure to a variety of problems, including premature death in people with heart or lung disease; nonfatal heart attacks; irregular heartbeat; aggravated asthma; decreased lung function; and increased respiratory symptoms, such as irritation of the airways, coughing or difficulty breathing. People with heart or lung diseases, children, and older adults are the most likely to be affected by particle pollution exposure.

29. In addition to causing human health problems, PM causes environmental damage. Particles can be carried over long distances by wind and then settle on ground or water. Depending on their chemical composition, the effects of settling may include making lakes and streams acidic; changing the nutrient balance in river basins; depleting nutrients in soil; damaging sensitive forests and crops; affecting diversity of ecosystems; and contributing to acid rain.

30. Under Sections 108 and 109 of the federal Clean Air Act, EPA is required to establish National Ambient Air Quality Standards ("NAAQS") for each "criteria air pollutant" to protect the nation's public health and welfare. "[E]ffects on welfare include[ ], but [are] not limited to, effects on soils, water, crops, vegetation, manmade materials, animals, wildlife, weather, visibility, and climate, damage to and deterioration of property, and hazards to transportation, as well as effects on economic values and on personal comfort and well-being, whether caused by transformation, conversion, or combination with other air pollutants." 42 U.S.C. § 7602(h).

31. PM is a criteria air pollutant. EPA has established primary and secondary NAAQS for coarse particulate matter, or "PM_{10}," 40 C.F.R. § 50.6, and for fine particulate matter, or "$PM_{2.5}$," *id.* at § 50.7. PM_{10} consists of inhalable particles with diameters that are generally ten micrometers and smaller. 42. U.S.C. § 7602(t). $PM_{2.5}$ consists of inhalable particles that are 2.5 micrometers and smaller. The NAAQS specify a maximum amount of PM to be present in the outdoor air. *See* 40 C.F.R. §§ 50.6, 50.7.

32. EPA has delegated to DEQ authority to issue air quality permits in Idaho. Under the Clean Air Act, State air rules like DEQ's "shall" include "enforceable emission limitations" and other control measures, means, or techniques as necessary or appropriate to meet Clean Air Act requirements. 42 U.S.C. § 7410(a)(2)(A). State plans "shall" include a "program to provide for the enforcement" of the limitations and measures described in subparagraph (A), and for the "regulation of the modification and construction of any stationary source . . . to assure that [NAAQS] are achieved." *Id.* § 7410(a)(2)(C). EPA's Clean Air Act regulations require each State plan to "set forth legally enforceable procedures" that enable the State to determine whether the construction of a facility will result in a violation of its air pollution control strategies or interfere with attaining or maintaining the NAAQS. 40 C.F.R. § 51.160(a). These legally enforceable procedures: must include means by which the State will prevent construction if the facility will violate air pollution control strategies or will interfere with attaining or maintaining the NAAQS; and must provide for the applicant to submit information on the "location, design, construction, and operation of such facility . . . as may be necessary" to permit the state to "to make the determination" that the facility will comply with its air pollution control strategies and the NAAQS. *Id.* § 51.160(b)–(c). "The legally enforceable procedures in § 51.160(b) must also require" the State to provide opportunity for public comment on information

submitted by the applicant and on the State's analysis of the effects on ambient air quality. *Id.* § 51.161(a). Under the Rules for the Control of Air Pollution in Idaho, DEQ is required to ensure that no PTC shall be granted for a new or modified stationary source unless the applicant shows to the satisfaction of DEQ that the source would not cause or significantly contribute to a violation of any NAAQS. IDAPA 58.01.01.203.02. To satisfy these requirements, DEQ must assess air impacts using maximum potential emissions as limited by either the capacity of the unit/operation or as limited by enforceable permit provisions. *See* IDAPA 58.01.01.006.88. Prior to issuing a permit to contruct, DEQ must provide an opportunity for public comment by making available DEQ's proposed action together with information provided by the applicant and with DEQ's analysis of air quality impacts. IDAPA 58.01.01.209.c.

B. PM_{10} Pollution from the SGP & Flaws in the PTC

33. According to DEQ's Statement of Basis for the SGP, the SGP has the potential to emit 55.7 tons per year of PM_{10} from a variety of sources. The generation of dust from ore haul trucks traveling along haul roads is the most significant source, estimated to be approximately 55% of all modeled PM_{10} emissions. The next most significant source is open pit drilling fugitive emissions, estimated by DEQ to account for approximately 24% of all modeled emissions.

34. DEQ modeled receptors at various locations along the SGP's ambient air boundary and determined that the maximum potential emissions will be below (and thus comply with) the 24-hour PM_{10} NAAQS. DEQ found the maximum 24-hour PM_{10} pollution from the SGP would be 123.5 ug/m^3, which is 82.3% of the NAAQS.

35. For each of the reasons below, DEQ's determination that the SGP will not cause or contribute to a violation of the PM_{10} NAAQS and its action approving the PTC violates the Clean Air Act, violates EPA's Clean Air Act regulations, violates the Idaho Air Rules, and is

otherwise arbitrary, capricious, made on unlawful procedure, and an abuse of discretion and must be set aside under I.C. § 67-5279.

36. First, important variables affecting the quantity of PM_{10} generated by the ore haul trucks are not directly limited and enforceable as PTC permit conditions. Perpetua estimated the quantity of PM_{10} that would be emitted by the ore haul trucks based on EPAs compilation of air emissions factors (AP-42 Chapter 13.2.2) and their subsequent analysis of sources used by the EPA to develop Chapter 13.2.2. Critical variables that Perpetua used as inputs to PM emission calculations include: the average empty weight of ore haul trucks; the average loaded weight of ore haul trucks; the total number of larger versus smaller ore haul trucks (CAT 789D versus CAT 740B); the silt content of the haul road being traveled; the number of days per year with precipitation greater than or equal to 0.01 inches per day; and the total number vehicle miles traveled by ore haul trucks. However, only one of these critical variables is directly limited and enforceable as a condition in the PTC: the silt content of the haul roads. *See* PTC condition 3.13.

37. Instead of developing PTC conditions for these other critical variables, DEQ relied on a surrogate limit in the PTC (total ore haulage per day, *see* PTC conditions 3.5) and on plans that have not yet been developed and have not been subject to public comment,—a Fugitive Dust Control Plan ("FDCP") and a Haul Road Capping Plan ("HRCP")—to claim the PTC ensures enforceable compliance with 24-hour PM_{10} NAAQS. Without developing the FDCP and HRCP first, without taking public comment on them, and without including important variables as enforceable permit conditions, there is no assurance the SGP will comply with the 24-hour PM_{10} NAAQS, even with the total ore haulage per day limit. Perpetua used a very specific combination of these variables to arrive at a quantity of ore haul truck generated PM_{10} that they contend ensures compliance with the NAAQS. Changing these variables in any number

of ways (ways which are not precluded by any conditions in the PTC) can result in higher PM_{10} levels—levels so high that they exceed the NAAQS. As just one example, merely changing the ratio of large to small ore haul trucks used by Perpetua (to include more small trucks) could cause a violation of the NAAQS.

38. Second, DEQ assumed 93.3% of all haul road PM_{10} emissions from the SGP can be controlled by using an unspecified combination, volume, and frequency of water sprays and chemical dust suppressants. This extremely high level of control which DEQ assumed Perpetua can achieve is based on Perpetua's interpretation of AP-42 Chapter 13.2.2. AP-42 Chapter 13.2.2 discusses the critically important variables surrounding control efficiencies (in particular to chemical suppressants, some of which can reasonably be assumed to apply to water too):

> The control effectiveness of chemical dust suppressants appears to depend on (a) the dilution rate used in the mixture; (b) the application rate (volume of solution per unit road surface area); (c) the time between applications; (d) the size, speed and amount of traffic during the period between applications; and (e) meteorological conditions (rainfall, freeze/thaw cycles, etc.) during the period. Other factors that affect the performance of dust suppressants include other traffic characteristics (e. g., cornering, track-on from unpaved areas) and road characteristics (e. g., bearing strength, grade). The variabilities in the above factors and differences between individual dust control products make the control efficiencies of chemical dust suppressants difficult to estimate. Past field testing of emissions from controlled unpaved roads has shown that chemical dust suppressants provide a PM-10 control efficiency of **about 80 percent when applied at regular intervals of 2 weeks to 1 month (**emphasis added**).**

39. None of the above variables, however, have any specific and enforceable permit conditions within the PTC to ensure a 93.3% control efficiency. Instead, the PTC has a permit condition (permit condition 2.6) only requiring the permittee to develop and submit the FCDP and HRCP, which merely describe how these variables will be addressed 30 days before start-up of the SGP. Permit condition 2.6 details what variables contributing to PM_{10} control effectiveness must be detailed in the FCDP, but the specific details that are so important to

control efficiency (e.g., the amount of water or chemical suppressants applied and the frequency of application) are undetermined at present, have not been subject to public comment, and are left to Perpetua to decide at a later date. A lesser control efficiency, even just slightly lesser, could result in large enough PM_{10} emissions to violate the NAAQS. In fact, if the SGP were to instead achieve 80% control (as EPA found through past field testing of chemical dust suppressants), then the SGP's PM_{10} emissions could exceed the NAAQS.

40. Third, DEQ relied on monitoring and record keeping (permit condition 3.16) using devices and methodologies in the Operation and Maintenance ("O&M") Manual for the potential to emit limit associated with the 180,000 tons per day hauling in permit condition 3.5. However, the O&M Manual has not yet been developed, submitted to the public for comment, ~~or~~ reviewed and revised by DEQ, or incorporated into and made enforceable under the Permit. The O&M Manual is critical to ensuring the 180,000 tons per day hauling condition is satisfied, and the 180,000 tons per day is critical to DEQ's determination under IDAPA 58.01.01.203.02 that the SGP will not exceed the NAAQS. Additionally, DEQ is authorized to require plans and to impose any reasonable conditions on permits, but instead of doing so here, it is letting Perpetua do this later, outside of the permit process. *See* IDAPA 58.01.01.202.03 (authorizing DEQ to obtain from permit applicant "[a]ny additional information, plans, specifications, evidence or documents the Department may require to make the determinations required under [the PTC sections of the Air Rules]"); IDAPA 58.01.01.211 (authorizing DEQ to "impose any reasonable conditions upon an approval" of a PTC); IDAPA 58.01.01.121 (authorizing DEQ to require schedules, reports, records, monitoring, and plans to ensure compliance with Air Rules); IDAPA 58.01.01.122.03.g (authorizing DEQ to issue an information order to provide any "information the Department may require").

41. Fourth, DEQ assumed there would be 120 days of recordable precipitation at the SGP (defined as recording precipitation of 0.01 inch or greater) as a variable in its ore haul road fugitive PM emission calculations. This 120 days comes from general geographic guidance from AP-42 Chapter 13.2.2-1. DEQ, however, should have used local meteorological data. Section 6.8 (Meteorological Data) of DEQ's *Guideline for Performing Air Quality Impact Analyses* states: "The meteorological data used in the modeling analysis should be representative of the meteorological conditions at the particular site of the proposed construction or modification." Days of recordable precipitation is an important variable affecting the SGP's emissions of PM_{10} from ore haul roads. DEQ's failure to use the most representative site data is counter to this guidance and increases the risk of miscalculation of ore haul road emissions. As a result, DEQ failed to ensure PM_{10} emissions from the SGP will comply with the NAAQS.

C. Arsenic Pollution & Regulation

42. Arsenic is a naturally occurring element in soils and minerals. When soil or rock containing arsenic is disturbed, arsenic may enter the air, water, and land from wind-blown dust and from run-off and leaching. The EPA classifies inorganic arsenic as a "human carcinogen," based on evidence in human studies of links to lung, bladder, kidney, skin, and liver cancers.

43. Arsenic released from the soil and rock as airborne dust causes environmental damage. Airborne arsenic pollutes soil, plants, and water resources when it is removed from the air by rain, snow, or gradually settling. Studies have shown that there is a strong correlation between arsenic concentrations in water and in the tissues of fish collected from arsenic-polluted waters. Plants may also absorb arsenic in their leaves and root system from arsenic-polluted soil. The health effects of long-term ingestion of arsenic include developmental effects, diabetes, pulmonary disease, cardiovascular disease, and skin, bladder, or lung cancer.

44. Arsenic is a Toxic Air Pollutant regulated by DEQ. DEQ is required to ensure that no permit to construct shall be granted for a new or modified stationary source unless emissions of TAPs from the constructed source would not injure or unreasonably affect human or animal life or vegetation as required by Section 161. IDAPA 58.01.01.203.03. Section 161 states, "any contaminant which is by its nature toxic to human or animal life or vegetation shall not be emitted in such quantities or concentrations as to alone, or in combination with other contaminants, injure or unreasonably affect human or animal life or vegetation." IDAPA 58.01.01.161.

45. To comply with these TAPs regulations, emissions from a facility must not exceed the Acceptable Ambient Concentrations of Carcinogens ("AACC") at the ambient air boundary. For each carcinogenic TAP, IDAPA 58.01.01.586 lists the applicable TAP and its AACC in ug/m^3 as an annual average. The AACC can practically be defined as the concentration of a TAP that, if an individual was exposed to yearly over a 70-year lifetime, would equate to a cancer development probability risk of 1 in 1,000,000. *See* IDAPA 58.01.01.006.125 & 58.01.01.210.12.

46. In order to determine a facility's TAP concentration at their ambient air boundary, and as noted similarly for PM_{10} emissions, DEQ must assess air impacts using maximum potential emissions as limited by either the capacity of the unit/operation or as limited by enforceable permit provisions. *See* IDAPA 58.01.01.006.88.

D. Arsenic Pollution from the SGP & Flaws in the PTC

47. There are numerous arsenic sources at the SGP, including drilling, blasting, excavating, hauling, silos, rock dumps, and storage and tailing piles. Table 3 in the SGP TAPs Addendum indicates that the maximum arsenic Potential Total Emissions ("PTE") is 0.544 lbs/hr

at the maximum mine production rate of 180,000 tons/day. The largest source of arsenic emissions are haul roads estimated at 0.464 lbs/yr (Table B1-W3 in SOB). PTE estimates for arsenic are calculated using the same formulas and Emission Factors as total particulate and PM_{10} emission rates. As such, like the PM and PM_{10} emission estimates discussed already, the arsenic emission estimates are similarly underestimated and equally unreliable.

48. During the permitting process, DEQ determined that the SGP's estimated arsenic emissions and concentrations at the ambient air boundary were excessive and would not meet the AACC for arsenic. To get around this problem, Perpetua chose to employ a process known as T-RACT. T-RACT is a demonstration that allows a permittee to analyze and employ reasonably available control technologies ("RACT") that could be applied to a source of TAPs. If RACT does not sufficiently reduce toxic emissions to below the AACC, then the permittee is allowed a 10-fold increase in the AACC and can employ production limitations to ensure compliance with the now 10-times-bigger AACC. These production limitations should then be incorporated as enforceable permit conditions. *See* IDAPA 58.01.01.210.13–14.

49. As part of the T-RACT determination process, the applicant must supply, and DEQ must consider, information on a variety of factors relevant to determining a "reasonable" control technology including, but not limited to, control effectiveness, economic costs, operational feasibility, and associated environmental impact. IDAPA 58.01.01.210.14a–d.

50. Perpetua submitted to DEQ a T-RACT demonstration for arsenic emissions from open-pit drilling and ore haul roads. Perpetua determined that the most effective RACT for open-pit drilling was dry drilling with dust collectors and that the most effective RACT for ore haul roads was water sprays and chemical suppressants. In its T-RACT demonstration, Perpetua

included limited qualitative discussion, and no quantitative support, regarding economic considerations. Perpetua failed to provide any discussion of environmental impacts.

51. DEQ approved Perpetua's T-RACT demonstration and granted Perpetua a 10-fold increase in allowable arsenic pollution, subject to operational limitations to reduce PTE. And as modeled by DEQ, arsenic pollution from the SGP would comply with this larger AACC.

52. For each of the reasons below, DEQ's approval of Perpetua's T-RACT demonstration for arsenic, its analysis determining the SGP will not exceed the AACC and thus will not injure or unreasonably affect human or animal life or vegetation, and its action approving the PTC violates the Clean Air Act, violates EPA's Clean Air Act regulations, violates the Idaho Air Rules, and is otherwise arbitrary, capricious, made on unlawful procedure, and an abuse of discretion and must be set aside under I.C. § 67-5279.

53. First, the T-RACT demonstration contained no persuasive economic information and no discussion at all regarding associated environmental impacts, despite the requirements to do so in IDAPA 58.01.01.210.14. There will be water quality and biological impacts associated with Perpetua's use of substantial amounts of chemical dust suppressants and water that have not been considered in the PTC. For example, the use of chemical dust suppressants like magnesium chloride can cause toxicity in trees and can lead to tree death. Magnesium chloride is also known to adversely affect aquatic ecosystems. Moreover, the proposed water source for dust control is primarily water collected in runoff ponds (captured rain or snowfall that has become contaminated through the contact of mine facilities), groundwater, and surface water from the East Fork of the South Fork of the Salmon River. USGS sampling indicates elevated arsenic in these waters. The environmental impact of using magnesium chloride or arsenic-polluted water as dust suppression methods was never considered as part of the T-RACT demonstration.

Likewise, the T-RACT demonstration did not provide sufficient economic support for Perpetua's decision to use water and chemical dust suppressants as compared to paving the haul roads, even though paving was shown to achieve the highest reasonable dust control efficiency.

54. Second, because the underlying particulate and PM_{10} emissions estimates and particulate control assumptions are unreliable in numerous respects, as already discussed above, so too are the estimated arsenic emissions. The SGP's estimated arsenic emissions were based on its PM_{10} emissions. PM_{10} emissions from the SGP may be higher, and their control effectiveness may be lower, than DEQ assumed, in which case arsenic emissions would also be higher and might exceed the AACC.

55. Third, Perpetua's and DEQ's TAPs analyses substantially reduce the SGP's purported arsenic emissions using three improper averaging tactics: (1) averaging emissions over a 5-year period for the T-RACT input to ambient toxics modeling; (2) averaging the estimated annual ambient modeling impacts across two multi-year scenarios; and (3) averaging the resultant 16-year total emissions over the 70-year human lifetime to assert compliance. Nothing in the Idaho Air Rules allows for multi-year emissions averaging and ambient air concentration adjustments. Rather, the arsenic AACC is an annual average. *See* IDAPA 58.01.01.586). DEQ's T-RACT regulations require comparing the estimated maximum annual ambient air arsenic concentration to 10 times the listed annual AACC. IDAPA 58.01.01.12.b. Therefore, to determine compliance with the AACC requires that DEQ estimate the SGP's maximum 1-year annual arsenic emissions and compare it to the annual arsenic AACC.

56. By relying on these improper averaging tactics, DEQ fails to show the SGP will satisfy the arsenic AACC and the resulting analysis masks potentially severe human health and environmental impacts of SGP's potential arsenic emissions. The underlying analyses supporting

the TAPs requirements allows for a 1-in-1,000,000 excess cancer risk factor. The T-RACT approval increases that risk 10-fold to a 1-in-100,000 excess cancer risk factor. IDAPA 58.01.01.12.b. Perpetua's multi-year averaging of emission rates combined with DEQ's decision to allow the full lifetime exposure (70 years) to be imposed on receptors during the 16-year estimated life of mine increases the cancer risk by another order of magnitude to the 1-in-10,000 range or higher. Combined with uncertainties associated with the underlying particulate emissions calculations noted above, the SGP may result in extremely dangerous arsenic exposures.

57. While not the basis for a separate claim for relief, Petitioners note that excacerbating this cancer risk is the fact that under DEQ's incremental TAPs regulations (*see* IDAPA 58.01.01.585), when DEQ considers permitting any additional sources of arsenic in the area over the next 70 years (such as an extension of the life of the SGP, expansion of the facility itself, and/or any adjacent facilities seeking a similar permit, like the potential Horse Heaven project), DEQ will not have to consider the arsenic emissions authorized by this PTC.

E. DEQ's Ambient Air Boundary for the SGP

58. The Clean Air Act and Idaho Air Rules require meeting various air standards, including the NAAQS and TAPs, in ambient air. *See*, *e.g.*, IDAPA 58.01.01.006.11 (NAAQS), 58.01.01.006.125 (TAPs). EPA defines "ambient air" as "that portion of the atmosphere, external to buildings, to which the general public has access." 40 C.F.R. § 50.1(e). In defining an ambient air boundary, the EPA has long followed a policy that exempts "the atmosphere over land owned or controlled by the source and to which public access is precluded . . ." from ambient air. EPA's Revised Policy on Exclusions from "Ambient Air" (Nov. 2018) states that "it is appropriate to exclude the atmosphere over land owned or controlled by the stationary source, where the owner

or operator of the source employs measures, which may include physical barriers, that are effective in deterring or precluding access to the land by the general public."

59. The Idaho Air Rules define "ambient air" as "[t]hat portion of the atmosphere, external to building, to which the general public has access." IDAPA 58.01.01.005.09. To exclude areas from consideration as ambient air, the following conditions must be met: (1) the permittee must have the legal authority to exclude the general public from the area; (2) the boundary to ambient air must be clearly discernible to the general public; (3) the general public must be effectively precluded from assessing the facility; and (4) the general public is not considered employees of the facility; those having official business with the facility; guests of the facility, including participants in facility routes and those seeking access for a specific purpose.

60. Perpetua established an operations boundary (the active industrial site where mining activities and heavy equipment operation will occur) for the purposes of excluding this area from ambient air analysis, and for excluding public access. The area includes the current Stibnite Road point of entry and proposed site access via the Burntlog Route. According to Perpetua, access inside the operations boundary will be restricted for the life of the mine by physical barriers at points of potential access, as well as natural features of the landscape that prevent public access.

61. DEQ's determination to exclude the access route from ambient air protections, and its action approving the PTC violates the Clean Air Act, violates EPA's Clean Air Act regulations, violates the Idaho Air Rules, and is otherwise arbitrary, capricious, made on unlawful procedure, and an abuse of discretion and must be set aside under I.C. § 67-5279.

62. Perpetua has indicated that it intends to allow access to the general public through the mine site between Stibnite Road at Sugar Creek and Thunder Mountain Road at Meadow Creek. Furthermore, this roadway is currently accessible to and has been regularly used by the general public. And while Perpetua claims that it has "legal and practical ability to enforce its control over roadway access," the Forest Service has not yet completed its NEPA analysis and approval of the SGP, which would include a decision on whether it will require or will not permit general public access through the mine site.

63. DEQ states that the route would be managed in accordance with the Stibnite Road Access Management Plan ("AMP"). DEQ, however, relied on an ambiguous description of measures and requirements to preclude public access and ensure that those traveling over the road can be classified as "guests" of the mine.

64. PTC condition 2.7 requires the development of an AMP to address whether the NAAQS apply to the mine's access road through the Perpetua site given the extent of public access allowed. PTC condition 2.8 allows the AMP to be developed later, after the PTC was issued and without public comment, and it does not require the AMP to be enforceable. For the AMP to preclude the applicability of the NAAQS along the access road, the AMP must be reviewed and approved by DEQ, it must be reviewed through public comment, and it must be enforceable under the PTC.

65. Without full disclosure and knowledge of the exact measures and requirements in the AMP and enforceable permit limits, DEQ cannot make a determination of whether exclusion of the access road from ambient air protections complies with EPA's ambient air policy and the Idaho Air Rules, nor can DEQ determine whether the SGP will comply with the NAAQS and TAPs.

F. DEQ's Failure to Require Ambient Air Monitoring for the SGP

66. DEQ has the authority to require ambient air monitoring to determine the effect emissions from the stationary source or facility may have on the air quality of the area potentially impacted by the source. IDAPA 58.01.01.211.01(d).

67. DEQ received comments from the Nez Perce Tribe, EPA Region 10, ICL, and SSFS urging the PTC to require ambient air monitoring to verify the SGP's compliance with the NAAQS and TAPs increments. But DEQ declined, stating in the Response to Comments (pg. 16): "DEQ disagrees that a PM/PM_{10} ambient monitoring network is necessary to make the PTC practically enforceable." DEQ states in the Response to Comments that any violation of the permit would be processed in accordance with DEQ's enforcement procedures manual.

68. However, without ambient air monitoring, it will be impossible for DEQ to assess whether the SGP's operation is in compliance with NAAQS and TAPs increments at any given time. Ambient air monitoring is necessary because of the large uncertainty surrounding dust control efficiency and emissions factors associated with the SGP for PM_{10} and arsenic, as well as the lack of enforceable permit conditions for many important variables, as already described in this Petition.

RELIEF REQUESTED

69. An agency action, like DEQ's issuance of the PTC, may be reversed if it is in violation of constitutional or statutory provisions, is in excess of statutory authority, is made on unlawful procedure, or is arbitrary, capricious or an abuse of discretion. I.C. § 67-5279. When an agency action is not affirmed, it shall be set aside, in whole or in part, and remanded for further proceedings as necessary. *Id.*

70. As stated above, under the Idaho Air Rules, DEQ must not issue a PTC unless it determines: (1) "the stationary source or modification would comply with all applicable local, state or federal emission standards"; (2) "the stationary source would not cause or significantly contribute to a violation of any ambient air quality standard"; and (3) "the emissions of toxic air pollutants from the stationary source or modification would not injure or unreasonably affect human or animal life or vegetation as required by Section 161." IDAPA 58.01.01.203. Prior to issuing a permit to contruct, DEQ must provide an opportunity for public comment by making available DEQ's proposed action together with the information provided by the applicant and with DEQ's analysis. IDAPA 58.01.01.209.c. To ensure compliance with the NAAQS and other air pollution control strategies, the Clean Air Act and EPA's Clean Air Act regulations require state air rules like DEQ's: to include "enforceable emission limitations" and other measures, 42 U.S.C. § 7410(a)(2)(A); to include a "program to provide for the enforcement" of such measures, and to regulate the construction of any stationary source, *id.* § 7410(a)(2)(C); to "set forth legally enforceable procedures" for determining whether the construction of a facility will comply with control strategies and NAAQS, 40 C.F.R. § 51.160(a); to require sufficient information needed "to make the determination" whether the facility will comply with air pollution control strategies and the NAAQS, i*d.* § 51.160(c); and to provide opportunity for public comment on information submitted by the applicant and on the agency's analysis of the effects to air quality. *Id.* § 51.161(a). Based on the flaws in DEQ's issuance of the PTC described above, DEQ's action is in violation of these provisions of the Idaho Air Rules, the Clean Air Act, and EPA's Clean Air Act regulations, and is otherwise arbitrary, capricious, made on unlawful procedure, and an abuse of discretion and must be reversed.

71. By issuing the PTC in its current form, DEQ failed to adequately protect the public and environment from harmful air pollution causing injury to the Nez Perce Tribe, ICL, SSFS, and their members and supporters. To redress these injuries, Petitioners respectfully request the Board set aside and remand the PTC and direct DEQ to correct the following errors prior to issuing any new or revised PTC:

Ore Haul Road PM_{10} & Arsenic Emissions

A. DEQ must develop and include in the PTC enforceable permit conditions for the maximum average empty weight of ore haul trucks, the maximum average loaded weight of ore haul trucks, the maximum total number vehicle miles traveled annually by ore haul trucks, the silt content of the roadbed, the arsenic content of the silt in the roadbed, and any other important variables affecting the SGP's fugitive emissions of PM_{10} and arsenic from vehicle traffic on mine haul roads. To develop such permit conditions and ensure compliance with the NAAQS and TAP limits, DEQ must reevaluate and recalculate fugitive emissions of PM_{10} and arsenic.

B. Silt and arsenic levels should be included as permit conditions and monitored regularly *in situ,* rather than from stockpiles as applied to the roadbed.

C. Instead of assuming 120 days of recordable precipitation at the SGP as a variable within ore haul road fugitive PM emission calculations, as done by the applicant based off general geographic guidance from AP-42 chapter 13.2.2-1, DEQ must recalculate all fugitive emissions after analyzing local meteorological data sources to determine a more accurate and representative number of days with recordable precipitation.

FDCP, AMP, O&M Manual, & HRCP

D. DEQ must require Perpetua to submit the FDCP, AMP, O&M Manual, and HRCP (collectively, "Plans"), must provide for public comment on the Plans, must review and revise

Plans to ensure the SGP's emissions comply with IDAPA 58.01.01.203, and must incorporate the Plans as enforceable PTC conditions.

Arsenic Averaging

E. DEQ must remove the 5-year averaging for arsenic emissions, the averaging of estimated annual ambient modeling impacts across two multi-year scenarios, and the 16/70 life of mine versus lifetime exposure adjustment for the SGP's maximum arsenic ambient concentration it used to assess arsenic TAPs compliance. DEQ must use the SGP's highest 1-year arsenic emission rates for each scenario evaluated and repeat the modeling analyses using these rates. DEQ must use the maximum annual ambient arsenic concentration from the single emission scenario producing the highest annual concentration for any 1-year as the point of compliance. *See* IDAPA 58.01.01.210.03b ("The point of compliance is the receptor site that is estimated to have the highest ambient concentration of the toxic air pollutant of all the receptor sites that are located either at or beyond the facility property boundary or at a point of public access . . . ."). DEQ must assess the impact of the SGP's maximum 1-year annual emissions from the single emission configuration by comparing to the T-RACT AACC for arsenic (10 times the AACC value published in IDAPA 58.01.01.586), without averaging over multiple years, and without adjusting for the alleged 16-year life of the mine or the 70-year lifetime exposure.

Ambient Air Boundary Monitoring

F. As part of any PTC for the SGP, DEQ must require ambient air boundary monitoring, as provided for by IDAPA 58.01.01.211.01(d), to ensure compliance with the NAAQS and the TAPs increments. DEQ must require Perpetua to submit an ambient air boundary monitoring plan ("AABMP"), must take public comment on the AABMP, must review and revise the AABMP, and must incorporate the AABMP as enforceable PTC conditions. At a

minimum, the AABMP must provide a strategy for monitoring the ambient air concentrations of PM_{total}, PM_{10}, $PM_{2.5}$ and arsenic at the SGP's ambient air boundary. The AABMP must be developed according to best industry and regulatory practices, consulting contemporary sources (e.g., DEQ or EPA guidance, similarly established plans for other state permits, etc.). At a minimum, monitoring stations must be required for areas of the ambient air boundary in which DEQ ambient air modeling results (specifically results using operating scenario W3 and BULKRN meteorological data) show receptors with 24-hour PM_{10} or arsenic concentrations within 70% of the applicable NAAQS or AACC (without consideration to multi-year emissions averaging and 16/70 adjustment).

Environmental & Economic Impacts of Arsenic Control Technology

G. DEQ must require Perpetua to update their T-RACT analysis to include analysis of "environmental impacts caused by the control technology that cannot be mitigated, including, but not limited to, water pollution and the production of solid wastes," including the use of magnesium chloride and its aquatic life and tree toxicity effects, as well as using arsenic-contaminated water sources for dust suppression. IDAPA 58.01.01.210.14.c.ii. DEQ must also require the updated T-RACT to adequately address the "economic feasibility of a control technology or other requirement, including the costs of necessary mitigation measures, for a particular source," including detailed consideration of the economic feasibility of paving haul roads to better control fugitive dust emissions. IDAPA 58.01.01.210.14.d. DEQ must provide the updated T-RACT demonstration for public comment, must review and revise the T-RACT demonstration, and must incorporate enforceable PTC conditions from the T-RACT demonstration in the PTC.

CONCLUSION

72. When it issued the PTC for the SGP, DEQ violated the federal Clean Air Act, EPA's Clean Air Act regulations, and the Idaho Air Rules; and it acted arbitrarily, capriciously, and on unlawful procedure and abused its discretion under I.C. § 67-5279. Accordingly, the Board should vacate and withdraw the PTC and remanded to DEQ to correct all errors.

BEFORE THE OFFICE OF ADMINISTRATIVE HEARINGS
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047 _____ NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON Petitioners, v. IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent, and PERPETUA RESOURCES IDAHO, INC., Intervenor.	Agency Case No. 0101-22-01 OAH Case No. 23-245-01 RESPONSE TO FIRST AMENDED PETITION TO INITIATE CONTESTED CASE: AIR PERMIT TO CONSTRUCT P-2019.0047 (JUN. 17, 2022)

RESPONSE TO FIRST AMENDED PETITION TO INITIATE CONTESTED CASE- 1

COMES NOW, Respondent, the Idaho Department of Environmental Quality (Department), by and through the Office of the Attorney General, and hereby submits this Response to First Amended Petition to Initiate Contested Case in accordance with the Rules of Administrative Procedure before the Board of Environmental Quality, IDAPA 58.01.23.161.

FACTUAL AVERMENTS

The Department cannot separately admit or deny each fact alleged in the Petition because the factual averments were not made separately. Moreover, the Petition is written in the style of a legal brief, which intermingles the Petitioners' alleged facts with their arguments. Therefore, it difficult to discern whether a statement is a factual averment, argument, a conclusion of law or a combination of any of these. For this reason, any statements of fact set forth in the Petition that are not explicitly admitted or agreed upon, are hereby denied. Without waiving this objection, the Department responds as follows:

A. "INTRODUCTION" Section

The Department does not disagree with the facts alleged in Paragraph One. The Department admits that the Stibnite Gold Project ("SGP") is located approximately ten miles east of the town of Yellow Pine, Idaho, but has insufficient information to admit or deny the claim that the SGP is located with the Nez Perce Tribe's aboriginal homeland, as stated in Paragraph Two. The Department generally agrees with the statements in Paragraph Three but does not agree with the characterization of dust emissions, which are described as "massive." The Department denies the statements in Paragraph Four.

The Department will abide by the request for service in Paragraph Five and admits the statement of jurisdiction in Paragraph Six. Paragraphs Seven and Eight contain no

facts which can be admitted or denied. The Department has insufficient information regarding the Nez Perce Tribe to admit or deny the factual averments in Paragraphs Nine through Thirteen. However, whether the Nez Perce Tribe has standing, a conclusion of law asserted within Paragraph Ten, is disputed, and therefore denied. The Department denies the claim in Paragraph Twelve that the Nez Perce Tribe will suffer injuries from permitted dust emissions at the SGP.

Similarly, the Department can neither admit nor deny the assortment of factual averments scattered throughout paragraphs Fourteen through Nineteen, which generally describe the constituencies, goals, and activities of the Petitioners, Idaho Conservation League and Save the South Fork Salmon. The Department admits that all the Petitioners submitted multiple comments to the Department regarding the Department's Permit to Construct ("PTC"). However, the Department denies the statements claiming that these entities will suffer injuries from permitted dust emissions. The Department admits the statements in Paragraphs Twenty and Twenty-One.

B. **Section I "Overview of SGP & Chronology of DEQ's Issuing the PTC"**

The Department agrees with the course of events as set forth in Paragraphs Twenty-Two through Twenty-Six. However, the Department avers that the permittee, Perpetua Resources Idaho, Inc. ("Perpetua"), followed the Department's process of submitting a draft permit and then responding to requests for further information from the Department.

C. **Section II A, "PM_{10} Pollution and Regulation"**

The Department generally agrees with the statements of fact and the directly cited materials provided in Paragraphs Twenty-Eight through Thirty-Two.

D. **Section II B, "PM_{10} Pollution from the SGP & Flaws in the PTC"**

The Department largely agrees with the statements in Paragraph Thirty-Three, except that the generation of dust from trucks traveling along haul roads is estimated to be approximately 55% of all *fugitive mining* emissions, or 53% of all modeled PM_{10} emissions. The statements in Paragraph Thirty-Four appear to be correct.

Paragraphs Thirty-Five through Forty-One contain mixed statements of fact and argument, which must be denied. Generally, the Department agrees that the Fugitive Dust Control Plan and Haul Road Capping Plan will be important for ensuring compliance with air quality standards. Those plans do not currently exist but will be subject to the Department's approval, and individual provisions within each plan will be enforceable through the PTC. Thus, the Department denies the allegations that those plans are not directly enforceable.

E. **Section II C, "Arsenic Pollution & Regulation"**

The Department agrees with the Petitioners' description of arsenic as a toxic air pollutant in Paragraphs Forty-Two through Forty-Five. The Department neither admits nor denies the statement in Paragraph Forty-Six, which references the definition of "Potential to Emit/Potential Emissions" at IDAPA 58.01.01.006.88.

F. **Section II D, "Arsenic Pollution from the SGP & Flaws in the PTC"**

The Department largely agrees with the substance of Paragraphs Forty-Seven through Forty-Nine. Regarding Paragraph Fifty, the Department agrees that Perpetua submitted to the Department a T-RACT demonstration. The Department agrees with the statements in Paragraph Fifty-One but denies the allegations in Fifty-Two through Fifty-Seven.

G. **Section II E, "DEQ's Ambient Air Boundary for the SGP"**

The Department agrees with the averments in Paragraphs Fifty-Eight, Fifty-Nine, and Sixty; however, the definition of "ambient air" is found at IDAPA 58.01.01.006.10. The Department disagrees with the arguments contained in Sixty-One through Sixty-Five.

H. **Section II F, "DEQ's Failure to Require Ambient Air Monitoring for the SGP"**

The Department agrees with the statements in Paragraphs Sixty-Six and Sixty-Seven but disagrees with the arguments in Paragraph Sixty-Eight.

LEGAL AUTHORITY

The contested permit was issued pursuant to Title 39 Idaho Code and the Rules for the Control of Air Pollution in Idaho, IDAPA 58.01.01 *et. seq*.

ADDITIONAL FACTS

The Department's Air Quality Permitting Response to Public Comments (June 17, 2022), Exhibit A, which can be found at:

https://www2.deq.idaho.gov/admin/LEIA/api/document/download/16969

contains the factual underpinnings supporting the issuance of the PTC as well as the Department's positions on fugitive dust control efficiency (Third Response to Comments 1-4), monitoring, recordkeeping, and reporting (Third Response to Comments 5-9), operational plans (Third Response to Comments 10-18), estimation of potential emissions (Third Response to Comments 19-30), the applicability of "ambient air" standards (Comments 35-36), and the T-RACT process (Comment 39-41). The Department's PTC and associated Statement of Basis, Exhibit B, can be found at:

https://www2.deq.idaho.gov/admin/LEIA/index.html?view=folder&id=3144

RELIEF SOUGHT

The Department requests the Board issue an order affirming the Department's action.

DATED: January 17, 2023, FOR RESPONDENT:

BEFORE THE BOARD OF ADMINISTRATIVE HEARINGS
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047 _____ NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON, Petitioners, v. IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent, and PERPETUA RESOURCES IDAHO, INC. Intervenor-Respondent.	Agency Case No. 0101-22-01 OAH Case No. 23-245-01 **SCHEDULING ORDER**

On January 13, 2023, the parties filed a Joint Motion to Enter Stipulated Scheduling Order and a proposed Stipulated Scheduling Order. Good cause appearing therefor, the hearing officer hereby orders that the following deadlines and discovery parameters shall govern this matter, unless amended jointly by the parties and approved by the hearing officer, pursuant to BEQ Procedural Rules 003.010 and 162.02 and AG Procedural Rules 513, 520, 521, and 710:

Fact Discovery:

Discovery shall open on **upon entry of this order.**

The Parties shall limit discovery to documents or information in the possession of the Department. The Parties shall issue all requests for production, interrogatories, or otherwise request documents by **January 31, 2023.**

The Department shall respond to all discovery requests by **February 14, 2023.** Each Party shall serve upon the other Parties any additional documentary evidence they deem relevant to these proceedings by **February 14, 2023.**

If any Party believes that discovery is required from any other party, besides the Department, they shall meet and confer to determine an appropriate scope of discovery and response deadline.

Dispositive Motions:

Petitioners shall file a joint motion for summary judgment by **April 14, 2023.**

The Department and Perpetua Resources Idaho, Inc. ("Perpetua") shall file their respective responses by **May 12, 2023.** To the extent the Department or Perpetua believe it is necessary to file a motion for summary judgment, such motions shall be filed by **May 12, 2023**, and all briefing on such motions shall be combined with the briefing on the respective responses.

Petitioners shall file a joint reply by **June 9, 2023.** If the Department or Perpetua file a motion for summary judgment, the Petitioners' response shall be combined with their joint reply and filed on **June 9, 2023**.

If the Department and Perpetua file motion(s) for summary judgment, they shall file their respective reply briefs by **June 23, 2023**

The Parties will coordinate with the hearing officer a date for the hearing on the motion(s) for summary judgment on the next status conference held in this matter.

If all issues are not resolved on the order on the motion(s) for summary judgment, the Parties shall meet and confer to develop a proposed schedule to govern prehearing matters and a hearing. The proposed schedule developed by the Parties, if any, shall be filed as a proposed scheduling order within 14 days of the order on the motion(s) for summary judgment.

Finally, it is hereby ordered that all future filings shall be served on Paula Wilson as the Hearing Coordinator via email at Paula.Wilson@deq.idaho.gov, in addition to the service parties identified in the January 3, 2023 Notice of Appointment of Hearing Officer.

Date this 19th day of January, 2023.

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047 _____ NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON Petitioners, v. IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent, and PERPETUA RESOURCES IDAHO, INC., Intervenor.	Agency Case No. 0101-22-01 OAH Case No. 23-245-01 RESPONDENT'S MOTION TO EXTEND DEADLINE FOR DISCOVERY AND MODIFY THE SCHEDULING ORDER DATED JANUARY 19, 2023

RESPONDENT'S MOTION TO EXTEND DEADLINE FOR DISCOVERY AND MODIFY THE SCHEDULING ORDER DATED JANUARY 19, 2023 - 1

Pursuant to the Scheduling Order entered on January 19, 2023 ("Scheduling Order"), discovery responses from the Idaho Department of Environmental Quality ("Department") are due February 14, 2023. However, the Department has determined that the more time will be necessary to fully respond to the Petitioners' discovery requests. Therefore, the Department respectfully moves the Office of Administrative Hearings to extend the time permitted for a response to the Petitioners' request to February 21, 2023.

The Department has consulted with Petitioners' counsel who do not oppose the extension sought in this motion.

CONCLUSION

For the reasons stated above, the Department respectfully requests the Hearing Officer to extend the time permitted for discovery under the Scheduling Order and to modify the dates set forth in the Scheduling Order accordingly.

Attorney for Save the South Fork Salmon

BEFORE THE OFFICE OF ADMINISTRATIVE HEARINGS
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047	
	Agency Case No. 0101-22-01
NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON	OAH Case No. 23-245-01
	PETITIONERS' MOTION FOR SUMMARY JUDGMENT
Petitioners,	
v.	
IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY,	
Respondent,	
and	
PERPETUA RESOURCES IDAHO, INC.	
Intervenor.	

Pursuant to IDAPA 58.01.23, Idaho Rule of Civil Procedure 56, and the January 19, 2023 Scheduling Order in this matter, Petitioners Nez Perce Tribe, Idaho Conservation League, and Save the South Fork Salmon move for the Hearing Officer to enter summary judgment in Petitioners' favor on the claims in First Amended Petition to Initiate Contested Case: Air Quality Permit to Construct P-2019.0047 (Jun. 17, 2022), challenging the Idaho Department of Environmental Quality's issuance of a permit to construct (the "Permit") to Perpetua Resources Idaho, Inc. for the Stibnite Gold Project.

Summary judgment is appropriate, as the claims involve no genuine dispute of material fact, and Petitioners are entitled to judgment as a matter of law.

This Motion is supported by the accompanying: Petitioners' Opening Brief in Support of Motion for Summary Judgment; the Declaration of Bryan Hurlbutt; and Exhibits 1-14 to the Hurlbutt Declaration. This Motion is also supported by the pleadings and files before the Hearing Officer.

WHEREFORE, Petitioners respectfully request the Hearing Officer grant this Motion for Summary Judgment, enter judgment in Petitioners' favor, and set aside and remand the Permit to DEQ.

//

//

//

//

Dated this 14th day of April, 2023.

Respectfully submitted,

/s/ Bryan Hurlbutt

INTRODUCTION 1

THE CLEAN AIR ACT AND IDAHO RULES 2

STATEMENT OF FACTS 5

I. THE STIBNITE GOLD PROJECT 5

II. OVERVIEW OF PERPETUA'S APPLICATION AND DEQ'S APPROVAL 6

III. PM_{10} EMISSIONS FROM THE PROJECT 7

IV. ARSENIC EMISSIONS FROM THE PROJECT 9

V. AMBIENT AIR BOUNDARY AND THE STIBNITE ROAD ACCESS ROUTE 11

VI. LACK OF AMBIENT AIR MONITORING AT THE PROJECT SITE 12

APPLICABLE LEGAL STANDARD 13

ARGUMENT 14

I. DEQ'S DECISION TO EXCLUDE THE STIBNITE ACCESS ROUTE FROM AMBIENT AIR PROTECTIONS IS UNALWFUL 14

II. DEQ'S DETERMINATIONS THAT PROJECT WILL COMPLY WITH PM_{10} AND ARSENIC LIMITS ARE ARBITRARY AND VIOLATE THE RULES 19

A. DEQ's Assumption that Perpetua Will Prevent 93.3% of Fugitive Dust Emissions Is Unreasonable and Violates the Air Rules. 19

B. DEQ Failed to Include Conditions Restricting Ore Haul Truck Weights, Sizes, and Miles Traveled in the Permit. 23

C. DEQ Failed to Use Representative Precipitation Data. 25

D. DEQ Failed to Include in the Permit Monitoring and Recordkeeping Requirements Critical to Ensuring Haul Limits are Met. 26

III. DEQ'S RELIANCE ON FUTURE PLANS TO BE PREPARED BY PERPETUA OUTSIDE OF THE PTC PROCESS VIOLATES THE AIR RULES AND CAA 28

IV. DEQ MUST REQUIRE AMBIENT AIR MONITORING 31

V. DEQ FAILED TO ANALYZE ECONOMIC INFORMATION AND ENVIRONMENTAL IMPACTS IN THE ARSENIC T-TRACT 32

VI. DEQ IMPROPERLY DILUTED PROJECT ARSENIC EXPOSURE, MASKING THE TRUE HEALTH RISKS IN VIOLATION OF THE AIR RULES.....34

VII. THE PERMIT MUST BE SET ASIDE AND REMANDED TO DEQ TO CORRECT ALL ERRORS 37

CONCLUSION.....38

Petitioners Nez Perce Tribe, Idaho Conservation League, and Save the South Fork Salmon challenge the Idaho Department of Environmental Quality's ("DEQ" or "Department") approval of a permit to construct (the "Permit") issued to Perpetua Resources Idaho, Inc. ("Perpetua") for the proposed Stibnite Gold Project ("SPG" or "Project"): a massive open-pit mine in Valley County, Idaho. As proposed, Perpetua would excavate 340 million tons of waste rock to mine and process approximately 100 million tons of ore, using 55 miles of haul truck routes over 16 years. Blasting, excavating, ore hauling, and other Project activities will emit air pollutants, including coarse particulate matter ("PM_{10}") and arsenic. PM_{10} and arsenic are regulated under the federal Clean Air Act and Idaho's air pollution regulations, because they can cause significant and severe health and environmental hazards.

When it issued the Permit, DEQ concluded that the Project would comply with applicable limits on PM_{10} and arsenic. But in reaching these conclusions, DEQ made many unreasonable assumptions, deviated from established permitting practices, and failed to follow governing laws, regulations, and guidance. For example, DEQ repeatedly deferred developing and imposing important conditions in the Permit, leaving these to be developed by Perpetua later–if at all–and shielded from public scrutiny. DEQ also employed a new tactic to dilute the arsenic exposures associated with the Project so that they appear to be a mere 23% of what they will be in actuality.

As a result of these and other errors, DEQ failed to account for a large portion of the Project's PM_{10} and arsenic emissions, and underestimated the degree to which they will degrade ambient air quality and threaten public health and the environment. The Permit is thus arbitrary, capricious, an abuse of discretion, and/or contrary to law under relevant legal standards and the Idaho Administrative Procedure Act ("APA"). The Hearing Officer should grant summary judgment for Petitioners, set aside the Permit, and remand for DEQ to correct these errors.

THE CLEAN AIR ACT AND IDAHO AIR RULES

The federal Clean Air Act ("CAA"), 42 U.S.C. § 7401 *et seq.*, was passed to "protect and enhance the quality of the Nation's air resources" by prescribing national ambient air quality standards ("NAAQS") which state and regional authorities are required to either maintain or make progress toward. To achieve the CAA's goals, Congress directed the Environmental Protection Agency ("EPA") to establish primary and secondary NAAQS for any pollutant "reasonably . . . anticipated to endanger public health or welfare" and to periodically review and revise those standards. *Id.* §§ 7408(a)(1)(A), 7409(a)(1), (d). The CAA also requires the EPA to divide up the country into areas designated as "nonattainment," "attainment," or "unclassified" based on whether these areas meet the NAAQS. *Id.* § 7407(d).

States have the primary responsibility for assuring that air quality within their borders meets the NAAQS. Each state must establish a state implementation plan (SIP), which is submitted to EPA for review. *Id.* § 7410. To be approved by EPA, each SIP must "include enforceable emission limitations and other control measures, means, or techniques . . . as may be necessary or appropriate to meet the applicable requirements of [the CAA]." *Id.* § 7410(a)(2)(A); 40 C.F.R. § 52.02(a). States can adopt and enforce their own standards regarding emissions "provided such state standard is no less stringent than any applicable federally mandated SIP provision." *Nat. Res. Def. Council v. Thomas*, 845 F.2d 1088, 1090 (D.C. Cir. 1988).

The CAA requires that State air rules "shall" include "enforceable emission limitations" and other control measures, means, or techniques as necessary or appropriate to meet CAA requirements. 42 U.S.C. § 7410(a)(2)(A). SIPs "shall" also include a "program to provide for the enforcement" of the limitations and measures described in subparagraph (A), and for the

"regulation of the modification and construction of any stationary source . . . to assure that [NAAQS] are achieved." *Id.* § 7410(a)(2)(C).

EPA's CAA regulations require each SIP to "set forth legally enforceable procedures" that enable the State to determine whether the construction of a facility will result in a violation of its air pollution control strategies or interfere with attaining or maintaining the NAAQS. 40 C.F.R. § 51.160(a). These legally enforceable procedures must include means by which the State will prevent construction if the facility will violate air pollution control strategies or interfere with attaining or maintaining the NAAQS, and they must provide for the applicant to submit information on the "location, design, construction, and operation of such facility . . . as may be necessary" to permit the State to "to make the determination" that the facility will comply with its air pollution control strategies and the NAAQS. *Id.* § 51.160(b)–(c). "The legally enforceable procedures in § 51.160(b) must also require" the State to provide opportunity for public comment on information submitted by the applicant and on the State's analysis of the effects on ambient air quality. *Id.* § 51.161(a).

EPA has delegated to DEQ authority to issue air quality permits in Idaho pursuant to the Rules for the Control of Air Pollution in Idaho ("Air Rules"), IDAPA 58.01.01. Prior to construction of a facility, the owner or operator must first obtain a permit to construct ("PTC") from DEQ which satisfies the applicable requirements of the Air Rules. Air Rules Section 201.

A PTC application "shall be accompanied by all information necessary to perform any analysis or make any determination required under Sections 200 through 228." Air Rules Section 202. The applicant must provide the following required information: "Site information, plans, descriptions, specifications, and drawings showing the design of the stationary source, facility, or modification, the nature and amount of emissions (including secondary emissions),

and the manner in which it will be operated and controlled." Air Rules Section 202.01.a.i. The applicant must also provide: "Any additional information, plans, specifications, evidence or documents that the Department may require to make the determinations required under Sections 200 through 225 shall be furnished upon request." Air Rules Section 202.03.

Among other determinations, DEQ cannot issue a PTC unless it determines that the facility: (1) "would comply with all applicable federal emissions standards;" (2) "would not cause or significantly contribute to a violation of any ambient air quality standards" (i.e., the NAAQS); and (3) "emissions of toxic air pollutants . . . would not injure or unreasonably affect human or animal life or vegetation as required by Section 161." Air Rules Section 203.

When making these determinations, DEQ must consider the source's "potential to emit" ("PTE"), which is defined as:

> The maximum capacity of a facility or stationary source to emit an air pollutant under its physical and operational design. Any physical or operational limitation on the capacity of the facility or source to emit an air pollutant, including air pollution control equipment and restrictions on hours of operation or on the type or amount of material combusted, stored or processed, shall be treated as part of its design if the limitation or the effect it would have on emissions is state or federally enforceable. Secondary emissions do not count in determining the potential to emit of a facility or stationary source.

Air Rules Section 006.88.

For all PTC applications, DEQ must provide an opportunity for public comment. Air Rules Section 209.01.c. The Air Rules also require DEQ to issue either an "approval," a "conditional approval," or a "denial." Air Rules Sections 209.01.b.i & ii, c.iv. DEQ "may impose any reasonable conditions" upon the facility in the PTC. Air Rules Section 211. DEQ can also authorize revisions to permits, but such revisions must go through the Air Rule Section 209 public comment process if the revision results in an increase in emissions or if deemed appropriate by the DEQ director. Air Rules Section 209.04.b.iii.

STATEMENT OF FACTS

I. THE STIBNITE GOLD PROJECT.

Perpetua proposes to construct and operate a conventional open-pit mine with ore preparation and gold extraction facilities approximately 10 miles east of the town of Yellow Pine, in Valley County, Idaho. *See* PET 049-51.[1] The Project is located on a combination of public National Forest and private lands. *Id.* The Project is also geographically located within the Nez Perce Tribe's aboriginal homeland and within the area over which the Nez Perce Tribe has Treaty-reserved rights and resources.

The Project includes 3 years of development and construction activities, followed by approximately 12 years of mining. *Id.* The Project would require "construction of significant infrastructure," including a power transmission line, a primary mine site access road, onsite haul roads, an ore processing facility, onsite workspaces, employee housing and recreation, water storage and distribution facilities, and sewage disposal facilities. *Id.* Conventional open-pit mining methods including drilling, blasting, excavating, and hauling will be used to extract ore and waste rock (termed development rock) from three open pits. *Id*. Over the life of the mine, approximately 340 million tons of waste rock would be handled and 100 million tons of ore will be mined from the three pits. *Id.* A fleet of large trucks will haul ore and waste rock using a network of over 55 miles of unpaved haul roads at the mine site. PET 065.

The Permit issued by DEQ is the first of over 50 permits required from various local, state, and federal agencies for the proposed mine. Perpetua is currently in the process of seeking

[1] Petitioners' Exhibits, which include documents from DEQ's project record and documents exchanged during discovery, were Bates numbered and are filed with the accompanying Hurlbutt Declaration. Citations to Petitioners' Exhibits are cited here as "PET [Bates #]."

these other permits for the proposed Project, including from the U.S. Forest Service, U.S. Army Corps of Engineers, and U.S. Fish and Wildlife Service.

II. OVERVIEW OF PERPETUA'S APPLICATION AND DEQ'S APPROVAL.

Perpetua (previously Midas Gold) submitted a PTC application to DEQ on August 20, 2019. *See* PET 052-54 (SOB Application Chronology). Between that date and March 6, 2020, DEQ determined that the application was incomplete, requested additional information, and received supplementary materials from Perpetua no fewer than four times. *Id.* On May 15, 2020, DEQ deemed Perpetua's application complete. *Id.*

Between May 15, 2020, and March 16, 2022, DEQ developed three versions of the draft Permit and released them for public comment. *Id.* As noted in comments submitted by the Nez Perce Tribe, ICL, SSFS, and other members of the public and agencies, the first two draft versions of the Permit (the "September 2020" and "February 2021" Draft Permits) contained significant shortcomings. *See* PET 617-34 (DEQ Response to Comments ("RTC")). After taking public comment, DEQ deemed the September 2020 draft Permit deficient and required updated information from Perpetua, including updated hazardous air pollutants ("HAP") and toxic air pollutants ("TAP") emissions estimates. *See* PET 052-54..

DEQ subsequently updated the draft Permit in February 2021, and took public comment. *Id.* Following additional comments, DEQ determined that the February 2021 draft Permit was deficient and required additional information from Perpetua, including Prevention of Significant Deterioration ("PSD") emissions estimates and regulatory applicability for the lime manufacturing plant. *Id.*

DEQ revised the February 2021 draft PTC and released it for public comment on January 13, 2022. *Id.* Comments were submitted by the Nez Perce Tribe, ICL, SSFS, EPA, and

Ian von Lindern of Terragraphics International Foundation. *See* PET 550-616. Commenters raised numerous concerns and urged DEQ to gather additional information, to perform additional modeling and analysis, and to develop additional enforceable permit conditions and limits prior to issuing a final Permit. *See id.*

DEQ rejected most of the issues raised by the commenters. *See id.* And on June 17, 2022, DEQ issued the final Permit (PET 001) along with the Statement of Basis ("SOB") (PET 044) and Response to Comments ("RTC") (PET 549).

III. PM_{10} EMISSIONS FROM THE PROJECT.

Particulate matter ("PM") is a "criteria air pollutant." Under CAA Sections 108 and 109, EPA is required to establish NAAQS for each criteria pollutant to protect the nation's public health and welfare. The NAAQS specify a maximum amount of PM to be present in the outdoor air. *See* 40 C.F.R. §§ 50.6, 50.7. EPA established primary and secondary NAAQS for coarse particulate matter, or "PM_{10}," and for fine particulate matter, or "$PM_{2.5}$". 40 C.F.R. § 50.6-50.7. PM_{10} consists of inhalable particles with diameters that are generally ten micrometers and smaller; whereas, $PM_{2.5}$ consists of inhalable particles that are 2.5 micrometers and smaller. *Id.*

DEQ found that the Project has the potential to emit 986 tons per year of PM_{10} from a variety of controlled fugitive sources, plus 55.7 additional tons per year of PM_{10} from a variety of controlled point sources. PET 064 (Table 3). The generation of dust from ore haul trucks traveling along haul roads is the most significant source, representing approximately 72% of all fugitive PM_{10} emissions, and 68% of all modeled PM_{10} emissions. *See id.* The next most significant sources of PM_{10} are from drilling and blasting activities, which together account for an estimated 21% of all fugitive PM_{10} emissions (20% of all emissions). *See id.*

To evaluate whether the Project would comply with the PM_{10} NAAQS, DEQ modeled receptors at various locations along the Project's ambient air boundary and found the Project would exceed the 24-hour PM_{10} NAAQS at one receptor, when using a single-value for PM_{10} background at the site. PET 351-53 (SOB, App'x B at "TAPs Addendum Modeling Review"). DEQ then used seasonal and monthly background PM_{10} values to find that the maximum 24-hour PM_{10} pollution from the Project would be 123.5 micrograms per meter cubed ("ug/m^3), which is 82.3% of the NAAQS. PET 351 (Table 7).

Among other factors, these modeled PM_{10} emissions are based on Permit Condition 3.5 limiting Perpetua's production to no more than 180,000 tons per day, and no more than an average of 135,000 tons per day on a rolling five-year basis. *See* PET 055 (Table 1). They also depend on Perpetua achieving a 93.3% rate of control of fugitive dust. *Id.* Achieving these and other Permit conditions, and assumptions used in the modeling, also depend on future plans called for in the Permit, including a Fugitive Dust Control Plan ("FDCP"), Operations and Maintenance Plan ("O&M Plan"), and Haul Road Capping Plan ("HRCP"). *See* PET 009, 012, 020 (Permit Conditions 2.6, 2.20, 3.13); PET 090-91.

During public comment, Petitioners, EPA, and other commenters warned that DEQ unreasonably assumed PM_{10} emissions would be this low. PET 555-59. Specifically, Petitioners and EPA commented that DEQ unreasonably assumed Perpetua would be able to control 93.3% of dust it would otherwise emit on haul roads, and pointed out that DEQ's assumptions relied on the yet-to-be determined details of numerous future plans that have not yet been developed by Perpetua, submitted to DEQ, or included as conditions of the Permit. *Id.*

In its comments, EPA underscored that achieving 93.3% control for excavation and haul roads, and 90% control for drilling, "are critical to ensuring no violation of the NAAQS and

Title V HAP limits." PET 555. EPA warned that the Permit lacks conditions necessary to assure Perpetua achieves these efficiencies and that record fails to show those efficiencies are achievable based on site-specific conditions. PET 555-56. EPA also noted that DEQ failed to provide evidence to support its claim that a 90% control using magnesium chloride could be improved by also using water sprays to achieve a 93.3% control. PET 557.

Similarly, the NPT commented that DEQ had not demonstrated that 93.3% control was attainable or enforceable under the Permit. PET 555. And as ICL and SSFS pointed out in their comments, of the facilities Perpetua and DEQ pointed to as demonstrating compliance with high control rates, only one of these facilities was actually verified to have achieved that rate. PET 557-58. Furthermore, only one of these facilities was a gold mining operation. *Id.*

IV. ARSENIC EMISSIONS FROM THE PROJECT.

Arsenic is a Toxic Air Pollutant ("TAP") regulated by DEQ. Air Rules Section 586. DEQ determined arsenic is the largest projected TAP emission from the Project. PET 069. DEQ found that the Project could emit 0.544 lbs/hr at the maximum mine production rate of 180,000 tons per day. PET 067. Arsenic is a component of rocks, soils, and dust at the Project site, so arsenic emissions are essentially a percentage of the Project's PM_{10} emissions, and like with PM_{10}, the largest source of Project arsenic emissions are haul roads, estimated at 0.464 lbs/hr. PET 062.

No PTC can be granted unless DEQ determines the applicant showed "the emissions of toxic air pollutants from the . . . source . . . would not injure or unreasonably affect human health or animal life or vegetation as required by Section 161." Air Rules Section 203.03. Section 161 states, "[a]ny contaminant which is by its nature toxic to human or animal life or vegetation shall not be emitted in such quantities or concentrations as to alone, or in combination with other contaminants, injure or unreasonably affect human or animal life or vegetation." Air Rules

Section 161. For each carcinogenic TAP, including arsenic, the Air Rules set Acceptable Ambient Concentrations of Carcinogens ("AACC"), where each AACC is an annual average in ug/m^3. Air Rules Section 586. To demonstrate compliance with these TAPs requirements, ambient impacts must be less than the AACC. Air Rule Section 203; *see also* PET 470.

Because of the Project's high arsenic emissions, Perpetua used what DEQ described in the SOB as "a highly refined TAPs analysis approach to demonstrate compliance with applicable TAP increments." PET 332.

As one part of this approach, DEQ approved Perpetua's "T-RACT demonstration" to allow a 10-times increase in the arsenic AACC. *Id.* As the Air Rules provide, a permittee can analyze reasonable available control technologies ("RACT") that could be applied to a source of TAPs. *See* Air Rules Section 210.14. If using RACT does not sufficiently reduce toxic emissions to below the AACC, then the permittee is allowed a 10-fold increase in the AACC and can employ production limitations to ensure compliance with the now increased AACC. *See* Air Rules Section 210.12.b. Perpetua submitted to DEQ a T-RACT demonstration for arsenic emissions from open-pit drilling and ore haul roads. *See* PET 543-548 (SOB, App'x G, "T-RACT Analysis"). For open-pit drilling, Perpetua determined dry drilling with dust collectors was the most effective RACT. PET 545. For ore haul roads, Perpetua determined that the application of chemical dust suppressant, supplemented with frequent watering, as the RACT. PET 548.

As another part of this approach, DEQ allowed what it called an "AACC adjustment for the Operational Life of the Mine." PET 332. Under this approach, instead of comparing the highest annual average ambient arsenic concentration during the Project lifetimes to the T-RACT adjusted AACC (which is also an annual average), DEQ stretched out and diluted the arsenic

concentrations from the 16-year Project lifetime over a longer 70-year human life. *See* PET 344. During permitting, DEQ staff noted that this approach had not been used before, and raised concerns about whether it was permissible under the Air Rule. *See* PET 817-24; PET 825-30.

During public comment, Petitioners questioned DEQ's novel tactic for diluting the apparent arsenic exposure by spreading it over 70 years, and warned that without this the Project would exceed the arsenic AACC, even with the T-RACT adjustment. PET 596, 605, 609. Petitioners also warned that DEQ failed to assess the environmental impacts caused by the control technology, including by applying large amounts of magnesium chloride to roads to control dust, which can accumulate over time to toxic concentrations in trees and soils and can impact water. PET 596, 612.

In the end, DEQ approved Perpetua's T-RACT demonstration and, thus, granted a 10-fold increase in allowable arsenic pollution combined with using the creative new "adjustment" to dilute the apparent arsenic exposure by spreading it over 70 years so that DEQ could determined the Project would comply with this larger AACC. *See* PET 332.

V. AMBIENT AIR BOUNDARY AND THE STIBITE ROAD ACCESS ROUTE.

The CAA and Idaho Air Rules require Perpetua to meet various air standards, including the NAAQS and TAPs AACCs, in ambient air. *See*, *e.g.*, Air Rules Sections 006.11 (NAAQS), 006.125 (TAPs). EPA's CAA regulations define "ambient air" as "that portion of the atmosphere, external to buildings, to which the general public has access." 40 C.F.R. § 50.1(e).

The Stibnite Road Access Route ("Route") is a road that passes through what Perpetua and DEQ have defined as the mine's operations boundary and the ambient air boundary, and the inside of that boundary is the active industrial site where Project mining activities and heavy equipment operation will occur. PET 049 (map). Perpetua has indicated that it will not cut off

public access along the Stibnite Road Access Route during mine operations, and as explained by DEQ, Perpetua "will manage an access route to provide the general public with limited access through the [Project] site between Stibnite Road at Sugar Creek and Thunder Mountain Road at Meadow Creek." PET 310.

In public comments, Petitioners urged DEQ to count the Stibnite Road Access Route as ambient air where air quality standards would have to be met, since Perpetua plans to allow public access on the Route. PET 590-92. But DEQ excluded everything within the mine operations boundary from ambient air—including the Stibnite Road Access Route. *See id.*; *see also* PET 049 (map).

In its comments, EPA urged: "Given the unique situation with a public access road traversing the mine site, the key assumptions, parameters, and methodologies used to preclude public access from the mine site must be fully disclosed in the permit record and the necessary requirements be included in the permit and available for public review and comment." PET 569. But instead of following EPA's advice, DEQ is instead allowing Perpetua to develop an Access Management Plan ("AMP") to address these issues later without public review. PET 010, 070.

VI. LACK OF AMBIENT AIR MONITORING AT THE PROJECT SITE.

DEQ has the authority to require ambient air monitoring to determine the effect emissions from the stationary source or facility may have on the air quality of the area potentially impacted by the source. Air Rules Section 211.01(d). Petitioners and EPA urged DEQ to require ambient air monitoring to verify Project compliance with the NAAQS and AACCs. PET 560-64. DEQ responded that it "recognizes the uncertainty of predicted impacts (from the use of dispersion models) in complex terrain, the uncertainty in predicted impacts when using modeling techniques for fugitive emission sources, the uncertainty in emission factors and equations, the

uncertainty and variability in input parameters to emission equations, and the variability in background pollutant concentrations." PET 561. Despite all of this uncertainty, DEQ refused to require Perpetua to perform any ambient air monitoring. PET 561-62.

APPLICABLE LEGAL STANDARDS

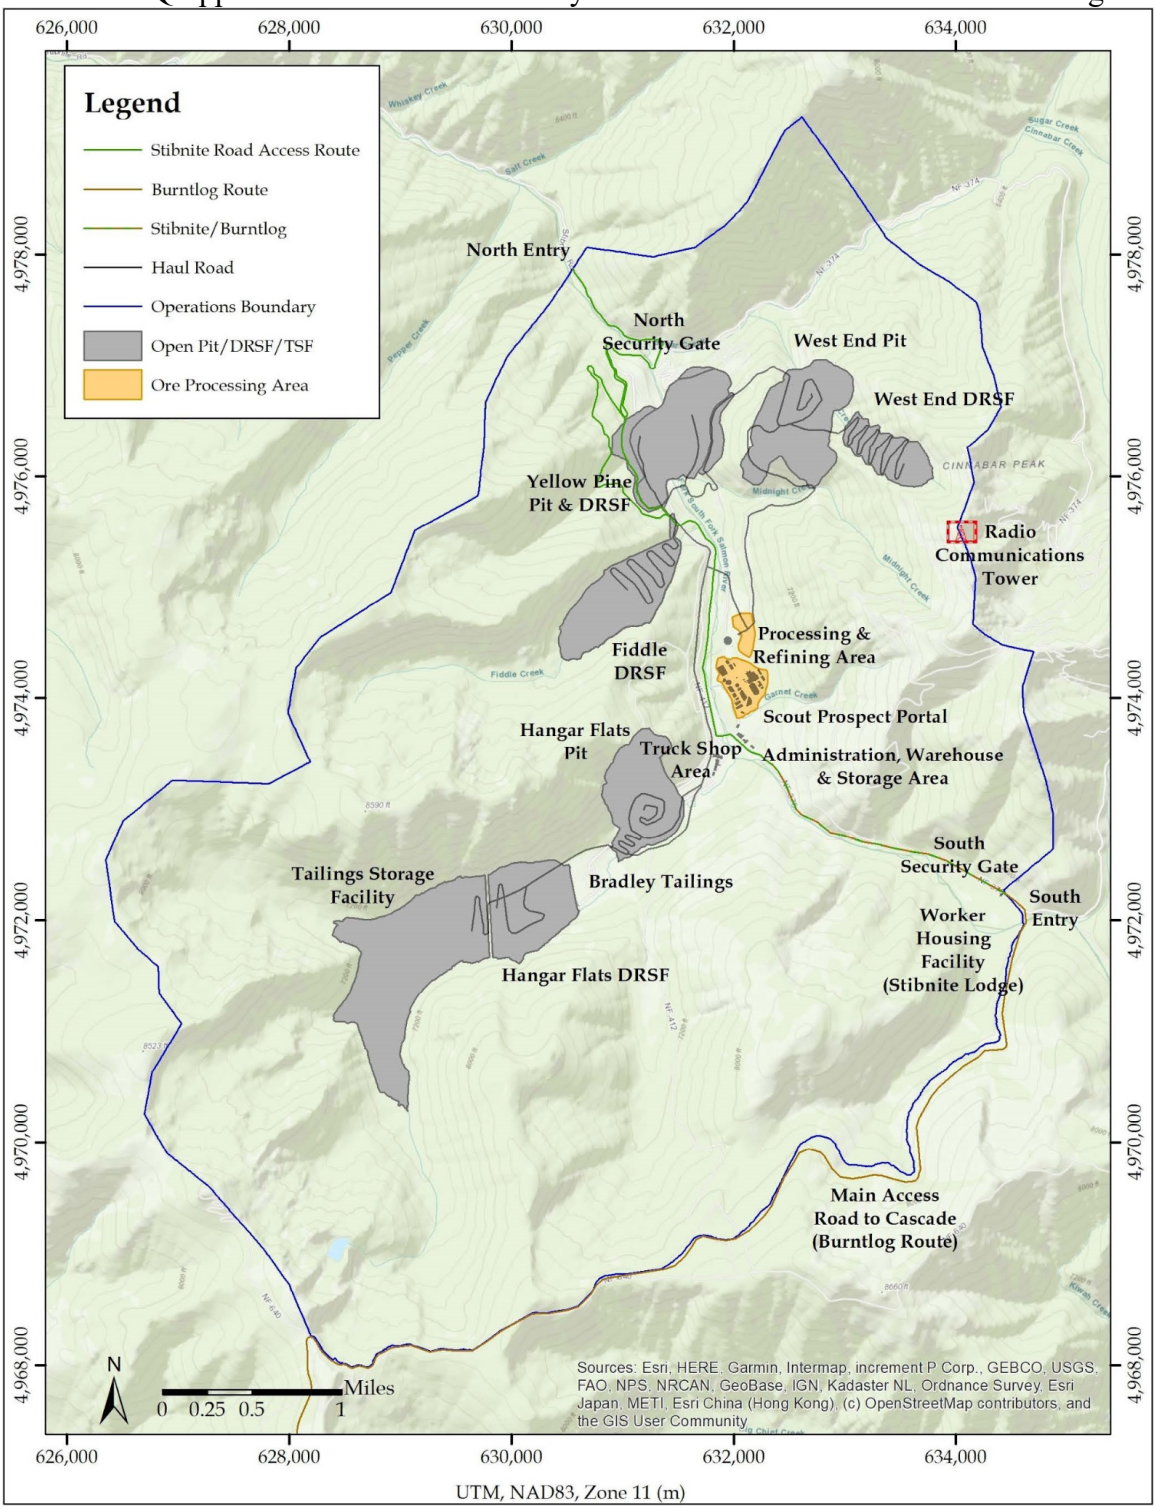
Petitioners bring this contested case to challenge DEQ's action in issuing the Permit. Under the Idaho APA, an agency action like issuing the Permit will be overturned where its findings, inferences, conclusions, or decisions are: "(a) in violation of constitutional or statutory provisions; (b) in excess of the statutory authority of the agency; (c) made upon unlawful procedure; (d) not supported by substantial evidence on the record as a whole; or (e) arbitrary, capricious, or an abuse of discretion." Idaho Code ("I.C."). § 67-5279(3). *See 917 Lusk v. City of Boise*, 158 Idaho 12, 14 (2015).

"An action is capricious if it was done without a rational basis. It is arbitrary if it was done in disregard to the facts and circumstances presented or without adequate determining principles." *Am. Lung Ass'n of Idaho/Nev. v. Idaho State Dep't of Agric.*, 142 Idaho 544, 547 (2006) (citations omitted). Under the "well-established standard of review to evaluate whether there has been an abuse of discretion" the "decision-maker must have perceived the issue in question as discretionary, acted within the outer limits of its discretion and consistently with the legal standards applicable to the available choices, and reached its own decision through an exercise of reasons." *917 Lusk*, 158 Idaho at 14 (quotations omitted).

Motions for summary judgment before the Board are allowed by IDAPA 58.01.23.162.02 and are governed by the Idaho Rules of Civil Procedure ("I.R.C.P."). Summary judgment is proper here under I.R.C.P. 56(c), because there is no genuine issue as to any material fact and Petitioners are entitled to judgment as a matter of law. I.R.C.P. 56(c).

ARGUMENT

I. DEQ'S DECISION TO EXCLUDE THE STIBNITE ACCESS ROUTE FROM AMBIENT AIR PROTECTIONS IS UNLAWFUL.



Health-based limits on pollution, such as the NAAQS and TAPs, form the foundation of the CAA and the Air Rules, and these limits must be met in "ambient air." By contrast, in areas excluded from ambient air, a facility does not have to demonstrate compliance with the NAAQS or TAPs. Both EPA and DEQ define "ambient air" as "that portion of the atmosphere . . . to which the general public has access." 40 C.F.R. § 50.19(c); Air Rules Section 006.10. "The essence of EPA's regulatory definition of ambient air links ambient air to public access." *Resisting Envtl. Destruction on Indigenous Lands (REDOIL) v. U.S. EPA*, 716 F.3d 1155, 1164 (9th Cir. 2013). EPA's long-standing policy, accordingly, has been to exempt from ambient air only "the atmosphere over land owned or controlled by the source and to which public access is precluded." PET 772.

The Stibnite Road Access Route is a public access road traversing the Project site. S*ee* Fig. 1 below. Perpetua has committed to allowing public access on this Route during operations. PET 310 (SOB). The importance of maintaining public access was highlighted in public comments submitted to the Forest Service through the National Environmental Policy Act ("NEPA") process for the Project, "particularly for those in the Johnson Creek and Yellow Pine area who use Stibnite Road to access Thunder Mountain Road and points beyond." PET 529. Maintaining access to these important recreational areas "is consistent with the [Forest Service] travel management plan." PET 530.

Because the public will be able to use the Route, it qualifies as ambient air where health-based air quality standards must be met. DEQ, however, excluded Perpetua's entire operations boundary (shown in Fig. 1 below) from ambient air–including the Route. DEQ's decision to

exclude the Route from ambient air cannot be squared with the CAA, the Air Rules, and EPA's national ambient air policy.

Fig. 1. Map reproduced from SOB (PET 049) showing Project operations boundary, which is also the DEQ-approved ambient air boundary. The Stibnite Road Access Route is in green.

As the Supreme Court stated in *Train v. Natural Resources Defense Council, Inc.*, 421 U.S. 60, 65 (1975), ambient air "is the statute's term for outdoor air used by the general public." EPA's policy for excluding certain portions from ambient air explains:

> [T]he EPA's policy allowing exclusion of some areas external to buildings is not based on language in the regulatory definition mandating exclusion or providing particular criteria for such an exclusion, but rather, is inferred as the inverse of what is affirmatively covered by that definition (*i.e.*, if "ambient air" is defined as that to which the general public has access, then that to which the general public does not have access is not ambient air. . . . The EPA continues to view the "general public" to include any person(s) other than those who are permitted access to the property as employees or business invitees of a specific stationary source (including trespassers).

PET 779. It is clear from EPA's policy that the exemption from ambient air is available only for areas where the general public *will be precluded from entering*–both because there is no legal right to access, as well as no "physical or practical access." *Id.* The Permit, however, does not preclude access by the general public. Rather, it permits Perpetua to allow public access and, therefore, inappropriately exempts the Route from ambient air.

To circumvent this problem, DEQ maintains that the "roadway is not public" because Perpetua "has sole control of access through the site" and "is not obligated to allow access." PET 590, 592. Furthermore, DEQ erroneously rationalized because Perpetua will have the ability to "state the conditions of allowed access," the general public passing through the mine site to access public land are now "guests of [Perpetua] in the same manner as those touring the facility as part of a classroom fieldtrip [sic]." PET 590. Disavowing itself of any responsibility for mine "guests," including schoolchildren, DEQ explained: "Since those requesting access to the site are guests of [Perpetua] and no longer members of the public, health and safety of such guests . . . is the responsibility of [Perpetua] and outside of the scope of the PTC." PET 570. DEQ's

rationalization is disingenuous, and as EPA warns in its policy "would expand the exclusion beyond reason and deny the protection of the NAAQS to large numbers of people." PET 779.

This interpretation of EPA's ambient air policy requires the anomalous conclusion that the mere *ability* to preclude the general public is the same as *actually* precluding the general public. EPA's policy for excluding a facility from ambient air is based on "that to which the general public does not have access." PET 772. Physical access "addresses whether the general public is able to, *under actual circumstances*, enter a particular parcel of land." PET 779 (emphasis added). The actual circumstances here are that Perpetua plans, with limited exceptions (like during blasting), to continue to allow public access on the Route during the life of the Project. PET 310. Because the general public will actually have access—as Perpetua has consistently committed—the Route is ambient air.

DEQ guidelines further support this point. Those guidelines state that an applicant's proposal to exclude an area from ambient air "must include justification that demonstrates the facility has reasonable control of the area and *effectively precludes public access on a routine basis*." PET 743 (emphasis added). Notably, DEQ guidelines identify the precise situation here—when "general public [is] allowed on site as a part of a right-of-way easement or common service road"—as being ambient air. PET 744. Again, while Perpetua would "state the conditions of allowed access" on the Route, Perpetua is not precluding public access. PET 087.

DEQ guidelines also provide that the "'general public' is considered anyone not directly associated with the facility." PET 743. This contradicts DEQ's assertion that people traveling the Route to access public lands are not the general public but are rather "guests" of the mine. *See* PET 529. DEQ's contorted definition of the general public as "guests" of the mine has no rational basis and does not make them "directly associated with the facility."

The Permit requirement for Perpetua to develop and follow an Access Management Plan does not change this. Under Permit Condition 2.7, the AMP is supposed to specify the "measures to be used to discourage public access to the facility." PET 010. It also provides that: "Only registered guests of the facility will be allowed access to or through the facility." *Id.* Again, simply classifying general members of the public seeking to pass through the facility as "registered guests" does not convert them to people who are directly associated with the facility.

Furthermore, as EPA warned in its comments: "Given the unique situation with a public access road traversing the mine site, the key assumptions, parameters, and methodologies used to preclude public access from the mine site must be fully disclosed in the permit record and the necessary requirements be included in the permit and available for public review and comment." PET 569. But instead of fully disclosing these key assumptions, parameters, and methodologies in the Permit, DEQ is letting Perpetua develop these later, without public comment or full DEQ review. Under Permit Condition 2.8, Perpetua need not submit the AMP to DEQ until 30 days prior to startup. PET 010.

DEQ cannot issue a Permit first and leave important issues to be addressed in the AMP outside the required permit process, behind closed doors, and without full DEQ review. Without full disclosure and review of the specific measures and requirements in the AMP, DEQ had no rational basis for concluding that the Route can be properly excluded from ambient air, rendering that decision arbitrary and capricious. DEQ's decision to exclude the access road from ambient air protections is thus arbitrary and capricious and fails to comply with the CAA, the Air Rules, and EPA and DEQ policies, and places the public at risk. The Hearing Officer should grant summary judgment for Petitioners, set aside the Permit, and order DEQ on remand to include the Route as ambient air.

II. DEQ'S DETERMINATION THAT THE PROJECT WILL COMPLY WITH PM_{10} AND ARSENIC LIMITS IS ARBITRARY AND VIOLATES THE AIR RULES.

Even using DEQ's ambient air boundary, DEQ's determinations that the Project's potential to emit will not cause or contribute to an exceedance of the PM_{10} NAAQS and the arsenic AACC—as required under Air Rules Section 203 prior to issuing a PTC—are arbitrary and capricious and violate the Air Rules, must be set aside and remanded.

When it made these determinations, DEQ relied on modeling that included a number of important inputs, including: the percentage of fugitive dust emissions that Perpetua will effectively control; the sizes and weights of, and miles traveled by, Perpetua's ore haul trucks; the number of days of recordable precipitation; and others. However, the values DEQ used for each of these inputs were unreasonable and/or not included as enforceable Permit conditions, as set forth in the sections below. Thus, Perpetua's actual operations, and the site conditions, might differ from what was assumed in the modeling, and PM_{10} and arsenic concentrations could violate applicable standards even if Perpetua fully complies with the terms of the Permit.

A. DEQ's Assumption that Perpetua Will Prevent 93.3% of Fugitive Dust Emissions Is Unreasonable and Violates the Air Rules.

A critical factor affecting fugitive dust emissions, and therefore whether the Project will comply with the PM_{10} NAAQS and arsenic AACC limits, is the degree to which Perpetua will effectively control dust from haul roads.[2] When it approved the Permit, DEQ assumed that Perpetua will achieve a 93.3% control efficiency of all haul road dust by using a combination of water sprays and chemical dust suppressants. *See* PET 065. However, as EPA and other commenters pointed out, it is highly questionable whether 93.3% fugitive dust control is

[2] There are other sources of fugitive dust emissions at the facility, including "drilling and blasting activities, crushing and ore handling equipment, ore and rock storage piles, and unpaved roadways." PET 064. However, fugitive dust emissions from unpaved roadways represents a majority of the estimated PM_{10} and arsenic emissions from the facility. PET 061, 063 (Table 3).

realistically attainable for this Project, and the Permit lacks conditions necessary to ensure that Perpetua will achieve such a high level of control. *See* PET 554-559.

EPA has found, for example, that chemical dust suppressants achieved only 80% control efficiency, far less than the 93.3% DEQ relied on. Specifically, "past field testing of emissions from controlled unpaved roads has shown that chemical dust suppressants provide a PM_{10} control efficiency of about 80 percent when applied at regular intervals of 2 weeks to 1 month." PET 809. If Perpetua achieved only 80% control of dust emissions, then 20% of dust will be emitted (2,218 tons per year), compared to emitting only 6.7% of dust as assumed in the modeling (713 tons per year). This means, at a realistic 80% control level, Perpetua would generate *3 times* the amount of dust than what was assumed in the modeling DEQ relied on when it determined the Project would not exceed the PM_{10} NAAQS and the arsenic AACC.

Additionally, DEQ asserted that chemical suppressants could achieve 90% dust control on their own, asserted that water could 33.3% alone, and then assumed that combined these two practices could achieve 93.3%. PET 143. But as EPA and other commenters stated in their comments, DEQ failed to provide any support for its assumption that the *combination* of magnesium chloride sprays and water sprays would improve the control efficiency at all, let alone to 93.3%. *See* PET 555, 557. For example, the application of water may dissolve the bond between the chemical suppressant and road particles, thus decreasing the control efficiency—not increasing it.

Furthermore, even if one assumes that the high 93.3 % dust control efficiency could technically be achieved, the Permit fails to include enforceable limits on the spray frequency and rates, and other important factors, affecting whether Perpetua will in fact achieve anywhere near 93.3% dust control. EPA guidance identifies the following factors bearing on the effectiveness of

chemical dust suppressants: (a) the dilution rate used in the mixture; (b) the application rate (volume of solution per unit road surface area); (c) the time between applications; (d) the size, speed, and amount of traffic during the period between applications; and (e) meteorological conditions (rainfall, freeze/thaw cycles, etc.) during the period. PET 797-816.

To be sure, the Permit includes conditions related to dust control. Permit Conditions 2.1 through 2.5 require Perpetua to take "reasonable precautions" to monitor and maintain records related to dust emissions; but they do not specify the quantity or frequency of spray or other important variables. *See* PET 008-09. Permit Condition 2.6 requires Perpetua to develop the Fugitive Dust Control Plan ("FDCP"), which will become an enforceable part of the Permit, with a "list of all potential sources of fugitive dust emissions and the following reasonable precautions to minimize fugitive dust emissions." PET 009. But Permit Condition 2.6 does not set out those "reasonable precautions" such as requirements for the frequency or quantity of sprays and other important variables. Instead, Condition 2.6 directs Perpetua to "[d]evelop specific criteria to determine what frequency and type (water and/or chemical) of dust suppressant must be applied, and appropriate suppressant application rates." PET 010.

This vague direction for Perpetua to develop "criteria to determine" spray frequency, rates, and types in no way assures that Perpetua will both develop and follow criteria to actually achieve its ambitious 93.3% control efficiency—or anywhere close to it. This is especially so since the FDCP will be developed by Perpetua and submitted to DEQ for approval 30 days prior to startup, without public comment. *Id.*

Notably, DEQ itself recognized that it will be "challenging to consistently and continuously achieve the targeted level of fugitive dust control for emissions from traffic on unpaved roadways, with over 55 miles of haul truck routes within the operations boundary a fleet

of 32 haul trucks weighting between 37 and 357 tons, and a targeted dust control efficiency of 93.3% accomplished by application of both dust suppressant and water controls." PET 064. Later in the SOB, DEQ admitted that meeting 93.3% was based on an "assumption" that Perpetua would appropriately apply water and magnesium chloride, that "vigilant inspection and monitoring" would be required, and that additional measures beyond those actually required by the Permit would be necessary in the FDCP:

> Reduction of PM emissions from haul roads by a combined 93.3% was supported by assuming appropriate application of water and magnesium chloride dust suppression; DEQ is cognizant that to consistently achieve this level of control requires conscientious efforts, vigilant inspection and monitoring, and a comprehensive FDCP. Because continuous operation was proposed, suppression measures will need to account for and accommodate all weather conditions including diurnal and seasonal variability, and all traffic loads including mining and public traffic along publicly accessible roads. Conditions outside of what may normally be anticipated may require additional measures such as a reduction in vehicle speeds or selection of a more effective chemical dust suppressant. Although the FDCP specifies a minimum of efforts required, additional operational limits and monitoring are to be considered moving forward and evaluated for incorporation into the FDCP.

PET 090.

DEQ's modeling staff similarly recognized that "it is critical for NAAQS compliance that this high level of control [(93.3%)] be achieved." PET 275. The modeling staff called this "an aggressive level of control," adding that this "high level of emission control was needed to demonstrate compliance with NAAQS." PET 325. In fact, DEQ modeled what would happen if Perpetua cut its operations by a third (hauling 120,000 tons per day instead of the authorized 180,000 tons per day) and achieved only 90% dust control; DEQ found that this slightly lower dust control, even when combined with a major cut in mining activity, would cause exceedances of the PM_{10} 24-hour NAAQS. PET 325-26. Ultimately, DEQ's modeling team "recommend[ed]

that *the permit require an aggressive implementation of measures to achieve above 93% control* efficiency for fugitive particulate emissions from roadways." PET 328 (emphasis added).

But DEQ failed to require such "aggressive implementation" and "vigilant inspection and monitoring" in the Permit, instead relying on the vague direction for Perpetua to consider some of these issues later in its FDCP. Like with the AMP, DEQ once again failed to develop important conditions as part of the Permit and is instead leaving important issues to be addressed by Perpetua later in the FDCP, outside the required permit process, behind closed doors, and without full review by the public. Without determining first what dust suppressant types, frequencies, and rates can actually achieve such a high 93.3% control level, and without including those types, frequencies, and rates as enforceable Permit requirements, the Project's potential to emit fugitive dust is higher than what DEQ assumed. Contrary to DEQ's determinations, Perpetua's operations would cause a violation of the PM_{10} NAAQS and arsenic AACC, even while fully complying with the Permit.

B. DEQ Failed to Include Conditions Restricting Ore Haul Truck Weights, Sizes, and Miles Traveled in the Permit.

The amount of fugitive dust Perpetua will emit is also dependent on the weights and sizes of the ore haul trucks it uses, and on the miles those trucks travel. As DEQ admitted in the SOB, "accurate determination of site-specific parameters characterizing road conditions and vehicle traffic was *critical* to estimating particulate matter emissions and ambient air impacts." PET 062 (emphasis added). Important traffic-related modeling parameters for the Project include: the average empty weight of ore haul trucks; the average loaded weight of ore haul trucks; the number of larger versus smaller ore haul trucks (CAT 789D versus CAT 740B); and the total miles traveled by ore haul trucks. PET 798. *See also* PET 061.

Despite recognizing they were "critical" to PM emissions and air impacts, the Permit failed to include any enforceable Permit conditions for these parameters. As Perpetua admits: "the average loaded weight of ore haul trucks, the size of trucks used, . . . and the total number of vehicle miles traveled by ore haul trucks were not included as specific conditions in the PTC." *Perpetua's Resp. to First Amended Petition*, ¶ 36. Because these are not specified Permit requirements, Perpetua could use different sizes and weights of trucks, and drive them a different number of miles, than what was used in the modeling for the Permit, reviewed by the public, and reviewed and approved by DEQ—all without violating any enforceable condition of the Permit.

Without enforceable conditions for these important vehicle parameters, DEQ could not reasonably claim when it issued the Permit that the facility will not cause or significantly contribute to a violation of the PM_{10} NAAQS and that it will comply with the arsenic AACC under Air Rules Section 203.

In its comments, EPA urged DEQ to include as enforceable permit conditions those "parameters and assumptions used to develop the fugitive dust emission factors estimates for the haul roads and access roads" including "mean vehicle weight (tons), speed limit (mph), and daily vehicle miles traveled." PET 556. Once again, DEQ relied on the yet-to-be developed FDCP. *See* PET 061. However, while Permit Condition 2.6 states that measures specified in the FDCP will be incorporated by reference and will be enforceable, PET 009, there is no requirement that the FDCP actually address these and other important traffic-related parameters.

While Permit Condition 2.6 identifies minimum items the FDCP should include, *see* PET 009-10, nowhere does it require Perpetua to specify the average empty weight of ore haul trucks, the average loaded weight of ore haul trucks, the total number of larger versus smaller ore haul trucks (CAT 789D versus CAT 740B), or the total number vehicle miles traveled by ore

haul trucks. There is simply no requirement for Perpetua to include these variables in its future plan. Thus, there is no assurance that any, let alone all, of these important variables will be addressed in the FDCP and will become enforceable permit conditions. And even if Perpetua voluntarily chooses to address these variables in those future plans, there is no requirement that Perpetua will set these variables at levels that cause the same (or less) dust emissions than was assumed in the modeling.

As a result, Perpetua's operations could cause a violation of the PM_{10} NAAQS and could exceed acceptable arsenic levels even while complying with the Permit and with future plans adopted under it. DEQ, thus, lacked any reasonable basis for concluding the Project will comply with PM_{10} NAAQS and arsenic AACC Air Rules Section 203.

C. DEQ Failed to Use Representative Precipitation Data.

Another important input to the model estimating the Project's fugitive dust emissions is the number of days per year of recordable precipitation, defined as recording precipitation of 0.01 inch or greater, as precipitation can reduce fugitive dust emissions. *See* PET 061, 062; PET 809. Rather than use available site-specific meteorological data to calculate fugitive dust emissions from haul roads, DEQ used a generic value in EPA guidance to assume that there are 120 days of recordable precipitation at the Project site. *See* PET 146; *see also* PET 805 (map). This was arbitrary and counter to DEQ guidance.

For modeling ambient air impacts, Section 6.8 of DEQ's Guideline for Performing Air Quality Impact Analyses states: "The meteorological data used in the modeling analysis should be representative of the meteorological conditions at the particular site of the proposed construction or modification." PET 745. DEQ had and used local data for its ambient air impacts

modeling. PET 301 (discussing use of "historic 30-year (1985-2014) precipitation data from the Taylor Ranch station in Idaho (closest station from which this type of data is available)").

But when it came to calculating fugitive dust emissions from Project haul roads, DEQ failed to use this same local data and instead relied on the more generic 120 days per year number. The failure to use the local, representative data undermines DEQ's estimates of Project road emissions, and DEQ's determinations that the project will not cause or contribute to a violation of the PM_{10} NAAQS and arsenic AACC.

D. DEQ Failed to Include in the Permit Monitoring and Recordkeeping Requirements Critical to Ensuring Haul Limits Are Met.

Perhaps the most critical factor affecting the Project's dust emissions is the amount of ore and waste rock (development rock) hauled during operations. The more ore and waste rock hauled, the more fugitive dust emissions. DEQ did include Permit limits on ore haul. Permit Condition 3.5 limits Perpetua to haul no more than 180,000 tons per day, and no more than an average of 135,000 tons per day on a rolling five-year basis. PET 019. But the Permit lacks any developed and enforceable monitoring requirements to ensure these critical haul limits are met.

As EPA warned in its comments, the "monitoring methods associated with the haul roads appear to be unenforceable as they do not specify how the monitoring and recordkeeping demonstrating compliance with the applicable . . . limitations will be achieved." PET 561. EPA added that the "permit must include all monitoring, recordkeeping and reporting necessary to assure compliance with the permit emission limitations and applicable requirements." *Id.*

But instead of including all such monitoring, recordkeeping, and reporting as specific Permit conditions, DEQ again relied on a future plan to be prepared by Perpetua outside the normal PTC permitting process, like it did with the AMP and the FDCP. Permit Condition 3.16 requires: "Each day, the permit shall monitor and record the amount of ore and DR transported

on haul trucks (T/day)." PET 020. However, the Permit fails to establish how such monitoring will be accomplished. Instead, the Permit directs: "The devices and methodologies used to measure weights shall be identified in the O&M Manual." *Id.* The O&M (operation and maintenance) Manual is required to: "Describe each monitoring device and methodology used to measure weight rates of materials to demonstrate compliance with each material throughput limit," including 180,000 T/day haul limit. PET 013. But the O&M Manual (like the AMP and FDCP) is a "permittee-developed document" which Perpetua need not submit to DEQ until 30 days prior to startup. PET 013-14.

As DEQ admitted in the SOB, "[c]ompliance is assured by complying with the [O&M Manual] monitoring and recordkeeping requirements." PET 563. But because the O&M Manual was not developed, released to the public for comment, or reviewed and revised by DEQ when it issued the Permit, DEQ had no reasonable basis for assuming O&M Manual will be adequate to ensure sufficient monitoring and recordkeeping requirements will be developed and, therefore, that compliance will be met. And because actually complying with the haul limits is critical to limiting fugitive dust emissions, DEQ's determinations under Air Rules Section 203 that the Project will not cause or contribute to any NAAQS violations and will meet the TAPs AACCs were unreasonable.

In summary, without developing and including important variables and factors as enforceable conditions before issuing the Permit, and without using representative precipitation data, as set forth in the sections above, there was no reasonable basis for DEQ to assume the Project will comply with the 24-hour PM_{10} NAAQS and arsenic AACC. For these reasons, the Hearing Officer should set aside and remand the Permit and order that these conditions be developed as part of the normal PTC process, and not through an after-the-fact, secret process, to

ensure the Project will comply with the PM_{10} NAAQS and arsenic AACC. Without doing so, DEQ has no reasonable basis for concluding the Project will not cause or contribute to violation of these air standards.

III. DEQ'S RELIANCE ON FUTURE PLANS TO BE PREPARED BY PERPETUA OUTSIDE OF THE PTC PROCESS VIOLATES THE AIR RULES AND CAA.

As discussed in sections above, DEQ deferred addressing many issues during the PTC permitting process and will let Perpetua address those issues in the future through various plans. These "Plans" include the AMP (Supra I), FDCP (Supra II.A & B), and O&M Manual (Supra II.D). *See also* PET 565-70. The Plans also include the Haul Road and Capping Plan ("HRCP"). *Id.* Under Permit Condition 3.13, the HRCP is to include a sampling plan for analyzing the arsenic concentration of materials Perpetua uses, a silt content sampling plan, and details about maintenance procedures and the frequency Perpetua will inspect haul roads. PET 019-20. Like the AMP, FDCP, and O&M Manual, the HRCP was not developed as part of the PTC permitting process. *See id.* All of the Plans are to be developed by Perpetua later and submitted to DEQ for 30 days prior to starting operations, without public comment. PET 010, 014, 020 (Permit Conditions 2.8, 2.21, 3.13).

DEQ's reliance on these future Plans violates the CAA and the Air Rules, and is otherwise arbitrary and capricious. No provisions in the Air Rules authorize DEQ to save portions of a PTC to be developed later, outside the normal PTC permitting process. Rather, the Air Rules require DEQ to process PTC applications only when they are complete, require DEQ to ensure the applicant has submitted sufficient information so DEQ can make all required determinations for PTCs, and requires DEQ to take public comment. *See* Air Rules Section 209.

During permitting, but not after, the applicant must provide: "Site information, plans, descriptions, specifications, and drawings showing the design of the stationary source, facility, or

modification, the nature and amount of emissions (including secondary emissions), and the manner in which it will be operated and controlled." Air Rules Section 202.01.a.i. Additionally, DEQ is authorized to obtain from the applicant during the permitting process "[a]ny additional information, plans, specifications, evidence or documents the Department may require to make the determinations required [to issue a PTC]." Air Rules Section 202.03. And in response to a PTC application, the Air Rules require DEQ ultimately to issue either an "approval," a "conditional approval," or a "denial." Air Rules Sections 209.01.b.i & ii, c.iv.

Similarly, to ensure compliance with the NAAQS and other air pollution control strategies, the CAA and EPA's CAA regulations require State air rules like DEQ's to include: "enforceable emission limitations" and other measures, 42 U.S.C. § 7410(a)(2)(A); a "program to provide for the enforcement" of such measures, and to regulate the construction of any stationary source, *id.* § 7410(a)(2)(C); "legally enforceable procedures" for determining whether the construction of a facility will comply with control strategies and NAAQS, 40 C.F.R. § 51.160(a); sufficient information needed "to make the determination" whether the facility will comply with air pollution control strategies and the NAAQS, i*d.* § 51.160(c); and an opportunity for public comment on information submitted by the applicant and on the agency's analysis of the effects to air quality. *Id.* § 51.161(a).

Here, instead of following these requirements, DEQ rushed forward and issued Perpetua what is essentially a *partial, incomplete PTC*, based on incomplete information and analysis, and lacking numerous permit conditions. DEQ will effectively issue a complete PTC later, after Perpetua develops and submits to DEQ additional plans, information, and conditions through the AMP, HRCP, FDCP, and O&M Manual, shielded from public review and outside the normal PTC process required by the Air Rules and the CAA.

Not only does DEQ's reliance on these Plans fail to comport with the Air Rules and the CAA provisions discussed above, but it also undermines DEQ's determinations that the Project will comply with air quality standards. Because DEQ has deprived the public of meaningful involvement, and has failed to conduct a full and adequate review of the application before it issued the Permit, DEQ cannot reasonably claim that the Project will comply with the PM_{10} NAAQS and arsenic AACC.

Federal courts have rejected similar tactics when it comes to Clean Water Act ("CWA") permitting. In one case, the Second Circuit recognized that CWA permitting schemes that do not allow for public review of best management practices incorporated into permits violate the CWA. *Waterkeeper Alliance v. U.S. EPA*, 399 F.3d 486, 503-504 (2d Cir. 2005). The Second Circuit held that a permit that relies on best management practices but does not specifically list those best management practies in the permit itself "deprives the public of the opportunity for the sort of regulatory participation that the Act guarantees because [such a permit] effectively shields the . . . management plans from public scrutiny and comment." *Id*. at 503. The Ninth Circuit has similarly held that "programs that are designed by regulated parties must, in every instance, be subject to meaningful review by an appropriate regulating entity to ensure that each such program reduces the discharge of pollutants to the maximum extent practicable [i.e., the relevant statutory standard]." *Envtl Def. Ctr. v. U.S. EPA*, 344 F.3d 832, 856 (9th Cir. 2003).

By allowing Perpetua to provide plans, descriptions, specifications, and information about the manner in which the facility will be operated and controlled at a later date after the Permit has already been approved, DEQ has similarly circumvented the Air Rules and CAA permitting requirements, deprived the public of meaningful comment, and undermined DEQ's determinations that the Project will comply with applicable standards. The Hearing Officer

should grant summary judgment to Petitioners, set aside the Permit and order DEQ to: require Perpetua to submit the AMP, FDCP, O&M Manual, and HRCP; to provide for public comment on the Plans; to review and revise Plans to ensure the Project's emissions, as limited by enforceable conditions, comply with Air Rules Section 203; and to complete these steps before issuing a new Permit—not after.

IV. DEQ MUST REQUIRE AMBIENT AIR MONITORING.

DEQ has the authority to require ambient air monitoring to determine the effect emissions from the stationary source or facility may have on the air quality of the area potentially impacted by the source. Air Rules Section 211.01(d). During public comment, EPA and Petitioners urged DEQ to require ambient air monitoring to verify the Project's compliance with the NAAQS and TAP AACCs. PET 560-64.

As EPA commented: "Given the high level of uncertainty in the assumptions and requirements to ensure compliance with the PM_{10} 24-hr NAAQS, the addition of post-construction ambient monitoring requirements is highly prudent." PET 561. EPA recommended that DEQ "add a permit requirement for the source to deploy a fenceline PM10 monitoring network . . . to demonstrate 24-hour and annual PM10 NAAQS compliance." *Id*. Similarly, ICL and SSFS urged ambient air boundary monitoring because of the "uncertainty surrounding dust control efficiency and emissions factors." PET 565. But DEQ declined.

Without ambient air monitoring, it will be impossible for DEQ to assess whether Perpetua is indeed complying with the NAAQS and TAPs AACCs. For example, DEQ admitted that Perpetua aims to achieve a "high" and "aggressive" level of dust control, which DEQ modelers recommended requires aggressive implementation in the Permit. PET 275, 325, 328. Furthermore, as already discussed, DEQ failed to establish numerous Permit conditions related to

potential emissions and related to monitoring and reporting, instead relying on future Perpetua Plans (the FDCP, O&M Manual, and HRCP). This approach leaves it highly uncertain how the Project will operate and what the emissions will in fact be. If DEQ is going to employ these approaches, then it is imperative to require Perpetua to conduct ambient air monitoring.

The Hearing Officer should grant Petitioners summary judgment, set aside the Permit, and order DEQ to require on remand that the Permit include ambient air boundary monitoring, as provided for by Air Rules Section 211.01(d), to ensure compliance with the NAAQS and AACCs. Prior to issuing any Permit, DEQ must require Perpetua to submit an ambient air boundary monitoring plan ("AABMP"), must take public comment on the AABMP and then review and revise the AABMP, and must incorporate the terms of the AABMP as enforceable Permit conditions.

V. DEQ FAILED TO ANALYZE ECONOMIC INFORMATION AND ENVIRONMENTAL IMPACTS IN THE ARSENIC T-RACT.

As described in the background, Perpetua submitted a T-RACT demonstration, which DEQ granted, thereby endorsing Perpetua's plan to use chemical dust suppressants combined with frequent watering to reduce dust emissions from Project roads, and allowing a 10-fold increase in the AACCs—acceptable concentrations of arsenic and other TAPs in the ambient air during operations. *See* PET 544-548 ("T-RACT Analysis"). DEQ's approval of Perpetua's T-RACT is arbitrary and capricious and violates the Air Rules because DEQ failed to consider the economic costs, operational feasibility, and environmental impacts of Perpetua's plan.

The Air Rules dictate that, as part of the T-RACT determination process, an applicant must supply, and DEQ must consider, information relevant to the "control technologies or other requirements the applicant believes to be T-RACT." Air Rules Sections 210.14.a-b. Factors that DEQ must consider include, but are not limited to: control effectiveness, economic costs,

operational feasibility, and associated environmental impacts. Air Rules Sections 210.14.a–d. As the Third Circuit has explained, "RACT is not designed to rubber-stamp existing control methods" and the controlling agency's review "must satisfy both technological and economic feasibility." *Sierra Club v. U.S. EPA*, 972 F.3d 290, 295 (3d Cir. 2020). As the court explained in *Sierra Club*:

> The EPA explains, "[t]he technological feasibility of applying an emission reduction method to a particular source should consider the source's process and operating procedures, raw materials, physical plant layout, and any other environmental impacts such as water pollution, waste disposal, and energy requirements." Whereas the economic feasibility "considers the cost of reducing emissions and the difference in costs between the particular source and other similar sources that have implemented emission reduction."

Id. Despite these requirements, DEQ approved Perpetua's T-RACT demonstration even though it failed to include any information at all about the environmental impacts of the control technologies, and failed to include information about the economic costs and operational feasibility of employing them.

As for environmental impacts, Petitioners warned that applying large amounts of magnesium chloride to roads to control dust can accumulate over time to toxic concentrations in trees and soils, impact water, and compromise aquatic environments. PET 596, 612. Additionally, the water that will be used to supplement dust control measures will be from sources that already have elevated arsenic levels, so "frequent watering" may cause additional environmental harm. PET 612. But the T-RACT Analysis failed to include any information about these or any other environmental impacts of Perpetua's proposed dust control technologies. *See* PET 543-548. By wholly failing to address this, it is unknown whether to what degree Perpetua's aggressive magnesium chloride application will harm the environment. DEQ,

thus, failed to comply with the requirement to consider this information under Air Rules Sections 210.14.c.ii.

The economic and operational feasibility analysis fairs no better. The T-RACT Analysis states that paving roads would achieve better dust control but is "costly" and will not be used for the Project. PET 545-47. This is the *only* economic information—if that even counts as such—in the T-RACT analysis. *See* PET 544-548. Again, DEQ must address the "economic feasibility of a control technology or other requirement, including the costs of necessary mitigation measures, for a particular source." Air Rules Section 210.14.d. But the T-RACT Analysis includes no information about the economic feasibility of Perpetua's proposed control technology. *See* PET 544-48. It is thus unknown how much it will cost Perpetua to employ the type of "aggressive" magnesium chloride application and the "vigilant" practices and monitoring necessary, whether sufficient supplies are even available, and if this plan is otherwise feasible.

The Hearing Officer should grant Petitioners summary judgment, set aside the Permit, and remand for a complete T-RACT analysis under the Air Rules.

VI. DEQ IMPROPERLY DILUTED PROJECT ARSENIC EXPOSURE, MASKING THE TRUE HEALTH RISKS IN VIOLATION OF THE AIR RULES.

Even with the T-RACT adjusted arsenic AACC—which allows Perpetua 10 times the normal limit—DEQ recognized that the Project would still exceed the arsenic AACC. To avoid this problem, DEQ contrived a new tactic to artificially reduce the apparent arsenic exposure by spreading out the actual arsenic exposure resulting from the 16-year Project over a longer 70-year human lifetime. *See* PET 332, 344 (SOB, App'x B). This new trick artificially reduces the apparent concentration of arsenic to a mere 23% (16/70 x 100) of what the arsenic concentration will actually be each year during the Project.

Nothing in the Air Rules allows for diluting arsenic (or any TAPs) concentrations like this. Under Air Rule Section 203:

> No permit to construct shall be granted for a new or modified stationary source unless the applicant shows to the satisfaction of the Department all of the following:
>
> . . .
>
> 03. Toxic Air Pollutants. *Using the methods provided in Section 210*, the emissions of toxic air pollutants from the stationary source or modification would not injure or unreasonably affect human or animal life or vegetation as required by Section 161. *Compliance with all applicable toxic air pollutant carcinogenic increments* and toxic air pollutant non-carcinogenic increments will also demonstrate preconstruction compliance with Section 161 with regards to the pollutants listed in Sections 585 and 586.

(emphases added).

The applicable TAPs "carcinogenic increments" that must be met to satisfy Section 203.03 are the AACCs, which are *annual average* ambient concentrations. *See* Air Rules Section 586. The "methods provided in Section 210" that must be followed to satisfy Section 203.03 spell out in detail how to estimate TAPs emissions and ambient concentrations. *See* Air Rules Section 210. Section 210 even allows applicants to seek a 10 times larger AACC through T-RACT—a huge leniency, which DEQ allowed Perpetua. *Id.* But nothing in Section 210 allows DEQ to grant *even greater leniency* when it comes to meetings the AACCs, such as by diluting a project's 16-year TAPs concentrations over 70 years. *See* Air Rules Section 210.[3]

DEQ permitting staff recognized this problem, and documented their concerns in two memos. *See* PET 817-24; PET 825-30. DEQ staff acknowledged that this approach had not been used before, stating that requiring the methods in Section 210 is "certainly how DEQ has used

[3] This point is reinforced by the fact that the Air Rules explicitly grant leniency for short-term sources operating for five years or less, but not for other temporary facilities. *See* Air Rules, 210.15

this in the past." PET 819.[4] DEQ staff questioned whether this novel approach was allowed under the Air Rules. *See*, *e.g.*, PET 822 ("Can a 70 year average concentration be used for comparison to AACCs rather than a single year average for Section 210 analyses?"). DEQ staff also cautioned that "DEQ would need legal opinion as to whether this meets requirements of Section 210." PET 817.

The record does not reveal whether DEQ ever sought or obtained a legal opinion on this issue. But in the end, DEQ broke from its established practice of comparing annual average arsenic exposures from a facility to the annual average AACC. Instead, DEQ spread the arsenic exposures from the 16-year Project over 70 years, reducing the supposed arsenic exposure to a mere 23% of what it will really be during Perpetua's operations.

Had DEQ compared the annual arsenic concentration during the Project to the annual T-RACT adjusted AACC (as required by the Air Rules and as DEQ has done in the past), then the arsenic emissions would vastly *exceed* the T-RACT adjusted AACC. Applying the novel "lifetime exposure adjustment" to dilute the Project's annual arsenic concentration by 16/70, DEQ calculated a Maximum Modeled Lifetime Exposure Concentration of 0.00095 ug/m^3 of arsenic. PET 348 (Table 6). *See also* PET 344. This value is less than (about 41% of) the T-RACT adjusted arsenic AACC of 0.0023 ug/m^3 (*see* Air Rules Section 586). DEQ's dilution can be removed by multiplying 0.00095 ug/m^3 by 70 and then dividing by 16, which results in an *annual* arsenic exposure during the Project of 0.0042 ug/m^3. This value, which represents the arsenic exposure that will actually occur during the 16 years of the Project, is 181% of the T-RACT adjusted arsenic AACC.

[4] Further confirming that this is a novel approach, DEQ found no responsive documents to Petitioners' RFP No. 8, which requested: "Provide all air permits issued by IDEQ, other than the PTC, that applied a 70-year 'lifetime' average for any carcinogenic TAP in comparison to the associated AACC, including statements of basis." PET 835.

DEQ's creative paper exercise thus not only violates the Air Rules, but it creates a real risk to public health, allowing arsenic exposures of 181% of T-RACT adjusted AACC. EPA explained this well in comments submitted in January 2023 to the Forest Service for its ongoing review of the Project:

> [T]his screening threshold is not necessarily intended to be compared against a 70-year lifetime scenario where 57 years of the period assumes zero exposure. . . . Under IDEQ's hazardous air pollutant program, in practice, project impacts from the maximum year of emissions would typically be compared to the annual average AACC for arsenic.
>
> If the impacts were determined using annual average emissions during the period of the project only, the resulting arsenic concentrations would exceed the AACC.

PET 677. And EPA added: "There is significant uncertainty in the emission rates of fugitive dust associated with the project such that arsenic emissions could be underpredicted." PET 677-78.

DEQ's disregard of the Air Rules and break from past practice to mask the true arsenic exposure risks from the Project cannot be condoned. The Hearing Officer should grant summary judgment for Petitioners, set aside the Permit, and order DEQ to evaluate TAPs without spreading exposures during the 16-year Project over any longer time frame.

VII. THE PERMIT MUST BE SET ASIDE AND REMANDED TO DEQ TO CORRECT ALL ERRORS.

Under the Idaho APA, when an agency action is not affirmed, it "shall" be set aside, in whole or in part, and remanded for further proceedings as necessary. I.C. § 67-5279. *See also In re Variance ZV2011-2*, 156 Idaho 491, 496 (Idaho 2014) (vacating and remanding arbitrary agency action for further proceedings consistent with the Court's opinion). Upon granting summary judgment for Petitioners on any of their claims above, the Hearing Officer must set aside the Permit and remand to DEQ for further proceedings to correct the errors DEQ made when it issued the Permit.

CONCLUSION

For the foregoing reasons, Petitioners respectfully request that the Hearing Officer grant Petitioners' Motion for Summary Judgment and set aside and remand the Permit.

BEFORE THE OFFICE OF ADMINISTRATIVE HEARINGS
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047	
	Agency Case No. 0101-22-01
NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON	OAH Case No. 23-245-01
	DECLARATION OF BRYAN HURLBUTT
Petitioners,	
v.	
IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY,	
Respondent,	
and	
PERPETUA RESOURCES IDAHO, INC.	
Intervenor.	

I, BRYAN HURLBUTT, hereby declare as follows:

1. The following facts are personally known to me, and if called as a witness, I could and would competently testify thereto. I am over eighteen years of age.

2. I am counsel of record representing Petitioners Nez Perce Tribe and Idaho Conservation League in this matter.

3. The attached Exhibits 1 – 14 are true and correct copies of the following documents, which were produced during discovery in this matter:

Doc. No.	Bates No.	Document Description
1	PET 001–043	Final Permit to Construct (June 17, 2022)
2	PET 044–548	DEQ Statement of Basis (June 17, 2022)
3	PET 549–634	DEQ Response to Comment (June 17, 2022)
4	PET 635–652	Petitioners ICL/SSFS Comment Letter (Mar. 16, 2022)
5	PET 653–662	Petitioners Nez Perce Comment Letter (Mar. 14, 2022)
6	PET 663–672	EPA Comment Letter on PTC (Mar. 16, 2022)
7	PET 673–700	EPA Comment Letter on SDEIS (Jan. 10, 2023)
8	PET 701–771	DEQ Guideline for Performing Air Quality Impact Analysis (July 2021)
9	PET 772–785	EPA Revised Policy on Ambient Air (2019)
10	PET 786–796	EPA Guidance on Enforceability Requirements (1995)
11	PET 797–816	EPA Guidance on Unpaved Roads and Particulate Matter (2006)
12	PET 817–824	Arsenic Modeling Addendum Review
13	PET 825–830	Schilling, DEQ Position on the Arsenic Modeling Addendum
14	PET 831–837	DEQ Response to Petitioners' First Discovery Requests and Requests for Production of Documents

I declare under penalty of perjury that the foregoing is true and correct to the best of my knowledge, information, and belief, and based on my personal experiences.

Signed this 14th day of April, 2023 in Boise, Idaho.

Air Quality

PERMIT TO CONSTRUCT

Permittee	Perpetua Resources Idaho, Inc.
Permit Number	P-2019.0047
Project ID	62288
Facility ID	085-00011
Facility Location	Forest Service Roads NF-374 and NF-412 Stibnite, Idaho 83611

Permit Authority

This permit (a) is issued according to the "Rules for the Control of Air Pollution in Idaho" (Rules), IDAPA 58.01.01.200–228; (b) pertains only to emissions of air contaminants regulated by the State of Idaho and to the sources specifically allowed to be constructed or modified by this permit; (c) has been granted on the basis of design information presented with the application; (d) does not affect the title of the premises upon which the equipment is to be located; (e) does not release the permittee from any liability for any loss due to damage to person or property caused by, resulting from, or arising out of the design, installation, maintenance, or operation of the proposed equipment; (f) does not release the permittee from compliance with other applicable federal, state, tribal, or local laws, regulations, or ordinances; and (g) in no manner implies or suggests that the Idaho Department of Environmental Quality (DEQ) or its officers, agents, or employees assume any liability, directly or indirectly, for any loss due to damage to person or property caused by, resulting from, or arising out of design, installation, maintenance, or operation of the proposed equipment. Changes in design, equipment, or operations may be considered a modification subject to DEQ review in accordance with IDAPA 58.01.01.200–228.

Date Issued June 17, 2022

1 Permit Scope

Purpose

1.1 This is an initial permit to construct (PTC) for ore processing, ore concentration and refining, and ancillary equipment at the Stibnite Gold Project (SGP).

Regulated Sources

1.2 Table 1.1 lists all sources of regulated emissions in this permit.

Source ID No.	Source	Control Equipment
Mining		
	Drilling activities	Reasonable control and Fugitive Dust Control Plan (FDCP) Dust collection systems on drilling rigs Control efficiency: 90%
	Blasting activities	Reasonable control & FDCP
	Excavating and hauling activities	Reasonable control & FDCP – Chemical suppression and water sprays Control efficiency: 93.3% for PM/PM_{10} (haul roads) Haul road capping with low-arsenic (90 ppm or less) quartzite
	Rock dumps and storage piles	Reasonable control & FDCP
PS1–2-L/U	(2) Prill Silos #1-2 Maximum capacity: 100 T (each)	Loading – None Unloading – None
Ore Processing		
OC1	Loader Transfer of Ore to Grizzly	Reasonable control & FDCP – Water sprays and moisture carryover
OC2	Grizzly to Apron Feeder	
OC3	Conveyor – Apron Feeder to Dribble	
OC4	Conveyor – Apron Feeder to Grizzly	
OC5	Conveyor – Dribble to Grizzly	
OC6	Grizzly to Primary Crusher or Coarse Ore Stockpile Feed	
OC7	Primary Crusher	Reasonable control & FDCP – Water sprays and moisture carryover
OC8	Conveyor – Coarse Ore Stockpile Feed Transfer to Stockpile	
OC9	Stockpile Transfer to Reclaim Conveyors	Reasonable control & FDCP – Below-grade of storage piles Control efficiency: 80% for PM/PM_{10}
OC10	Conveyor – Reclaim Conveyors to SAG Mill Feed Conveyor	
OC11	Conveyor – SAG Mill Feed Transfer to SAG Mill	Reasonable control & FDCP – Enclosure Control efficiency: 80% for PM/PM_{10}
OC12	Pebble Crusher	Reasonable control & FDCP – Water sprays and moisture carryover
OC13	Pebble Discharge to SAG Mill Feed	
Ore Concentration and Refining		
CN Tanks	Cyanide Leach Tanks and Cyanide Detox Tanks	Chemical treatment (lime, caustic soda, hydrogen peroxide, copper sulfate, etc.)
Float Tanks	Floatation Tanks	None

Source ID No.	Source	Control Equipment
AC	Autoclave (AC)	Venturi Scrubber (VS1) Vent Gas Cleaning Tower (ST1) Vent Gas Steam Condensation Tower (CT1) Carbon Filter (CA5) Type: sulfur-impregnated activated carbon Form: granulated
EW	Electrowinning Cells and Pregnant Solution Tank	Shared Carbon Filter (CA2) Type: sulfur-impregnated activated carbon Form: granulated
MR	Mercury Retort	Condenser Carbon Filter (CA3) Type: sulfur-impregnated activated carbon Form: granulated
MF	Induction Melting Furnace	Baghouse (BH2) Carbon Filter (CA4) Type: sulfur-impregnated activated carbon Form: granulated
CKD	Carbon Regeneration Kiln (Drum)	Wet Scrubber (WS2) Carbon Filter (CA1) Type: sulfur-impregnated activated carbon Form: granulated
Tailings and Maintenance Pond activities		Chemical treatment, reasonable control & FDCP
Process Heating		
ACB	POX Boiler (for AC) Maximum capacity: 17 MMBtu/hr Fuel: propane	None
HS	Strip Circuit Solution Heater Maximum capacity: 5 MMBtu/hr Fuel: propane	None
CKB	Carbon Regeneration Kiln Burners Maximum capacity: 2.255 MMBtu/hr Fuel: propane	None
PV	Propane Vaporizer Maximum capacity: 0.1 MMBtu/hr Fuel: propane	None
LKC	PFR Shaft Lime Kiln Combustion Maximum capacity: 22.0 MMBtu/hr Fuel: propane	None

Source ID No.	Source	Control Equipment
Lime Production		
LS1	Limestone transfer to Primary Crusher Hopper	Reasonable control & FDCP
LS2	Primary Crusher Maximum capacity: 1,130 T/day	
LS3	Primary Screen	
LS4	Secondary Crusher	
LS5	Secondary Screen	
LS6	Conveyor – Limestone to Ball Mill Feed Bin	
LS7	Conveyor – Limestone to Ball Mill Feed	
LS8	Conveyor – Ball Mill Feed to Ball Mill	
LSBM	Limestone Ball Mill	Reasonable control & FDCP Baghouse (BH3)
LS9	Conveyor – Limestone to Kiln Feed Bin	Reasonable control & FDCP
LS10	Conveyor – Limestone to Lime Kiln Feed	
LS11	Fines Screen	
LS12	Conveyor – Kiln Feed to PFR Shaft Lime Kiln	
LK	Parallel Flow Regenerative (PFR) Shaft Kiln	Reasonable control & FDCP Baghouse (BH4)
LCR	Lime Mill Crusher	Reasonable control & FDCP Baghouse (BH5)
LS-L/U	Bucket Elevator – Pebble Lime Silo Loading	Loading – Bin Vent Filter
	Pebble Lime Silo discharge to Lime Slaker	Unloading – Wet Scrubber (WS3)
LS1-L/U	SAG Mill Lime Silo #1 Maximum capacity: 250 T/day	Loading – Bin Vent Filter Unloading – None
MillS2-L/U	SAG Mill Lime Silo #2 Maximum capacity: 250 T/day	Loading – Bin Vent Filter Unloading – None
ACS1	AC Lime Silo #1 Maximum capacity: 1,000 T/day	Loading – Bin Vent Filter Unloading – None
ACS2	AC Lime Silo #2 Maximum capacity: 1,000 T/day	Loading – Bin Vent Filter Unloading – None
ACS3	AC Lime Silo #3 Maximum capacity: 1,000 T/day	Loading – Bin Vent Filter Unloading – None
ACS4	AC Lime Silo #4 Maximum capacity: 500 T/day	Loading – Bin Vent Filter Unloading – None
Aggregate Production		
PCSP1	Portable Crushing and Screening Plant 1 Crushers, screens, and conveyors	Reasonable control & FDCP – water sprays and moisture carryover
PCSP2	Portable Crushing and Screening Plant 2 Crushers, screens, and conveyors	Reasonable control & FDCP – water sprays and moisture carryover
Concrete Production		
CM	Central Mixer Loading Maximum capacity: 120 T/hr	Reasonable control & FDCP – Controls may include water sprays, enclosures, hoods, curtains, shrouds, movable and telescoping chutes, and central duct collection systems.
CS1-L/U	Cement/Shotcrete Silo #1 Maximum capacity: 80 T	Loading – Bin Vent Filter Unloading – None
CS2-L/U	Cement/Shotcrete Silo #2 Maximum capacity: 80 T	Loading – Bin Vent Filter Unloading – None
CA-L/U	Aggregate Bin Maximum capacity: 2,400 T	Loading – None Unloading – None

Source ID No.	Source	Control Equipment
Heating, Ventilation, and Air Conditioning (HVAC)		
H1M	Mine Air Heater #1 Maximum capacity: 4 MMBtu/hr Fuel: propane	None
H2M	Mine Air Heater #2 Maximum capacity: 4 MMBtu/hr Fuel: propane	None
HM	(4) Mill HVAC Heaters #1-4 Maximum capacity: 1.0 MMBtu/hr (each) Fuel: propane	None
HAC	Autoclave HVAC Heater Maximum capacity: 0.25 MMBtu/hr Fuel: propane	None
HR	Refinery HVAC Heater Maximum capacity: 0.25 MMBtu/hr Fuel: propane	None
HA	Admin HVAC Heater Maximum capacity: 0.25 MMBtu/hr Fuel: propane	None
HMO	(2) Mine Ops. HVAC Heaters Maximum capacity: 0.25 MMBtu/hr (each) Fuel: propane	None
HTS	(2) Truck Shop HVAC Heaters Maximum capacity: 1.0 MMBtu/hr (each) Fuel: propane	None
HW	(3) Warehouse HVAC Heaters Maximum capacity: 1.0 MMBtu/hr (each) Fuel: propane	None

Source ID No.	Source	Control Equipment
Emergency Power Generation and Fire Suppression		
EDG1	Camp Emergency Generator Date of construction: 2007 or later Maximum capacity: 1,000 bkW Maximum operation: 100 hr/yr (non-emergency) Fuel: ultra-low sulfur diesel (ULSD) Displacement: <10 L/cyl	EPA Tier 2 certified or better
EDG2	Plant Emergency Generator #1 Date of construction: 2007 or later Maximum capacity: 1,000 bkW Maximum operation: 100 hr/yr (non-emergency) Fuel: ULSD Displacement: <10 L/cyl	EPA Tier 2 certified or better
EDG3	Plant Emergency Generator #2 Date of construction: 2007 or later Maximum capacity: 1,000 bkW Maximum operation: 100 hr/yr (non-emergency) Fuel: ULSD Displacement: <10 L/cyl	EPA Tier 2 certified or better
EDFP	Mill Fire Pump Date of construction: 2009 or later Maximum capacity: 200 bkW Maximum operation: 100 hr/yr (non-emergency) Fuel: ULSD Displacement: <10 L/cyl	None
Fuel Storage		
TG1–TG2	Mine Site Gasoline Tanks (#1 through #2) Maximum capacity: 5,000 gal each	Lids or other appropriate closure with gasketed seal and submerged filling
TD3–TD10	Mine Site Diesel Tanks (#3 through #10)	Lids or other appropriate closure

2 Facility-Wide

Fugitive Dust

2.1 All reasonable precautions shall be taken to prevent particulate matter from becoming airborne in accordance with IDAPA 58.01.01.650-651. In determining what is reasonable, consideration will be given to factors such as the proximity of dust-emitting operations to human habitations and/or activities and atmospheric conditions which might affect the movement of PM. Some of the reasonable precautions include, but are not limited to, the following:

- Use, where practical, of water or chemicals for control of dust in the demolition of existing buildings or structures, construction operations, the grading of roads, or the clearing of land.
- Application, where practical, of asphalt, oil, water, or suitable chemicals to, or covering of dirt roads, material stockpiles, and other surfaces which can create dust.
- Installation and use, where practical, of hoods, fans, and fabric filters or equivalent systems to enclose and vent the handling of dusty materials. Adequate containment methods should be employed during sandblasting or other operations.
- Covering, when practical, open-bodied trucks transporting materials likely to give rise to airborne dusts.
- Paving of roadways and their maintenance in a clean condition, where practical.
- Prompt removal of earth or other stored material from streets, where practical.

2.2 At least once every 12 hours, the permittee shall monitor and maintain records of the frequency and the methods used (e.g., water, chemical dust suppressants) to reasonably control fugitive dust emissions.

2.3 The permittee shall maintain records of all fugitive dust complaints received. The permittee shall take appropriate corrective action as expeditiously as practicable after receipt of a valid complaint. The records shall include, at a minimum, the date that each complaint was received and a description of the following: the complaint, the permittee's assessment of the validity of the complaint, any corrective action taken, and the date the corrective action was taken.

2.4 Each day during daylight hours and under normal operating conditions, the permittee shall conduct a facility-wide inspection of potential sources of fugitive emissions from the following equipment: drilling activities, blasting activities, excavating and hauling activities, rock dumps and storage piles, ore processing, aggregate production, and central mixer loading. These sources are identified in the Fugitive Dust Control Plan to ensure that the methods used to reasonably control fugitive dust emissions are effective. If emissions are not being reasonably controlled the permittee shall take corrective action as expeditiously as practicable. The permittee shall maintain records of the results of each fugitive dust emissions inspection. The records shall include, at a minimum, the date of each inspection and a description of the following: the permittee's assessment of the conditions existing at the time fugitive emissions were present (if observed), any corrective action taken in response to the fugitive dust emissions, and the date the corrective action was taken.

2.5 Fugitive dust control measures shall be applied to haul roads on a frequency such that visible emissions from vehicle traffic on a haul road do not exceed 10% opacity. When emissions are observed at any time to exceed this control trigger level, an appropriate control measure such as those defined in the Fugitive Dust Control Plan (FDCP) shall be used to reasonably control the emissions of fugitive dust. If the control measure chosen does not adequately control fugitive dust emissions, the permittee shall employ additional control measures until fugitive dust control is achieved.

2.6 The permittee shall develop and maintain a FDCP to ensure compliance with fugitive dust requirements (Permit Conditions 2.1–2.5) and also fugitive dust best management practices at the lime production, aggregate production, and concrete plants in accordance with IDAPA 58.01.01.799. The permittee shall comply with the FDCP at all times. The requirements specified in the FDCP shall be incorporated by reference to this permit and shall be enforceable permit conditions. At a minimum, the FDCP shall contain a list of all potential sources of fugitive dust emissions and the following reasonable precautions to minimize fugitive dust emissions (Permit Condition 2.1):

- Post and limit the maximum speed of haul trucks in accordance with the FDCP. Signs shall be posted along the haul route and placed so they are visible to vehicles entering and leaving the site of operations.
- Apply water or suitable dust suppressant chemicals (e.g., magnesium chloride, calcium chloride) to disturbed areas, haul roads, equipment staging areas, parking areas, and storage piles during the dry season and at other times as necessary to control fugitive dust.
- Prior to onset of winter conditions each year, the condition of haul and access roads should be assessed before freeze-up and required maintenance needed to maintain the roads through the winter months should be performed, and any preventative dust suppression activities should be completed before the roads are frozen and liquid application of suppressants or water are unrealistic.
- Apply water or suitable dust suppressant chemicals to transfer points, screening operations, and crushing operations identified in the FDCP as necessary to control fugitive dust. Transfer points include points where material (e.g., ore and development rock (DR), lime, aggregate, cement, etc.) is transferred to or from a belt conveyor, conveying system, bucket elevator, screening operation, or stockpile. Controls shall include manual water spray capability or installing, operating, and maintaining water spray bars at transfer points to wet the material and to provide moisture carryover for downstream control. Controls shall also include limiting drop heights in truck loading, front-end loader dumping, and conveying operations to ensure a homogeneous flow of material.
- Apply water or suitable dust suppressant chemicals to storage piles as necessary to control fugitive dust. Water may need to be applied to storage piles before and during truck loading, and when stockpiled ore and waste rock is not processed promptly in order to avoid drying and becoming airborne. Stockpile height should be limited to limit disturbance.
- Apply appropriate dust control at the initial point of material handling to suppress dust throughout the material handling process.
- Apply crushed gravel to haul roads, equipment staging areas, and other areas as necessary to limit migration of fine sediment.
- Install wind fences or barriers around, place below grade, or enclose all storage piles, parking areas, and equipment staging areas as necessary to control fugitive dust. This is required for

the Stockpile Transfer to Reclaim Conveyors (OC9), Reclaim Conveyors to SAG Mill Feed Conveyor (OC10), and SAG Mill Feed Transfer to SAG Mill conveyor (OC11).

- Develop specific criteria to determine what frequency and type (water and/or chemical) of dust suppressant must be applied, and appropriate suppressant application rates. Chemical dust suppressants shall be applied consistent with manufacturer's instructions and recommendations.
- Develop and implement precautionary measures to address high-wind events, such as when average (sustained) wind speed is forecast to exceed 25 miles per hour.
- Provide training/orientation to all relevant employees regarding FDCP requirements, including the necessity of restricting public access as specified in the Access Management Plan (AMP). Visible emissions evaluations shall be conducted by the permittee's employees who are certified visible emission observers.
- At least once each year, evaluate FDCP requirements to identify additional requirements and evaluate effectiveness of practices, including dust suppressant application rates, as appropriate.

2.7 The permittee shall develop and maintain an AMP that identifies the facility boundary and all primary and secondary access points, and clearly specifies measures used to discourage public access to the facility. The permittee shall comply with the measures identified in the AMP at all times. The measures specified in the AMP shall be incorporated by reference to this permit and shall be enforceable permit conditions. At a minimum, the AMP shall include requirements to:

- Observe all primary access points to preclude unauthorized public access. Onsite personnel shall be available for this purpose during active mining and mineral processing operations. Public access to the facility may be monitored by the use of security escort vehicles or manned guardhouses, or sufficiently precluded by the use of locked gates, barriers, or equivalent measures. Primary access points include the North and South Security Gates.
- Post warning signs and periodically patrol secondary access points to the facility to preclude public access. Onsite personnel shall be available for this purpose. Plans shall be described in the AMP, including identifying the access points monitored, the frequency of patrol, and measures employed to discourage access (e.g., locked gates, barriers, natural features, etc.). Secondary access points include secondary roadways and trails traversing the facility.
- Only registered guests of the facility will be allowed access to or through the facility. Those seeking to be a guest for the sole purpose of passing through the facility to another destination shall be provided a registration sheet that explains Perpetua's requirements for accessing the site and identifies potential hazards of the site.

2.8 Copies of the FDCP and AMP shall be submitted to DEQ for approval 30 days prior to startup at the address provided (Permit Condition 2.26), and shall remain onsite at all times. Any changes to the FDCP or the AMP shall be submitted to DEQ for review, comment, and approval 30 days prior to the change.

Visible Emissions

2.9 The permittee shall not discharge any air pollutant to the atmosphere from any point of emission for a period or periods aggregating more than three minutes in any 60-minute period which is greater than 20% opacity as determined by the test methods and procedures contained in IDAPA 58.01.01.625. These provisions shall not apply when the presence of uncombined water, nitrogen oxides, and/or chlorine gas is the only reason for the failure of the emission to comply with this permit condition.

2.10 Each day during daylight hours and under normal operating conditions, the permittee shall conduct a facility-wide inspection of potential point sources of visible emissions including stacks, vents, and functionally equivalent openings. Sources that are monitored using a continuous opacity monitoring system (COMS) are not required to comply with this permit condition. The inspection shall consist of a see/no see evaluation for each potential source of visible emissions. If any visible emissions are present from any point of emission, the permittee shall either:

- Take appropriate corrective action as expeditiously as practicable to eliminate the visible emissions. Within 24 hours of the initial see/no see evaluation and after the corrective action, the permittee shall conduct a see/no see evaluation of the emissions point in question. If the visible emissions are not eliminated, the permittee shall comply with the following; or
- Perform a Method 9 opacity test in accordance with the procedures outlined in IDAPA 58.01.01.625. A minimum of 30 observations shall be recorded when conducting the opacity test. If opacity is greater than 20% for a period or periods aggregating more than three minutes in any 60-minute period, the permittee shall take all necessary corrective action and report the exceedance in the annual compliance certification and in accordance with IDAPA 58.01.01.130-136.

2.11 The permittee shall maintain records of the results of each visible emission inspection and each opacity test when conducted. The records shall include, at a minimum, the date and results of each inspection and test and a description of the following: the permittee's assessment of the conditions existing at the time visible emissions are present (if observed), any corrective action taken in response to the visible emissions, and the date corrective action was taken.

2.12 The permittee shall have a certified opacity reader onsite at all times during operation of any regulated sources (in Table 1.1). The reader shall be certified in using the test methods and procedures of EPA Reference Methods 9 and knowledgeable of Method 22 procedures.

2.13 Reserved.

Odor

2.14 The permittee shall not allow, suffer, cause, or permit the emission of odorous gases, liquids, or solids into the atmosphere in such quantities as to cause air pollution in accordance with IDAPA 58.01.01.776.01.

2.15 The permittee shall maintain records of all odor complaints received. If the complaint has merit, the permittee shall take appropriate corrective action as expeditiously as practicable. The records shall include, at a minimum, the date that each complaint was received and a description of the following: the complaint, the permittee's assessment of the validity of the complaint, any corrective action taken, and the date the corrective action was taken.

Fuels

2.16 The permittee shall not sell, distribute, use, or make available for use any distillate fuel oil containing more than the following percentages of sulfur, in accordance with IDAPA 58.01.01.725:

- ASTM Grade 1 fuel oil - 0.3% by weight.
- ASTM Grade 2 fuel oil - 0.5% by weight.

2.17 The permittee shall maintain documentation of supplier verification of fuel oil sulfur content on an as-received basis to ensure compliance with fuel specifications (Permit Condition 2.16).

2.18 The maximum throughput of gasoline to the Gasoline Tanks (TG1, TG2) shall not exceed 100,000 gallons per month (gal/mo).

2.19 After startup, each month the permittee shall maintain records demonstrating compliance with gasoline throughput limits, by tracking either amounts loaded or amounts dispensed from each Gasoline Tank.

O&M Manual

2.20 Thirty days prior to startup of any process equipment (Permit Condition 2.13), the permittee shall develop and maintain an Operation and Maintenance (O&M) manual to ensure compliance with emission limits (Permit Conditions 2.9, 2.13, 4.3, and 5.3) and the control equipment maintenance and operation general provision (Permit Condition 7.2). The O&M manual shall be a permittee-developed document based upon, but independent from, manufacturer-supplied operating manuals. The permittee shall operate control equipment in accordance with the O&M manual at all times. The requirements in the O&M manual shall be incorporated by reference to this permit and shall be enforceable permit conditions. At a minimum, the O&M manual shall include the following for all (Table 1.1):

- Identify the manufacturer, model, date of manufacture, and maximum capacity (as-built) for each regulated emission source assigned a source ID, and for each control device in the service of ore concentration and refining, lime production, and concrete production (in Table 1.1). For each wet scrubber, vent gas cleaning tower, venturi scrubber, carbon filter, baghouse and bin vent filter cartridge control device, a copy of the vendor-supplied performance guarantee shall be included. For each engine, a copy of the EPA tier certification shall be included. For each cyanide leach tank and for each cyanide detox tank, the tank dimensions (e.g., diameter) shall be included.
- Establish operating ranges for control equipment, based on manufacturer specifications and conditions measured during performance testing.
    - Minimum pressure drop across each wet scrubber, vent gas cleaning tower, and venturi scrubber;
    - Minimum circulation flow rate for each wet scrubber, vent gas cleaning tower, venturi scrubber;
    - Maximum inlet gas stream temperature to each carbon filter;
    - Maximum pressure drop across each carbon filter;
    - Minimum pressure drop across each baghouse; and
    - Minimum coolant flow rate in the mercury retort (MR) condenser and vent gas steam condensation tower;

- Describe the procedures for proper operation, startup, and shutdown of control equipment, based on manufacturer specifications.
- Describe the schedule and procedures for routine inspection (Permit Condition 2.10), maintenance, repair, and replacement of control equipment.
    - See-no-see visible emissions inspection of each wet scrubber, carbon filter, baghouse, and bin vent shall be conducted at least once per day.
    - At least once every six months, the drum lining of the carbon regeneration kiln shall be visually inspected for structural damage and cracks.
    - The dates, times, and results from each inspection (as required by Permit Condition 2.11), corrective action, maintenance, repair, and replacement of control equipment shall be recorded at least once per month.
    - The replacement dates for each baghouse and bin vent filter cartridge and for each activated carbon filter medium shall be recorded at the time of each replacement. For cartridges, records shall include the manufacturer and model. For carbon filters, records shall include the manufacturer, type, and form of medium added. Records shall also include any changes in supplier and other relevant information.
    - All carbon filter beds shall be disposed of in an acceptable manner in compliance with all applicable state rules and federal regulations.
- Describe the schedule and procedures for corrective action that will be taken if visible emissions are present from wet scrubber (WS2, WS3), carbon filter (CA1, CA2, CA3, CA4, CA5), baghouse (BH2, BH3, BH4, BH5), or bin vent filter (LS, LS1, MillS2, ACS1, ACS2, ACS3, ACS4, CS1, CS2) control equipment at any time. Procedures should include how to determine whether filter cartridges are ruptured or are not appropriately secured in place, and how to determine whether the wet scrubber, condenser, and carbon filters are operating properly.
- Describe each monitoring device and methodology used to measure weight rates of materials to demonstrate compliance with each material throughput limit (Permit Conditions 3.5–3.9, 4.8–4.11, and 5.4–5.8). Procedures for proper installation, calibration, and maintenance shall be included.
- Describe each monitoring device and methodology used to measure the volumetric rates of materials to demonstrate compliance with the electrowinning cells and pregnant solution tank throughput limit (Permit Condition 4.12). Procedures for proper installation, calibration, and maintenance shall be included.
- Describe each monitoring device and methodology used to monitor pH, temperature, and free cyanide in each cyanide leach tank, each cyanide detox tank, and each tailings reclaim stream to comply with Cyanide Emissions Limit Compliance Monitoring (Permit Condition 4.18). Procedures for proper installation, calibration, and maintenance shall be included.
- Describe the methodology and sample calculations used to estimate monthly and rolling 12-month facility-wide cyanide emissions to assess compliance with the Cyanide Emissions Limit (Permit Condition 4.4). Calculations shall be based on the pH, temperature, and free cyanide concentrations that are measured each day, and the methodology used shall be consistent with the permittee's application as addended December 18, 2020 and shall be based on the following equation:

    $r_v = k_g \alpha_0 C_l H A F_a F_w$

where,

r_v = hydrogen cyanide emissions from surface (g/s)

k_g = gas phase mass transfer coefficient (m/s)

α_0 = non-ionized cyanide fraction determined from pH and pK_a (ionization coefficient)

C_l = total liquid phase free cyanide concentration (g/m^3)

H = Henrys Law Coefficient (g/m^3 per g/m^3)

A = process surface area (m^2)

F_a = area factor

F_w = wind factor

- Describe the monitoring methodology used to monitor xanthates usage (Permit Condition 4.19).

2.21 The O&M manual shall be submitted for approval to DEQ 30 days prior to startup of any ore processing, ore concentration and refining, lime production, or aggregate production emission source regulated by this permit (as identified in Table 1.1) at the address provided (Permit Condition 2.26), and shall remain onsite at all times. Any changes to the O&M manual shall be submitted to DEQ for review, comment, and approval 30 days prior to the change.

Incorporation of Federal Requirements

2.22 Unless expressly provided otherwise, any reference in this permit to any document identified in IDAPA 58.01.01.107.03 shall constitute the full incorporation into this permit of that document for the purposes of the reference, including any notes and appendices therein. Documents include, but are not limited to:

- Standards of Performance for New Stationary Sources (NSPS) 40 CFR 60, Subpart A – General Provisions.
- NSPS 40 CFR 60, Subpart LL – Standards of Performance for Metallic Mineral Processing Plants. Each crusher (OC7, OC12), conveyor belt transfer point (OC2–OC6, OC9–OC11, OC13), and truck unloading station (OC1) is an affected facility.
- NSPS 40 CFR 60, Subpart OOO – Standards of Performance for Nonmetallic Mineral Processing Plants. Each crusher (LS2, LS4), grinding mill (LSBM), screening operation (LS3, LS5, LS11), belt conveyor (LS6–LS10, LS12), and storage bin (LS1) is an affected facility.
- NSPS 40 CFR 60, Subpart IIII – Standards of Performance for Stationary Compression Ignition Internal Combustion Engines. Each emergency generator engine and fire pump (EDG1, EDG2, EDG3, and EDFP) is an affected facility.
- National Emission Standards for Hazardous Air Pollutants for Source Categories (NESHAP) 40 CFR 63, Subpart A – General Provisions.
- NESHAP 40 CFR 63, Subpart EEEEEEE – National Emission Standards for Hazardous Air Pollutants: Gold Mine Ore Processing and Production Area Source Category. The collection of ore pretreatment processes including the autoclave (AC) and the carbon process including the carbon regeneration kiln (CKD), the electrowinning cells and pregnant solution tank (EW), the mercury retort (MR), and the induction melting furnace (MF) are affected facilities.

- NESHAP 40 CFR 63, Subpart ZZZZ – National Emission Standards for Hazardous Air Pollutants for Stationary Reciprocating Internal Combustion Engines (RICE). Each emergency generator engine and fire pump (EDG1, EDG2, EDG3, and EDFP) is an affected facility.
- NESHAP 40 CFR 63, Subpart CCCCCC – National Emission Standards for Hazardous Air Pollutants for Source Category: Gasoline Dispensing Facilities. Each gasoline fuel storage tank (TG1, TG2) is an affected facility.

The permittee shall comply with all applicable NSPS and NESHAP requirements. For permit conditions referencing or cited in accordance with any document incorporated by reference (including permit conditions identified as NSPS or NESHAP), should there be any conflict between the requirements of the permit condition and the requirements of the document, the requirements of the document shall govern, including any amendments to that regulation.

2.23 In accordance with IDAPA 58.01.01.314.06, the permittee shall notify DEQ in writing the date upon which the Tier I source (e.g., gold ore concentration and refining process equipment) commences operation. The notification shall be titled, "TIER I SOURCE NOTIFICATION OF COMMENCING OPERATION," and shall include the name of the permittee, the permit and project numbers, the date the permit was issued, and the date the Tier I source commences operation. The notification shall be submitted to DEQ within five (5) days of commencing operation and shall be sent to:

Air Quality Permitting
Idaho Department of Environmental Quality
1410 N. Hilton
Boise, ID 83706-1255

2.24 In accordance with IDAPA 58.01.01.313.01.b., the permittee shall submit a complete application to DEQ at the address provided (Permit Condition 2.26) for an initial Tier I operating permit within 12 months of becoming a Tier I source or commencing operation.

Test Methods

2.25 Except as otherwise specified in this permit and in IDAPA 58.01.01.157.02, when testing is required the following test methods shall be used to measure pollutant emissions.

Table 2.1 Test Methods

Pollutant		Test Method	Additional Requirements
H_2SO_4		EPA Method 8	
$PM_{2.5}$ or PM_{10}		EPA Methods 5 and 202, or 201A and 202	Particulate matter (PM), including condensable PM as defined in IDAPA 58.01.01.006 with an aerodynamic diameter less than or equal to a nominal 10 micrometers for PM_{10}, and less than or equal to a nominal 2.5 micrometers for $PM_{2.5}$.
Opacity	point	EPA Method 9	For NSPS and NESHAP sources, use IDAPA 58.01.01.625 and Method 9. For other sources, use IDAPA 58.01.01.625 only.
	fugitive	EPA Method 22	Visible fugitive PM.

Notifications

2.26 All requests, reports, applications, submittals, certifications, and other communications required by this permit shall be submitted to:

Air Quality Permit Compliance
Department of Environmental Quality
Boise Regional Office
1445 N. Orchard St.
Boise, Idaho 83706

phone: (208) 373-0550
fax: (208) 373-0287

3 Mining and Ore Processing

3.1 Process Description

Conventional open-pit mining methods including drilling, blasting, excavating, and hauling will be used to extract ore and waste rock, termed development rock (DR). Hydraulic shovels and front-end loaders will be used to load ore and DR into haul trucks. DR will be used for construction, restoration, and backfilling, or hauled to dedicated development rock storage facilities (DRSF). Approximately 340 million tons of DR will be handled over the life of the mine.

The SGP will include three years of pre-mining development and construction activities, followed by an operating mine life of approximately 12 years. Mining will occur in three open pits: Yellow Pine Pit (YPP), Hangar Flats pit (HFP), and West End pit (WEP). Legacy tailings from the Meadow Creek valley (Bradley Tailings [BT]) will also be reclaimed and reprocessed. Surface exploration drilling will occur within the pits and underground within the Scout Prospect decline.

Ore will be hauled to the primary crusher area, where it will be fed directly into the crusher dump pocket or stockpiled. The ore crushing plant will be designed to operate at a maximum rate of 25,000 tons per calendar day (T/day). Approximately 100 million tons of ore will be mined from the three pits over the life of the project.

The metal-recovery process from ore will include conventional crushing and grinding, followed by froth-flotation circuits that will generate separate gold-silver and antimony-silver concentrates. The antimony-silver concentrate will be shipped offsite for refining, whereas additional onsite processing of the gold-silver concentrate will include pressure oxidation, carbon-in-leach circuits, and refining processes to recover gold and minor amounts of silver. The finely ground leftover ore material from the mineral-recovery process, termed tailings, will be neutralized, thickened, and transported via a pipeline to the tailings storage facility.

3.2 Control Device Descriptions

Table 3.1 contains a description of control equipment used to control emissions from mining and ore processing activities.

Table 3.1 Mining and Ore Processing Control Device Descriptions

Emission Sources	Control Devices
Mining	
Drilling activities	Reasonable control and Fugitive Dust Control Plan (FDCP) Dust collection systems on drilling rigs Control efficiency: 90%
Blasting activities	Reasonable control & FDCP
Excavating and hauling activities	Reasonable control & FDCP Chemical suppression and water sprays Control efficiency: 93.3% for PM/PM_{10} (haul roads) Haul road capping with low-arsenic quartzite
Rock dumps and storage piles	Reasonable control & FDCP
(2) Prill Silos #1-2 Maximum capacity: 100 T (each)	None
Ore Processing	
Loader Transfer of Ore to Grizzly	Reasonable control & FDCP Water sprays and moisture carryover
Grizzly to Apron Feeder	
Apron Feeder to Dribble	
Apron Feeder to Grizzly	
Dribble to Grizzly	
Grizzly to Primary Crusher or Coarse Ore Stockpile Feed	
Primary Crusher	Reasonable control & FDCP Water sprays and moisture carryover
Coarse Ore Stockpile Feed Transfer to Stockpile	
Stockpile Transfer to Reclaim Conveyors	Reasonable control & FDCP Below-grade of storage piles Control efficiency: 80% for PM/PM_{10}
Reclaim Conveyors to SAG Mill Feed Conveyor	
SAG Mill Feed Transfer to SAG Mill	Reasonable control & FDCP Enclosure Control efficiency: 80% for PM/PM_{10}
Pebble Crusher	Reasonable control & FDCP Water sprays and moisture carryover
Pebble Discharge to SAG Mill Feed	

Operating Limits

3.3 Drilling Limits

The permittee shall drill no more than 1,200 blast holes per day.

3.4 Blasting Limits

The permittee shall complete no more than two blasting operations per day.

3.5 Daily Hauling and Excavating Limits

The permittee shall haul no more than 180,000 tons per day (T/day) of ore and DR.

The permittee shall haul no more than 135,000 T/day of ore and DR, based on a 5-year rolling average.

3.6 Life of Mine Hauling and Excavating Limits

The permittee shall haul no more than 788.4 million tons (MT) of ore and DR from all deposits over the life of the mine and no more than 394.2 MT of ore and DR from the West End deposit over the life of the mine.

3.7 Primary Crusher Limit

The permittee shall process ore as the raw material in the primary crusher, and the maximum input to the primary crusher shall not exceed 25,000 T/day.

3.8 Pebble Crusher Limit

The permittee shall process ore as the raw material, and the maximum input to the pebble crusher shall not exceed 27,600 T/day.

3.9 Prill Loading Limit

The permittee shall not load in excess of 200 T/day and 9,000 tons per any consecutive 12-month period of prill (ammonium nitrate) to the prill silos.

3.10 Mining and Ore Processing Dust Control

The permittee shall control emissions from mining and ore processing emission sources (Table 3.1) in accordance with the Fugitive Dust Control Plan.

3.11 Drilling Rigs Dust Control System

The permittee shall install and operate dust collection systems with a minimum control efficiency of 90% on all drilling rigs in accordance with the O&M manual (Permit Condition 2.20). The dust collection systems shall be in operation at all times when the drilling rigs are operated.

3.12 Ore Processing Equipment Water Sprays

The permittee shall install, operate, and maintain water sprays in accordance with the O&M manual (Permit Condition 2.20) to control PM emissions from each ore processing crusher and conveyor. Water sprays shall operate according to the FDCP when this equipment is operated to ensure compliance with Fugitive Dust requirements (Permit Conditions 2.1–2.6).

3.13 Haul Road Capping

The permittee shall cap haul roads that are outside of the Yellow Pine Pit (YPP), Hangar Flats Pit (HFP), and West End Pit (WEP) and development rock storage facilities (DRSF) including the Yellow Pine DRSF, Fiddle DRSF, and Hangar Flats DRSF with low-arsenic material.

The permittee shall use low-arsenic quartzite rock deposits from the WEP, or other material with equal or lower arsenic concentration, as capping material. Low-arsenic quartzite rock is defined as material with a median arsenic concentration of 90 parts per million (ppm) or less.

The permittee shall use capping material with a maximum of 4.0% silt content.

The permittee shall develop and maintain a Haul Road Capping Plan (HRCP) that identifies the low-arsenic quartzite rock deposits in the West End pit based on core sample analyses. The permittee shall comply with the measures identified in the HRCP at all times. The measures specified in the HRCP shall be incorporated by reference to this permit and shall be enforceable permit conditions. At a minimum, the HRCP shall include:

- The low-arsenic quartzite rock sampling plan including standard operational procedure for sampling, frequency of sampling, and ASTM (or equivalent) method of analysis for arsenic concentration.
- The frequency of inspection of the haul roads and maintenance procedures.
- The silt content sampling plan including standard operational procedure for sampling, frequency of sampling, and ASTM (or equivalent) method of analysis for silt content.

A copy of the HRCP shall be submitted to DEQ for approval 30 days prior to startup at the address provided (Permit Condition 2.26), and shall remain onsite at all times. Any changes to the HRCP shall be submitted to DEQ for review, comment, and approval 30 days prior to the change.

Monitoring and Recordkeeping Requirements

3.14 Drilling Limits Monitoring

Each day, the permittee shall monitor and record the number of blast holes drilled.

3.15 Blasting Limits Monitoring

Each day, the permittee shall monitor and record the number of blasting operations completed.

3.16 Daily Hauling and Excavating Monitoring

Each day, the permittee shall monitor and record the amount of ore and DR transported on haul trucks (T/day). The devices and methodologies used to measure weights shall be identified in the O&M Manual.

Each calendar month, the permittee shall monitor and record the amount of ore and DR transported on haul trucks in tons per month (T/mo) and in tons per year (T/yr). Annual amounts of ore and DR transported shall be determined by summing the monthly amount over the previous consecutive 12-month period. The annual amounts of ore and DR transported shall be used to calculate the 5-year rolling average in T/day.

3.17 Life of Mine Hauling and Excavating Limit Monitoring

Each day, the permittee shall monitor and record the amount of ore and DR transported on haul trucks from all deposits (T/day) and the amount of ore and DR transported on haul trucks (T/day) from the West End deposit. The devices and methodologies used to measure weights shall be identified in the O&M Manual.

Each calendar month, the permittee shall monitor and record the amount of ore and DR transported on haul trucks in tons per month (T/mo) and in tons per year (T/yr) from all deposits and the West End deposit. Annual amounts of ore and DR transported shall be determined by summing the monthly amount over the previous consecutive 12-month period. The annual amounts of ore and DR transported shall be used to calculate the life of mine total (MT) for all deposits and the West End deposit.

3.18 Primary Crusher Limit Monitoring

Each day, the permittee shall monitor and record the tons of ore input to the crusher (T/day). The devices and methodologies used to measure weights shall be identified in the O&M Manual.

3.19 Pebble Crusher Limit Monitoring

Each day, the permittee shall monitor and record the tons of ore input to the pebble crusher (T/day). The devices and methodologies used to measure weights shall be identified in the O&M Manual.

3.20 Prill Loading Limit Monitoring

Each day, the permittee shall monitor and record the amount of prill loaded to all of the prill silos combined in tons (T/day). The devices and methodologies used to measure weights shall be identified in the O&M Manual.

Each month, the permittee shall monitor and record the amount of prill loaded to all of the prill silos combined in tons per month (T/mo) and in tons per year (T/yr) to demonstrate compliance with the annual prill silos limit. Annual prill loaded shall be determined by summing the monthly input over the previous consecutive 12-month period.

4 Ore Concentration and Refining

4.1 Process Description

The autoclave is a pressure oxidation (POX) vessel used to oxidize gold gold-silver concentrate at elevated temperature and pressure in the presence of oxygen. Upon exiting the autoclave, the slurry is cooled in flash vessels and neutralized using lime and caustic soda prior to being sent to the vat leaching circuit for gold and silver recovery. A dilute sodium cyanide solution is added to the leach tanks to dissolve the gold and silver from the ore. Leached "pulp" is sent to multistage carbon-in-pulp (CIP) and/or carbon-in-leach (CIL) tanks, where gold is recovered onto activated carbon. The autoclave is located in the POX Building and the exhaust from the autoclave passes through a venturi scrubber, vent gas cleaning tower, vent gas steam condensation tower, and carbon filter.

Carbon loaded with gold is removed and washed with acid, then stripped with a caustic solution. This mineral-bearing solution is sent to the electrowinning cells and pregnant solution tank (EW). The EW cells remove the gold from the solution by plating it onto cathodes consisting of stainless-steel plates with steel wool. The EW cell exhaust passes through a carbon adsorption column (CA2), where remaining mercury vapor is adsorbed onto sulfur-impregnated activated carbon (SIAC). The stripped carbon must be periodically regenerated in the carbon regeneration kiln. Exhaust from the carbon regeneration kiln passes through a carbon adsorption bed (CA1), where mercury is adsorbed onto SIAC.

Gold concentrate is loaded into the mercury retort (MR), where it is heated under vacuum to drive off mercury. The MR exhaust passes through a shell-and-tube condenser to cool the exhaust and condense the mercury vapor into a liquid, which is collected by the mercury trap. The exhaust passes through a carbon adsorption column (CA3), where remaining vapor mercury is adsorbed onto SIAC.

After retorting, the gold concentrate is transferred to the electric induction melting furnace. Only retorted concentrate is melted in the furnace. The exhaust passes through a carbon adsorption column (CA4), where remaining mercury vapor is adsorbed onto SIAC. The electrowinning cells and pregnant solution tank, carbon regeneration kiln, MR, and induction melting furnace are located in the Refinery Building.

4.2 Control Device Descriptions

Table 4.1 Ore Concentration and Refining Control Device Descriptions

Emissions Unit / Processes	Control Devices	Emission Points
Cyanide Leach Tanks and Cyanide Detox Tanks	Chemical treatment (lime, caustic soda, hydrogen peroxide, copper sulfate, etc.)	Various
Flotation Tanks	None	
Autoclave	Venturi Scrubber (VS1) Minimum pressure drop and Minimum circulation flow rate in O&M	Autoclave Carbon Filter Stack
	Vent Gas Cleaning Tower (ST1) Minimum pressure drop and Minimum circulation flow rate in O&M	
	Vent Gas Steam Condensation Tower (CT1) Minimum coolant flow rate in O&M	
	Carbon Filter (CA5) Maximum pressure drop established in O&M Maximum inlet gas stream temperature established in O&M and by Subpart EEEEEEE	
POX Boiler	None	POX Boiler Stack
Electrowinning Cells and Pregnant Solution Tank	Shared Carbon Filter (CA2) Maximum pressure drop established in O&M Maximum inlet gas stream temperature established in O&M and by Subpart EEEEEEE in O&M	Electrowinning Cells and Pregnant Solution Tank Shared Carbon Filter Stack
Strip Circuit Solution Heater	None	Strip Circuit Solution Heater Stack
Mercury Retort	Condenser Minimum coolant flow rate established in O&M	Mercury Retort Carbon Filter Stack
	Carbon Filter (CA3) Maximum pressure drop established in O&M Maximum inlet gas stream temperature established in O&M and by Subpart EEEEEEE	
Induction Melting Furnace	Baghouse (BH2) Minimum pressure drop established in O&M	Induction Melting Furnace Carbon Filter Stack
	Carbon Filter (CA4) Maximum pressure drop established in O&M Maximum inlet gas stream temperature established in O&M and by Subpart EEEEEEE	
Carbon Regeneration Kiln	Wet Scrubber (WS2) Minimum pressure drop and Minimum circulation flow rate established in O&M	Carbon Regeneration Kiln Carbon Filter Stack
	Carbon Filter (CA1) Maximum pressure drop established in O&M Maximum inlet gas stream temperature established in O&M and by Subpart EEEEEEE	
Carbon Regeneration Kiln Burners	None	Carbon Regeneration Kiln Burners Stack
Propane Vaporizer	None	Propane Vaporizer Stack
Tailings and Maintenance Pond	None	Various

Emission Limits

4.3 Ore Concentration and Refining Equipment Emissions Limits

Emissions from ore concentration and refining equipment stacks shall not exceed any corresponding emission rate limits (Table 4.2).

Table 4.2 Ore Concentration and Refining Emissions Limits [a]

Source Description	PM / PM_{10} / $PM_{2.5}$ [b]	NO_x	CO	VOC	SO_2	H_2SO_4
	lb/hr [c]	lb/hr [c]	lb/hr [c]	lb/hr [c]	lb/hr [c]	lb/hr [c]
Autoclave (AC)	5.08				0.65	2.03
Carbon regeneration kiln (CKD)	0.42	0.01	0.12	0.11		
Electrowinning cells and pregnant solution tank (EW)	0.07					
Mercury retort (MR)	0.01 [d]					
Induction melting furnace (MF)	2.84					

a) In absence of any other credible evidence, compliance is ensured by complying with permit operating, monitoring, and recordkeeping requirements.
b) Particulate matter (PM) including condensable PM as defined in IDAPA 58.01.01.006, with an aerodynamic diameter less than or equal to a nominal 10 micrometers for PM_{10}, and less than or equal to a nominal 2.5 micrometers for $PM_{2.5}$.
c) Pounds per hour, as determined by a test method prescribed by IDAPA 58.01.01.157, EPA reference test method, continuous emission monitoring system (CEMS) data, or DEQ-approved alternative.
d) For this emission limit, compliance may be demonstrated as measurement below detection limits, when addressed as part of a performance test protocol that is approved by DEQ.

4.4 Cyanide Emissions Limit

Facility-wide emissions shall not exceed 1.99 tons per any consecutive 12-month period of cyanide compounds.

4.5 Carbon Disulfide Emissions Limit

Facility-wide emissions shall not exceed 0.063 tons per any consecutive 12-month period of carbon disulfide.

Operating Limits

4.6 Xanthates Usage

The permittee shall use potassium amyl xanthate (PAX) for flotation treatment. Total xanthate usage shall not exceed 1,700 tons per any consecutive 12-month period.

4.7 POX Boiler Operation

Operation of the POX Boiler shall be limited to the autoclave start-up operation only.

4.8 Autoclave Input

The permittee shall process ore concentrate as the raw material in the autoclave, and the maximum input to the autoclave shall not exceed 6,960 T/day.

4.9 Mercury Retort Input

The permittee shall process precious metal concentrate as the raw material in the mercury retort, and the maximum input to the mercury retort shall not exceed 1,000 pounds per batch (lb/batch) and 21 tons per any consecutive 12-month period.

Precious metal concentrate includes material loaded with precious metals produced by electrowinning, flotation and gravity separation, and other gold concentration or precipitation processes; and material collected from the wash-down of equipment and surfaces contacted with precious metals that have been concentrated through these concentration methods.

4.10 Induction Melting Furnace Input

The permittee shall process retorted concentrate as the raw material in the induction melting furnace, and the input to the induction melting furnace shall not exceed 1,000 lb/batch, and 21 tons per any consecutive 12-month period. Retorted concentrate includes precious metal

concentrate that has been retorted and dust collected from the baghouse and fume hood of the induction melting furnace.

4.11 Carbon Regeneration Kiln Input

The permittee shall process carbon filters as the raw material in the carbon regeneration kiln, and the maximum input to the carbon regeneration kiln shall not exceed 7.2 T/day.

4.12 Electrowinning Cells and Pregnant Solution Tank Throughput

The permittee shall process mineral-bearing solution as the raw materials in the electrowinning cells and pregnant solution tank, and the maximum throughput for the electrowinning cells and pregnant solution tank shall not exceed 100 gallons per minute (gpm).

4.13 Autoclave Venturi Scrubber, Vent Gas Cleaning Tower, Vent Gas Steam Condensation Tower, and Carbon Filter

The permittee shall install, operate, and maintain venturi scrubber (VS1), vent gas cleaning tower (ST1), vent gas steam condensation tower (CT1), and carbon filter (CA5) systems in accordance with the O&M manual (Permit Condition 2.20) and consistent with manufacturer's recommendations. All emissions from the autoclave shall be ducted to these control devices at all times to ensure compliance with autoclave emission limits (Table 4.2).

4.14 Electrowinning Cells and Pregnant Solution Tank Shared Carbon Filter

The permittee shall install, operate, and maintain a carbon filter (CA2) in accordance with the O&M manual (Permit Condition 2.20) and consistent with manufacturer's recommendations. All emissions from the electrowinning cells and pregnant solution tank shall be ducted to a carbon filter at all times to ensure compliance with electrowinning cells and pregnant solution tank emission limits (Table 4.2).

4.15 Mercury Retort Condenser and Carbon Filter

The permittee shall install, operate, and maintain a condenser and carbon filter (CA3) in series in accordance with the O&M manual (Permit Condition 2.20) and manufacturer's recommendations. All emissions from the mercury retort (MR) shall be ducted to the condenser and activated carbon filter at all times to ensure compliance with mercury retort emission limits (Table 4.2).

- The MR shall be fully enclosed in the refinery building.
- The air pressure within the MR shall be maintained lower than the room air pressure such that air flows into the MR at all times when the MR is operating. The MR door shall be kept closed at all times during operation.
- The permittee shall not operate the MR unless the chilled water condenser is operating, carbon filter in place, and the condenser coolant flow rate is maintained within the range specified in the O&M manual.
- The condenser and carbon filter shall be maintained and operated in accordance with the O&M manual.
- All liquid mercury captured from the MR shall be stored in closed containers.

4.16 Induction Melting Furnace Baghouse and Carbon Filter

The permittee shall install, operate, and maintain a baghouse (BH2) and carbon filter (CA4) in series in accordance with the O&M manual (Permit Condition 2.20) and manufacturer's recommendations. All emissions from the induction melting furnace shall be ducted to the

baghouse and carbon filter at all times during operation to ensure compliance with induction melting furnace emission limits (Table 4.2).

4.17 Carbon Regeneration Kiln Wet Scrubber and Carbon Filter

The permittee shall install, operate, and maintain a wet scrubber (WS2) and carbon filter (CA1) in series in accordance with the O&M manual (Permit Condition 2.20) and consistent with manufacturer's recommendations. All emissions from the carbon regeneration kiln shall be ducted to the wet scrubber and a carbon filter at all times to ensure compliance with carbon regeneration kiln drum emission limits (Table 4.2).

Monitoring and Recordkeeping

4.18 Cyanide Emissions Limit Compliance Monitoring

On at least a daily basis, the permittee shall monitor and record the pH, temperature, and free cyanide concentration levels in grams per cubic meter (g/m^3) of each cyanide leach tank, detox tank, and tailings reclaim stream, and use this information to estimate monthly facility-wide cyanide emissions using the equation and calculation methodology in the O&M Manual (Permit Condition 2.20).

Each month, the permittee shall estimate the monthly and rolling 12-month facility-wide cyanide emissions. Monthly facility-wide cyanide emissions shall be estimated from all emission sources including cyanide leach tanks, detox tanks, electrowinning cells and pregnant solution tank, and barren tanks. Rolling 12-month facility-wide cyanide emissions shall be estimated by summing the monthly emissions from all sources over the previous consecutive 12-month period. The rolling 12-month facility-wide cyanide emissions shall be used to assess compliance with the Cyanide Emissions Limit (Permit Condition 4.4).

4.19 Xanthates Usage Monitoring

Each month, the permittee shall monitor and record the xanthates delivered to the facility and the xanthates used by the facility in tons per month (T/mo) and in tons per 12-month period to demonstrate compliance with the xanthates usage limit. Annual delivery and usage shall be determined by summing the respective monthly amounts over the previous consecutive 12-month period. The methodologies used to measure xanthates usage shall be identified in the O&M Manual.

4.20 POX Boiler Operation Monitoring

Each month, the permittee shall monitor and record the operating hours of the POX Boiler, in hours (hr/mo) and in hours per 12-month period (hr/yr). Annual hours shall be determined by summing the monthly hours over the previous consecutive 12-month period.

4.21 Autoclave Input Monitoring

Each day, the permittee shall monitor and record the material input to the autoclave in tons (T/day) to demonstrate compliance with the autoclave input limit. The devices and methodologies used to measure weights shall be identified in the O&M Manual, and the devices shall be installed in accordance with the requirements of NESHAP Subpart EEEEEEE.

4.22 Mercury Retort Input Monitoring

Each day, the permittee shall monitor and record the material input to the mercury retort in pounds (lb/day) to demonstrate compliance with the daily mercury retort input limit. The devices and methodologies used to measure weights shall be in accordance with the requirements of NESHAP Subpart EEEEEEE.

Each month, the permittee shall monitor and record the material input to the mercury retort in T/mo and T/yr to demonstrate compliance with the annual mercury retort input limit. Annual material input shall be determined by summing the monthly input over the previous consecutive 12-month period.

4.23 Induction Melting Furnace Input Monitoring

Each day, the permittee shall monitor and record the material input to the induction melting furnace in pounds (lb/day) to demonstrate compliance with the daily induction melting furnace input limit. The devices and methodologies used to measure weights shall be identified in the O&M Manual.

Each month, the permittee shall monitor and record the material input to the induction melting furnace in T/mo and in T/yr to demonstrate compliance with the annual induction melting furnace input limit. Annual material input shall be determined by summing the monthly input over the previous consecutive 12-month period.

4.24 Carbon Regeneration Kiln Input Monitoring

Each day, the permittee shall monitor and record the material input to the carbon regeneration kiln in tons (T/day) to demonstrate compliance with the carbon regeneration kiln input limit. The devices and methodologies used to measure weights shall be identified in the O&M Manual.

4.25 Electrowinning Cells and Pregnant Solution Tank Throughput Monitoring

Each day, the permittee shall monitor and record the material throughput in the electrowinning cells and pregnant solution tank in gallons per minute (gpm) to demonstrate compliance with the Electrowinning Cells and Pregnant Solution Tank Throughput limit. The devices and methodologies used to measure weights shall be identified in the O&M Manual.

4.26 Autoclave Venturi Scrubber and Vent Gas Cleaning Tower Monitoring

The permittee shall install, calibrate, operate, and maintain devices for monitoring the circulation flow rate in the venturi scrubber, the circulation flow rate in the vent gas cleaning tower, the pressure drop across the venturi scrubber, and the pressure drop across the vent gas cleaning tower for the autoclave.

At least once per shift, the permittee shall monitor and record the circulation flow rate in the venturi scrubber, the circulation flow rate in the vent gas cleaning tower, the pressure drop across the venturi scrubber, and the pressure drop across the vent gas cleaning tower to ensure compliance with O&M specifications.

4.27 Autoclave Vent Gas Steam Condensation Tower Monitoring

The permittee shall install, calibrate, operate, and maintain devices for monitoring the coolant flow rate to the vent gas steam condensation tower for the autoclave.

At least once per shift, the permittee shall monitor and record the coolant flow rate to the vent gas steam condensation tower to ensure compliance with O&M specifications.

4.28 Autoclave Carbon Filter Monitoring

The permittee shall install, calibrate, operate, and maintain devices for monitoring the inlet gas stream temperature to the carbon filter, and the pressure drop across the carbon filter for the autoclave.

At least once per shift, the permittee shall monitor and record the inlet gas stream temperature and pressure drop across the carbon filter to ensure compliance with O&M specifications.

4.29 Electrowinning Cells and Pregnant Solution Tank Shared Carbon Filter Monitoring

The permittee install, calibrate, operate, and maintain devices for monitoring the inlet gas stream temperature to the carbon filter, and the pressure drop across the carbon filter for the electrowinning cells and pregnant solution tank.

At least once per shift, the permittee shall monitor and record the inlet gas stream temperature and pressure drop across the carbon filter to ensure compliance with O&M specifications.

4.30 Mercury Retort Condenser and Carbon Filter Monitoring

The permittee shall install, calibrate, operate, and maintain devices for monitoring the coolant flow rate in the condenser, the inlet gas temperature to the carbon filter, the pressure drop across the carbon filter, and the difference between the pressure inside the MR and the air pressure in the room.

At least once per shift, the permittee shall monitor and record the coolant flow rate to the condenser, the inlet gas stream temperature, the pressure drop across the carbon filter, and the difference between the pressure inside the MR and the air pressure in the room to ensure compliance with O&M specifications.

4.31 Induction Melting Furnace Baghouse and Carbon Filter Monitoring

The permittee shall install, calibrate, operate, and maintain devices for monitoring the pressure drop across the baghouse, the inlet gas stream temperature to the carbon filter, and the pressure drop across the carbon filter for the induction melting furnace.

At least once per shift, the permittee shall monitor and record the pressure drop across the induction melting furnace baghouse, the inlet gas stream temperature to the carbon filter, and pressure drop across the carbon filter to ensure compliance with O&M specifications.

4.32 Carbon Regeneration Kiln Wet Scrubber and Carbon Filter Monitoring

The permittee shall install, calibrate, operate, and maintain a device for monitoring the circulation flow rate in the wet scrubber, the pressure drop across the wet scrubber, the inlet gas stream temperature to the carbon filter, and the pressure drop across the carbon filter for the carbon regeneration kiln.

At least once per shift, the permittee shall monitor and record the circulation flow rate, the pressure drop across the carbon regeneration kiln wet scrubber, the inlet gas stream temperature to the carbon filter, and the pressure drop across the carbon filter to ensure compliance with O&M specifications.

Testing

4.33 Ore Concentration and Refining Equipment Performance Tests

Within 180 days after initial startup, performance testing shall be conducted to demonstrate compliance with the following Ore Concentration and Refining Equipment Emissions Limits. The permittee shall conduct three separate test runs for each performance test using the appropriate test method (Permit Condition 2.25). The source test shall be conducted under "worst-case normal" conditions as required by IDAPA 58.01.01.157 and the General Provisions of this permit, and the source test report shall contain documentation that the test was conducted under these conditions.

- $PM_{10}/PM_{2.5}$ and H_2SO_4 in lb/hr from the Autoclave Wet Scrubber Stack
- $PM_{10}/PM_{2.5}$ in lb/hr from the Carbon Regeneration Kiln Carbon Filter Stack

- $PM_{10}/PM_{2.5}$ in lb/hr from the Electrowinning Cells and Pregnant Solution Tank Shared Carbon Filter Stack
- $PM_{10}/PM_{2.5}$ in lb/hr from the Mercury Retort Carbon Filter Stack
- $PM_{10}/PM_{2.5}$ in lb/hr from the Induction Melting Furnace Carbon Filter Stack

4.34 Ore Concentration and Refining Equipment Performance Tests Monitoring

The permittee shall monitor and record the following during each performance test:

- Material input rates for all ore concentration and refining process equipment (Permit Conditions 4.21 through 4.25) during each test run.
- Control equipment monitoring relevant to the stack tested (Permit Condition 4.26 through 4.32), measured at least once during each test run.
- The visible emissions observed for the stack tested during each test, using the methods specified in IDAPA 58.01.01.625 (Permit Condition 2.9).

5 Lime, Aggregate, and Concrete Production

5.1 Process Description

The lime, aggregate, and cement batch plants produce raw materials necessary for mining and ore concentration and refining operations. Lime is used in ore processing for pH control. Aggregate and cement are used in concrete production, with aggregate also used in road construction.

Lime production consists of a limestone crushing, screening, and grinding plant and lime storage silos. The limestone grinding process utilizes a baghouse to reduce emissions during processing. Each storage silo has a bin vent filter used to reduce PM emissions during silo loading.

Aggregate production consists of two portable crushing and screening plants and aggregate and cement storage silos. Each portable crushing and screening plant utilizes water sprays and moisture carryover to reduce emissions during processing. Each storage silo has a bin vent filter used to reduce PM emissions during silo loading.

Concrete production consists of a central mix batch plant and cement storage silos. The central mix batch plant utilizes controls that may include water sprays, enclosures, hoods, curtains, shrouds, movable and telescoping chutes, and central duct collection systems to reduce PM emissions during processing. Each storage silo has a bin vent filter used to reduce PM emissions during silo loading.

5.2 Control Device Descriptions

Table 5.1 Lime, Aggregate, and Concrete Production Control Device Descriptions

Lime Production Plant Emissions Unit / Processes	Control Devices	Emission Points
Limestone transfer to Primary Crusher Hopper	Reasonable control & FDCP	Various

Emission Limits

5.3 Lime, Aggregate, and Concrete Production Emission Limits

Emissions from the lime production plant stacks shall not exceed any emission rate limit in the following table.

Table 5.2 Lime, Aggregate, and Concrete Production Plant Emission Limits [a]

Source Description	PM [b]	PM_{10} [b]	$PM_{2.5}$ [b]	NO_x	CO	VOC	SO_2
	lb/hr [c]	lb/hr [c]	lb/hr [c]	lb/hr [c]	lb/hr [c]	lb/hr [c]	lb/hr [c]
Lime Production							
Parallel Flow Regenerative Shaft Kiln (LK, LKC)	1.08	1.08	1.08	4.82	4.98	0.19	0.39
Limestone Ball Mill (LSBM)	1.90	1.60	0.57				
Lime Mill Crusher (LCR)	0.28	0.24	0.09				
Lime Mill screens and conveyors (LS2, LS4, LS3, LS5, LS11, LS1, LS6–LS10, LS12)	3.66	1.34	0.20				
Mill Lime Silo loading (each) (LS1L, MillS2L)	0.06	0.02	0.01				
Mill Lime Silo unloading (each) (LS1U, MillS2U)	0.10	0.06	0.01

Portable Crushing and Screening Plant 1	0.63	0.23	0.03				
Portable Crushing and Screening Plant 2	0.63	0.23	0.03				
Concrete Production							
Central Mix Plant (CM, CS1, CS2, CA)	2.10	0.94	0.14				

a) In absence of any other credible evidence, compliance is ensured by complying with permit operating, monitoring, and recordkeeping requirements.

b) Particulate matter (PM) including condensable PM as defined in IDAPA 58.01.01.006, with an aerodynamic diameter less than or equal to a nominal 10 micrometers for PM_{10}, and less than or equal to a nominal 2.5 micrometers for $PM_{2.5}$.

c) Pounds per hour, as determined by a test method prescribed by IDAPA 58.01.01.157, EPA reference test method, continuous emission monitoring system (CEMS) data, or DEQ-approved alternative.

Operating Requirements

5.4 Primary Crusher Limit

The permittee shall process limestone as the raw material, and the maximum input to the primary crusher shall not exceed 1,130 T/day.

5.5 Parallel Flow Regenerative Kiln Limit

The permittee shall process lime as the raw material in the Parallel Flow Regenerative Kiln. The maximum output from the kiln shall not exceed 169 T/day and 52,377 tons per any consecutive 12-month period.

5.6 Portable Crushing and Screening Plant 1 Input Limit

The permittee shall process aggregate as the raw material, and the maximum input to the Portable Crushing and Screening Plant 1 shall not exceed 2,000 T/day.

5.7 Portable Crushing and Screening Plant 2 Input Limit

The permittee shall process aggregate as the raw material, and the maximum input to the Portable Crushing and Screening Plant 2 shall not exceed 2,000 T/day.

5.8 Central Mix Input Limit

The permittee shall process cement and aggregate as the raw materials, and the maximum input to the central mix plant shall not exceed 2,480 T/day and 560,000 tons per any consecutive 12-month period.

5.9 Lime Silos Input Limit

The permittee shall load lime as the raw material, and the maximum input to the Mill Lime Silos and the AC Lime Silos shall not exceed 4,000 T/day and 70,000 tons per any consecutive 12-month period combined.

5.10 Lime, Aggregate, and Concrete Production Dust Control

The permittee shall control emissions from lime production, aggregate production, and concrete production emission sources (Table 5.1) in accordance with the Fugitive Dust Control Plan.

5.11 Portable Crushing and Screening Plant Water Sprays

The permittee shall install, operate, and maintain water sprays in accordance with the O&M manual (Permit Condition 2.20) to control PM emissions from each portable crushing and screening plant. Water sprays shall operate at all times, except as specified in the O&M manual during winter conditions, when this equipment is operated to ensure compliance with Fugitive Dust requirements (Permit Conditions 2.1–2.6).

5.12 Parallel Flow Regenerative Kiln Baghouse

The permittee shall install, operate, and maintain a baghouse system (BH4) in accordance with the O&M manual (Permit Condition 2.20) and consistent with manufacturer's recommendations. All emissions from the parallel flow regenerative kiln shall be ducted to the baghouse at all times to ensure compliance with parallel flow regenerative emission limits.

5.13 Limestone Ball Mill Baghouse

The permittee shall install, operate, and maintain a baghouse system (BH3) in accordance with the O&M manual (Permit Condition 2.20) and consistent with manufacturer's recommendations. All emissions from the limestone ball mill shall be ducted to the baghouse at all times to ensure compliance with limestone ball mill emission limits.

5.14 Lime Mill Crusher Baghouse

The permittee shall install, operate, and maintain a baghouse (BH5) in accordance with the O&M manual (Permit Condition 2.20) and consistent with manufacturer's recommendations.
All emissions from the lime mill crusher shall be ducted to the baghouse at all times to ensure compliance with limestone ball mill emission limits.

5.15 Pebble Lime Silo Wet Scrubber

The permittee shall install, operate, and maintain a wet scrubber on the Pebble Lime Silo discharge (LS) in accordance with the O&M manual (Permit Condition 2.20) and consistent with manufacturer's recommendations. All emissions during discharge from the Pebble Lime Silo shall be ducted to the wet scrubber to ensure compliance with pebble lime silo emission limits (Table 5.2).

5.16 Silo Bin Vent Filters

The permittee shall install, operate, and maintain a bin vent filter on each silo (LS1, MillS2, ACS1, ACS2, ACS3, ACS4, LS, CS1, CS2) in accordance with the O&M manual (Permit Condition 2.20) and consistent with manufacturer's recommendations. All emissions during loading of each silo shall be ducted to the corresponding bin vent filter to ensure compliance with corresponding silo emission limits (Table 5.2).

Monitoring and Recordkeeping Requirements

5.17 Primary Crusher Monitoring

Each day, the permittee shall monitor and record the material input to the Primary Crusher in tons (T/day) to demonstrate compliance with the daily Primary Crusher Limit. The devices and methodologies used to measure weights shall be identified in the O&M Manual.

5.18 Parallel Flow Regenerative Kiln Limit Monitoring

Each day, the permittee shall monitor and record the material output from the Parallel Flow Regenerative Kiln in tons (T/day) to demonstrate compliance with the daily Parallel Flow Regenerative Kiln Limits. The devices and methodologies used to measure weights shall be identified in the O&M Manual.

Each month, the permittee shall calculate and record the material output from the Parallel Flow Regenerative Kiln in T/mo and in T/yr to demonstrate compliance with the annual Parallel Flow Regenerative Kiln Limit. Annual material output shall be determined by summing the monthly output over the previous consecutive 12-month period.

5.19 Portable Crushing and Screening Plant 1 Input Limit Monitoring

Each day, the permittee shall monitor and record the material input to the Portable Crushing and Screening Plant 1 plant in tons (T/day) to demonstrate compliance with the daily Portable Crushing and Screening Plant 1 Input Limit. The devices and methodologies used to measure weights shall be identified in the O&M Manual.

5.20 Portable Crushing and Screening Plant 2 Input Limit Monitoring

Each day, the permittee shall monitor and record the material input to the Portable Crushing and Screening Plant 2 plant in tons (T/day) to demonstrate compliance with the daily Portable Crushing and Screening Plant 2 Input Limit. The devices and methodologies used to measure weights shall be identified in the O&M Manual.

5.21 Central Mix Input Limit Monitoring

Each day, the permittee shall monitor and record the material input to the Central Mix Plant in tons (T/day) to demonstrate compliance with the daily Central Mix Input Limit. The devices and methodologies used to measure weights shall be identified in the O&M Manual.

Each month, the permittee shall calculate and record the material input to the central mix plant in T/mo and in T/yr to demonstrate compliance with the annual Central Mix Input Limit. Annual

material input shall be determined by summing the monthly input over the previous consecutive 12-month period.

5.22 Lime Silos Input Limit Monitoring

Each day, the permittee shall monitor and record the material input to the Mill Lime Silos and the AC Lime Silos in tons (T/day) to demonstrate compliance with the daily Lime Silos Input Limit. The devices and methodologies used to measure weights shall be identified in the O&M Manual.

Each month, the permittee shall calculate and record the material input to the Mill Lime Silos and the AC Lime Silos in T/mo and in T/yr to demonstrate compliance with the annual Lime Silos Input Limit. Annual material input shall be determined by summing the monthly input over the previous consecutive 12-month period.

5.23 Parallel Flow Regenerative Kiln Baghouse Monitoring

The permittee shall install, calibrate, operate, and maintain a device for monitoring the pressure drop across the parallel flow regenerative kiln baghouse. At least once per shift, the permittee shall monitor and record the pressure drop across the parallel flow regenerative kiln baghouse to demonstrate compliance with O&M specifications.

5.24 Limestone Ball Mill Baghouse Monitoring

The permittee shall install, calibrate, operate, and maintain a device for monitoring the pressure drop across the limestone ball mill baghouse. At least once per shift, the permittee shall monitor and record the pressure drop across the limestone ball mill kiln baghouse to demonstrate compliance with O&M specifications.

5.25 Lime Mill Crusher Baghouse Monitoring

The permittee shall install, calibrate, operate, and maintain a device for monitoring the pressure drop across the lime mill crusher baghouse. At least once per shift, the permittee shall monitor and record the pressure drop across the lime mill crusher kiln baghouse to demonstrate compliance with O&M specifications.

5.26 Pebble Lime Silo Wet Scrubber Monitoring

The permittee shall install, calibrate, operate, and maintain a device for monitoring the circulation flow rate in the pebble lime silo wet scrubber, and the pressure drop across the pebble lime silo wet scrubber. At least once per shift, the permittee shall monitor and record the circulation flow rate and the pressure drop across the pebble lime silo wet scrubber to demonstrate compliance with O&M specifications.

6 Engines

6.1 Process Description

Stationary internal combustion engines (ICE) for emergency power generation and fire suppression are essential to ensure safety and uninterrupted essential operations in case of unforeseen power failures or emergency situations. Portable diesel-fired light plant engines provide supplemental lighting as needed; these are not regulated by this permit and will be operated as nonroad engines defined in 40 CFR 1068.30.

6.2 Emission Standards for Emergency Generators and Fire Pump Engines

In accordance with 40 CFR 60.4205(b) and 40 CFR 60.4206, EDG1, EDG2, and EDG3 shall be EPA Tier II Certified engines and must comply with the emission standards for new nonroad CI engines in § 60.4202, for all pollutants, for the same model year and maximum engine power and must be operated and maintained so that they achieve the emission standards as required in §§60.4204 and 60.4205 over the entire life of the engine.

In accordance with 40 CFR 60.4205(c), EDFP must comply with the emission standards in Table 4 to the Subpart for all pollutants.

6.3 Emergency Generator and Fire Pump Engine Operation

Operation of each emergency generator engine (EDG1, EDG2, EDG3) and each fire pump engine (EDFP) shall not exceed 1 hour per day (hr/day) and 100 hr/yr for non-emergency purposes.

6.4 Emergency Generator Monitoring Requirements

In accordance with 40 CFR 60.4209(a), EDG1, EDG2, and EDG3 shall have non-resettable hour meters installed prior to startup.

6.5 Emergency Generator Compliance Requirements

In accordance with 40 CFR 60.4211(f), EDG1, EDG2, and EDG3 must be operated according to the requirements in paragraphs (f)(1) through (3) of this section of the Subpart. In order for the engines to be considered emergency stationary ICE under this subpart, any operation other than emergency operation, maintenance and testing, emergency demand response, and operation in non-emergency situations for 50 hours per year, as described in paragraphs (f)(1) through (3) of this section, is prohibited. If you do not operate the engine according to the requirements in paragraphs (f)(1) through (3) of this section, the engine will not be considered an emergency engine under this subpart and must meet all requirements for non-emergency engines.

(1) There is no time limit on the use of emergency stationary ICE in emergency situations.

(2) You may operate your emergency stationary ICE for any combination of the purposes specified in paragraphs (f)(2)(i) through (iii) of this section for a maximum of 100 hours per calendar year. Any operation for non-emergency situations as allowed by paragraph (f)(3) of this section counts as part of the 100 hours per calendar year allowed by this paragraph (f)(2).

(i) Emergency stationary ICE may be operated for maintenance checks and readiness testing, provided that the tests are recommended by federal, state or local government, the manufacturer, the vendor, the regional transmission

organization or equivalent balancing authority and transmission operator, or the insurance company associated with the engine. The owner or operator may petition the Administrator for approval of additional hours to be used for maintenance checks and readiness testing, but a petition is not required if the owner or operator maintains records indicating that federal, state, or local standards require maintenance and testing of emergency ICE beyond 100 hours per calendar year.

(ii) Emergency stationary ICE may be operated for emergency demand response for periods in which the Reliability Coordinator under the North American Electric Reliability Corporation (NERC) Reliability Standard EOP-002-3, Capacity and Energy Emergencies (incorporated by reference, see § 60.17), or other authorized entity as determined by the Reliability Coordinator, has declared an Energy Emergency Alert Level 2 as defined in the NERC Reliability Standard EOP-002-3.

(iii) Emergency stationary ICE may be operated for periods where there is a deviation of voltage or frequency of 5 percent or greater below standard voltage or frequency.

(3) Emergency stationary ICE may be operated for up to 50 hours per calendar year in non-emergency situations. The 50 hours of operation in non-emergency situations are counted as part of the 100 hours per calendar year for maintenance and testing and emergency demand response provided in paragraph (f)(2) of this section. Except as provided in paragraph (f)(3)(i) of this section, the 50 hours per calendar year for non-emergency situations cannot be used for peak shaving or non-emergency demand response, or to generate income for a facility to an electric grid or otherwise supply power as part of a financial arrangement with another entity.

(i) The 50 hours per year for non-emergency situations can be used to supply power as part of a financial arrangement with another entity if all of the following conditions are met:

(A) The engine is dispatched by the local balancing authority or local transmission and distribution system operator.

(B) The dispatch is intended to mitigate local transmission and/or distribution limitations so as to avert potential voltage collapse or line overloads that could lead to the interruption of power supply in a local area or region.

(C) The dispatch follows reliability, emergency operation or similar protocols that follow specific NERC, regional, state, public utility commission or local standards or guidelines.

(D) The power is provided only to the facility itself or to support the local transmission and distribution system.

(E) The owner or operator identifies and records the entity that dispatches the engine and the specific NERC, regional, state, public utility commission or local standards or guidelines that are being followed for dispatching the engine. The local balancing authority or local transmission and distribution system operator may keep these records on behalf of the engine owner or operator.

6.6 Emergency Generator and Fire Pump Engine Operation Monitoring

Each month, the permittee shall monitor and record the emergency and non-emergency operating hours of each emergency generator and fire pump engine, in hr/mo and in hr/yr to demonstrate compliance with the emergency generator and fire pump engine operation limit. Annual operation shall be determined by summing the monthly hours over the previous consecutive 12-month period.

6.7 Engines Subject to Regulation Notification

With the exception of the emergency generator and fire pump engines (identified in Table 1.1) and engines used to propel vehicles, notification shall be provided to DEQ if an engine (including any previously operated as a nonroad engine) will be operated onsite at a specific location beyond 12 months, and no longer meets criteria for regulation as a nonroad engine. Notification shall be provided as soon as practicable in advance of exceeding 12 months of operation at a single location and within 30 days after the engine ceases to meet the definition of nonroad engine in 40 CFR 1068.30.

- A nonroad engine may include engines that are portable or transportable, meaning designed to be and capable of being carried or moved from one location to another (e.g., portable light plant engines). Indicia of transportability include, but are not limited to, wheels, skids, carrying handles, dolly, trailer, or platform.
- A portable or transportable internal combustion engine is not a nonroad engine if it remains or will remain at a location for more than 12 consecutive months, or a shorter period of time for an engine located at a seasonal source. A location is any single site at a building, structure, facility, or installation. Any engines (or engine) that replace(s) an engine at a location and is intended to perform the same or similar function as the engine(s) replaced are included in calculating the consecutive time period. Permitting requirements and emission standards may become applicable when an engine becomes a stationary source.

7 General Provisions

General Compliance

7.1 The permittee has a continuing duty to comply with all terms and conditions of this permit. All emissions authorized herein shall be consistent with the terms and conditions of this permit and the "Rules for the Control of Air Pollution in Idaho." The emissions of any pollutant in excess of the limitations specified herein, or noncompliance with any other condition or limitation contained in this permit, shall constitute a violation of this permit, the "Rules for the Control of Air Pollution in Idaho," and the Environmental Protection and Health Act (Idaho Code §39-101, et seq).

[Idaho Code §39-101, et seq.]

7.2 The permittee shall at all times (except as provided in the "Rules for the Control of Air Pollution in Idaho") maintain in good working order and operate as efficiently as practicable all treatment or control facilities or systems installed or used to achieve compliance with the terms and conditions of this permit and other applicable Idaho laws for the control of air pollution.

[IDAPA 58.01.01.211]

7.3 Nothing in this permit is intended to relieve or exempt the permittee from the responsibility to comply with all applicable local, state, or federal statutes, rules, and regulations.

[IDAPA 58.01.01.212.01]

Inspection and Entry

7.4 Upon presentation of credentials, the permittee shall allow DEQ or an authorized representative of DEQ to do the following:

- Enter upon the permittee's premises where an emissions source is located, emissions-related activity is conducted, or where records are kept under conditions of this permit;
- Have access to and copy, at reasonable times, any records that are kept under the conditions of this permit;
- Inspect at reasonable times any facilities, equipment (including monitoring and air pollution control equipment), practices, or operations regulated or required under this permit; and
- As authorized by the Idaho Environmental Protection and Health Act, sample or monitor, at reasonable times, substances or parameters for the purpose of determining or ensuring compliance with this permit or applicable requirements.

[Idaho Code §39-108]

Construction and Operation Notification

7.5 This permit shall expire if construction has not begun within two years of its issue date, or if construction is suspended for one year.

[IDAPA 58.01.01.211.02]

7.6 The permittee shall furnish DEQ written notifications as follows:

- A notification of the date of initiation of construction, within five working days after occurrence; except in the case where pre-permit construction approval has been granted then notification shall be made within five working days after occurrence or within five working days after permit issuance whichever is later;
- A notification of the date of any suspension of construction, if such suspension lasts for one year or more; and

- A notification of the initial date of achieving the maximum production rate, within five working days after occurrence - production rate and date.

[IDAPA 58.01.01.211.01]

- A notification of the anticipated date of initial start-up of the stationary source or facility not more than sixty days or less than thirty days prior to such date; and
- A notification of the actual date of initial start-up of the stationary source or facility within fifteen days after such date.

[IDAPA 58.01.01.211.03]

Performance Testing

7.7 If performance testing (air emissions source test) is required by this permit, the permittee shall provide notice of intent to test to DEQ at least 15 days prior to the scheduled test date or shorter time period as approved by DEQ. DEQ may, at its option, have an observer present at any emissions tests conducted on a source. DEQ requests that such testing not be performed on weekends or state holidays.

7.8 All performance testing shall be conducted in accordance with the procedures in IDAPA 58.01.01.157. Without prior DEQ approval, any alternative testing is conducted solely at the permittee's risk. If the permittee fails to obtain prior written approval by DEQ for any testing deviations, DEQ may determine that the testing does not satisfy the testing requirements. Therefore, at least 30 days prior to conducting any performance test, the permittee is encouraged to submit a performance test protocol to DEQ for approval. The written protocol shall include a description of the test method(s) to be used, an explanation of any or unusual circumstances regarding the proposed test, and the proposed test schedule for conducting and reporting the test.

7.9 Within 60 days following the date in which a performance test required by this permit is concluded, the permittee shall submit to DEQ a performance test report. The report shall include a description of the process, identification of the test method(s) used, equipment used, all process operating data collected during the test period, and test results, as well as raw test data and associated documentation, including any approved test protocol.

[IDAPA 58.01.01.157]

Monitoring and Recordkeeping

7.10 The permittee shall maintain sufficient records to ensure compliance with all of the terms and conditions of this permit. Monitoring records shall include, but not be limited to, the following: (a) the date, place, and times of sampling or measurements; (b) the date analyses were performed; (c) the company or entity that performed the analyses; (d) the analytical techniques or methods used; (e) the results of such analyses; and (f) the operating conditions existing at the time of sampling or measurement. All monitoring records and support information shall be retained for a period of at least five years from the date of the monitoring sample, measurement, report, or application. Supporting information includes, but is not limited to, all calibration and maintenance records, all original strip-chart recordings for continuous monitoring instrumentation, and copies of all reports required by this permit. All records required to be maintained by this permit shall be made available in either hard copy or electronic format to DEQ representatives upon request.

[IDAPA 58.01.01.211]

Excess Emissions

7.11 The permittee shall comply with the procedures and requirements of IDAPA 58.01.01.130-136 for excess emissions. The provisions of IDAPA 58.01.01.130-136 shall govern in the event of conflicts between the excess emissions general provisions and the regulations of IDAPA 58.01.01.130-136.

During an excess emissions event, the permittee shall, with all practicable speed, initiate and complete appropriate and reasonable action to correct the conditions causing the excess emissions event; to reduce the frequency of occurrence of such events; to minimize the amount by which the emission standard is exceeded; and shall, as provided below or upon request of DEQ, submit a full report of such occurrence, including a statement of all known causes, and of the scheduling and nature of the actions to be taken.

[IDAPA 58.01.01.132]

7.12 In all cases where startup, shutdown, or scheduled maintenance of any equipment or emission unit is expected to result or results in an excess emissions event, the permittee shall demonstrate compliance with IDAPA 58.01.01.133.01(a) through (d), including, but not limited to, the following:

- Prohibiting any scheduled startup, shutdown, or maintenance resulting in excess emissions shall occur during any period in which an Atmospheric Stagnation Advisory or a Wood Stove Curtailment Advisory has been declared by DEQ.
- Notifying DEQ of the excess emissions event as soon as reasonably possible, but no later than two hours prior to, the start of the event, unless the permittee demonstrates to DEQ's satisfaction that a shorter advance notice was necessary.
- Reporting and recording the information required pursuant to the excess emissions reporting and recordkeeping requirements and IDAPA 58.01.01.135 and 136 for each excess emissions event due to startup, shutdown, or scheduled maintenance.

[IDAPA 58.01.01.133]

7.13 In all cases where upset or breakdown of equipment or an emissions unit, or the initiation of safety measures, results or may result in an excess emissions event, the permittee shall demonstrate compliance with IDAPA 58.01.01.134.01(a) and (b) and the following:

- Immediately undertake all appropriate measures to reduce and, to the extent possible, eliminate excess emissions resulting from the event and to minimize the impact of such excess emissions on the ambient air quality and public health.
- Notify DEQ of any upset, breakdown, or safety event that results in excess emissions. Such notification shall identify the time, specific location, equipment or emissions unit involved, and (to the extent known) the cause(s) of the occurrence. The notification shall be given as soon as reasonably possible, but no later than 24 hours after the event, unless the permittee demonstrates to DEQ's satisfaction that the longer reporting period was necessary.
- Report and record the information required pursuant to the excess emissions reporting and recordkeeping facility wide conditions and IDAPA 58.01.01.135 and 136 for each excess emissions event caused by an upset, breakdown, or safety measure.

- During any period of excess emissions caused by upset, breakdown, or operation under facility safety measures, DEQ may require the permittee to immediately reduce or cease operation of the equipment or emissions unit causing the period until such time as the condition causing the excess has been corrected or brought under control. Such action by DEQ shall be taken upon consideration of the factors listed in IDAPA 58.01.01.134.03 and after consultation with the permittee.

[IDAPA 58.01.01.134]

7.14 The permittee shall submit a written report to DEQ for each excess emissions event, no later than 15 days after the beginning of such an event. Each report shall contain the information specified in IDAPA 58.01.01.135.02.

[IDAPA 58.01.01.135]

7.15 The permittee shall maintain excess emissions records at the facility for the most recent five calendar-year period. The excess emissions records shall be made available to DEQ upon request and shall include the information requested by IDAPA 58.01.01.136.03(a) and (b) as summarized in the following:

- An excess emissions log book for each emissions unit or piece of equipment containing copies of all reports that have been submitted to DEQ pursuant to IDAPA 58.01.01.135 for the particular emissions unit or equipment; and
- Copies of all startup, shutdown, and scheduled maintenance procedures and upset, breakdown, or safety preventative maintenance plans that have been developed by the permittee in accordance with IDAPA 58.01.01.133 and 134, and facility records as necessary to demonstrate compliance with such procedures and plans.

[IDAPA 58.01.01.136]

Certification

7.16 All documents submitted to DEQ—including, but not limited to, records, monitoring data, supporting information, requests for confidential treatment, testing reports, or compliance certification—shall contain a certification by a responsible official. The certification shall state that, based on information and belief formed after reasonable inquiry, the statements and information in the document(s) are true, accurate, and complete.

[IDAPA 58.01.01.123]

False Statements

7.17 No person shall knowingly make any false statement, representation, or certification in any form, notice, or report required under this permit or any applicable rule or order in force pursuant thereto.

[IDAPA 58.01.01.125]

Tampering

7.18 No person shall knowingly render inaccurate any monitoring device or method required under this permit or any applicable rule or order in force pursuant thereto.

[IDAPA 58.01.01.126]

Transferability

7.19 This permit is transferable in accordance with procedures listed in IDAPA 58.01.01.209.06.

[IDAPA 58.01.01.209.06]

Severability

7.20 The provisions of this permit are severable, and if any provision of this permit to any circumstance is held invalid, the application of such provision to other circumstances, and the remainder of this permit, shall not be affected thereby.

[IDAPA 58.01.01.211]

Statement of Basis

Permit to Construct No. P-2019.0047
Project ID 62288

Perpetua Resources Idaho, Inc.
Stibnite, Idaho

Facility ID 085-00011

Final

June 17, 2022

Kelli Wetzel KW
Permit Writer

The purpose of this Statement of Basis is to satisfy the requirements of IDAPA 58.01.01.et seq, Rules for the Control of Air Pollution in Idaho, for issuing air permits.

ACRONYMS, UNITS, AND CHEMICAL NOMENCLATURE

AAC	acceptable ambient concentrations
AACC	acceptable ambient concentrations for carcinogens
acfm	actual cubic feet per minute
ANFO	ammonium nitrate/fuel oil
As	arsenic
ASTM	American Society for Testing and Materials
bkW	brake kilowatt
BT	Bradley Tailings
Btu	British thermal units
CAA	Clean Air Act
CAM	Compliance Assurance Monitoring
CAS No.	Chemical Abstracts Service registry number
Cd	cadmium
CEMS	continuous emission monitoring systems
cfm	cubic feet per minute
CFR	Code of Federal Regulations
CI	compression ignition
CMS	continuous monitoring systems
CO	carbon monoxide
CO_2	carbon dioxide
CO_2e	CO_2 equivalent emissions
COC	contaminants of concern
COMS	continuous opacity monitoring systems
DEQ	Department of Environmental Quality
DR	development rock
DRSF	development rock storage facilities
dscf	dry standard cubic feet
EF	emission factors
EIS	Environmental Impact Statement required by the National Environmental Policy Act
EL	screening emission levels
EPA	United States Environmental Protection Agency
FDCP	Fugitive Dust Control Plan
FDRSF	Fiddle Development Rock Storage Facility
Forest Service	United States Forest Service
GACT	Generally Available Control Technology
gpm	gallons per minute
gr	grains (1 lb = 7,000 grains)
H_2SO_4	Sulfuric Acid
HAP	hazardous air pollutants
HFDRSF	Hangar Flats Development Rock Storage Facility
HFP	Hangar Flats Pit
Hg	mercury
hp	horsepower
hr/yr	hours per consecutive 12-calendar-month period
HVAC	heating, ventilation, and air conditioning
ICE	internal combustion engines
IDAPA	a numbering designation for all administrative rules in Idaho promulgated in accordance with the Idaho Administrative Procedures Act
km	kilometers
lb/hr	pounds per hour
lb/qtr	pound per quarter

LMP	lime manufacturing plant
MACT	Maximum Achievable Control Technology
MMGU	Middle Marble Geologic Unit
PRI	Perpetua Resources Idaho, Inc.
MMBtu	million British thermal units

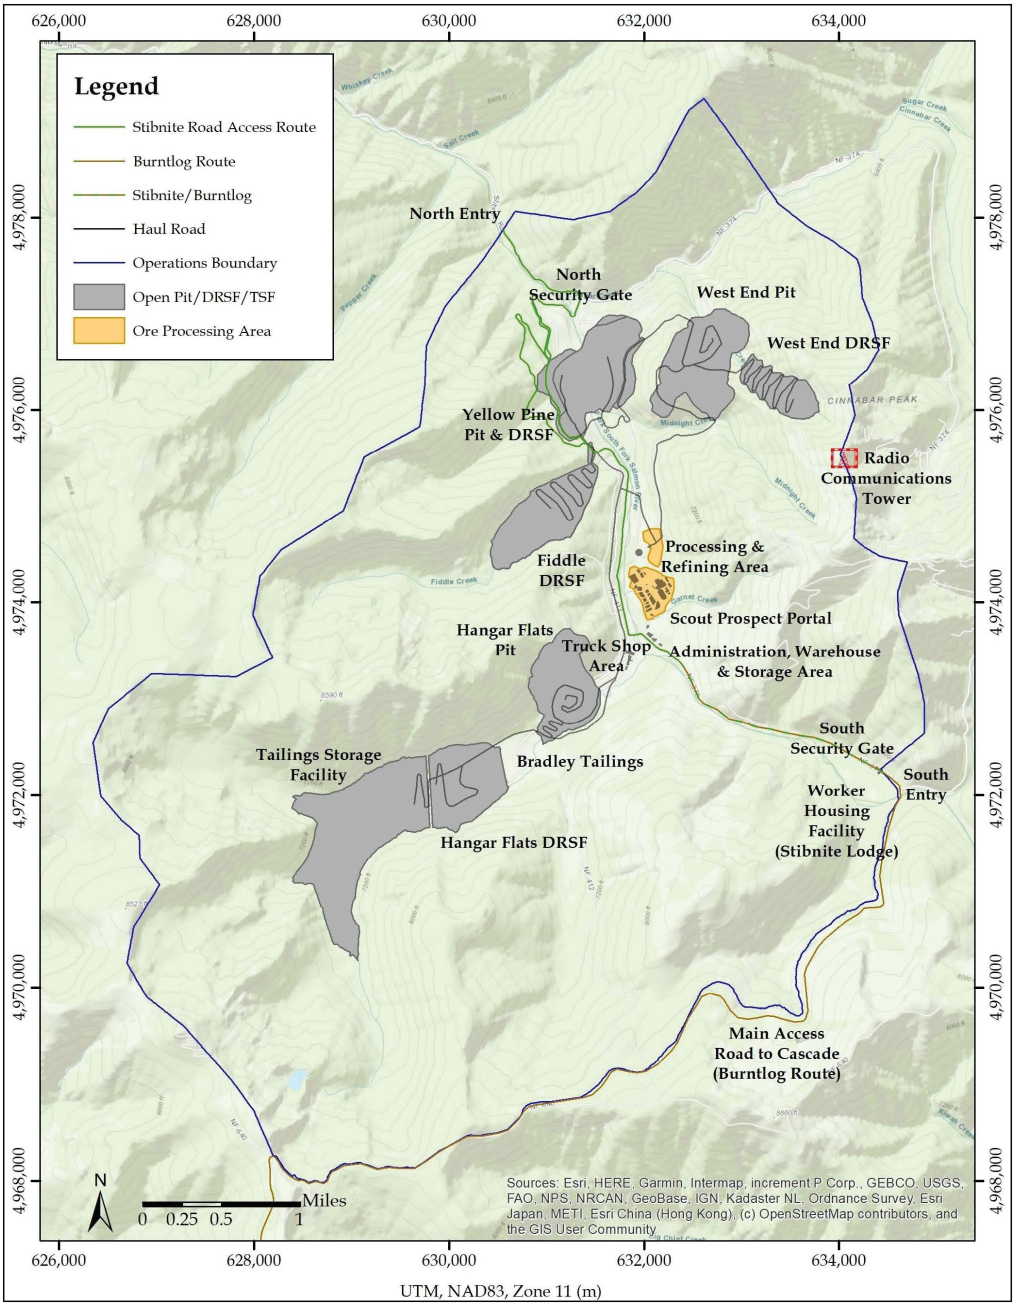
NSPS	New Source Performance Standards
NSR	New Source Review
O&M	operation and maintenance
O_2	oxygen
PAH	polycyclic aromatic hydrocarbons
Pb	lead
PM	particulate matter
$PM_{2.5}$	particulate matter with an aerodynamic diameter less than or equal to a nominal 2.5 micrometers
PM_{10}	particulate matter with an aerodynamic diameter less than or equal to a nominal 10 micrometers
POM	polycyclic organic matter
POX	pressure oxidation
ppm	parts per million
PSD	Prevention of Significant Deterioration
PTC	permit to construct
PTE	potential to emit
PW	process weight rate
RICE	reciprocating internal combustion engines
Rules	*Rules for the Control of Air Pollution in Idaho*
SAG	semi-autogenous grinding
Sb	antimony
scf	standard cubic feet
SCL	significant contribution limits
Se	selenium
SGP	Stibnite Gold Project
SIP	State Implementation Plan
SM	synthetic minor
SM80	synthetic minor facility with emissions greater than or equal to 80% of a major source threshold
SO_2	sulfur dioxide
STKP	crusher stockpile
Subsection 210.20	HAP TAP exemption for NSPS and NESHAP sources in IDAPA 58.01.01.210.20
T/day	tons per calendar day
T/hr	tons per hour
T/yr	tons per consecutive 12-calendar-month period
TAP	toxic air pollutants
ULSD	ultra-low sulfur diesel
U.S.C.	United States Code
VOC	volatile organic compounds
WEDRSF	West End Development Rock Storage Facility

WEP	West End pit
YPDRSF	Yellow Pine Development Rock Storage Facility
YPP	Yellow Pine Pit
$\mu g/m^3$	micrograms per cubic meter



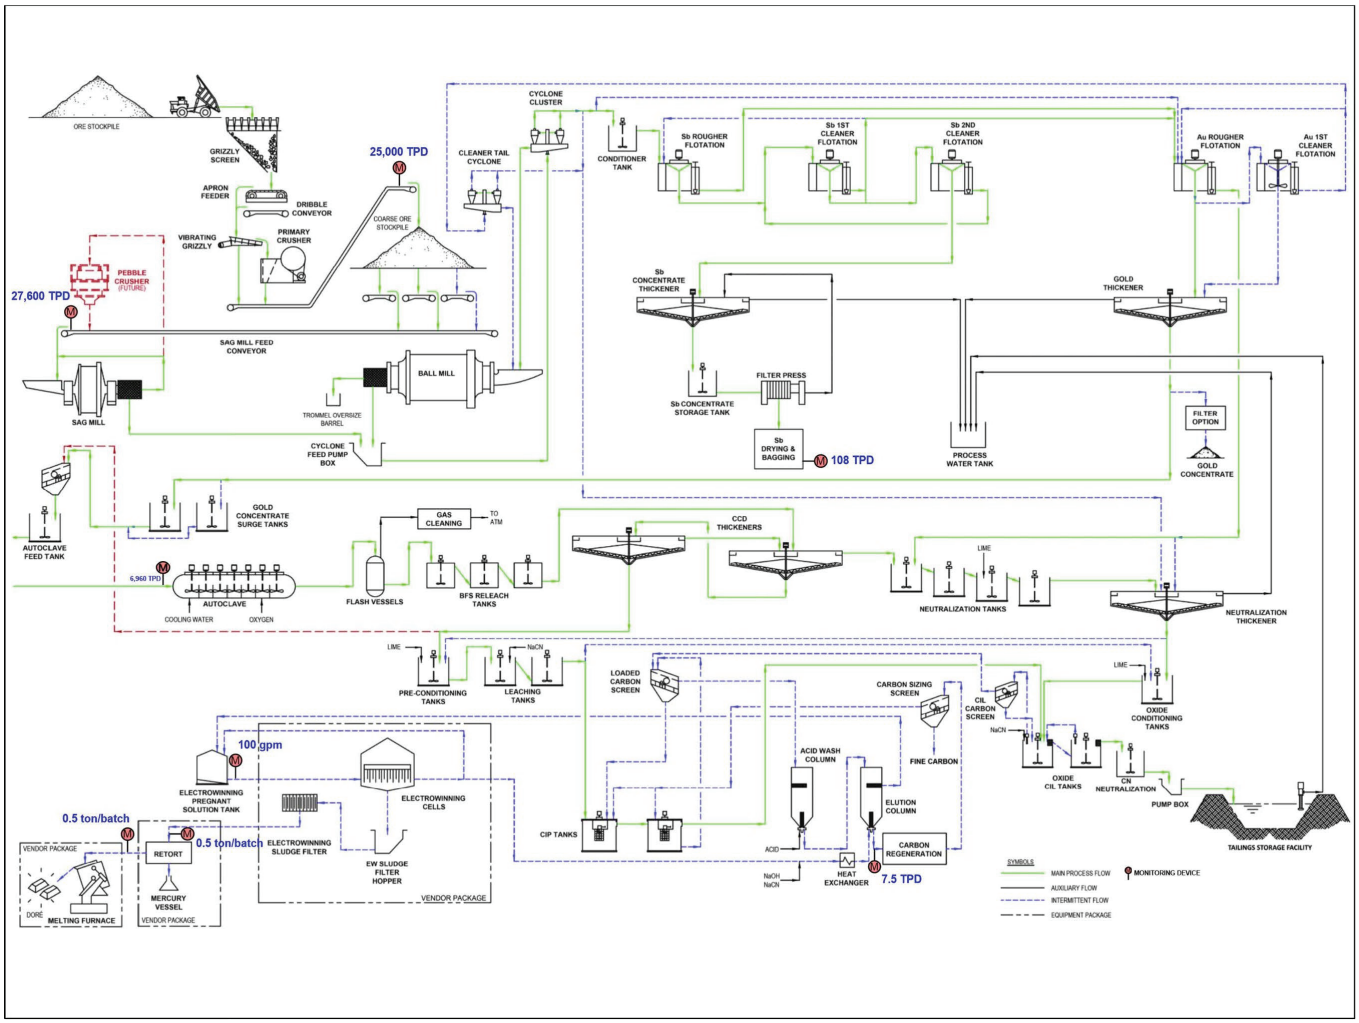
FACILITY INFORMATION

Description

Perpetua Resources Idaho, Inc. (PRI) proposes to construct and operate the Stibnite Gold Project (SGP), consisting of conventional open-pit mining, ore preparation, and gold extraction operations.

SGP is to be located in Valley County at the intersection Forest Service roads NF-374 and NF-412 (Stibnite Road), approximately 10 miles east of Yellow Pine. The proposed Burntlog Route access road will provide year-round access to the site. The project comprises a combination of public national forest and private lands. The mining operations boundary within which public access will be excluded is defined in Figure 1. This operations boundary also defines the ambient air boundary used in all ambient air quality impact analyses.

Figure 1 PROJECT AREA OF OPERATIONS



SGP will require the construction of significant infrastructure, including a power transmission line, a primary mine site access road, onsite haul roads, an ore processing facility, onsite workspaces, employee housing and recreation, water storage and distribution facilities, and sewage disposal facilities.

Conventional open-pit mining methods including drilling, blasting, excavating, and hauling will be used to extract ore and waste rock, termed development rock (DR). Hydraulic shovels and front-end loaders will be used to load ore and DR into haul trucks. DR will be used for construction, restoration, and backfilling, or hauled to the dedicated development rock storage facilities (DRSF). Approximately 340 million tons of DR will be handled over the life of the mine.

The SGP will include three years of pre-mining development and construction activities, followed by an operating mine life of approximately 12 years. Mining will occur in three open pits: Yellow Pine Pit (YPP), Hangar Flats pit (HFP), and West End pit (WEP). Although there will be overlap in mine development construction and operations, the general sequence of mining will be the YPP deposit, followed by the HFP and WEP deposits. Legacy tailings from the Meadow Creek valley (Bradley Tailings [BT]) will also be reclaimed and reprocessed during the initial project schedule. Surface exploration drilling will occur within the pits and within the Scout Prospect decline (underground exploration) throughout the mine operation period. Restoration and reclamation of other legacy mining features will occur prior to mining, throughout the life of the mine, and as part of the mine closure.

Figure 2 DIAGRAM OF PROCESS FLOWS

Ore will be hauled to the primary crusher area, where it will be fed directly into the crusher dump pocket or stockpiled. The ore crushing plant will be designed to operate at a maximum rate of 25,000 tons per calendar day (T/day). Approximately 100 million tons of ore will be mined from the three pits over the life of the project. The metal-recovery process from ore will include conventional crushing and grinding, followed by froth-flotation circuits that will generate separate gold-silver and antimony-silver concentrates. The antimony-silver concentrate will be shipped offsite for refining, whereas additional onsite processing of the gold-silver concentrate will include pressure oxidation, carbon-in-leach circuits, and refining processes to recover gold and minor amounts of silver. The finely ground leftover ore material from the mineral-recovery process, termed tailings, will be neutralized, thickened, and transported via a pipeline to the tailings storage facility. A diagram of ore processing and ore concentration and refining process flows is provided in Figure 2.

Permitting History

This is the initial PTC for a new facility, thus there is no permitting history.

Application Scope

This permit is the initial PTC for this facility.

The applicant has proposed to conduct mining operations and to install and operate ore processing, ore concentration and refining, and ancillary equipment:

- Drilling, blasting, excavating, hauling operations, rock dumps and storage piles, and prill silos;
- Ore processing operations (OC1–OC13);
- Ore concentration and refining operations (AC, EW, MR, MF, CKD);
- Process heating (ACB, CKB, PV, HS, LKC);
- Lime production operations (LS1–LS12, LSBM, LS-L/U, LK, LCR, LS1-L/U, MillS2-L/U, ACS1–ACS4);
- Aggregate production operations (PCSP1, PCSP2);
- Concrete production operations (CM; CS1–CS2-L/U, CA-L/U);
- Heating, Ventilation, and Air Conditioning heaters (H1M–H2M, HM, HAC, HR, HA, HMO, HTS, HW);
- Emergency generator engines (EDG1–EDG3, EDFP); and
- Fuel storage (TG1–TG2, TD3—TD10).

Application Chronology

August 20, 2019	DEQ received an application and an application fee.
August 29 – September 13, 2019	DEQ provided an opportunity to request a public comment period on the application and proposed permitting action.
September 19, 2019	DEQ determined that the application was incomplete.
October 4, 2019	DEQ received a preliminary response and supplemental information from the applicant, including a request to delegate authority of responsible official.
October 9, 2019	DEQ approved the request to delegate authority of responsible official.
October 15, 2019	DEQ met with the applicant to review and discuss the preliminary response.
October 22, 2019	DEQ determined that the application remained incomplete while the applicant prepared a response to the remaining items previously identified (9/19/19), and included a summary of recommendations provided at the meeting (10/15/19).
November 8, 2019	DEQ requested additional information from the applicant via email, relating to items previously identified (9/19/19).
November 21, 2019	DEQ received a request from the applicant for extension until November 27, 2019 to respond.
November 27, 2019	DEQ received supplemental information from the applicant, including a revised application with updated emissions inventories and modeling analyses.
December 24, 2019	DEQ determined that the application was incomplete.
January 8, 2020	DEQ received a request from the applicant for extension until February 7, 2020 to respond.
January 31, 2020	DEQ requested additional information from the applicant via email, relating to items previously identified (12/24/19).
February 5, 2020	DEQ received supplemental information from the applicant, including a revised application with updated emissions inventories and modeling analyses.
March 6, 2020	DEQ determined that the application was incomplete.
April 2, 2020	DEQ received a request from the applicant for extension until April 15, 2020 to respond.
April 15, 2020	DEQ received supplemental information from the applicant, including updated modeling analyses.
May 15, 2020	DEQ determined that the application was complete.
June 24, 2020	DEQ received the final application including all updates.
July 6, 2020	DEQ made available the draft permit and statement of basis for peer and regional office review.
July 14, 2020	DEQ made available the draft permit and statement of basis for applicant review.
July 31, 2020	DEQ made available an updated draft statement of basis Appendix B for applicant review.

August 3 and 13, 2020	DEQ received comments from the applicant on the draft permit and statement of basis.
August 20, 2020	DEQ received the permit processing fee.
September 10 – October 12, 2020	DEQ provided a public comment period on the proposed action.
October 12, 2020	DEQ received substantive comments and a request to extend the public comment period.
October 13 – November 11, 2020	DEQ extended the public comment period on the proposed action.
October 27, 2020	DEQ provided an information meeting during the extended public comment period.
November 11, 2020	DEQ received substantive comments during the extended comment period.
November 20, 2020	DEQ requested additional information from the applicant to address substantive public comments received, including missing TAP and HAP emission estimates.
November 25 and December 11, 2020	DEQ extended the time required to respond to public comments received until February 22, 2021 to allow additional time for the applicant and DEQ to respond to substantive public comments.
December 17, 2020	DEQ received a response to the request for additional information from the applicant.[1]
December 18 and 21, 2020	DEQ received supplemental information from the applicant, including a response and HAP/TAP addendum to the application,[2] updated HAP and TAP emissions estimates,[3] updated TAP modeling analyses,[4] and supporting references.[5]
January 28, 2021	DEQ received updated modeling files with corrections for formaldehyde and sulfuric acid, and an updated figure showing TAP modeled impacts.
February 8, 2021	DEQ made available the draft permit, statement of basis, and response to comments for peer and regional office review.
February 18 – March 19, 2021	DEQ provided a public comment period on the proposed action as updated to address the HAP and TAP addendum and updates.
February 23, 2021	DEQ received notification from the applicant of a facility name change from Midas Gold Idaho, Inc. to Perpetua Resources Idaho, Inc.
March 3, 2021	DEQ provided an information meeting during the public comment period.
March 4, 18, and 19, 2021	DEQ received comments during the extended comment period.
April 5, 2021	DEQ received substantive comments during the extended comment period.

April 6, 2021	DEQ extended the time required to respond to public comments received until June 4, 2021 to allow additional time for the applicant and DEQ to respond to substantive public comments.
April 6, 2021	DEQ requested additional information from the applicant to address Prevention of Significant Deterioration (PSD) emissions estimates and regulatory applicability for the lime manufacturing plant.
April 16, 2021	DEQ received a response to the request for additional information from the applicant, including identification of emission sources comprising the lime manufacturing plant.[6]
September 14, 2021	DEQ received an updated TAP modeling protocol addendum from the applicant.[7]
September 23, 2021	DEQ received supplemental information from the applicant regarding the lime plant source status determination.[8]
October 6, 2021	DEQ received an updated TAP/HAP addendum including an updated emission inventory and modeling files.[9]
December 9, 2021	DEQ made available the draft permit and statement of basis for applicant review.
January 13, 2022 – March 16, 2022	DEQ provided a public comment period with a 30 day extension on the proposed permit to address the TAP/HAP addendum and updates.
June 17, 2022	DEQ issued the final permit, first, second, and third responses to comments, and statement of basis.

TECHNICAL ANALYSIS

Emissions Units and Control Equipment

Table 1 lists all sources of regulated emissions.

Table 1 EMISSIONS UNIT AND CONTROL EQUIPMENT INFORMATION

Source ID No.	Source	Control Equipment	Maximum Process Rate
Mining			
	Drilling activities	Reasonable control and Fugitive Dust Control Plan (FDCP) Dust collection systems on drilling rigs Control efficiency: 90%	1,200 holes/day
	Blasting activities	Reasonable control & FDCP	2 blasts/day
	Excavating and hauling activities	Reasonable control & FDCP – Chemical suppression and water sprays Control efficiency: 93.3% for PM/PM_{10} (haul roads) Haul road capping with low-arsenic quartzite	180,000 T/day 135,000 T/day 5-year rolling average 788.4 MT of ore and rock from all deposits 394.2MT of ore and rock from the West End deposit
	Rock dumps and storage piles	Reasonable control & FDCP	n/a
PS1–2-L/U	(2) Prill Silos #1-2 Maximum capacity: 100 T (each)	Loading – None Unloading – None	200 T/day and 9,000 T/yr (combined)
Ore Processing			
OC1	Loader Transfer of Ore to Grizzly	Reasonable control & FDCP – Water sprays and moisture carryover	25,000 T/day
OC2	Grizzly to Apron Feeder		
OC3	Conveyor – Apron Feeder to Dribble		
OC4	Conveyor – Apron Feeder to Grizzly		
OC5	Conveyor – Dribble to Grizzly		
OC6	Grizzly to Primary Crusher or Coarse Ore Stockpile Feed		
OC7	Primary Crusher	Reasonable control & FDCP – Water sprays and moisture carryover	
OC8	Conveyor – Coarse Ore Stockpile Feed Transfer to Stockpile		
OC9	Stockpile Transfer to Reclaim Conveyors	Reasonable control & FDCP – Below-grade of storage piles Control efficiency: 80% for PM/PM_{10}	27,600 T/day
OC10	Conveyor – Reclaim Conveyors to SAG Mill Feed Conveyor		
OC11	Conveyor – SAG Mill Feed Transfer to SAG Mill	Reasonable control & FDCP – Enclosure Control efficiency: 80% for PM/PM_{10}	
OC12	Pebble Crusher	Reasonable control & FDCP – Water sprays and moisture carryover	
OC13	Pebble Discharge to SAG Mill Feed		
Ore Concentration and Refining			
CN Tanks	Cyanide Leach Tanks and Cyanide Detox Tanks	Chemical treatment (lime, caustic soda, hydrogen peroxide, copper sulfate, etc.)	1.99 T/yr of CN (facility-wide)
Float Tanks	Floatation Tanks	None	1,700 T/yr PAX

Table 1 EMISSIONS UNIT AND CONTROL EQUIPMENT INFORMATION

Source ID No.	Source	Control Equipment	Maximum Process Rate
AC	Autoclave (AC)	Venturi Scrubber (VS1) Vent Gas Cleaning Tower (ST1) Vent Gas Steam Condensation Tower (CT1) Carbon Filter (CA5) Type: sulfur-impregnated activated carbon Form: granulated	6,960 T/day
EW	Electrowinning Cells and Pregnant Solution Tank	Shared Carbon Filter (CA2) Type: sulfur-impregnated activated carbon Form: granulated	100 gpm
MR	Mercury Retort	Condenser Carbon Filter (CA3) Type: sulfur-impregnated activated carbon Form: granulated	1,000 lb/batch and 21 T/yr
MF	Induction Melting Furnace	Baghouse (BH2) Carbon Filter (CA4) Type: sulfur-impregnated activated carbon Form: granulated	
CKD	Carbon Regeneration Kiln (Drum)	Wet Scrubber (WS2) Carbon Filter (CA1) Type: sulfur-impregnated activated carbon Form: granulated	7.2 T/day
Tailings and Maintenance Pond activities		Chemical treatment, reasonable control & FDCP	1.99 T/yr of CN (facility-wide)
Process Heating			
ACB	POX Boiler (for AC) Maximum capacity: 17 MMBtu/hr Fuel: propane	None	operation is limited to AC startup only
HS	Strip Circuit Solution Heater Maximum capacity: 5 MMBtu/hr Fuel: propane	None	n/a
CKB	Carbon Regeneration Kiln Burners Maximum capacity: 2.255 MMBtu/hr Fuel: propane	None	n/a
PV	Propane Vaporizer Maximum capacity: 0.1 MMBtu/hr Fuel: propane	None	n/a
LKC	PFR Shaft Lime Kiln Combustion Maximum capacity: 22.0 MMBtu/hr Fuel: propane	None	n/a

HR	Refinery HVAC Heater Maximum capacity: 0.25 MMBtu/hr Fuel: propane	None	n/a
HA	Admin HVAC Heater Maximum capacity: 0.25 MMBtu/hr Fuel: propane	None	n/a
HMO	(2) Mine Ops. HVAC Heaters Maximum capacity: 0.25 MMBtu/hr (each) Fuel: propane	None	n/a
HTS	(2) Truck Shop HVAC Heaters Maximum capacity: 1.0 MMBtu/hr (each) Fuel: propane	None	n/a
HW	(3) Warehouse HVAC Heaters Maximum capacity: 1.0 MMBtu/hr (each) Fuel: propane	None	n/a

Table 1 EMISSIONS UNIT AND CONTROL EQUIPMENT INFORMATION

Source ID No.	Source	Control Equipment	Maximum Process Rate
Emergency Power Generation and Fire Suppression			
EDG1	Camp Emergency Generator Date of construction: 2007 or later Maximum capacity: 1,000 bkW Maximum operation: 100 hr/yr (non-emergency) Fuel: ultra-low sulfur diesel (ULSD) Displacement: <10 L/cyl	EPA Tier 2 certified	1 hr/day and 100 hr/yr
EDG2	Plant Emergency Generator #1 Date of construction: 2007 or later Maximum capacity: 1,000 bkW Maximum operation: 100 hr/yr (non-emergency) Fuel: ULSD Displacement: <10 L/cyl	EPA Tier 2 certified	1 hr/day and 100 hr/yr
EDG3	Plant Emergency Generator #2 Date of construction: 2007 or later Maximum capacity: 1,000 bkW Maximum operation: 100 hr/yr (non-emergency) Fuel: ULSD Displacement: <10 L/cyl	EPA Tier 2 certified	1 hr/day and 100 hr/yr
EDFP	Mill Fire Pump Date of construction: 2009 or later Maximum capacity: 200 bkW Maximum operation: 100 hr/yr (non-emergency) Fuel: ULSD Displacement: <10 L/cyl	None	1 hr/day and 100 hr/yr
Fuel Storage			
TG1–TG2	Mine Site Gasoline Tanks (#1 through #2) Maximum capacity: 5,000 gal each	Lids or other appropriate closure with gasketed seal and submerged filling	<100,000 gal/mo
TD3–TD10	Mine Site Diesel Tanks (#3 through #10)	Lids or other appropriate closure	n/a

Emissions Inventories

Potential to Emit

IDAPA 58.01.01 defines Potential to Emit (PTE) as the maximum capacity of a facility or stationary source to emit an air pollutant under its physical and operational design. Any physical or operational limitation on the capacity of the facility or source to emit an air pollutant, including air pollution control equipment and restrictions on hours of operation or on the type or amount of material combusted, stored or processed, shall be treated as part of its design if the limitation or the effect it would have on emissions is state or federally enforceable. Secondary emissions did not count in determining the PTE of a facility or stationary source.

Using this definition of PTE, an emissions inventory was developed for the SGP (see Appendix A). Emissions estimates of criteria pollutant and hazardous air pollutant (HAP) PTE were based on project-specific activity rates (e.g., continuous operation with the exception of the POX Boiler and emergency generator engines, design production rates, material haul rates, blasting agent usage rates, reagent usage rates, etc.), process design (e.g., open-pit mining, process concentration and pH, parallel flow regenerative lime production, central mix concrete production, haul fleet, etc.), emission abatement techniques (e.g., dust suppressant, chemical treatment, carbon filter, baghouse, bin vent filtration, wet scrubber, venturi scrubber, vent gas cleaning tower, and vent gas steam condensation tower control equipment), material characteristics (e.g., moisture content, road silt content, haul route distances, etc.), site conditions (onsite meteorological data, precipitation, etc.), and emission factors based on AP-42,[10] representative source test emissions data, and representative emission limits. Estimated emissions from the autoclave and the carbon regeneration kiln relied on emissions data from representative source test emissions data, scaled to the proposed equipment capacity. Estimated emissions from fuel storage tanks relied on TANKS[11] emission estimation software and projected annual gasoline and ULSD usage rates. Estimated emissions from the emergency generator engines relied on the use of certified engine emission factors.

Uncontrolled PTE

Using the definition of PTE, uncontrolled PTE is then defined as the maximum capacity of a facility or stationary source to emit an air pollutant under its physical and operational design. Any physical or operational limitation on the capacity of the facility or source to emit an air pollutant, including air pollution control equipment and restrictions on hours of operation or on the type or amount of material combusted, stored or processed, shall **not** be treated as part of its design **since** the limitation or the effect it would have on emissions **is not** state or federally enforceable.

The uncontrolled PTE is used to determine if a facility is a "synthetic minor" source of emissions. Synthetic minor sources are facilities that have an uncontrolled PTE for regulated air pollutants or HAP above an applicable major source threshold without permit limits.

For PRI, uncontrolled PTE was based upon a worst-case for operation of the facility of continuous operation at proposed maximum material throughput and fuel input rates (Table 1), without consideration of control equipment. For batch operations, the number of operations necessary to achieve the proposed daily throughput rates was assumed in estimating emissions (MR, MF). Silo loading and unloading operations were assumed to occur at most once per day (LS1-L/U, MillS2-L/U, LS-L/U, PS-L/U, ACS1–ACS4-L/U, CS1–CS2-L/U, CA-L/U). Fuel storage was based on estimated facility-wide fuel usage rates (TG1, TG2 and TD3—TD10). For the purposes of maintenance and testing, emergency power generation operations were assumed to occur 1 hour per day and 100 hours per year (EDG1–EDG3, EDFP). With the exception of the POX Boiler in which operation is limited to AC startup only, continuous operation at maximum fuel input rates was assumed for all process heating and HVAC equipment.

Total	**560**	**337**	**164**	**29.47**	**36.16**	**4.68**	**6.27**

Although not explicitly calculated, it was confirmed by PRI in the response to a request for additional information[1] that the uncontrolled HAP PTE for SGP is estimated to exceed 25 tons per year (T/yr) without application of the specified control equipment (Table 1). Arsenic HAP PTE from haul roads at a controlled emission rate of 0.464 pounds per hour (lb/hr) and accounting for 93.3% control efficiency exceeds 20 T/yr, supporting that uncontrolled HAP PTE exceeds 10 T/yr of single HAP and 25 T/yr of total HAP.

Pre-Project PTE

Pre-project PTE is used to establish the change in emissions at a facility as a result of this project. Because this is a new facility, pre-project emissions are set to zero for all criteria pollutants.

Post-Project PTE

Post-project PTE is used in determining the change in emissions at a facility and in determining the facility's classification as a result of this project. Post-project PTE includes all permit limits resulting from this project.

In addition to assuming continuous operation of the facility at the proposed material throughput and fuel input rates, post-project emissions estimates account for the use of dust suppressant, chemical treatment, carbon filter, baghouse, bin vent filtration, wet scrubber, venturi scrubber, vent gas cleaning tower, and vent gas steam condensation tower control equipment.

A variety of factors impact emissions from unpaved roadways, and it was recognized that accurate determination of site-specific parameters characterizing road conditions and vehicle traffic was critical to estimating particulate matter emissions and ambient air impacts. PRI provided site-specific information to support parameters such as silt content, mean vehicle weight, and dust suppressant control efficiencies, and provided an analysis evaluating the conservatism of the resulting emission factor (AP-42).[12] To ensure operation consistent with these parameters and to reasonably control fugitive emissions, compliance with requirements identified in the FDCP is required by

[12] Appendix A – Model Parameter / Assumption / Data Level of Conservatism IDEQ Forms to the Stibnite Gold Project Permit to Construct Application, PRI, revised June 23, 2020 (2020AAG1078).

the permit. Further discussion of the sensitivity of predicted air quality impacts is provided in the Ambient Air Quality Impact Analyses section.

The following table presents the post-project PTE for criteria pollutants from all emissions units at the facility as determined by DEQ staff. Because this is a new facility, the post-project PTE is equivalent to the facility-wide PTE. Refer to Appendix A for a summary of the calculations and the assumptions used to determine emissions from each source, and the Facility Classification section for a review of facility classifications based on uncontrolled and controlled PTE.

a) Controlled average emission rate in tons per year is an annual average, based on the proposed annual operating scenarios and annual limits.

b) Estimated emissions from the "W3" scenario resulted in the most emissions across most activities, with the exception of material load/unload and wind erosion activities, which occurred in the Y1, H1, W1, and B1 scenarios. Totals reported are for the "W3" scenario.

c) In the response to a request for additional information, PRI confirmed that antimony process dryer and bagging operation emission sources (Sb1 and Sb2) initially proposed would be replaced by a dewatering/packaging circuit. As a result, these emission sources have been removed from the permit and post-project PTE.

Fourteen operational scenarios were evaluated by the applicant and verified by DEQ in order to estimate maximum hourly, daily, and annual potential emissions from sources. These scenarios encompassed all feasible origin and destination location combinations for locating ore and development rock. A summary of these scenarios is provided in Table 4. Although drilling, blasting, excavating, and hauling activities are not expected to be confined to a single scenario in practice, emissions in each scenario were conservatively estimated at the maximum daily proposed processing rate (180,000 of ore and rock) to allow for maximum operational flexibility, and to evaluate potential air quality impacts. Scenarios having the greatest potential emissions (i.e., the top seven) were those with the longest origin-to-destination distances, which resulted in increased emissions evident in onsite hauling and material loading and unloading activities. Consequently, the W3 scenario having the maximum origin-to-destination distance (16,415 daily vehicle miles traveled) is representative of maximum potential emissions.

Table 4 OPERATING SCENARIOS

Scenario	Origin [a]	Destination [a]
Y1	YPP	STKP
Y2	YPP	FDRSF
Y3	YPP	HFDRSF
H1	HFP	STKP
H2	HFP	FDRSF
H3	HFP	HFDRSF
H4	HFP	YPDRSF
W1	WEP	STKP
W2	WEP	FDRSF
W3	WEP	HFDRSF
W4	WEP	YPDRSF
W5	WEP	WEDRSF
B1	BT	STKP
B2	BT	HFDRSF

a) Where ore and rock origin and destination locations as depicted in Figure 1 are abbreviated as follows:
YPP = Yellow Pine Pit, HFP = Hangar Flats pit, WEP = West End pit, BT = Bradley Tailings, STKP = Primary Crusher Stockpile, FDRSF = Fiddle DRSF, HFDRSF = Hangar Flats DRSF, YPDRSF = Yellow Pine DRSF, WEDRSF = West End DRSF, and DRSF = development rock storage facilities.

There are numerous sources of fugitive dust emissions at the facility, including drilling and blasting activities, crushing and ore handling equipment, ore and rock storage piles, and unpaved roadways. Calculated at maximum daily processing rates, emissions from these sources would tend to be conservatively estimated. But it is also recognized that uncertainties exist in some of the emission factors used, and that predicted modeled impacts may be sensitive to emissions from such sources. In particular, it may prove challenging to consistently and continuously achieve the targeted level of fugitive dust control for emissions from traffic on unpaved roadways, with over 55 miles of haul truck routes within the mining operations boundary, a fleet of 32 haul trucks weighing between 37 and 357 tons, and a targeted dust control efficiency of 93.3% accomplished by application of both dust suppressant and water controls. Based on this, and the scale of operations, a detailed Fugitive Dust Control Plan (FDCP) was required (Permit Conditions 2.6). It is noted that PRI projected actual annual production at approximately 42.7 million T/yr, or 65% of the permitted annual production limit of 65.7 million T/yr (Permit Condition 3.5), and that as a result actual emissions are expected to be lower than presented.

Change in PTE

The change in facility-wide PTE is used to determine if a public comment period may be required and to determine the processing fee per IDAPA 58.01.01.225. The following table presents the facility-wide change in the potential to emit for criteria pollutants, which for a new source is equivalent to the facility-wide and post-project PTE.

Table 5 CHANGES IN PTE FOR REGULATED AIR POLLUTANTS

Source	PM	PM_{10}	$PM_{2.5}$	CO	NO_x	VOC	SO_2
	T/yr [(a)]	T/yr [(a)]	T/yr [(a)]	T/yr [(a)]	T/yr [(a)]	T/yr [(a)]	T/yr [(a)]

Post-Project PTE	86.6	55.7	35.8	29.5	36.2	4.7	6.3
Changes in Potential to Emit	**86.6**	**55.7**	**35.8**	**29.5**	**36.2**	**4.70**	**6.30**

a) Controlled average emission rate in tons per year is an annual average, based on the proposed annual operating scenarios and annual limits.

Controlled Hazardous and Toxic Air Pollutant Emissions

A summary of the estimated PTE for hazardous air pollutants (HAP) and emissions increases (PTE) for non-carcinogenic and carcinogenic toxic air pollutants (TAP) and for potential is provided in the following table (Table 6). This table and the Ambient Air Quality Impact Analyses were updated to include new and updated TAP emission estimates from additional emission sources identified in public comments and in a response and HAP/TAP addendum to the application provided by PRI.[2,3]

All permitted fugitive and point emission sources were evaluated in the new HAP and TAP emission estimates. In Table 6 below, HAP and TAP PTE emissions estimates are for the highest emissions year Scenario "W3" referenced from Table B1-W3 of Appendix B to the HAP/TAP addendum and 'TblB1' worksheet in the supporting spreadsheet. Process and production activities include ore processing; ore concentration and refining; process heating; aggregate production; concrete production; heating, ventilation, and air conditioning (HVAC); emergency power generation and fire suppression; and fuel storage. Mining and leaching activities include drilling, blasting, excavating, hauling, prill silos, rock dumps and storage piles, and tailings. Metal HAP and TAP emissions from process materials were based on metal concentration profiles from onsite core samples of ore and limestone materials, including 98 samples of SGP limestone[13] and over 55,000 samples of SGP ore.[14,15] As a conservative assumption, the limestone profile was also used for emissions from aggregate materials. Mercury emissions from the LK were estimated by assuming all mercury in the limestone feed is volatilized and emitted. For each non-mercury metal HAP and TAP, emissions from the LK were calculated as PM emissions multiplied by the median metal concentration measured. Elemental analysis of core samples was complemented with an evaluation of whether each result represented a regulated HAP and/or TAP substance (element or compound) in Table 2 of the HAP/TAP addendum.[2]

TAP also classified as HAP emitted from sources addressed by New Source Performance Standards (NSPS) or National Emission Standards for Hazardous Air Pollutants (NESHAP) were not required to be evaluated for compliance with TAP increments in accordance with IDAPA 58.01.01.210.20 (Subsection 210.20). Guidance and clarification of Subsection 210.20 source exemptions were included in the Subsection 210.20 (IDAPA 58.01.01.210.20) section and in the response to public comments document that is part of the final permit package for this permitting action. Some of the screening levels for non-carcinogenic and carcinogenic TAP were exceeded as a result of this project and required modeling. Modeling was required for aluminum, barium, calcium carbonate, calcium oxide, cyanide, iron, manganese, phosphorus, sulfuric acid, thallium, and vanadium because the 24-hour average non-carcinogenic screening emission levels (EL) in IDAPA 58.01.01.585 were exceeded. Modeling was required for arsenic, beryllium, cadmium, formaldehyde, and nickel because the annual average carcinogenic EL in IDAPA 58.01.01.586 were exceeded. Refer to the Ambient Air Quality Impact Analyses section and Appendix B for additional discussion.

Zinc [i]	0.029	0.125	2.2E-03	8.8E-03	0.031	0.134	0.031	0.667

a) HAP and TAP PTE emissions estimates are for the highest emissions year Scenario W3, referenced from Table B1-W3 of Appendix B to the HAP/TAP addendum and 'TblB1' worksheet in the supporting spreadsheet. Process and production activities include ore processing; ore concentration and refining; process heating; aggregate production; concrete production; heating, ventilation, and air conditioning (HVAC); emergency power generation and fire suppression; and fuel storage. Mining and leaching activities include drilling, blasting, excavating, hauling, prill silos, rock dumps and storage piles, and tailings.

b) Controlled average emissions rates in pounds per hour (lb/hr). Emissions rates for non-carcinogens are daily averages, based on the proposed daily operating scenarios and limits. Emissions rates for carcinogens are annual averages, based on the proposed annual operating scenarios and limits.

c) Controlled average emissions rates in tons per year (T/yr) are annual averages, based on the proposed annual operating scenarios and annual limits.

d) Adjusted TAP emissions and screening emission levels (EL) as specified in IDAPA 58.01.01.585-586 for purposes of TAP preconstruction compliance demonstrations. For TAP, adjusted emissions do not include sources addressed by NSPS and NESHAP in accordance with IDAPA 58.01.01.210.20 Table 9.

e) Carcinogenic TAP as identified in IDAPA 58.01.01.586.

f) Polycyclic aromatic hydrocarbon (PAH). The group of seven PAH with a single EL are regulated as polycyclic organic matter (POM) equivalent in potency to benzo(a)pyrene as specified in IDAPA 58.01.01.586.

g) Adjusted mercury emissions (which are not TAP) are reported in pounds per year (lb/yr) and do not include fugitive sources and sources addressed by NESHAP 40 CFR 63 for comparison to the Mercury Emission Standard threshold of 25 lb/yr. Facility-wide mercury PTE emission rates were calculated as annual average based on federally-enforceable NESHAP Subpart EEEEEEE limits, and exceed values referenced from Table B1-W3 of Appendix B to the HAP/TAP addendum and 'TblB1' worksheet in the supporting spreadsheet (which account for the proposed mercury control devices for refinery process sources AC, EW, MR, MF, CKD).

h) Total hazardous air pollutant (HAP) emissions from all permitted sources and activities (combined). The maximum potential emissions of any single HAP is hydrogen chloride.

i) Toxic air pollutant that is not also a hazardous air pollutant (i.e., non-HAP TAP) and is not included in HAP totals.

j) Dichlorobenzene is regulated as both the ortho- and para- isomers (o-dichlorobenzene and 1,4-dichlorobenzene). For the purposes of TAP compliance, the lowest EL (and therefore most conservative) is listed.

HAP and TAP particulate metals are indirectly regulated via facility-wide fugitive dust requirements for particulate matter (PM) (Permit Conditions 2.1–2.8, 3.10, 5.10), material throughput and operational limits (Permit Conditions 3.3–3.9, 4.6–4.12, 5.4–5.9, 6.2-6.3, 6.5), PM emission limits (Permit Conditions 4.3, 5.3), control device requirements (Permit Conditions 3.11–3.13, 4.13–4.17, 5.12–5.16), and associated testing, monitoring, recordkeeping, and reporting requirements. Because usage of process reagents were not correlated to material throughput rates and not otherwise inherently limited, HAP emissions limits and usage limits were established for potassium amyl xanthate (PAX) and sodium cyanide (Permit Conditions 4.4–4.6). Cyanide emissions were sensitive to leachant concentration and basicity, and monitoring of these parameters was established (Permit Condition 4.5) to ensure compliance with the emission limit. Monitoring of these limits and process parameters also ensure compliance with the major threshold for each individual HAP of 10 tons per year (T/yr).

Ambient Air Quality Impact Analyses

The applicant has demonstrated preconstruction compliance to DEQ's satisfaction that emissions from this facility will not cause nor significantly contribute to a violation of any ambient air quality standard. The applicant has also demonstrated preconstruction compliance to DEQ's satisfaction that the emissions increase due to this permitting action will not exceed any acceptable ambient concentration (AAC) or acceptable ambient concentration for carcinogens (AACC) for toxic air pollutants (TAP). A summary of the Ambient Air Impact Analysis for TAP is provided in Appendix B.

As presented in the modeling memorandum in Appendix B, the estimated emission rates of PM_{10}, $PM_{2.5}$, SO_2, CO, NO_x, and certain TAP from this project exceeded applicable screening emission levels (EL) and published DEQ modeling thresholds established in IDAPA 58.01.01.585-586 and in the State of Idaho Air Quality Modeling Guideline.[16] The facility-wide emission rate of lead (Pb) was determined to be below the "below regulatory concern" (BRC) threshold level of less than 10% of the "significant" emission rate defined in IDAPA 58.01.01.006 (i.e., less than 0.06 T/yr) and therefore modeling was not required.[16] Refer to the Emissions Inventories section for additional information concerning the emissions inventories.

New and updated TAP increment compliance demonstrations[4] were provided after evaluation of fugitive particulate TAP emissions from emission sources (Table 6) as identified in public comments and in a response and HAP/TAP addendum to the application provided by PRI.[2] For non-HAP TAP, all sources were evaluated for TAP compliance by comparison of facility-wide emissions to applicable screening emission levels (EL). After exclusion of sources addressed by NSPS and NESHAP (Table 9), applicable concrete production, HVAC emission sources, and gold mining operations were evaluated for HAP TAP compliance by comparison of adjusted emissions to applicable EL. Refer to the Emissions Inventories section for estimates of HAP and TAP emissions (as summarized in Table 6) and to the Subsection 210.20 (IDAPA 58.01.01.210.20) section for relevant guidance and discussion of sources addressed by NSPS and NESHAP. With the exception of 16 TAP, estimated emission increases of non-carcinogenic and carcinogenic TAP demonstrated preconstruction compliance with TAP standards in accordance with IDAPA 58.01.01.210.07 using controlled average emission rates. Modeling analyses conducted in the development of TAP rules supports that if controlled average emission rates do not exceed applicable screening emission levels (EL) in IDAPA 58.01.01.585–586, controlled ambient concentrations are expected to be below the applicable acceptable ambient concentration (AAC/AACC).

Estimated emission increases of aluminum, arsenic, barium, beryllium, cadmium, calcium carbonate, calcium oxide, cyanide, formaldehyde, iron, manganese, nickel, phosphorus, sulfuric acid, thallium, and vanadium (16 TAP) demonstrated preconstruction compliance with TAP standards in accordance with IDAPA 58.01.01.210.08 for controlled ambient concentrations. Modeling analyses demonstrated preconstruction compliance with the acceptable ambient concentrations for the eleven non-carcinogenic TAP (AAC) in IDAPA 58.01.01.585. Emission limits (Permit Condition 4.3), operational and material throughput limits (Permit Conditions 3.3–3.9, 4.6–4.12, 5.4–5.9), fugitive dust control requirements (Permit Conditions 2.1–2.8), and control equipment requirements (Permit Conditions 2.6, 3.11–3.13, 4.13–4.17, and 5.12–5.16) limit these TAP emissions in accordance with IDAPA 58.01.01.210.08.c, limit Pb to BRC, and limit PM, PM_{10} ,and $PM_{2.5}$ to below the emission rates relied upon in the NAAQS evaluation of ambient air impacts in the modeling analyses. The remaining five carcinogenic TAP were modeled using an emission inventory that includes T-RACT controls and other emission inventory refinements (see the T-RACT Analysis section).

Arsenic represented the single greatest HAP TAP emission; adjusted arsenic HAP TAP emissions at 0.544 pounds per hour (lb/hr) did not exceed 42% of the applicable AACC. Iron (Fe) represented the greatest single non-HAP TAP emission at over 15 lb/hr, which did not exceed 4% of the applicable AAC. Any uncertainties in metal TAP emission estimates are not expected to affect compliance with TAP provisions.

---

[16] Criteria pollutant thresholds in Table 2, State of Idaho Guideline for Performing Air Quality Impact Analyses, Doc ID AQ-011, September 2013, criteria pollutant BRC thresholds as provided in IDAPA 58.01.01.221.01, and DEQ guidance pertaining to BRC (2014ACF3).

It was recognized that accurately defining the mining operations boundary and controlling public access within that boundary was critical to estimating ambient air impacts. To ensure operation consistent with the defined mining operations boundary, site-specific access control measures will be employed. PRI has committed to identifying and complying with these site-specific access control measures in an Access Management Plan (AMP, as required by Permit Condition 2.7).[17] Refer to Appendix E for a description and discussion of the mining operations boundary and control measures that may be included in this plan.

An ambient air quality impact analyses document has been crafted by DEQ based on a review of the modeling analysis submitted in the application. That document is part of the final permit package for this permitting action (refer to Appendix B). Refer to the Emissions Inventories section and Appendix A for additional information concerning development of the emissions inventories.

T-RACT Analysis

Further evaluation of the sources of HAP emissions that were previously considered addressed by the NESHAP Subpart EEEEEEE per IDAPA 58.01.01.210.20(b), specifically the mining emissions, was conducted by SGP. Estimated emission increases of aluminum, arsenic, barium, beryllium, cadmium, calcium carbonate, calcium oxide, cyanide, formaldehyde, iron, manganese, nickel, phosphorus, sulfuric acid, thallium, and vanadium (16 TAP) exceeded the screening emission levels. Modeling analyses demonstrated preconstruction compliance with the acceptable ambient concentrations for the eleven non-carcinogenic TAP (AAC) in IDAPA 58.01.01.585. The remaining five carcinogenic TAP were modeled using an emission inventory that includes T-RACT controls, long-term mining production limits (Permit Conditions 3.5 and 3.6), constructing the Burntlog access road with offsite material containing minimal level arsenic concentrations, updating the bulldozing emission factor using the SGP site-specific silt content of 4 percent, and the elimination of modeling scenario W5 as a potential operating scenario as the West End DRSF will not be constructed.

In accordance with IDAPA 58.01.01.210.12, the proposed T-RACT ambient concentrations at the point of compliance for each applicable TAP are less than, or equal to, the T-RACT ambient concentration (i.e., less than 10 times the applicable AACC listed in IDAPA 58.01.01.586).

In accordance with IDAPA 58.01.01.210.14, this T-RACT analysis included consideration of available control technologies and/or "The application of a design, equipment, work practice or operational requirement, or combination thereof", for compliance with the T-RACT requirements. This included a search of EPA's RACT, BACT, LAER Clearinghouse to identify available control technologies. To meet the T-RACT requirements, the permit requires the control measures determined to meet T-RACT as summarized in the following table. These control measures were selected based upon consideration of the technological feasibility for this process/operation, the economic feasibility, energy requirements, and environmental impacts.

Table 7 T-RACT CONTROL MEASURES

TAP	Proposed T-RACT Control Measures	Permit Conditions
Arsenic, Beryllium, Cadmium, Formaldehyde, Nickel	Drilling rigs dust control system	3.11
Arsenic	Chemical dust suppressant with frequent watering on roads	2.1 – 2.6
	Haul road capping	3.13

In accordance with IDAPA 58.01.01.210.12.d and 58.01.01.210.14.e, emission limits and other permit conditions for each T-RACT pollutant have been incorporated into the permit as summarized in the table above to assure that the facility will be operated in the manner described in the preconstruction compliance demonstration. A detailed T-RACT analysis is provided in the updated HAP/TAP addendum[9] and is included in Appendix G.

[17] Attachment 2 – Stibnite Road Access Management Plan to the Stibnite Gold Project Permit to Construct Application, PRI, revised June 23, 2020 (2020AAG1078).

REGULATORY ANALYSIS

Attainment Designation (40 CFR 81.313)

The facility is located in Valley County, which is designated as attainment or unclassifiable for $PM_{2.5}$, PM_{10}, SO_2, NO_2, CO, and Ozone. Refer to 40 CFR 81.313 for additional information.

Facility Classification

The AIRS/AFS facility classification codes are as follows:

For HAP (hazardous air pollutants) only:

A = Use when any one HAP has permitted emissions > 10 T/yr or if the aggregate of all HAP (Total HAP) has permitted emissions > 25 T/yr.

SM80 = Use if a synthetic minor (uncontrolled HAP emissions are > 10 T/yr or if the aggregate of all uncontrolled HAP (Total HAP) emissions are > 25 T/yr and permitted emissions fall below applicable major source thresholds) and the permit sets limits > 8 T/yr of a single HAP or ≥ 20 T/yr of Total HAP.

SM = Use if a synthetic minor (uncontrolled HAP emissions are > 10 T/yr or if the aggregate of all uncontrolled HAP (Total HAP) emissions are > 25 T/yr and permitted emissions fall below applicable major source thresholds) and the permit sets limits < 8 T/yr of a single HAP and/or < 20 T/yr of Total HAP.

B = Use when the potential to emit (i.e. uncontrolled emissions and permitted emissions) are below the 10 and 25 T/yr HAP major source thresholds.

UNK = Class is unknown.

For All Other Pollutants:

A = Use when permitted emissions of a pollutant are > 100 T/yr.

SM80 = Use if a synthetic minor for the applicable pollutant (uncontrolled emissions are > 100 T/yr and permitted emissions fall below 100 T/yr) and permitted emissions of the pollutant are ≥ 80 T/yr.

SM = Use if a synthetic minor for the applicable pollutant (uncontrolled emissions are > 100 T/yr and permitted emissions fall below 100 T/yr) and permitted emissions of the pollutant are < 80 T/yr.

B = Use when the potential to emit (i.e. uncontrolled emissions and permitted emissions) are below the 100 T/yr major source threshold.

UNK = Class is unknown.

Table 8 REGULATED AIR POLLUTANT FACILITY CLASSIFICATION

Pollutant	Uncontrolled PTE (T/yr)	Permitted PTE (T/yr)	Major Source Thresholds (T/yr)	AIRS/AFS Classification
PM	560	86.6	**100**	SM80
PM_{10}	337	55.7	**100**	SM
$PM_{2.5}$	164	35.8	**100**	SM
SO_2	6.27	6.3	**100**	B
NO_x	36.16	36.2	**100**	B
CO	29.47	29.5	**100**	B
VOC	4.68	4.7	**100**	B
HAP (single)	>20	3.666	**10**	SM
Total HAP	>25	12.68	**25**	SM

Based on the uncontrolled PTE summarized in Table 2 and controlled PTE summarized above and in Table 3, Table 6, and Appendix A, the permittee will be a "synthetic minor" source of PM, PM_{10}, $PM_{2.5}$, and HAP emissions for new source review and Title V (Tier I) permitting purposes. The uncontrolled PTE for the remaining criteria pollutants (SO_2, NO_x, CO, VOC) confirm PRI will be a natural minor source for these emissions.

Permit to Construct (IDAPA 58.01.01.201)

The permittee has requested that a PTC be issued to the facility for the proposed new emission sources. Therefore, a permit to construct is required in accordance with IDAPA 58.01.01.201. This permitting action was processed in accordance with the procedures of IDAPA 58.01.01.200-228.

Tier II Operating Permit (IDAPA 58.01.01.401)

IDAPA 58.01.01.401 ..... Tier II Operating Permit

The application was submitted for a permit to construct (refer to the Permit to Construct (IDAPA 58.01.01.201) section), and an optional Tier II operating permit has not been requested. Therefore, the procedures of IDAPA 58.01.01.400–410 were not applicable to this permitting action.

Subsection 210.20 (IDAPA 58.01.01.210.20)

IDAPA 58.01.01.210.20..... NSPS and NESHAP Sources

No demonstration of compliance with the TAP provisions is required to obtain a PTC or to demonstrate PTC exemption criteria for a new source or for modification of an existing source if the TAP is also a listed HAP from:

The equipment or activity covered by a NSPS or NESHAP; or

The source category of equipment or activity addressed by a NSPS or NESHAP even if the equipment or activity is not subject to compliance requirements under the federal rule.

Emission sources covered or addressed by NSPS or NESHAP are identified in the following table, and guidance on interpretation of "addressed" is provided in Appendix F. For the sources identified, emissions of TAP that are also HAP (HAP TAP) were excluded from TAP compliance demonstrations (i.e., excluded from comparison to TAP EL and from modeling to demonstrate compliance with TAP AAC/AACC, as discussed in the Ambient Air Quality Impact Analyses).

Table 9 NSPS and NESHAP Sources

NESHAP / NSPS	Source Category Covered & Addressed	Sources
NESHAP Subpart ZZZZ [a] NSPS Subpart IIII	Any industry using a stationary internal combustion engine	*Emergency Power Generation* EDG1, EDG2, EDG3, EDFP
NESHAP Subpart AAAAA [a] NSPS Subpart HH	Any lime manufacturing plant	*Lime Production* LK, LKC, LS12, LS-L/U, LCR
NESHAP Subpart CCCCCC [a]	Any gasoline dispensing facility Includes any operation that transfers and stores gasoline	*Gasoline Fuel Storage and Dispensing* TG1–TG2
NESHAP Subpart EEEEEEE [a]	Gold ore mining Includes an establishment engaged in developing the mine site, mining, and/or beneficiating ores valued chiefly for their gold content, or in transformation of gold into bullion or doré bar in combination with mining activities	*Ore Concentration and Refining* AC, EW, MR, MF, CKD
NSPS Subpart LL	Any metallic mineral plant Includes any combination of equipment that extracts aluminum, copper, gold, iron, lead, molybdenum, silver, titanium, tungsten, uranium, zinc, and zirconium	*Ore Processing* OC1–OC13
NSPS Subpart OOO	Any nonmetallic mineral plant Includes plants processing crushed and broken stone, crushed and broken limestone, lime plants, sand and gravel, clay, etc.	*Aggregate Production* PCSP1, PCSP2 *Concrete Production* CA-L/U *Lime Production* LS1–LS11, LSBM
Source category that may not be subject to or may not be addressed by NSPS or NESHAP		*Concrete Production* CM, CS1-L/U, CS2-L/U *Heating, Ventilation, and Air Conditioning* H1M–H2M, HM, HAC, HR, HA, HMO, HTS, HW *Process Heating* ACB, CKB, PV, HS *Mining* drilling, blasting, excavating, hauling, prill silos, rock dumps and storage piles, tailings *Lime Storage and Crushing* LS1-LU, Mills2-L/U, ACS1-ASC4

a) NESHAP in 40 CFR 63.

NESHAP 40 CFR 63, Subpart EEEEEEE applies only to the following affected sources: each collection of "ore pretreatment processes" at a gold mine ore processing and production facility, each collection of "carbon processes with mercury retorts" at a gold mine ore processing and production facility, each collection of "carbon processes without mercury retorts" at a gold mine ore processing and production facility, and each collection of "non-carbon concentrate processes" at a gold mine ore processing and production facility. Ore pretreatment processes include the autoclave (AC). Carbon processes with mercury retort include the electrowinning cells and pregnant solution tank (EW), the mercury retort (MR), induction melting furnace (MF), and the carbon regeneration kiln (CKD). These sources are covered by NESHAP, as referenced in IDAPA 58.01.01.210.20.

Emissions of TAP from the gold mining operations such as drilling, blasting, excavating, hauling, prill silos, rock dumps and storage piles, and tailings are not covered by NESHAP Subpart EEEEEEE, as referenced in IDAPA 58.01.01.210.20. Further evaluation was conducted by SGP for these sources of HAP TAP emissions.

After exclusion of sources addressed by NSPS and/or NESHAP, the remaining sources were evaluated for compliance with TAP provisions. Emissions of each TAP from these sources (non-NESHAP-covered-or-addressed) were estimated and compared to the applicable screening emission level (as summarized in Table 6).

Mercury Emission Standard (IDAPA 58.01.01.215)

IDAPA 58.01.01.215..... Mercury Emission Standard for New or Modified Sources

No owner or operator may commence construction or modification of a stationary source or facility that results in an increase in annual potential emissions of mercury of 25 pounds or more unless the owner or operator has obtained a PTC under Sections 200–228 of the Rules. The PTC application shall include an MBACT analysis for the new or modified source or sources for review and approval by DEQ. A determination of applicability under Section 215 shall be based upon the best available information.

Fugitive emissions shall not be included in a determination of applicability under Section 215.

New or modified stationary sources within a source category subject to 40 CFR 63 are exempt from the requirements of Section 215.

IDAPA 58.01.01.215 sets requirements for mercury emissions. For this standard, fugitive emissions and sources in a source category subject to 40 CFR 63 are exempt. As identified in Table 9, emission sources within a source category subject to NESHAP 40 CFR 63, including Subpart ZZZZ, Subpart AAAAA, Subpart CCCCCC, and Subpart EEEEEEE were therefore exempt from this standard. Although non-applicable to area sources of HAP such as PRI, as a source category lime manufacturing plants are subject to NESHAP 40 CFR 63, Subpart AAAAA and associated sources (identified in Table 9) therefore exempt from this standard. Fugitive emissions from drilling, blasting, excavating, roadways (hauling), dozing, grading, storage piles, tailings and other fugitive and mobile emission sources were also exempt from this standard. Refer to the MACT/GACT Applicability (40 CFR 63) section for regulatory applicability analysis. No mercury emissions are expected from fuel storage, emergency power generation, and fire suppression sources.

After exclusion of sources within a source category subject to an area source NESHAP (40 CFR 63), aggregate production (crushers, screens, and conveyors), concrete production (aggregate bin), and heating, ventilation, and air conditioning (HVAC) units comprise the remaining sources that are applicable to the Mercury Emission Standard. Mercury emissions from these sources (non-fugitive and non-NESHAP-addressed) were estimated at less than 0.041 pounds per year (lb/yr), below the level at which MBACT review is required. Mercury emissions from propane combustion in HVAC sources are uncontrolled. Mercury emissions from materials processed in aggregate production and concrete production are controlled via water sprays and moisture carryover. As such controls are required for the portable crushing and screening plant, central mixer, and cement/shotcrete silos (Permit Conditions 2.1–2.8, 5.11, 5.12, and 5.16).

For the autoclave, electrowinning cells and pregnant solution tank, mercury retort, and induction melting furnace refinery sources (AC, EW, MR, MF) with enforceable NESHAP Subpart EEEEEEE mercury emission limits, potential emissions estimates (PTE) calculated consistent with these limits were included in the facility-wide mercury emission totals in Table 6. These values were substituted in lieu of the controlled emission estimates referenced from Table B1-W3 of Appendix B to the HAP/TAP addendum and ‘TblB1’ worksheet in the supporting spreadsheet. Although the mercury emissions from these sources are ultimately not included in the adjusted mercury emission totals for the purposes of the Mercury Emission Standard, these were used for the purposes of estimating HAP PTE consistent with enforceable limits.

Particulate Matter – New Equipment Process Weight Limitations (IDAPA 58.01.01.701)

IDAPA 58.01.01.701 ..... Particulate Matter – New Equipment Process Weight Limitations

IDAPA 58.01.01.700 through 703 set PM emission limits for process equipment based on when the piece of equipment commenced operation and the piece of equipment’s process weight (PW) in pounds per hour (lb/hr). IDAPA 58.01.01.701 establishes PM emission limits for equipment that commenced operation on or after October 1, 1979.

For equipment commencing operation on or after October 1, 1979, the PM allowable emission rate (E) is based on one of the following equations:

IDAPA 58.01.01.701.01.a: If PW is < 9,250 lb/hr; $E = 0.045 (PW)^{0.60}$

IDAPA 58.01.01.701.01.b: If PW is ≥ 9,250 lb/hr; $E = 1.10 (PW)^{0.25}$

For the new ore processing, ore concentration and refining, lime production, aggregate production, and concrete production equipment sources (Table 1) emissions (E) were calculated at the proposed maximum throughput rates (Table 1), and estimated emissions from all sources demonstrated compliance with this requirement. Compliance with operational and material throughput limits (Permit Conditions 3.3–3.9, 4.6–4.12, 5.4–5.9) and control equipment requirements (Permit Conditions 2.6, 3.11–3.13, 4.13–4.17, and 5.12–5.16) assure compliance with this standard, resulting in much lower emission rates.

Title V Classification (IDAPA 58.01.01.300, 40 CFR Part 70)

IDAPA 58.01.01.301 ..... Requirement to Obtain Tier I Operating Permit

Any source subject to 40 CFR 63, Subpart EEEEEEE is a Tier I source as defined in IDAPA 58.01.01.006.122.c. In accordance with IDAPA 58.01.01.313.01.b., the permittee must submit a complete application to DEQ for an initial Tier I operating permit within 12 months of becoming a Tier I source.

PRI has committed to applying for a Tier I permit. Detailed federal regulatory applicability were provided in the PTC application, and specific federally-applicable requirements will be incorporated into the Tier I. Refer to the NSPS Applicability (40 CFR 60), NESHAP Applicability (40 CFR 61), and MACT/GACT Applicability (40 CFR 63) sections below for additional information regarding applicable requirements.

Post-project facility-wide emissions from this facility do not have a PTE greater than 100 tons per year for criteria pollutants or 10 tons per year for any one HAP or 25 tons per year for all HAP combined as demonstrated previously in the Emissions Inventories section of this analysis. Although not a major facility as defined in IDAPA 58.01.01.008.10, any source subject to 40 CFR 63, Subpart EEEEEEE is a Tier I source as defined in IDAPA 58.01.01.006.122.c. In accordance with IDAPA 58.01.01.313.01.b., the permittee must submit a complete application to DEQ for an initial Tier I operating permit within 12 months of becoming a Tier I source. Refer to the NESHAP Applicability (40 CFR 61) section for additional discussion of Subpart EEEEEEE applicability.

Permit Condition 2.24 incorporates the requirement to obtain a Tier I permit in accordance with IDAPA 58.01.01.313.01.b.

PSD Classification (40 CFR 52.21)

40 CFR 52.21 ..... Prevention of Significant Deterioration of Air Quality

The project includes a lime manufacturing plant (LMP) that uses a Parallel Flow Regenerative Shaft Kiln (LK, LKC) to produce lime product from limestone by calcination, which is a designated facility as defined in 40 CFR 52.21(b)(1)(i)(a). As a designated facility, both fugitive and non-fugitive emissions from the lime plant must be counted toward a determination of a major stationary source with a threshold of 100 T/yr. SGP is a gold mine with a nested lime plant operating within the stationary source. The primary activity of the stationary source is the mining and processing of gold ore. As explained in the United States Environmental Protection Agency's (EPA) March 6, 2003, guidance,[18] an example is "A coal mine with an onsite coal cleaning plant with a thermal dryer. The primary activity of the source, in this example, is the mining of coal, and coal mines are not a listed source category. The coal cleaning plant, however, does fall within a listed source category. You include fugitive emissions only from the coal cleaning plant to determine if the source is a major stationary source." Gold mines are not a designated facility as defined in 40 CFR 52.21(b)(1)(i)(a). Therefore, emissions from the primary activity, the gold mining operation, are not included in the LMP major source determination as summarized in Table 10 below (values referenced are from 'PROC' tab in the emissions inventory spreadsheet, see Appendix A).

[18] "Clarification on fugitive emissions policy" letter to Janet McCabe, Assistant Commissioner, Office of Air Quality, Indiana Department of Environmental Management, March 6, 2003.

Using the definition of a LMP in the federal regulation Subpart AAAAA - National Emission Standards for Hazardous Air Pollutants for Lime Manufacturing Plants, the Subpart applies to each existing or new lime kiln(s) and their associated cooler(s), and processed stone handling (PSH) operations system(s). PSH operations systems includes all equipment associated with PSH operations beginning at the processed stone storage bin(s) or open storage pile(s) and ending where the processed stone is fed into the kiln. It includes man-made processed stone storage bins (but not open processed stone storage piles), conveying system transfer points, bulk loading or unloading systems, screening operations, surge bins, bucket elevators, and belt conveyors. These sources are included in the table below under the designated facility section. In addition, supporting equipment to the LMP has been included under the fugitive sources.

Post-Project PTE	**24.5**	**15.0**	**7.0**	**18.5**	**17.9**	**0.7**	**1.5**

a) Controlled average emission rate in tons per year is an annual average, based on the proposed annual operating scenarios and annual limits.

To be conservative, if the primary activity of the stationary source was not considered and the LMP was treated as the primary activity of the mine with a threshold of 100 T/yr including both fugitive and non-fugitive emissions, the LMP affected sources are summarized in Table 11 below (values referenced from 'PROC' tab in the emissions inventory spreadsheet, see Appendix A).

The source of marble, the Middle Marble Geologic Unit (MMGU), for the LMP is overburden excavated from the West End pit. Because of its location, the overburden must be removed even if it were not used for onsite lime production. A percentage of the West End pit overburden, 0.63%, will provide the lime plant feed over the life of the mine. The potential throughput rate of limestone (marble) feed to the SGP LMP primary crusher is 1,130 tons/day (limited by Permit Condition 5.4) and the potential overburden mining rate is 180,000 tons/day (limited by Permit Condition 3.5).

LMP throughput percentage calculation: 1,130 tons/day / 180,000 tons/day = 0.0063 or 0.63%

This percentage was used to conservatively calculate the potential annual emissions from the marble overburden mining associated with the LMP operation.

Table 11 LIME PLANT POTENTIAL TO EMIT INCLUDING FUGITIVES FROM MARBLE OVERBURDEN MINING

a) Controlled average emission rate in tons per year is an annual average, based on the proposed annual operating scenarios and annual limits.

b) Emissions are from Table 3 and multiplied by the percentage of overburden used as marble feed (<0.63%) to the SGP lime plant.

NSPS Applicability (40 CFR 60)

The permittee has affected facilities subject to New Source Performance Standards (NSPS). The POX Boiler (ACB) meets the definition of process heater rather than steam generating unit, and the use of a rotary lime kiln has not been proposed in the production of lime; therefore Subpart Dc and Subpart HH are not applicable. Initial regulatory applicability analyses and determinations are provided below; detailed analyses and explicit incorporation of applicable requirements is left to the required Tier I permit action as discussed in the Title V Classification (IDAPA 58.01.01.300, 40 CFR Part 70) section.

- Standards of Performance for New Stationary Sources (NSPS) 40 CFR 60, Subpart A – General Provisions. DEQ is delegated this Subpart.
- NSPS 40 CFR 60, Subpart LL – Standards of Performance for Metallic Mineral Processing Plants. DEQ is delegated this Subpart. Each crusher, conveyor belt transfer point, and truck unloading station is an affected facility.

- NSPS 40 CFR 60, Subpart OOO – Standards of Performance for Nonmetallic Mineral Processing Plants. DEQ is delegated this Subpart. Each crusher, grinding mill, screening operation, belt conveyor, and storage bin is an affected facility.
- NSPS 40 CFR 60, Subpart IIII – Standards of Performance for Stationary Compression Ignition Internal Combustion Engines. DEQ is delegated this Subpart. Each emergency generator engine and fire pump is an affected facility.

Emission sources regulated by Subpart LL, Subpart OOO, and Subpart IIII are identified in the incorporation of federal requirements condition (Permit Condition 2.22)

40 CFR 60, Subpart A ..... General Provisions

§60.1 ..... Applicability

(a) Except as provided in subparts B and C, the provisions of this part apply to the owner or operator of any stationary source which contains an affected facility, the construction or modification of which is commenced after the date of publication in this part of any standard (or, if earlier, the date of publication of any proposed standard) applicable to that facility.

(b) Any new or revised standard of performance promulgated pursuant to section 111(b) of the Act shall apply to the owner or operator of any stationary source which contains an affected facility, the construction or modification of which is commenced after the date of publication in this part of such new or revised standard (or, if earlier, the date of publication of any proposed standard) applicable to that facility.

Because the permittee will own or operate NSPS affected facilities, which have been proposed to commence construction after the date of publication of the relevant applicable NSPS standards (as listed above), general provisions in Subpart A are applicable.

40 CFR 60, Subpart A is incorporated by reference into Permit Condition 2.22, and specific applicable requirements will be incorporated into the Tier I operating permit.

40 CFR 60, Subpart Dc ..... Standards of Performance for Small Industrial-Commercial-Institutional Steam Generating Units

§60.40c ..... Applicability and delegation of authority.

(a) Except as provided in paragraphs (d), (e), (f), and (g) of this section, the affected facility to which this subpart applies is each steam generating unit for which construction, modification, or reconstruction is commenced after June 9, 1989 and that has a maximum design heat input capacity of 29 megawatts (MW) (100 million British thermal units per hour (MMBtu/h)) or less, but greater than or equal to 2.9 MW (10 MMBtu/h).

§60.41c ..... Definitions.

As used in this subpart, all terms not defined herein shall have the meaning given them in the Clean Air Act and in subpart A of this part.

...

Heat input *means heat derived from combustion of fuel in a steam generating unit and does not include the heat derived from preheated combustion air, recirculated flue gases, or exhaust gases from other sources (such as stationary gas turbines, internal combustion engines, and kilns).*

Heat transfer medium *means any material that is used to transfer heat from one point to another point.*

...

Process heater *means a device that is primarily used to heat a material to initiate or promote a chemical reaction in which the material participates as a reactant or catalyst.*

...

Steam generating unit *means a device that combusts any fuel and produces steam or heats water or heats any heat transfer medium. This term includes any duct burner that combusts fuel and is part of a combined cycle system. This term does not include process heaters as defined in this subpart.*

Although the Pressure Oxidation Boiler (POX Boiler) is between 10 and 100 MMBtu/hr in design heat input capacity (17 MMBtu/hr) and is proposed for construction after June 9, 1989, it meets the definition of process heater rather than steam generating unit, and therefore is not applicable to this subpart. The POX Boiler (ACB) is a device used to directly heat ore material via steam injection into the autoclave, to promote chemical oxidation reactions in which the heated ore participates as a reactant. DEQ is delegated this Subpart.

40 CFR 60, Subpart HH ..... Standards of Performance for Lime Manufacturing Plants

§60.340 ..... Applicability and designation of affected facility.

(a) The provisions of this subpart are applicable to each rotary lime kiln used in the manufacture of lime.

(b) The provisions of this subpart are not applicable to facilities used in the manufacture of lime at kraft pulp mills.

(c) Any facility under paragraph (a) of this section that commences construction or modification after May 3, 1977, is subject to the requirements of this subpart.

§60.341 ..... Definitions.

As used in this subpart, all terms not defined herein shall have the same meaning given them in the Act and in the General Provisions.

(a) Lime manufacturing plant *means any plant which uses a rotary lime kiln to produce lime product from limestone by calcination.*

(b) Lime product *means the product of the calcination process including, but not limited to, calcitic lime, dolomitic lime, and dead-burned dolomite.*

(c) Positive-pressure fabric filter *means a fabric filter with the fans on the upstream side of the filter bags.*

(d) Rotary lime kiln *means a unit with an inclined rotating drum that is used to produce a lime product from limestone by calcination.*

(e) Stone feed *means limestone feedstock and mill scale or other iron oxide additives that become part of the product.*

The use of a rotary lime kiln has not been proposed in the production of lime, and therefore the requirements of Subpart HH are not applicable. DEQ is delegated this Subpart.

40 CFR 60, Subpart LL ..... Standards of Performance for Metallic Mineral Processing Plants

§60.380 ..... Applicability and designation of affected facility.

(a) The provisions of this subpart are applicable to the following affected facilities in metallic mineral processing plants: Each crusher and screen in open-pit mines; each crusher, screen, bucket elevator, conveyor belt transfer point, thermal dryer, product packaging station, storage bin, enclosed storage area, truck loading station, truck unloading station, railcar loading station, and railcar unloading station at the mill or concentrator with the following exceptions. All facilities located in underground mines are exempted from the provisions of this subpart. At uranium ore processing plants, all facilities subsequent to and including the beneficiation of uranium ore are exempted from the provisions of this subpart.

(b) An affected facility under paragraph (a) of this section that commences construction or modification after August 24, 1982, is subject to the requirements of this part.

Because the permittee will own or operate a metallic mineral processing plant with a crusher at an open-pit mine; with crushers, conveyor belt transfer points, and truck unloading stations at the mill or concentrator; and because these are proposed to commence construction after August 24, 1982, requirements in Subpart LL are applicable.

40 CFR 60, Subpart LL is incorporated by reference into Permit Condition 2.22, and specific applicable requirements will be incorporated into the Tier I operating permit.

40 CFR 60, Subpart OOO ..... Standards of Performance for Nonmetallic Mineral Processing Plants

§60.670 ..... Applicability and designation of affected facility.

(a)(1) Except as provided in paragraphs (a)(2), (b), (c), and (d) of this section, the provisions of this subpart are applicable to the following affected facilities in fixed or portable nonmetallic mineral processing plants: each crusher, grinding mill, screening operation, bucket elevator, belt conveyor, bagging operation, storage bin, enclosed truck or railcar loading station. Also, crushers and grinding mills at hot mix asphalt facilities that reduce the size of nonmetallic minerals embedded in recycled asphalt pavement and subsequent affected facilities up to, but not including, the first storage silo or bin are subject to the provisions of this subpart.

(2) The provisions of this subpart do not apply to the following operations: All facilities located in underground mines; plants without crushers or grinding mills above ground; and wet material processing operations (as defined in §60.671).

(b) An affected facility that is subject to the provisions of subparts F or I of this part or that follows in the plant process any facility subject to the provisions of subparts F or I of this part is not subject to the provisions of this subpart.

(c) Facilities at the following plants are not subject to the provisions of this subpart:

(1) Fixed sand and gravel plants and crushed stone plants with capacities, as defined in §60.671, of 23 megagrams per hour (25 tons per hour) or less;

(2) Portable sand and gravel plants and crushed stone plants with capacities, as defined in §60.671, of 136 megagrams per hour (150 tons per hour) or less; and

(3) Common clay plants and pumice plants with capacities, as defined in §60.671, of 9 megagrams per hour (10 tons per hour) or less.

(d)(1) When an existing facility is replaced by a piece of equipment of equal or smaller size, as defined in §60.671, having the same function as the existing facility, and there is no increase in the amount of emissions, the new facility is exempt from the provisions of §§60.672, 60.674, and 60.675 except as provided for in paragraph (d)(3) of this section.

(2) An owner or operator complying with paragraph (d)(1) of this section shall submit the information required in §60.676(a).

(3) An owner or operator replacing all existing facilities in a production line with new facilities does not qualify for the exemption described in paragraph (d)(1) of this section and must comply with the provisions of §§60.672, 60.674 and 60.675.

(e) An affected facility under paragraph (a) of this section that commences construction, modification, or reconstruction after August 31, 1983, is subject to the requirements of this part.

(f) Table 1 of this subpart specifies the provisions of subpart A of this part 60 that do not apply to owners and operators of affected facilities subject to this subpart or that apply with certain exceptions.

Because the project contains crushers, grinding mills, screening operations, belt conveyors, and storage bins in a fixed or portable nonmetallic mineral processing plant, which are proposed to commence construction after August 31, 1983, requirements in Subpart OOO are applicable. The portable crushing and screening plants (PCSP1, PCSP2) will be rated at below 150 tons per hour (T/hr), and are therefore not subject to the provisions of Subpart OOO.

40 CFR 60, Subpart OOO is incorporated by reference into Permit Condition 2.22, and specific applicable requirements will be incorporated into the Tier I operating permit.

40 CFR 60, Subpart IIII..... Standards of Performance for Stationary Compression Ignition Internal Combustion Engines

§60.4200..... Am I subject to this subpart?

(a) The provisions of this subpart are applicable to manufacturers, owners, and operators of stationary compression ignition (CI) internal combustion engines (ICE) and other persons as specified in paragraphs (a)(1) through (4) of this section. For the purposes of this subpart, the date that construction commences is the date the engine is ordered by the owner or operator.

(1) Manufacturers of stationary CI ICE with a displacement of less than 30 liters per cylinder where the model year is:

(i) 2007 or later, for engines that are not fire pump engines;

(ii) The model year listed in Table 3 to this subpart or later model year, for fire pump engines.

(2) Owners and operators of stationary CI ICE that commence construction after July 11, 2005, where the stationary CI ICE are:

(i) Manufactured after April 1, 2006, and are not fire pump engines, or

(ii) Manufactured as a certified National Fire Protection Association (NFPA) fire pump engine after July 1, 2006.

(3) Owners and operators of any stationary CI ICE that are modified or reconstructed after July 11, 2005 and any person that modifies or reconstructs any stationary CI ICE after July 11, 2005.

(4) The provisions of §60.4208 of this subpart are applicable to all owners and operators of stationary CI ICE that commence construction after July 11, 2005.

(b) The provisions of this subpart are not applicable to stationary CI ICE being tested at a stationary CI ICE test cell/stand.

(c) If you are an owner or operator of an area source subject to this subpart, you are exempt from the obligation to obtain a permit under 40 CFR part 70 or 40 CFR part 71, provided you are not required to obtain a permit under 40 CFR 70.3(a) or 40 CFR 71.3(a) for a reason other than your status as an area source under this subpart. Notwithstanding the previous sentence, you must continue to comply with the provisions of this subpart applicable to area sources.

(d) Stationary CI ICE may be eligible for exemption from the requirements of this subpart as described in 40 CFR part 1068, subpart C (or the exemptions described in 40 CFR part 89, subpart J and 40 CFR part 94, subpart J, for engines that would need to be certified to standards in those parts), except that owners and operators, as well as manufacturers, may be eligible to request an exemption for national security.

(e) Owners and operators of facilities with CI ICE that are acting as temporary replacement units and that are located at a stationary source for less than 1 year and that have been properly certified as meeting the standards that would be applicable to such engine under the appropriate nonroad engine provisions, are not required to meet any other provisions under this subpart with regard to such engines.

Because the permittee will own or operate compression ignition (CI) internal combustion engines (ICE) which are proposed to commence construction after July 11, 2005 and which will be ordered after April 1, 2006 for the emergency generator engines, and which will be ordered after July 1, 2006 for the fire pump engine, requirements in Subpart IIII are applicable. The permittee has not requested or qualified for exemption pursuant to §60.4200(b), (d), or (e).

40 CFR 60, Subpart IIII is incorporated by reference into Permit Condition 2.22, and specific applicable requirements will be incorporated into the Tier I operating permit.

NESHAP Applicability (40 CFR 61)

The facility is not subject to any NESHAP requirements in 40 CFR 61.

MACT/GACT Applicability (40 CFR 63)

The permittee has proposed to operate as a minor source of hazardous air pollutant (HAP) emissions, and has affected facilities subject to the following National Emission Standards for Hazardous Air Pollutants (NESHAP). The lime manufacturing plant is proposed at an area source of HAP, and therefore is not applicable to Subpart AAAAA. The process boiler is at an area source of Applicability determinations and regulatory analyses are provided below.

- National Emission Standards for Hazardous Air Pollutants for Source Categories (NESHAP) 40 CFR 63, Subpart A – General Provisions. DEQ is delegated this Subpart for Tier I sources.
- NESHAP 40 CFR 63, Subpart ZZZZ – National Emission Standards for Hazardous Air Pollutants for Stationary Reciprocating Internal Combustion Engines (RICE). DEQ is delegated this Subpart. The emergency generator and fire pump engines (EDG1, EDG2, EDG3, and EDFP) are affected sources.
- NESHAP 40 CFR 63, Subpart CCCCCC – National Emission Standards for Hazardous Air Pollutants for Source Category: Gasoline Dispensing Facilities. DEQ is delegated this Subpart for Tier I sources. The gasoline fuel storage tanks (TG1, TG2) are affected sources.
- NESHAP 40 CFR 63, Subpart EEEEEEE – National Emission Standards for Hazardous Air Pollutants: Gold Mine Ore Processing and Production Area Source Category. DEQ is delegated this Subpart for Tier I sources. The collection of ore pretreatment processes and the carbon process with mercury retort are affected sources. Ore pretreatment processes include the autoclave (AC). Carbon processes with mercury retort include the electrowinning cells and pregnant solution tank (EW), the mercury retort (MR), induction melting furnace (MF), and the carbon regeneration kiln (CKD).

Emission sources regulated by Subpart EEEEEEE, Subpart CCCCCC, and Subpart ZZZZ are identified in the incorporation of federal requirements condition (Permit Condition 2.22)

40 CFR 63, Subpart A ..... General Provisions

§63.1..... Applicability.

(a) General. *(1) Terms used throughout this part are defined in §63.2 or in the Clean Air Act (Act) as amended in 1990, except that individual subparts of this part may include specific definitions in addition to or that supersede definitions in §63.2.*

(2) This part contains national emission standards for hazardous air pollutants (NESHAP) established pursuant to section 112 of the Act as amended November 15, 1990. These standards regulate specific categories of stationary sources that emit (or have the potential to emit) one or more hazardous air pollutants listed in this part pursuant to section 112(b) of the Act. This section explains the applicability of such standards to sources affected by them. The standards in this part are independent of NESHAP contained in 40 CFR part 61. The NESHAP in part 61 promulgated by signature of the Administrator before November 15, 1990 (i.e., the date of enactment of the Clean Air Act Amendments of 1990) remain in effect until they are amended, if appropriate, and added to this part.

(3) No emission standard or other requirement established under this part shall be interpreted, construed, or applied to diminish or replace the requirements of a more stringent emission limitation or other applicable requirement established by the Administrator pursuant to other authority of the Act (section 111, part C or D or any other authority of this Act), or a standard issued under State authority. The Administrator may specify in a specific standard under this part that facilities subject to other provisions under the Act need only comply with the provisions of that standard.

(4)(i) Each relevant standard in this part 63 must identify explicitly whether each provision in this subpart A is or is not included in such relevant standard.

(ii) If a relevant part 63 standard incorporates the requirements of 40 CFR part 60, part 61 or other part 63 standards, the relevant part 63 standard must identify explicitly the applicability of each corresponding part 60, part 61, or other part 63 subpart A (General) provision.

(iii) The General Provisions in this subpart A do not apply to regulations developed pursuant to section 112(r) of the amended Act, unless otherwise specified in those regulations.

…

(b) Initial applicability determination for this part. *(1) The provisions of this part apply to the owner or operator of any stationary source that—*

(i) Emits or has the potential to emit any hazardous air pollutant listed in or pursuant to section 112(b) of the Act; and

(ii) Is subject to any standard, limitation, prohibition, or other federally enforceable requirement established pursuant to this part.

(2) [Reserved]

(3) An owner or operator of a stationary source who is in the relevant source category and who determines that the source is not subject to a relevant standard or other requirement established under this part must keep a record as specified in §63.10(b)(3).

Because the permittee will own or operate stationary sources that emit HAP which are subject to standards, limitations, prohibitions, or other federally-enforceable requirements established pursuant to NESHAP, provisions in Subpart A are applicable.

40 CFR 63, Subpart A is incorporated by reference into Permit Condition 2.22, and specific applicable requirements will be incorporated into the Tier I operating permit.

40 CFR 63, Subpart ZZZZ..... National Emissions Standards for Hazardous Air Pollutants for Stationary Reciprocating Internal Combustion Engines

§63.6580..... What is the purpose of subpart ZZZZ?

Subpart ZZZZ establishes national emission limitations and operating limitations for hazardous air pollutants (HAP) emitted from stationary reciprocating internal combustion engines (RICE) located at major and area sources of HAP emissions. This subpart also establishes requirements to demonstrate initial and continuous compliance with the emission limitations and operating limitations.

§63.6585..... Am I subject to this subpart?

You are subject to this subpart if you own or operate a stationary RICE at a major or area source of HAP emissions, except if the stationary RICE is being tested at a stationary RICE test cell/stand.

(a) A stationary RICE is any internal combustion engine which uses reciprocating motion to convert heat energy into mechanical work and which is not mobile. Stationary RICE differ from mobile RICE in that a stationary RICE is not a non-road engine as defined at 40 CFR 1068.30, and is not used to propel a motor vehicle or a vehicle used solely for competition.

(b) A major source of HAP emissions is a plant site that emits or has the potential to emit any single HAP at a rate of 10 tons (9.07 megagrams) or more per year or any combination of HAP at a rate of 25 tons (22.68 megagrams) or more per year, except that for oil and gas production facilities, a major source of HAP emissions is determined for each surface site.

(c) An area source of HAP emissions is a source that is not a major source.

(d) If you are an owner or operator of an area source subject to this subpart, your status as an entity subject to a standard or other requirements under this subpart does not subject you to the obligation to obtain a permit under 40 CFR part 70 or 71, provided you are not required to obtain a permit under 40 CFR 70.3(a) or 40 CFR 71.3(a) for a reason other than your status as an area source under this subpart. Notwithstanding the previous sentence, you must continue to comply with the provisions of this subpart as applicable.

(e) If you are an owner or operator of a stationary RICE used for national security purposes, you may be eligible to request an exemption from the requirements of this subpart as described in 40 CFR part 1068, subpart C.

(f) The emergency stationary RICE listed in paragraphs (f)(1) through (3) of this section are not subject to this subpart. The stationary RICE must meet the definition of an emergency stationary RICE in §63.6675, which includes operating according to the provisions specified in §63.6640(f).

(1) Existing residential emergency stationary RICE located at an area source of HAP emissions that do not operate or are not contractually obligated to be available for more than 15 hours per calendar year for the purposes specified in §63.6640(f)(2)(ii) and (iii) and that do not operate for the purpose specified in §63.6640(f)(4)(ii).

(2) Existing commercial emergency stationary RICE located at an area source of HAP emissions that do not operate or are not contractually obligated to be available for more than 15 hours per calendar year for the purposes specified in §63.6640(f)(2)(ii) and (iii) and that do not operate for the purpose specified in §63.6640(f)(4)(ii).

(3) Existing institutional emergency stationary RICE located at an area source of HAP emissions that do not operate or are not contractually obligated to be available for more than 15 hours per calendar year for the purposes specified in §63.6640(f)(2)(ii) and (iii) and that do not operate for the purpose specified in §63.6640(f)(4)(ii).

Because the permittee will own or operate stationary RICE at an area source of HAP which are subject to standards, limitations, prohibitions, or other federally-enforceable requirements established pursuant to NESHAP, requirements in Subpart ZZZZ are applicable.

40 CFR 63, Subpart ZZZZ is incorporated by reference into Permit Condition 2.22, and specific applicable requirements will be incorporated into the Tier I operating permit.

40 CFR 63, Subpart AAAAA..... National Emission Standards for Hazardous Air Pollutants for Lime Manufacturing Plants

§63.7080..... What is the purpose of this subpart?

This subpart establishes national emission standards for hazardous air pollutants (NESHAP) for lime manufacturing plants. This subpart also establishes requirements to demonstrate initial and continuous compliance with the emission limitations.

§63.7081..... Am I subject to this subpart?

(a) You are subject to this subpart if you own or operate a lime manufacturing plant (LMP) that is a major source, or that is located at, or is part of, a major source of hazardous air pollutant (HAP) emissions, unless the LMP is located at a kraft pulp mill, soda pulp mill, sulfite pulp mill, beet sugar manufacturing plant, or only processes sludge containing calcium carbonate from water softening processes.

(1) An LMP is an establishment engaged in the manufacture of lime product (calcium oxide, calcium oxide with magnesium oxide, or dead burned dolomite) by calcination of limestone, dolomite, shells or other calcareous substances.

(2) A major source of HAP is a plant site that emits or has the potential to emit any single HAP at a rate of 9.07 megagrams (10 tons) or more per year or any combination of HAP at a rate of 22.68 megagrams (25 tons) or more per year from all emission sources at the plant site.

(b) [Reserved]

§63.7143..... What definitions apply to this subpart?

Terms used in this subpart are defined in the Clean Air Act, in §63.2, and in this section as follows:

...

Lime manufacturing plant (LMP) *means any plant which uses a lime kiln to produce lime product from limestone or other calcareous material by calcination.*

Lime product *means the product of the lime kiln calcination process including, calcitic lime, dolomitic lime, and dead-burned dolomite.*

Limestone *means the material comprised primarily of calcium carbonate (referred to sometimes as calcitic or high calcium limestone), magnesium carbonate, and/or the double carbonate of both calcium and magnesium (referred to sometimes as dolomitic limestone or dolomite).*

...

The lime manufacturing plant is proposed at an area source of HAP, and therefore is not subject to this Subpart.

40 CFR 60, Subpart CCCCCC..... National Emission Standards for Hazardous Air Pollutants for Source Category: Gasoline Dispensing Facilities

§63.11110..... What is the purpose of this subpart?

This subpart establishes national emission limitations and management practices for hazardous air pollutants (HAP) emitted from the loading of gasoline storage tanks at gasoline dispensing facilities (GDF). This subpart also establishes requirements to demonstrate compliance with the emission limitations and management practices.

§63.11111..... Am I subject to the requirements in this subpart?

(a) The affected source to which this subpart applies is each GDF that is located at an area source. The affected source includes each gasoline cargo tank during the delivery of product to a GDF and also includes each storage tank.

(b) If your GDF has a monthly throughput of less than 10,000 gallons of gasoline, you must comply with the requirements in §63.11116.

(c) If your GDF has a monthly throughput of 10,000 gallons of gasoline or more, you must comply with the requirements in §63.11117.

(d) If your GDF has a monthly throughput of 100,000 gallons of gasoline or more, you must comply with the requirements in §63.11118.

(e) An affected source shall, upon request by the Administrator, demonstrate that their monthly throughput is less than the 10,000-gallon or the 100,000-gallon threshold level, as applicable. For new or reconstructed affected sources, as specified in §63.11112(b) and (c), recordkeeping to document monthly throughput must begin upon startup of the affected source. For existing sources, as specified in §63.11112(d), recordkeeping to document monthly throughput must begin on January 10, 2008. For existing sources that are subject to this subpart only because they load gasoline into fuel tanks other than those in motor vehicles, as defined in §63.11132, recordkeeping to document monthly throughput must begin on January 24, 2011. Records required under this paragraph shall be kept for a period of 5 years.

(f) If you are an owner or operator of affected sources, as defined in paragraph (a) of this section, you are not required to obtain a permit under 40 CFR part 70 or 40 CFR part 71 as a result of being subject to this subpart. However, you must still apply for and obtain a permit under 40 CFR part 70 or 40 CFR part 71 if you meet one or more of the applicability criteria found in 40 CFR 70.3(a) and (b) or 40 CFR 71.3(a) and (b).

(g) The loading of aviation gasoline into storage tanks at airports, and the subsequent transfer of aviation gasoline within the airport, is not subject to this subpart.

(h) Monthly throughput is the total volume of gasoline loaded into, or dispensed from, all the gasoline storage tanks located at a single affected GDF. If an area source has two or more GDF at separate locations within the area source, each GDF is treated as a separate affected source.

(i) If your affected source's throughput ever exceeds an applicable throughput threshold, the affected source will remain subject to the requirements for sources above the threshold, even if the affected source throughput later falls below the applicable throughput threshold.

(j) The dispensing of gasoline from a fixed gasoline storage tank at a GDF into a portable gasoline tank for the on-site delivery and subsequent dispensing of the gasoline into the fuel tank of a motor vehicle or other gasoline-fueled engine or equipment used within the area source is only subject to §63.11116 of this subpart.

(k) For any affected source subject to the provisions of this subpart and another Federal rule, you may elect to comply only with the more stringent provisions of the applicable subparts. You must consider all provisions of the rules, including monitoring, recordkeeping, and reporting. You must identify the affected source and provisions with which you will comply in your Notification of Compliance Status required under §63.11124. You also must demonstrate in your Notification of Compliance Status that each provision with which you will comply is at least as stringent as the otherwise applicable requirements in this subpart. You are responsible for making accurate determinations concerning the more stringent provisions, and noncompliance with this rule is not excused if it is later determined that your determination was in error, and, as a result, you are violating this subpart. Compliance with this rule is your responsibility and the Notification of Compliance Status does not alter or affect that responsibility.

§63.11132..... What definitions apply to this subpart?

As used in this subpart, all terms not defined herein shall have the meaning given them in the Clean Air Act (CAA), or in subparts A and BBBBBB of this part. For purposes of this subpart, definitions in this section supersede definitions in other parts or subparts.

Dual-point vapor balance system *means a type of vapor balance system in which the storage tank is equipped with an entry port for a gasoline fill pipe and a separate exit port for a vapor connection.*

Gasoline *means any petroleum distillate or petroleum distillate/alcohol blend having a Reid vapor pressure of 27.6 kilopascals or greater, which is used as a fuel for internal combustion engines.*

Gasoline cargo tank *means a delivery tank truck or railcar which is loading or unloading gasoline, or which has loaded or unloaded gasoline on the immediately previous load.*

Gasoline dispensing facility (GDF) *means any stationary facility which dispenses gasoline into the fuel tank of a motor vehicle, motor vehicle engine, nonroad vehicle, or nonroad engine, including a nonroad vehicle or nonroad engine used solely for competition. These facilities include, but are not limited to, facilities that dispense gasoline into on- and off-road, street, or highway motor vehicles, lawn equipment, boats, test engines, landscaping equipment, generators, pumps, and other gasoline-fueled engines and equipment.*

Monthly throughput *means the total volume of gasoline that is loaded into, or dispensed from, all gasoline storage tanks at each GDF during a month. Monthly throughput is calculated by summing the volume of gasoline loaded into, or dispensed from, all gasoline storage tanks at each GDF during the current day, plus the total volume of gasoline loaded into, or dispensed from, all gasoline storage tanks at each GDF during the previous 364 days, and then dividing that sum by 12.*

Motor vehicle *means any self-propelled vehicle designed for transporting persons or property on a street or highway.*

Nonroad engine *means an internal combustion engine (including the fuel system) that is not used in a motor vehicle or a vehicle used solely for competition, or that is not subject to standards promulgated under section 7411 of this title or section 7521 of this title.*

Nonroad vehicle *means a vehicle that is powered by a nonroad engine, and that is not a motor vehicle or a vehicle used solely for competition.*

Submerged filling *means, for the purposes of this subpart, the filling of a gasoline storage tank through a submerged fill pipe whose discharge is no more than the applicable distance specified in §63.11117(b) from the bottom of the tank. Bottom filling of gasoline storage tanks is included in this definition.*

Vapor balance system *means a combination of pipes and hoses that create a closed system between the vapor spaces of an unloading gasoline cargo tank and a receiving storage tank such that vapors displaced from the storage tank are transferred to the gasoline cargo tank being unloaded.*

Vapor-tight *means equipment that allows no loss of vapors. Compliance with vapor-tight requirements can be determined by checking to ensure that the concentration at a potential leak source is not equal to or greater than 100 percent of the Lower Explosive Limit when measured with a combustible gas detector, calibrated with propane, at a distance of 1 inch from the source.*

Vapor-tight gasoline cargo tank *means a gasoline cargo tank which has demonstrated within the 12 preceding months that it meets the annual certification test requirements in §63.11092(f) of this part.*

Because the permittee will own or operate a gasoline dispensing facility (GDF) at an area source of HAP, requirements in Subpart CCCCCC are applicable. Because the permittee has committed to loading and dispensing of less than 100,000 gallons of gasoline per month (gal/mo), the requirements of 40 CFR 63.11117 will become applicable in accordance with 40 CFR 63.11111(b) and (c). Gasoline loading and dispensing is limited by Permit Condition 2.18 to avoid requirements applicable to GDF exceeding 100,000 gal/mo, and requires recordkeeping in accordance with 40 CFR 63.11111(e).

40 CFR 63, Subpart CCCCCC is incorporated by reference into Permit Condition 2.22, and specific applicable requirements will be incorporated into the Tier I operating permit.

40 CFR 63, Subpart EEEEEEE..... National Emission Standards for Hazardous Air Pollutants: Gold Mine Ore Processing and Production Area Source Category

§40 CFR 63.11640..... Am I subject to this subpart?

(a) You are subject to this subpart if you own or operate a gold mine ore processing and production facility as defined in §63.11651, that is an area source.

(b) This subpart applies to each new or existing affected source. The affected sources are each collection of "ore pretreatment processes" at a gold mine ore processing and production facility, each collection of "carbon processes with mercury retorts" at a gold mine ore processing and production facility, each collection of "carbon processes without mercury retorts" at a gold mine ore processing and production facility, and each collection of "non-carbon concentrate processes" at a gold mine ore processing and production facility, as defined in §63.11651.

(1) An affected source is existing if you commenced construction or reconstruction of the affected source on or before April 28, 2010.

(2) An affected source is new if you commenced construction or reconstruction of the affected source after April 28, 2010.

(c) This subpart does not apply to research and development facilities, as defined in section 112(c)(7) of the Clean Air Act (CAA).

(d) If you own or operate a source subject to this subpart, you must have or you must obtain a permit under 40 CFR part 70 or 40 CFR part 71.

§40 CFR 63.11651..... What definitions apply to this subpart?

Terms used in this subpart are defined in the Clean Air Act, in §63.2, and in this section as follows:

Autoclave *means a pressure oxidation vessel that is used to treat gold ores (primarily sulfide refractory ore) and involves pumping a slurry of milled ore into the vessel which is highly pressurized with oxygen and heated to temperatures of approximately 350° to 430 °F.*

Calomel-based mercury control system *means a mercury emissions control system that uses scrubbers to remove mercury from the gas stream of a roaster or combination of roasters by complexing the mercury from the gas stream with mercuric chloride to form mercurous chloride (calomel). These scrubbers are also referred to as "mercury scrubbers."*

Carbon adsorber *means a control device consisting of a single fixed carbon bed, multiple carbon beds or columns, carbon filter packs or modules, and other variations that uses activated carbon to remove pollutants from a gas stream.*

Carbon kiln *means a kiln or furnace where carbon is regenerated by heating, usually in the presence of steam, after the gold has been stripped from the carbon.*

Carbon processes with mercury retorts *means the affected source that includes carbon kilns, preg tanks, electrowinning cells, mercury retorts, and melt furnaces at gold mine ore processing and production facilities that use activated carbon, or resins that can be used as a substitute for activated carbon, to recover (adsorb) gold from the pregnant cyanide solution.*

Carbon processes without mercury retorts *means the affected source that includes carbon kilns, preg tanks, electrowinning cells, and melt furnaces, but has no retorts, at gold mine ore processing and production facilities that use activated carbon, or resins that can be used as a substitute for activated carbon, to recover (adsorb) gold from the pregnant cyanide solution.*

Concentrate *means the sludge-like material that is loaded with gold along with various other metals (such as silver, copper, and mercury) and various other substances, that is produced by electrowinning, the Merrill-Crowe process, flotation and gravity separation processes. Concentrate is measured as the input to mercury retorts, or for facilities without mercury retorts, as the input to melt furnaces before any drying takes place. For facilities without mercury retorts or melt furnaces, concentrate is measured as the quantity shipped.*

Deviation *means any instance where an affected source subject to this subpart, or an owner or operator of such a source:*

(1) Fails to meet any requirement or obligation established by this subpart, including but not limited to any emissions limitation or work practice standard;

(2) Fails to meet any term or condition that is adopted to implement an applicable requirement in this subpart and that is included in the operating permit for any affected source required to obtain such a permit; or

(3) Exceeds any operating limit established under this subpart.

Electrowinning *means a process that uses induced voltage on anode and cathode plates to remove metals from the continuous flow of solution, where the gold in solution is plated onto the cathode. Steel wool is typically used as the plating surface.*

Electrowinning Cells *means a tank in which the electrowinning takes place.*

Gold mine ore processing and production facility *means any industrial facility engaged in the processing of gold mine ore that uses any of the following processes: Roasting operations, autoclaves, carbon kilns, preg tanks, electrowinning, mercury retorts, or melt furnaces. Laboratories (see CAA section 112(c)(7)), individual prospectors, and very small pilot scale mining operations that processes or produces less than 100 pounds of concentrate per year are not a gold mine ore processing and production facility. A facility that produces primarily metals other than gold, such as copper, lead, zinc, or nickel (where these metals other than gold comprise 95 percent or more of the total metal production) that may also recover some gold as a byproduct is not a gold mine ore processing and production facility. Those facilities whereby 95 percent or more of total mass of metals produced are metals other than gold, whether final metal production is onsite or offsite, are not part of the gold mine ore processing and production source category.*

Melt furnace *means a furnace (typically a crucible furnace) that is used for smelting the gold-bearing material recovered from mercury retorting, or the gold-bearing material from electrowinning, the Merrill-Crowe process, or other processes for facilities without mercury retorts.*

Mercury retort *means a vessel that is operated under a partial vacuum at approximately 1,100° to 1,300 °F to remove mercury and moisture from the gold bearing sludge material that is recovered from electrowinning, the Merrill-Crowe process, or other processes. Mercury retorts are usually equipped with condensers that recover liquid mercury during the processing.*

Merrill-Crowe process *means a precipitation technique using zinc oxide for removing gold from a cyanide solution. Zinc dust is added to the solution, and gold is precipitated to produce a concentrate.*

Non-carbon concentrate processes *means the affected source that includes mercury retorts and melt furnaces at gold mine ore processing and production facilities that use the Merrill-Crowe process or other processes and do not use carbon (or resins that substitute for carbon) to recover (adsorb) gold from the pregnant cyanide solution.*

Ore dry grinding *means a process in which the gold ore is ground and heated (dried) prior to additional preheating or prior to entering the roaster.*

Ore preheating *means a process in which ground gold ore is preheated prior to entering the roaster.*

Ore pretreatment processes *means the affected source that includes roasting operations and autoclaves that are used to pre-treat gold mine ore at gold mine ore processing and production facilities prior to the cyanide leaching process.*

Pregnant solution tank (or preg tank) *means a storage tank for pregnant solution, which is the cyanide solution that contains gold-cyanide complexes that is generated from leaching gold ore with cyanide solution.*

Pregnant cyanide solution *means the cyanide solution that contains gold-cyanide complexes that are generated from leaching gold ore with a dilute cyanide solution.*

Quenching *means a process in which the hot calcined ore is cooled and quenched with water after it leaves the roaster.*

Roasting operation *means a process that uses an industrial furnace in which milled ore is combusted across a fluidized bed to oxidize and remove organic carbon and sulfide mineral grains in refractory gold ore. The emissions points of the roasting operation subject to this subpart include ore dry grinding, ore preheating, the roaster stack, and quenching.*

Because the permittee will own or operate a gold mine ore processing and production facility at an area source of HAP, requirements in Subpart EEEEEEE are applicable. The collection of ore pretreatment processes and the carbon process with mercury retort are affected sources. Ore pretreatment processes include the autoclave (AC). Carbon processes with mercury retort include the electrowinning cells and pregnant solution tank (EW), the mercury retort (MR), induction melting furnace (MF), and the carbon regeneration kiln (CKD).

Any source subject to 40 CFR 63, Subpart EEEEEEE is a Tier I source as defined in IDAPA 58.01.01.006.122.c. In accordance with IDAPA 58.01.01.313.01.b., the permittee must submit a complete application to DEQ for an initial Tier I operating permit within 12 months of becoming a Tier I source.

This subpart includes mercury emissions limits for the collection of new ore pretreatment processes and for the new carbon processes with mercury retort. This subpart also requires weight measurement devices for measuring ore throughput for the autoclave (AC) and mineral-bearing solution throughput for the electrowinning cells and pregnant solution tank (EW). Requires monitoring of mercury emissions, and monitoring of either inlet gas temperature for each process unit with a carbon filter (EW, MR, MF, CKD) or both water flow and pressure drop for each process unit with a wet scrubber not followed by a carbon filter (AC).

40 CFR 63, Subpart EEEEEEE is incorporated by reference into Permit Condition 2.22, and specific applicable requirements will be incorporated into the Tier I operating permit.

Permit Conditions Review

This section describes the permit conditions for this initial permit.

Permit Conditions 1.1–1.2 describe the purpose of this permitting action and the emission sources and the control equipment regulated by this permit. This reflects information presented in the application and relied upon in the development of emissions inventories, and in the evaluation of ambient air impacts in the modeling analyses. Refer to the Emissions Inventories and the Ambient Air Quality Impact Analyses sections for additional information concerning these analyses.

Because specific vendor and manufacturer information was unavailable at the time of permitting, documentation and testing requirements were included (Permit Condition 2.20) to verify consistency with the information specified in the application. Production values and limits were based on process flow diagrams and engineering design information provided.

Permit Conditions 2.1–2.8 incorporate fugitive dust emission limits and control requirements as required by IDAPA 58.01.01.650-651. Compliance is ensured by implementing reasonable control precautions and corrective actions when appropriate, excluding public access to operations, and complying with inspection, monitoring, recordkeeping, and notification requirements. Specific precautions are identified and required in the fugitive dust control plan (FDCP), and specific measures to control public access within the operations boundary are identified in and required by the Access Management Plan (AMP; Permit Conditions 2.6 and 2.7, respectively). A trigger level for haul roads was also established requiring employment of control measures (Permit Condition 2.5).

Reduction of PM emissions from each of the identified conveyors by 80% was supported by assuming location of these material transfers at below grade (OC9, OC10) or enclosure on all sides (OC11). Reduction of PM emissions from haul roads by a combined 93.3% was supported by assuming appropriate application of water and magnesium chloride dust suppression; DEQ is cognizant that to consistently achieve this level of control requires conscientious efforts, vigilant inspection and monitoring, and a comprehensive FDCP. Because continuous operation was proposed, suppression measures will need to account for and accommodate all weather conditions including diurnal and seasonal variability, and all traffic loads including mining and public traffic along publicly accessible roads. Conditions outside of what may normally be anticipated may require additional measures such as a reduction in vehicle speeds or selection of a more effective chemical dust suppressant. Although the FDCP specifies a minimum of efforts required, additional operational limits and monitoring are to be considered moving forward and evaluated for incorporation into the FDCP. Certification of employees for visible emissions inspection, training and orientation of relevant employees, and periodic evaluation of FDCP requirements are also required.

Access control measures are described in the Ambient Air Boundary section of the application (Section 5.6), and address primary access points, secondary access points, and surveillance.

Permit Conditions 2.9–2.12 incorporate visible emission limits and control requirements (Permit Condition 2.9) in accordance with IDAPA 58.01.01.625. Compliance is ensured by implementing corrective actions when appropriate and complying with inspection, monitoring, and recordkeeping requirements. Certification of employees for visible emissions inspection is also required.

Permit Condition 2.13 is listed as reserved to ensure the integrity of the permit numbering. The process weight rate permit condition has been removed because as discussed previously in the Process Weight section, compliance has been demonstrated with the process weight rule.

Permit Conditions 2.14–2.15 incorporate odorous emission limits in accordance with IDAPA 58.01.01.776.01. Compliance is ensured by complying with monitoring and recordkeeping requirements, including corrective action when appropriate.

Permit Conditions 2.16–2.17 incorporate sulfur content limits for distillate fuel oil, in accordance with IDAPA 58.01.01.725. Compliance is ensured by complying with monitoring and recordkeeping requirements.

Permit Conditions 2.18–2.19 limit facility-wide gasoline fuel throughput. Limiting gasoline throughput limits PTE, ensures avoidance of Subpart CCCCCC requirements applicable to GDF exceeding 100,000 gal/mo, and requires recordkeeping in accordance with 40 CFR 63.11111(e). Compliance is ensured by complying with monitoring and recordkeeping requirements.

Permit Conditions 2.20–2.21 require developing and complying with the requirements of an O&M manual to ensure compliance with control equipment maintenance and operation general provisions (Permit Condition 7.2). Documentation of as-built process equipment specifications and control equipment performance guarantees and establishing control equipment operating parameters and procedures were required, since these were relied upon in the development of emissions inventories, and in the evaluation of ambient air impacts in the modeling analyses. Compliance is ensured by complying with monitoring and recordkeeping requirements.

Permit Condition 2.22 incorporates applicable general compliance, notification, recordkeeping, reporting, general provisions, and other federal requirements by reference in accordance with IDAPA 58.01.01.107.03 and 590-591. Compliance is ensured by complying with applicable federal testing, monitoring, recordkeeping, and reporting requirements. In the event there is a conflict between the subparts and/or emission sources listed (Permit Condition 2.22), the federal requirements shall apply.

With regard to permit conditions referenced in accordance with federal requirements (i.e., NSPS and NESHAP requirements), should there be a conflict between the language of the permit condition and the language of the requirement, the language of the requirement shall govern. Refer to NSPS Applicability (40 CFR 60) and MACT/GACT Applicability (40 CFR 63) sections for additional information concerning applicable requirements.

Permit Conditions 2.23–2.24 require notification upon becoming a Tier I source and require the permittee to obtain a Tier I operation permit within 12 months of commencement of operation of any ore concentration and refining equipment (i.e., NESHAP Subpart EEEEEEE-affected sources) in accordance with IDAPA 58.01.01.313.01.b.

Permit Condition 2.25 specifies recommended test methods to be used when performance testing is required, unless otherwise specified in the permit, in accordance with IDAPA 58.01.01.157. The permittee is required to comply with notification and reporting requirements and is encouraged to submit performance test protocol to DEQ for approval prior to any performance testing in accordance with the performance testing general provisions (Permit Condition 7.7–7.9).

Permit Condition 2.26 provides DEQ agency contact information.

Permit Conditions 3.1–3.2 describe mining and ore processing equipment and controls. This reflects information presented in the application and relied upon in the development of emissions inventories, and in the evaluation of ambient air impacts in the modeling analyses.

Permit Conditions 3.3–3.9 establish limits on material throughput and production. These limits were relied upon in the development of emissions inventories and in the evaluation of ambient air impacts in the modeling analyses. Overall mine throughput is limited by hauling and excavating limits including T-RACT control measures (Permit Conditions 3.5 and 3.6). Compliance is ensured by complying with monitoring and recordkeeping requirements (Permit Conditions 3.14–3.20).

Permit Conditions 3.10 and 3.12 require measures to include in the FDCP to control fugitive emissions. Use of reasonable controls were relied upon in the development of emissions inventories and in the evaluation of ambient air impacts in the modeling analyses. Compliance is ensured by complying with fugitive dust monitoring and recordkeeping requirements (Permit Conditions 2.1–2.8).

Permit Conditions 3.11 and 3.13 establish a drilling rigs dust control system and a haul road capping plan. Use of these controls in the T-RACT analysis were relied upon in the evaluation of ambient air impacting in the modeling analyses. Compliance is ensured by complying with monitoring and recordkeeping requirements (Permit Conditions 3.11 and 3.13).

Permit Conditions 4.1–4.2 describe ore concentration and refining equipment and controls. This reflects information presented in the application and relied upon in the development of emissions inventories, and in the evaluation of ambient air impacts in the modeling analyses.

Permit Condition 4.3, and 4.33–4.34 establish emissions limits for ore concentration and refining equipment, consistent with estimates relied upon in the development of emissions inventories and in the evaluation of ambient air impacts in the modeling analyses for these sources. A sulfuric acid emission limit consistent with the modeled TAP emission rate from the autoclave was established in accordance with IDAPA 58.01.01.210.08. Compliance is ensured by complying with equipment operating and testing requirements (Permit Conditions 4.5–4.17, and 4.33–4.34).

Permit Conditions 4.4, 4.5–4.6, 4.7–4.12 and 4.18–4.25 limit operations of ore concentration and refining process equipment, consistent with the hours of operation, reagent usage, and material throughput assumptions relied upon in the development of emissions inventories and in the evaluation of ambient air impacts in the modeling analyses for these sources. Compliance is ensured by complying with monitoring and recordkeeping requirements (Permit Conditions 4.18–4.25). Cyanide is consumed, recycled, and destroyed in the process, and cyanide HAP emissions (and emission factors) dependent upon leachant concentration and basicity. Monitoring of these parameters was established to ensure that emissions do not exceed 10 T/yr of cyanide HAP to avoid classification as a HAP major source. Re-classification as a major source would affect NSPS and NESHAP applicability determinations, such as Subpart AAAAA as discussed in the NESHAP Applicability (40 CFR 61) section.

Permit Conditions 4.13–4.17 and 4.26–4.32 require control equipment for ore concentration and refining processes, consistent with controls relied upon in the development of emissions inventories and in the evaluation of ambient air impacts in the modeling analyses. Compliance is ensured by complying with monitoring and recordkeeping requirements (Permit Conditions 4.26–4.32).

Permit Condition 4.33 and 4.34 require testing of ore concentration and refining emission sources to demonstrate compliance with emissions limits (Permit Condition 4.3).

Permit Conditions 5.1–5.2 describe lime, aggregate, and concrete production equipment and controls. This reflects information presented in the application and relied upon in the development of emissions inventories, and in the evaluation of ambient air impacts in the modeling analyses.

Permit Condition 5.3 establishes emissions limits for lime, aggregate, and concrete production equipment, consistent with estimates relied upon in the development of emissions inventories and in the evaluation of ambient air impacts in the modeling analyses for these sources. Compliance is ensured by complying with equipment operating requirements (Permit Conditions 5.4–5.15).

Permit Conditions 5.4–5.9 and 5.17–5.22 limit operations of each lime, aggregate, and concrete production process equipment, consistent with material throughput assumptions relied upon in the development of emissions inventories and in the evaluation of ambient air impacts in the modeling analyses for these sources. Compliance is ensured by complying with monitoring and recordkeeping requirements (Permit Conditions 5.15–5.20).

Permit Conditions 5.10–5.11 require measures to include in the FDCP to control fugitive emissions. Use of water sprays, building enclosures, and reasonable controls were relied upon in the development of emissions inventories and in the evaluation of ambient air impacts in the modeling analyses. Compliance is ensured by complying with fugitive dust monitoring and recordkeeping requirements (Permit Conditions 2.1–2.8).

Permit Conditions 5.12–5.16 and 5.23–5.26 require control equipment for lime, aggregate, and concrete production processes, consistent with controls relied upon in the development of emissions inventories and in the evaluation of ambient air impacts in the modeling analyses. Compliance is ensured by complying with monitoring and recordkeeping requirements (Permit Conditions 5.23–5.26).

Permit Condition 6.1 describes the emergency power generation equipment. This reflects information presented in the application and relied upon in the development of emissions inventories, and in the evaluation of ambient air impacts in the modeling analyses.

Permit Conditions 6.2, 6.3, and 6.5 limit operations of each emergency power generation engine, consistent with the purpose and hours of operation assumptions relied upon in the development of emissions inventories, in the determination of federal regulatory applicability, and in the evaluation of ambient air impacts in the modeling analyses for these sources. Compliance is ensured by complying with monitoring, recordkeeping, and notification requirements (Permit Conditions 6.4, 6.6–6.7).

Permit Condition 7.1, the duty to comply general compliance provision, requires that the permittee comply with all of the permit terms and conditions pursuant to Idaho Code §39-101.

Permit Condition 7.2, the maintenance and operation general compliance provision, requires that the permittee maintain and operate all treatment and control facilities at the facility in accordance with IDAPA 58.01.01.211.

Permit Condition 7.3, the obligation to comply general compliance provision, specifies that no permit condition is intended to relieve or exempt the permittee from compliance with applicable state and federal requirements, in accordance with IDAPA 58.01.01.212.01.

Permit Condition 7.4, the inspection and entry provision, requires that the permittee allow DEQ inspection and entry pursuant to Idaho Code §39-108.

Permit Condition 7.5, the permit expiration construction and operation provision, specifies that the permit expires if construction has not begun within two years of permit issuance or if construction has been suspended for a year in accordance with IDAPA 58.01.01.211.02.

Permit Condition 7.6, the notification of construction and operation provision, requires that the permittee notify DEQ of the dates of construction and operation, in accordance with IDAPA 58.01.01.211.01 and 211.03.

Permit Condition 7.7, the performance testing notification of intent provision, requires that the permittee notify DEQ at least 15 days prior to any performance test to provide DEQ the option to have an observer present, in accordance with IDAPA 58.01.01.157.03.

Permit Condition 7.8, the performance test protocol provision, requires that any performance testing be conducted in accordance with the procedures of IDAPA 58.01.01.157 and encourages the permittee to submit a protocol to DEQ for approval prior to testing.

Permit Condition 7.9, the performance test report provision, requires that the permittee report any performance test results to DEQ within 60 days of completion, in accordance with IDAPA 58.01.01.157.04-05.

Permit Condition 7.10, the monitoring and recordkeeping provision, requires that the permittee maintain sufficient records to ensure compliance with permit conditions, in accordance with IDAPA 58.01.01.211.

Permit Condition 7.11, the excess emissions provision, requires that the permittee follow the procedures required for excess emissions events, in accordance with IDAPA 58.01.01.130-136.

Permit Condition 7.12, the certification provision, requires that a responsible official certify all documents submitted to DEQ, in accordance with IDAPA 58.01.01.123.

Permit Condition 7.13, the false statement provision, requires that no person make false statements, representations, or certifications, in accordance with IDAPA 58.01.01.125.

Permit Condition 7.14, the tampering provision, requires that no person render inaccurate any required monitoring device or method, in accordance with IDAPA 58.01.01.126.

Permit Condition 7.15, the transferability provision, specifies that this permit to construct is transferable, in accordance with the procedures of IDAPA 58.01.01.209.06.

Permit Condition 7.16, the severability provision, specifies that permit conditions are severable, in accordance with IDAPA 58.01.01.211.

PUBLIC REVIEW

Public Comment Opportunity

An opportunity for public comment period on the application was provided in accordance with IDAPA 58.01.01.209.01.c. During this time, there was a request for a public comment period on DEQ's proposed action. Refer to the Application Chronology for public comment opportunity dates.

Public Comment Period

Comment periods were made available to the public in accordance with IDAPA 58.01.01.209.01.c. An initial comment period and extension were provided to address the initial application and proposed action (i.e., permit and technical statement of basis), and a second comment period was provided to address updates to the proposed action resulting from a HAP/TAP application addendum[2] submitted by PRI that included new HAP and TAP emission estimates, additional information and discussion supporting HAP and TAP emission estimates, new and updated TAP increment compliance demonstrations which included particulate TAP emissions from fugitive sources, and a source-by-source inventory of HAP and TAP emissions. A third comment period was provided to address updates to the proposed action resulting from a lime plant source status determination[8] and a HAP/TAP application addendum[9] submitted by PRI that includes a T-RACT analysis and proposed control measures. During this time, comments were submitted in response to DEQ's proposed action. Refer to the Application Chronology for the dates of each public comment period.

A response to public comments document has been crafted by DEQ based on comments submitted during each public comment period. That document is part of the final permit package for this permitting action.

0.075 ton/ft^3

Material specific volume 13.3 ft^3/ton

TD volume (V) 1,896 ft^3

Conical surface calculations

Side slope 38 deg *Typical*

0.7 rad

Conical surface area (SA) Π × r × (h^2 + r^2)^0.5

Conical volume (V) (Π × h × r^2) ÷ 3

Conical base radius r = s × cos(slope)

Conical height h = s × sin(slope)

Sloped side length s = (h^2 + r^2)^0.5

Solution of conical volume equation

Replacing h and r with s × sin(slope) and s × cos(slope), respectively:

s = [3 × V/(pi × sin(slope) × cos^2(slope)]^(1/3) 16.8 ft

r 13.2 ft

h 10.3 ft

SA 698 ft^2

0.016 acre

1.1E-4 acre/ton-TD

Scaling Factors

ORE CONCETRATION AND REFINING

Source Data

Source ID	Description	Subpart 7E Allowable Limit lb/yr[1]	Oper. hr/yr	% of Subpart 7E for Controlled Systems %		Controlled Hg Emissions lb/hr	ton/yr	lb/yr
AC	Autoclave	213.4	8,760	[2]		0.000023	0.00010	0.20
EW,MR,MF,CKD	Refinery Sources (C. Kiln, EW, Retort, Furn	16.8		20%	[3]	0.000384	0.00168	3.36
7439-97-6 Mercury	Total	230.2				0.000407	0.00178	3.56

[1] *Subpart 7E Limit - Ore Pretreatment Processes (CFR 2018b)*

84 lb / MMton × 2,540,400 ton / yr × MMton / 1.0E+6 ton = 213.4 lb / yr

[1] *Subpart 7E Limit - Carbon Processes with Mercury Retorts*

0.8 lb / ton × 21 ton / yr = 16.8 lb / yr

[2] *Controlled SysCAD modeled emissions from Autoclave:* 0.0105 g/hr 2.3E-05 lb/hr 0.20 lb/yr (M3 2019)

[3] *Based on similar source (but with much higher ore Hg content) Hg reporting levels provided below:*

Goldstrike Refinery (2015 & 2016 Hg Reports) (NDEP 2015a) (NDEP 2016)

28.79 lb / yr × 251.00 ton / yr = 0.11 lb / MMton × ton / 0.8 lb = 14.3%

Twin Creeks Refinery (2015 & 2016 Hg Reports) (NDEP 2015a) (NDEP 2016)

31.27 lb / yr × 142.77 ton / yr = 0.22 lb / MMton × ton / 0.8 lb = 27.4%

APPENDIX B – AMBIENT AIR QUALITY IMPACT ANALYSES REVIEW MEMORANDUM

M E M O R A N D U M

DATE: January 6, 2022

TO: Kelli Wetzel, Permit Writer, Air Program

FROM: Pao Baylon, Modeling Review Analyst, Air Program
Through Kevin Schilling, Modeling Supervisor, Air Program

PROJECT: P-2019.0047 PROJ 62288, Permit for an Open-pit Gold Mine and On-site Ore Preparation and Gold Extraction Operation located in Valley County, Idaho.

SUBJECT: Demonstration of Compliance with IDAPA 58.01.01.203.02 (NAAQS) and 203.03 (TAPs) as it relates to air quality impact analyses.

1.0 Summary

Perpetua Resources Idaho, Inc. (PRI) submitted a Permit to Construct (PTC) application to construct and operate the Stibnite Gold Project (SGP) in Valley County, Idaho. The SGP will consist of conventional open-pit mining operations and onsite ore preparation and gold extraction processes. The potential air emissions from the SGP are less than the applicable major source thresholds for both criteria and hazardous air pollutants (HAP), and therefore, the facility is designated as a minor source for Title V and New Source Review (NSR) requirements, and an area source for National Emission Standards for Hazardous Air Pollutants (NESHAP) applicability. Project-specific air quality analyses involving atmospheric dispersion modeling of estimated emissions associated with the facility were submitted to DEQ to demonstrate that applicable emissions do not result in violation of a National Ambient Air Quality Standard (NAAQS) or Toxic Air Pollutant (TAP) increment as required by the Idaho Administrative Procedures Act 58.01.01.203.02 and 203.03 (Idaho Air Rules Section 203.02 and 203.03). This memorandum provides a summary of the applicability assessment for analyses and air impact analyses used to demonstrate compliance with applicable NAAQS and TAP increments, as required by Idaho Air Rules Section 203.02 and 203.03.

Air Sciences, Inc. (Air Sciences), on behalf of PRI, prepared the PTC application and performed ambient air impact analyses for this project. DEQ review of submitted data and DEQ analyses summarized by this memorandum addressed only the rules, policies, methods, and data pertaining to the air impact analyses used to demonstrate that estimated emissions associated with operation of the facility will not cause or significantly contribute to a violation of any applicable air quality standard. This review did not address/evaluate compliance with other rules or analyses not pertaining to the air impact analyses. Evaluation of emission estimates was the responsibility of the DEQ permit writer and is addressed in the main body of the DEQ Statement of Basis, and emission calculation methods were not evaluated in this modeling review memorandum.

DEQ reevaluated source-specific TAP regulatory applicability for the project after the February/March 2021 public comment period in response to expressed concerns regarding sources excluded as per *Idaho Air Rules* Section 210.20 (excluding sources that are "covered" or "addressed" by a federal rule). Air Sciences made substantial refinements in assessed operational scenarios and emission calculations, and they also worked with DEQ on a refined TAPs regulatory approach. Air Sciences addressed this issue separately from the NAAQS compliance demonstration presented in the main body of the PTC application and submitted the *Stibnite Gold Project Permit to Construct Application TAP Addendum* (*TAP Addendum*). Since all the refinements reduced calculated allowable particulate emissions from sources, the NAAQS compliance demonstration did not require revision for permit issuance. Impacts from revised sources would obviously be lower and still demonstrate compliance with NAAQS. DEQ's review of the *TAP Addendum* is discussed in the *TAPs Addendum Modeling Review Attachment* (*Modeling Review Attachment*) to this memorandum.

Table 1 presents key assumptions and results to be considered in the development of the permit. Idaho Air Rules require air impact analyses be conducted in accordance with methods outlined in 40 Code of Federal Regulations (CFR) 51, Appendix W *Guideline on Air Quality Models* (*Appendix W*). *Appendix W* requires that air quality impacts be assessed using atmospheric dispersion models with emissions and operations representative of design capacity or as limited by a federally enforceable permit condition.

The submitted information and analyses: 1) utilized appropriate methods and models; 2) was conducted using reasonably accurate or conservative model parameters and input data (review of emission estimates was addressed by the DEQ permit writer); 3) adhered to established DEQ guidelines for new source review dispersion modeling; 4) showed either a) that estimated potential/allowable emissions are at a

REC 0627

PET 261

level defined as below regulatory concern (BRC) and do not require a NAAQS compliance demonstration; b) that predicted pollutant concentrations from emissions associated with the project as modeled were below Significant Impact Levels (SILs) or other applicable regulatory thresholds; or c) that predicted pollutant concentrations from emissions associated with the project, when appropriately combined with co-contributing sources and background concentrations, were below applicable NAAQS at ambient air locations where and when the project has a significant impact; 5) showed that TAP emission increases associated with the project will not result in increased ambient air impacts exceeding allowable TAP increments. This conclusion assumes that conditions in Table 1 are representative of facility design capacity or operations as limited by a federally enforceable permit condition. The DEQ permit writer should use Table 1 and other information presented in this memorandum to generate appropriate permit provisions/restrictions to assure emissions do not exceed applicable regulatory thresholds requiring further analyses and to assure the requirements of *Appendix W* are met regarding emissions representative of design capacity or permit allowable rates.

Table 1. KEY ASSUMPTIONS USED IN MODELING ANALYSES.

Criteria/Assumption/Result	Explanation/Consideration
General Emission Rates. Emission rates used in the air impact analyses must represent maximum potential emissions as given by design capacity, inherently limited by the nature of the process or configuration of the facility, or as limited by the issued permit for the specific pollutant and averaging period.	Compliance has not been demonstrated for emission rates greater than those used in the air impact analyses.
Air Impact Analyses for Criteria Pollutant Emissions. Stibnite Gold Project (SGP) facility-wide maximum potential to emit are greater than the respective Level I thresholds for all criteria pollutants and averaging periods except for Lead. Therefore, modeling is triggered for applicable averaging periods for $PM_{2.5}$[a], PM_{10}[b], CO[c], NOx[d], and SO_2[e]. Modeling was not required for Lead.	Project-specific air impact analyses demonstrating compliance with NAAQS, as required by Idaho Air Rules Section 203.02, are required for pollutant increases above Below Regulatory Concern (BRC) thresholds, or for pollutants having an emissions increase that is greater than Level I modeling applicability thresholds (where the BRC exclusion cannot be used). DEQ modeling applicability thresholds were revised in July 2021. Revised thresholds were not used because the permit application was submitted prior to the revision.
Air Impact Analyses for TAP Emissions. TAP analyses were reworked after the February/March 2021 public comment period and submitted to DEQ in the *TAP Addendum*. DEQ's review of the *TAP Addendum* is discussed in the *Modeling Review Attachment* to this memorandum. SGP final facility-wide potential Toxic Air Pollutant (TAP) emissions exceed the respective screening emission levels (ELs) for aluminum, arsenic, barium, beryllium, cadmium, calcium carbonate, calcium oxide, cyanide, formaldehyde, iron, manganese, nickel, phosphorus, sulfuric acid, thallium, and vanadium. Therefore, air dispersion modeling was required for these 16 TAPs. TAPs also classified as Hazardous Air Pollutants (HAPs) emitted from sources addressed by New Source Performance Standards (NSPS) or National Emission Standards for Hazardous Air Pollutants (NESHAP) were not required to be evaluated for compliance with TAP increments in accordance with IDAPA 58.01.01.210.20.	A TAP increment compliance demonstration would be required for any TAPs with emissions above ELs. IDAPA 58.01.01.210.20 states that if TAP emissions from a specific source are addressed by NSPS or NESHAP, then a TAP impact analysis is not required for that TAP from that specific source.
Significant Impact Level Analysis Not Conducted. A Significant Impact Level (SIL) analysis was not conducted for the SGP facility.	Based on the magnitude of the facility-wide emissions and preliminary modeling analyses, it was determined that the impacts from the SGP emissions exceeded the SIL for most criteria pollutants. Therefore, SIL analyses were considered redundant and not performed for the project.
Multiple Modeling Scenarios. To evaluate the worst-case air impacts from the SGP facility, a total of 14 scenarios were modeled. These scenarios represent the hauling of material, which can be either ore or development rock (DR), from four	Conventional open-pit methods will be used to extract ore and DR from four possible origins (Yellow Pine Pit [YPP], Hangar Flats Pit [HFP], West End Pit [WEP], and Bradley Tailings [BT]). Ore and DR will be hauled to five possible

REC 0628

PET 262

Table 1. KEY ASSUMPTIONS USED IN MODELING ANALYSES.	
Criteria/Assumption/Result	**Explanation/Consideration**
possible origins (three pits and a tailings facility) to five possible destinations (ore will be hauled to the crushing area while DR will be hauled to one of four development rock storage facilities [DRSF]). Modeled design values listed in this modeling memo represent the worst-case modeling scenario for every modeled pollutant and averaging period.	destinations (Stockpile [STKP], Yellow Pine DRSF [YPDRSF], Hangar Flats DRSF [HFDRSF], West End DRSF [WEDRSF], and Fiddle DRSF [FDRSF]). Only 14 of the 20 possible scenarios were modeled. Six scenarios were not feasible because the timing of the activity within the sequence of mine operations makes the scenarios logistically impossible. Modeled results listed in this memo represent worst-case modeling scenarios.
Modeling of Material Origin and Destination. Each material origin location (YPP, HFP, WEP, and BT) was modeled as an AREA source. Ore destination (STKP) was modeled as a VOLUME source. Each DR destination (YPDRSF, HFDRSF, WEDRSF, and FDRSF) was modeled as a VOLUME source.	Each material origin location comprised appropriate emissions from drilling, material loading, dozing, and surface exploration. Ore destination comprised ore unloading emissions. Each DR destination comprised appropriate emissions from DR unloading, dozing, and wind erosion. For the four AREA and five VOLUME sources, the dimensions were developed by reasonably fitting an equal-area rectangle within the actual footprint of each fugitive source. For the pit and DRSF fugitive activity locations, the release height was based on the haul truck height. The applicable initial lateral dispersion for each VOLUME source was calculated from the respective shorter dimension and EPA-specified methods. The applicable initial vertical dispersion for each AREA and VOLUME source was calculated from the respective vertical dimension and EPA-specified methods.
Modeling of Haul Roads. A representative haul road network for hauling material from inside the pit to various destinations was developed for each of the 14 modeling scenarios.	The haul road network was divided into 22 sections. Each section was further divided into multiple segments with a length equal to twice the adjusted haul road width. Each of the segments was characterized as an individual VOLUME source in the model. Material hauling emissions associated with each origin-destination route were assigned to each segment along the route based on estimated total emissions along the route and traffic distribution along each section.
Modeling of Blasting Emissions. Blasting emissions were represented by a VOLUME source inside a pit (YPPBL, HFPBL, and WEPBL). Blasting is not expected to occur in BT but was modeled (BTBL) in order to streamline the permitting process.	The blasting physical parameters were developed from dimensions based on blast area used in the emission calculation. The blasting release height was the midpoint of the blasting height. The initial lateral and vertical dispersion dimensions for blasting were calculated per methods specified in the AERMOD User's Guide.
Modeling of Burntlog Route Access Road. The access road portion within the operations boundary was characterized by a series of LINE sources laid along the actual route.	Emissions associated with the portion of the Burntlog Route mine access road that is within project boundary (from the south gate to the process area) are included in the SGP analyses. These include dust emissions generated from travel of maintenance equipment, light-duty pickup trucks and buses used for employee, visitor, and contractor transportation, and heavy-duty trucks used for cargo (including fuel, consumables, machine parts, ore processing supplies, ore concentrate, etc.) and services (including food supplies, trash, recyclables, etc.) transportation. Release parameters for the LINE sources were based on an estimated average vehicle height. The access road emissions were evenly distributed along the road by dividing the total access road emissions by its total area.
Control of Fugitive Dust from Roadways. Fugitive particulate emissions from roadways were assumed to be controlled above 93%, which is an aggressive level of control.	The high level of emission control was needed to demonstrate compliance with NAAQS. Compliance is not demonstrated for emissions greater than those associated with above 93% control.

REC 0629

PET 263

Table 1. KEY ASSUMPTIONS USED IN MODELING ANALYSES.	
Criteria/Assumption/Result	**Explanation/Consideration**
NOx Chemistry and NO_2/NOx In-Stack Ratios. Ozone Limiting Method (OLM), a Tier 3 NO_2 screening method, was used to estimate the 1-hour and annual NO_2 impacts. The following NO_2/NOx In-Stack Ratios (ISR) were used in the modeling analyses: Blasting: 0.036 Diesel engines: 0.11 Propane heaters: 0.10	The OLM method requires an input of NO_2/NOx ISRs for each modeled source. The NO_2/NOx ratio for blasting was based on blasting plume measurements provided in published literature. The NO_2/NOx ratio for stationary diesel combustion sources was based on heavy-duty diesel trucks in the California Air Pollution Control Officers Association (CAPCOA) Guidance Document. This NO_2/NOx ratio (11 percent) is conservatively higher than the diesel combustion NO_2/NOx ratio provided in the EPA ISR database: 6 percent average, 9.8 percent maximum. The CAPCOA document and the EPA ISR database do not provide an NO_2/NOx ratio for propane boilers. The CAPCOA-recommended NO_2/NOx ratio for natural gas boilers was selected for the propane boilers. The natural gas boilers NO_2/NOx ratio is considered appropriate for the propane boilers because both are gaseous fuels with relatively similar combustion characteristics and are expected to have similar NO_2/NOx ratios. DEQ performed a sensitivity analysis using Tier 2 (Ambient Ratio Method 2), a more conservative NO_2 screening method, and found that the facility is safely below the 1-hour and annual NO_2 NAAQS.
Alternate Meteorological Data Processed Using Cloud Cover. An alternative meteorological dataset was processed without using the Bulk Richardson (BULKRN) method. This alternate processing (NON-BULKRN) used upper air data from Boise airport, supplemented with the cloud-cover data collected at the National Weather Service station in McCall, Idaho.	Meteorological data processing with and without BULKRN are considered acceptable regulatory options by EPA. The NON-BULKRN meteorological data yielded lower modeled design values than the meteorological data processed using the BULKRN method.
Ambient Air Boundary. PRI will legally control the SGP, an active industrial site where mining activities will occur, such as heavy equipment operation. Most areas of the mine will require strict safety protocols and controlled access. PRI has established an operations boundary to identify the area where public access will be excluded. Public access inside the operations boundary will be restricted for the life of the mine by physical barriers at points of potential access, including the current Stibnite Road point of entry and proposed site access via the Burntlog Route, as well as natural features of the landscape that prevent access.	Ambient air is defined in Section 006 of the Idaho Air Rules as "that portion of the atmosphere, external to buildings, to which the general public has access." Receptors must be placed at any portion of the atmosphere that is considered ambient air.
Onsite Background $PM_{2.5}$ and PM_{10} Concentrations. The following background $PM_{2.5}$ and PM_{10} concentrations were measured at SGP in 2014 and used in the cumulative NAAQS impact analysis: Annual $PM_{2.5}$: 3.5 µg/m^3 (weighted average of quarterly means) 24-hour $PM_{2.5}$: 15.0 µg/m^3 (98th percentile/8th high) 24-hour PM_{10}: 37.0 µg/m^3 (highest 1st high)	PRI developed an onsite monitoring program to collect site-specific meteorological parameters and determine ambient particulate matter ($PM_{2.5}$ and PM_{10}) concentrations at its Stibnite monitoring station. $PM_{2.5}$ and PM_{10} background concentrations were based on calendar year 2014 instead of the complete dataset (November 2013 through June 2015). For 24-hour PM_{10}, the design value is the *second-highest* 24-hour average concentration in a given year. However, the background value that was used in the modeling analyses represents the *first-highest* 24-hour average concentration measured in 2014. Therefore, using a larger background concentration adds a layer of conservatism to the calculated total impact for 24-hour PM_{10}.
NW AIRQUEST Background CO, NO_2, and SO_2 Concentrations. The following background concentrations for CO, NO_2, and SO_2 were used in the cumulative NAAQS impact analysis: 1-hour CO: 1,740 µg/m^3 8-hour CO: 1,110 µg/m^3	Gaseous pollutant background concentrations were determined using the Northwest International Air Quality Environmental Science and Technology Consortium (NW AIRQUEST) online tool. The NW AIRQUEST tool uses regional scale modeling of pollutants in Washington, Oregon, and Idaho, with model results adjusted according to

REC 0630

PET 264

Table 1. KEY ASSUMPTIONS USED IN MODELING ANALYSES.	
Criteria/Assumption/Result	**Explanation/Consideration**
1-hour NO_2: 4.3 µg/m^3 Annual NO_2: 0.9 µg/m^3 1-hour SO_2: 12.3 µg/m^3 3-hour SO_2: 16.8 µg/m^3	available monitoring data.
Medium-Traffic Background Concentrations. To provide additional information regarding the relative contribution of traffic emissions, background concentrations were obtained from NW AIRQUEST for the road section between mile markers 143 and 144 on Highway 55 passing through the town of McCall.	The McCall location is approximately 38 miles west of the SGP. The annual average daily traffic count for this road section is over 10,000 vehicles per day. Although the background concentrations at McCall are not representative of the rural SGP area, they provide additional information regarding the relative contribution of traffic emissions.
Weight-of-Evidence Analyses for 24-hour PM_{10}. PM_{10} modeling with meteorological dataset processed using the site-specific BULKRN method shows up to five hotspot receptors for Scenario W5 (the highest PM_{10} modeling scenario) that exceed NAAQS. All modeled violations occur during winter when the average snow depth and average precipitation at the project site are 21-68 inches and 6.0 inches, respectively. Therefore, fugitive road dust emissions during high-modeled impact hours could be overestimated. PM_{10} modeling simulation was based on a mining production rate of 180,000 ton/day of development rock (65,700,000 ton/year, which is more conservative than the expected peak production rate of 42,692,000 ton/year). To investigate the effect of a lower modeled mining production rate on design value concentrations, DEQ performed a modeling simulation where mining production rate was assumed to be 120,000 ton/day instead of 180,000 ton/day, but everything else was held constant. Maximum modeled concentration, when summed with the background concentration, is lower than the 24-hour PM_{10} NAAQS thereby demonstrating NAAQS compliance. DEQ's weight-of-evidence analyses conclude that, considering all the collective conservative layers of the modeling analyses, including the use of meteorological data processed by two different methods, there is a satisfactory level of confidence that operation of the project as described in the application will not cause or contribute to a violation of NAAQS.	Meteorological data processing with and without BULKRN are considered acceptable by EPA, with the BULKRN method utilizing more of the onsite collected meteorological parameters. However, the BULKRN-processed meteorological data yielded higher modeled design value impacts for the SGP facility than the meteorological data processed without the BULKRN method. DEQ's supplemental analyses suggest that when emissions are more-closely representative of typical daily mining production rates for a high-production period (everything else held constant), the SGP facility is able to demonstrate compliance with 24-hour PM_{10} NAAQS at those few receptors showing a potential violation when using meteorological data processed with the BULKRN method. PRI later determined that the WEDRSF will not be constructed. This change eliminated Scenario W5 as a potential operating scenario. DEQ reanalyzed PM_{10} impacts to account for the refinements, and results are presented in the *Modeling Review Attachment* to this memorandum.

[a.] Particulate matter with an aerodynamic diameter less than or equal to a nominal 2.5 micrometers.
[b.] Particulate matter with an aerodynamic diameter less than or equal to a nominal 10 micrometers.
[c.] Carbon monoxide.
[d.] Nitrogen oxides.
[e.] Sulfur dioxide.

Summary of Submittals and Actions

May 30, 2019 Modeling protocol was submitted to DEQ by Brown and Caldwell on behalf of the applicant.

June 27, 2019 Conditional modeling protocol approval was provided to Brown and Caldwell by DEQ.

August 21, 2019 Regulatory start date. PTC application and modeling report were prepared by Air Sciences on behalf of the applicant.

September 19, 2019 Application deemed incomplete by DEQ.

October 4, 2019 DEQ received a preliminary response and supplemental information from the

REC 0631

PET 265

	applicant.
October 15, 2019	DEQ met with the applicant to review and discuss the preliminary response.
October 22, 2019	DEQ determined that the application remained incomplete while the applicant prepared a response to remaining items previously identified, and included a summary of recommendations provided at the meeting.
November 8, 2019	DEQ requested additional information from the applicant via e-mail, relating to items previously identified.
November 21, 2019	Applicant requested extension until November 27, 2019 to respond to incompleteness.
November 27, 2019	DEQ received supplemental information from the applicant, including a revised application with updated emission inventories and modeling analyses.
December 24, 2019	DEQ determined that the application was incomplete.
January 8, 2020	Applicant requested extension until February 7, 2020 to respond to incompleteness.
February 5, 2020	DEQ received supplemental information from the applicant, including a revised application with updated emission inventories and modeling analyses.
March 6, 2020	DEQ determined that the application was incomplete.
April 2, 2020	Applicant requested extension until April 15, 2020 to respond to incompleteness.
April 15, 2020	DEQ received supplemental information from the applicant, including updated modeling analyses.
May 15, 2020	DEQ determined that the application was complete.
June 24, 2020	DEQ received the final updated application.
July 14, 2020	DEQ made available the draft permit and statement of basis for applicant review.
July 31, 2020	DEQ made available an updated draft statement of basis for applicant review.
August 3 and 13, 2020	DEQ received comments from the applicant on the draft permit and statement of basis.
September 10 – October 12, 2020	DEQ provided a public comment period on the proposed action.
October 12, 2020	DEQ received a request to extend the public comment period.
October 13 – November 11, 2020	DEQ extended the public comment period.

November 20, 2020	DEQ requested additional information from the applicant to address substantive public comments received, including missing HAP and TAP emission estimates.
December 18, 2020	DEQ received supplemental information from the applicant, including a HAP/TAP addendum, updated HAP and TAP emission estimates, and updated TAP modeling analyses.
January 28, 2021	DEQ received updated modeling files with corrections for formaldehyde and sulfuric acid, and an updated figure showing TAP modeled impacts.
February 18, 2021-March 19, 2021	DEQ provided a public comment period on the proposed action as updated to address the HAP and TAP addendum and updates.
February 23, 2021	DEQ received notification from the applicant of a facility name change from Midas Gold Idaho, Inc. to Perpetua Resources Idaho, Inc.
March 3, 2021	DEQ provided an information meeting during the public comment period.
September 14, 2021	DEQ received a TAP modeling protocol for revisions to the TAP analyses.
October 6, 2021	DEQ received the *TAP Addendum*, revising TAP analyses for the project.

2.0 Background Information

This section provides background information applicable to the project and the site proposed for the facility. It also provides a brief description of the applicable air impact analyses requirements for the project.

2.1 Project Description

The SGP will require the construction of significant infrastructure, including a power transmission line, a primary mine site access road, onsite haul roads, an ore processing facility, onsite workspaces, employee housing and recreation, water storage and distribution facilities, and sewage disposal facilities.

The SGP will include three years of pre-mining development and construction activities, followed by an operating mine life of approximately 12 years. Mining will occur in three open pits: Yellow Pine Pit (YPP), Hangar Flats Pit (HFP), and West End Pit (WEP). The general sequence of mining will be the YPP deposit, followed by the HFP and WEP deposits. Legacy tailings from the Meadow Creek valley (Bradley Tailings [BT]) also will be reclaimed and reprocessed during the initial project schedule. Surface exploration drilling will continue within the pits and the Scout Prospect decline (underground exploration) throughout the mine operation period. Restoration and reclamation of other legacy mining features will occur prior to mining, throughout the life of the mine, and as part of the mine closure.

Conventional open-pit methods including drilling, blasting, excavating, and hauling will be used to extract ore and waste rock, termed development rock (DR). Hydraulic shovels and front-end loaders will be used to load ore and DR into haul trucks. DR will be used for construction, restoration, and backfilling, or hauled to the dedicated development rock storage facilities (DRSF). Approximately 340 million tons of DR will be handled over the life of the mine. Ore will be hauled to the primary crusher area, where it will

REC 0633

PET 267

be fed directly into the crusher dump pocket or stockpiled. The ore crushing plant will be designed to operate at a maximum rate of 25,000 tons per day (ton/day). Approximately 100 million tons of ore will be mined from the three pits over the life of the project.

The metal-recovery process from ore will include conventional crushing and grinding, followed by froth-flotation circuits that will generate separate gold-silver and antimony-silver concentrates. The antimony-silver concentrate will be shipped offsite for refining, whereas additional onsite processing of the gold-silver concentrate will include pressure oxidation, carbon-in-leach circuits, and refining processes to recover gold and minor amounts of silver. The finely ground leftover ore material from the mineral-recovery process, termed tailings, will be neutralized, thickened, and transported via a pipeline to the tailings storage facility (TSF).

Lime used in the ore processing will either be purchased or manufactured onsite from limestone available at the site. In addition, certain construction and maintenance activities during operations may require sized aggregate. To allow for the operational flexibility to produce construction aggregate onsite, the application included two portable crushing and screening plants.

The following air pollutants are expected from operations at the SGP facility:

- Criteria air pollutants: carbon monoxide (CO), oxides of nitrogen (NOx), particulate matter less than 2.5 microns (μm) and 10 μm ($PM_{2.5}$ and PM_{10}), sulfur dioxide (SO_2), lead (Pb), and ozone (O_3) precursor volatile organic compounds (VOC)
- Hazardous air pollutants (HAP), including mercury (Hg)
- Other non-HAP toxic air pollutants (TAP)
- Greenhouse gases

Based on the uncontrolled potential to emit (PTE) and controlled PTE, the SGP facility will be a "synthetic minor" source of PM, PM_{10}, $PM_{2.5}$, and HAP emissions for new source review (NSR) and Title V (Tier I) permitting purposes. The uncontrolled PTE for the remaining criteria pollutants (SO_2, NOx, CO, VOC) confirm that the SGP facility will be a natural minor source for these emissions. Facility classification is reviewed by the permit writer. Detailed calculations and explanations are provided in the DEQ Statement of Basis.

The PTC addresses all air pollutant-emitting activities associated with the facility.

2.2 Facility Location and Area Classification

The SGP is located in the Stibnite-Yellow Pine Mining District in Valley County, central Idaho (Northing: 4,973,751 meters [m]; Easting: 632,038 m; UTM Zone 11), approximately 100 miles northeast of Boise, 38 miles east of McCall, and approximately 10 miles east of Yellow Pine. A facility location map for the SGP is presented in Figure 1. This figure also shows the proposed Burntlog Route (access road) that will provide a year-round safe access to the site. The SGP site layout is presented in Figure 2.

The Stibnite-Yellow Pine Mining District is characterized by historic mining activities and unpatented (federal land) and patented (private land) mining claims that include deposits of gold, silver, tungsten, and antimony. The district lies in both Boise National Forest (BNF) and Payette National Forest (PNF), but is administered by the PNF's Krassel Ranger District (Perpetua Resources Idaho 2017a). The project area terrain is characterized by narrow valleys 6,000 to 6,600 feet above mean sea level (amsl), surrounded by steep mountains ranging over 8,500 feet amsl. The main drainage basin in the project area is the East Fork of the South Fork of the Salmon River (EFSFSR).

REC 0634

PET 268

The EFSFSR joins Johnson Creek 16 miles downstream, near the village of Yellow Pine. The project area is encompassed by the watersheds of EFSFSR tributaries, including Sugar Creek, Meadow Creek, Johnson Creek, Riordan Creek, Burntlog Creek, Midnight Creek, and Trout Creek. Primary commercial activity in the area comprises mineral exploration, mining, logging, and dispersed recreation.

This area is designated as an attainment or unclassifiable area for SO_2, NO_2, CO, Lead, O_3, PM_{10}, and $PM_{2.5}$. The area is not classified as non-attainment for any criteria pollutants.

Figure 2. SGP SITE LAYOUT AND STIBNITE ROAD ACCESS ROUTE.

2.3 Air Impact Analyses Required for All Permits to Construct

Idaho Air Rules Sections 203.02 and 203.03:

> *No permit to construct shall be granted for a new or modified stationary source unless the applicant shows to the satisfaction of the Department all of the following:*

***02. NAAQS**. The stationary source or modification would not cause or significantly contribute to a violation of any ambient air quality standard.*

***03. Toxic Air Pollutants.** Using the methods provided in Section 210, the emissions of toxic air pollutants from the stationary source or modification would not injure or unreasonably affect human or animal life or vegetation as required by Section 161. Compliance with all applicable toxic air pollutant carcinogenic increments and toxic air pollutant non-carcinogenic increments will also demonstrate preconstruction compliance with Section 161 with regards to the pollutants listed in Sections 585 and 586.*

Atmospheric dispersion modeling, using computerized simulations, is used to demonstrate compliance with both NAAQS and TAPs. Idaho Air Rules Section 202.02 states:

***02. Estimates of Ambient Concentrations**. All estimates of ambient concentrations shall be based on the applicable air quality models, data bases, and other requirements specified in 40 CFR 51 Appendix W (Guideline on Air Quality Models).*

2.4 Significant Impact Level and Cumulative NAAQS Impact Analyses

If specific criteria pollutant emission increases associated with the proposed permitting project cannot qualify for a BRC exemption as per Idaho Air Rules Section 221, then the permit cannot be issued unless the application demonstrates that applicable emission increases will not cause or significantly contribute to a violation of NAAQS, as required by Idaho Air Rules Section 203.02.

The first phase of a NAAQS compliance demonstration is to evaluate whether the proposed facility/project could have a significant impact to ambient air. Section 3.1.1 of this memorandum describes the applicability evaluation of Idaho Air Rules Section 203.02. The Significant Impact Level (SIL) analysis for a new facility or proposed modification to a facility involves modeling estimated criteria air pollutant emissions from the facility or modification to determine the potential impacts to ambient air. Air impact analyses are required by Idaho Air Rules to be conducted in accordance with methods outlined in *Appendix W*. *Appendix W* requires that facilities be modeled using emissions and operations representative of design capacity or as limited by a federally enforceable permit condition.

A facility or modification is considered to have a significant impact on air quality if maximum modeled impacts to ambient air exceed the established SIL listed in Idaho Air Rules Section 006 (referred to as a "significant contribution" in Idaho Air Rules) or as incorporated by reference as per Idaho Air Rules Section 107.03.b. Table 2 lists the applicable SILs.

Table 2. APPLICABLE REGULATORY LIMITS.

Pollutant	Averaging Period	Significant Impact Levels[a] (µg/m^3)[b]	Regulatory Limit[c] (µg/m^3)	Modeled Design Value Used[d]
PM_{10}[e]	24-hour	5.0	150[f]	Maximum 6th highest[g]
$PM_{2.5}$[h]	24-hour	1.2	35[i]	Mean of maximum 8th highest[j]
	Annual	0.2	12[k]	Mean of maximum 1st highest[l]
Carbon monoxide (CO)	1-hour	2,000	40,000[m]	Maximum 2nd highest[n]
	8-hour	500	10,000[m]	Maximum 2nd highest[n]
Sulfur Dioxide (SO_2)	1-hour	3 ppb[o] (7.8 µg/m^3)	75 ppb[p] (196 µg/m^3)	Mean of maximum 4th highest[q]
	3-hour	25	1,300[m]	Maximum 2nd highest[n]
Nitrogen Dioxide (NO_2)	1-hour	4 ppb (7.5 µg/m^3)	100 ppb[s] (188 µg/m^3)	Mean of maximum 8th highest[t]
	Annual	1.0	100[r]	Maximum 1st highest[n]
Lead (Pb)	3-month[u]	NA	0.15[r]	Maximum 1st highest[n]

REC 0638

PET 272

	Quarterly	NA	1.5[r]	Maximum 1st highest[n]
Ozone (O_3)	8-hour	40 TPY VOC[v]	70 ppb[w]	Not typically modeled

a. Idaho Air Rules Section 006 (definition for significant contribution) or as incorporated by reference as per Idaho Air Rules Section 107.03.b.
b. Micrograms per cubic meter.
c. Incorporated into Idaho Air Rules by reference, as per Idaho Air Rules Section 107.
d. The maximum 1st highest modeled value is always used for the significant impact analysis unless indicated otherwise. Modeled design values are calculated for each ambient air receptor.
e. Particulate matter with an aerodynamic diameter less than or equal to a nominal 10 micrometers.
f. Not to be exceeded more than once per year on average over 3 years.
g. Concentration at any modeled receptor when using five years of meteorological data.
h. Particulate matter with an aerodynamic diameter less than or equal to a nominal 2.5 micrometers.
i. 3-year mean of the upper 98th percentile of the annual distribution of 24-hour concentrations.
j. 5-year mean of the 8th highest modeled 24-hour concentrations at the modeled receptor for each year of meteorological data modeled. For the SIL analysis, the 5-year mean of the 1st highest modeled 24-hour impacts at the modeled receptor for each year.
k. 3-year mean of annual concentration.
l. 5-year mean of annual averages at the modeled receptor.
m. Not to be exceeded more than once per year.
n. Concentration at any modeled receptor.
o. Interim SIL established by EPA policy memorandum.
p. 3-year mean of the upper 99th percentile of the annual distribution of maximum daily 1-hour concentrations.
q. 5-year mean of the 4th highest daily 1-hour maximum modeled concentrations for each year of meteorological data modeled. For the significant impact analysis, the 5-year mean of 1st highest modeled 1-hour impacts for each year is used.
r. Not to be exceeded in any calendar year.
s. 3-year mean of the upper 98th percentile of the annual distribution of maximum daily 1-hour concentrations.
t. 5-year mean of the 8th highest daily 1-hour maximum modeled concentrations for each year of meteorological data modeled. For the significant impact analysis, the 5-year mean of maximum modeled 1-hour impacts for each year is used.
u. 3-month rolling average.
v. An annual emissions rate of 40 ton/year of VOCs is considered significant for O_3.
w. Annual 4th highest daily maximum 8-hour concentration averaged over three years.

If modeled maximum pollutant impacts to ambient air from the emission sources associated with a new facility or modification exceed the SILs, then a cumulative NAAQS impact analysis is necessary to demonstrate compliance with NAAQS and Idaho Air Rules Section 203.02.

A cumulative NAAQS impact analysis for attainment area pollutants involves assessing ambient impacts (typically the design values consistent with the form of the standard) from potential/allowable emissions resulting from the project and emissions from any nearby co-contributing sources (including existing emissions from the facility that are unrelated to the project), and then adding a DEQ-approved background concentration value to the modeled result that is appropriate for the criteria pollutant/averaging-period at the facility location and the area of significant impact. The resulting pollutant concentrations in ambient air are then compared to the NAAQS listed in Table 2. Table 2 also specifies the modeled design value that must be used for comparison to the NAAQS. NAAQS compliance is evaluated on a receptor-by-receptor basis for the modeling domain.

If the cumulative NAAQS impact analysis indicates an exceedance of NAAQS, a culpability analysis can determine if this exceedance is due to emissions from the proposed project. The permit may not be issued if the proposed project has a significant contribution (exceeding the SIL) to the modeled violation. If project-specific impacts are below the SIL, then the project does not have a significant contribution to the specific violations.

Compliance with Idaho Air Rules Section 203.02 is generally demonstrated if: a) applicable specific criteria pollutant emission increases are at a level defined as BRC, using the criteria established by DEQ regulatory interpretation (DEQ 2014); or b) all modeled impacts of the SIL analysis are below the

REC 0639

PET 273

applicable SIL or other level determined to be inconsequential to NAAQS compliance; or c) modeled design values of the cumulative NAAQS impact analysis (modeling all emissions from the facility and co-contributing sources, and adding a background concentration) are less than applicable NAAQS at receptors where impacts from the proposed facility/modification exceeded the SIL or other identified level of consequence; or d) if the cumulative NAAQS analysis showed NAAQS violations, the impact of proposed facility/modification to any modeled violation was inconsequential (typically assumed to be less than the established SIL) for that specific receptor and for the specific modeled time when the violation occurred.

2.5 Toxic Air Pollutant Analyses

Emissions of toxic substances are generally addressed by Idaho Air Rules Section 161:

> *Any contaminant which is by its nature toxic to human or animal life or vegetation shall not be emitted in such quantities or concentrations as to alone, or in combination with other contaminants, injure or unreasonably affect human or animal life or vegetation.*

Permitting requirements for toxic air pollutants (TAPs) from new or modified sources are specifically addressed by Idaho Air Rules Section 203.03 and require the applicant to demonstrate to the satisfaction of DEQ the following:

> *Using the methods provided in Section 210, the emissions of toxic air pollutants from the stationary source or modification would not injure or unreasonably affect human or animal life or vegetation as required by Section 161. Compliance with all applicable toxic air pollutant carcinogenic increments and toxic air pollutant non-carcinogenic increments will also demonstrate preconstruction compliance with Section 161 with regards to the pollutants listed in Sections 585 and 586.*

Per Section 210, if the total project-wide emission increase of any TAP associated with a new source or modification exceeds screening emission levels (ELs) of Idaho Air Rules Section 585 or 586, then the ambient impact of the emission increase must be estimated. If ambient impacts are less than applicable Acceptable Ambient Concentrations (AACs) for non-carcinogens of Idaho Air Rules Section 585 and Acceptable Ambient Concentrations for Carcinogens (AACCs) of Idaho Air Rules Section 586, then compliance with TAP requirements has been demonstrated.

TAPs also classified as HAPs emitted from sources addressed by New Source Performance Standards (NSPS) or National Emission Standards for Hazardous Air Pollutants (NESHAP) were not required to be evaluated for compliance with TAP increments in accordance with IDAPA 58.01.01.210.20 (Subsection 210.20). The DEQ permit writer evaluates the applicability of specific TAPs to the Subsection 210.20 exclusion. Guidance and clarification of Subsection 210.20 source exemptions are included in the DEQ Statement of Basis.

IDAPA 58.01.01.215 sets requirements for mercury emissions. For this standard, fugitive emissions and sources in a source category subject to 40 CFR 63 are exempt. The DEQ permit writer evaluates the applicability of mercury emissions to the exemption criteria. Details are provided in the DEQ Statement of Basis. Adjusted mercury emissions from non-fugitive and non-NESHAP-addressed sources were below the level (25 pounds per year) at which Mercury Best Available Control Technology (MBACT) review is required.

REC 0640

PET 274

3.0 Analytical Methods and Data

This section describes the methods and data used in the analyses to demonstrate compliance with applicable air quality impact requirements. The DEQ Statement of Basis provides a discussion of the methods and data used to estimate criteria and TAP emission rates.

Air Sciences made substantial refinements in assessed operational scenarios, TAP emission calculations, and modeled TAP impacts in response to issues identified after the February/March 2021 public comment period. Air Sciences addressed these issues separately from the NAAQS compliance demonstration presented in the main body of the PTC application and submitted the revised analyses in the *TAP Addendum*. DEQ's review of the *TAP Addendum* is described in the *Modeling Review Attachment* to this memorandum. Since all the refinements resulted in reduced calculated allowable particulate emissions from sources, the previous NAAQS compliance demonstration (described in the main body of this *Modeling Review Memorandum*) did not require revision for permit issuance and remains unaltered. However, DEQ reanalyzed PM_{10} impacts to account for the largest refinements, and results are presented in the *Modeling Review Attachment*.

3.1 Emission Source Data

Emissions of criteria pollutants and TAPs resulting from operation of the SGP facility were estimated by Air Sciences for various applicable averaging periods. The calculation of potential emissions is the responsibility of the DEQ permit writer, and the representativeness and accuracy of emission estimates is not addressed in this modeling memorandum. DEQ air impact analysts are responsible for assuring that potential emission rates provided in the emission inventory are properly used in the model. The rates listed must represent the maximum allowable rate as averaged over the specified period.

Emission rates used in the impact modeling applicability analyses and any modeling analyses, as listed in this memorandum, should be reviewed by the DEQ permit writer and compared with those in the final emission inventory. All modeled criteria air pollutant and TAP emission rates must be equal to or greater than the facility's potential emissions calculated in the PTC emission inventory or proposed permit allowable emission rates.

Emissions from unpaved roads were calculated based on a control efficiency of 90% from chemical application and 33% from watering (combined control efficiency above 93%). Emission controls and emission calculations are not reviewed in this modeling memorandum. However, it is critical for NAAQS compliance that this high level of control be achieved.

Activity-specific (e.g., drilling, blasting, material crushing and conveying, refining, and other ancillary sources) emissions were estimated based on maximum activity rates, coupled with applicable emission estimation techniques. Maximum emissions were calculated on a short-term (hourly and daily) and long-term (annual) basis for ore processing and mining operations, as discussed below.

The ore-processing rate will range from 20,000 ton/day to 25,000 ton/day at full production. Therefore, maximum potential daily ore processing emissions were based on the maximum design rate of 25,000 ton/day. Maximum potential annual emissions were based on potential daily emissions multiplied by 365 days per year.

Emissions from mining operations (drilling, blasting, material extraction and movement, mobile mine machinery use, and other ancillary sources) vary for each year of the life of the mine (LOM). However,

REC 0641

PET 275

for the modeling analyses, the mining operation potential emissions were estimated using conservatively high maximum activity rates provided in Table 3.

Table 3. MINING ACTIVITY RATES FOR POTENTIAL EMISSION CALCULATIONS.

Activity	Maximum Rate		Comments
Drilling	600	holes per blast	--
Blasting	2	blasts per day	--
	1	blast per hour	--
Material extraction and hauling	180,000	tons per day	Ore or DR
Onsite dozing	144	hours per day	6 dozers operating continuously
Onsite grading	72	hours per day	3 graders operating continuously
Onsite water trucking	48	hours per day	2 trucks operating continuously

The potential hourly emission rates for ore processing and mining operation activities were calculated by dividing the daily rate by the 24 hour-per-day operation schedule, and annual rates were calculated by multiplying maximum daily emissions with 365 days per year. This is conservative because the mine is expected to operate for only 355 days per year.

The maximum mine production rate is approximately 42.7 million (MM) tons per year (ton/yr); however, a maximum daily production rate of 180,000 ton/day used for potential emission calculations results in a conservatively higher production rate of approximately 65.7 MMton/yr, approximately 50 percent higher than the projected production rate.

PRI will employ newer model year mining and maintenance machines (excavators, shovels, haul trucks, dozers, graders, portable light plants, etc.) that are expected to meet or exceed applicable regulatory emission standards. Non-road mobile equipment engines are exempt from permitting requirements; therefore, the tailpipe emissions resulting from fuel combustion in the non-road mobile equipment are not quantified for the SGP facility. Background concentrations from McCall, 38 miles west of the SGP, were used in the cumulative NAAQS impact analyses (Section 4.1.2) to conservatively account for the impact contribution of traffic emissions.

The approximately 38-mile long Burntlog Route mine access road will be outside the project ambient air boundary and open to the public. Traffic emissions on public roads generally are considered to be part of background concentrations. Therefore, emissions on the Burntlog Route mine access road that are outside of the project boundary are not included in the SGP analyses. However, the emissions associated with the portion of the Burntlog Route mine access road that is within project boundary (from the south gate to the process area) are included in the SGP analyses. These include dust emissions generated from travel of maintenance equipment, light-duty pickup trucks and buses used for employee, visitor, and contractor transportation, and heavy-duty trucks used for cargo (including fuel, consumables, machine parts, ore processing supplies, ore concentrate, etc.) and services (including food supplies, trash, recyclables, etc.) transportation.

3.1.1 Criteria Pollutant Modeling Applicability and Modeled Emission Rates

If project-specific emission increases for criteria pollutants would qualify for a BRC permit exemption as per Idaho Air Rules Section 221 if it were not for potential emissions of one or more pollutants exceeding the BRC threshold of 10 percent of emissions defined by Idaho Air Rules as significant, then a NAAQS compliance demonstration may not be required for those pollutants with emissions below BRC levels. DEQ's regulatory interpretation policy of exemption provisions of Idaho Air Rules is that: "*A DEQ NAAQS compliance assertion will not be made by the DEQ modeling group for specific criteria*

REC 0642

PET 276

pollutants having a project emissions increase below BRC levels, provided the proposed project would have qualified for a Category I Exemption for BRC emissions quantities except for the emissions of another criteria pollutant" (DEQ 2014). The interpretation policy also states that the exemption criteria of uncontrolled potential to emit (PTE) not to exceed 100 ton/year (Idaho Air Rules Section 220.01.a.i) is not applicable when evaluating whether a NAAQS impact analysis is required. A permit will be issued limiting PTE below 100 ton/year, thereby negating the need to maintain calculated uncontrolled PTE under 100 ton/year. The BRC exemption cannot be used to exempt a project from a pollutant-specific NAAQS compliance demonstration in most cases where a PTC is required for the action regardless of emission quantities, such as the modification of an existing emission or throughput limit.

A NAAQS compliance demonstration must be performed for pollutant increases that would not qualify for the BRC exemption from the requirement to demonstrate compliance with NAAQS.

Site-specific air impact modeling analyses may not be necessary for some pollutants, even where such emissions do not qualify for the BRC exemption. DEQ has developed modeling applicability thresholds, below which a site-specific modeling analysis is not required. DEQ generic air impact modeling analyses that were used to develop the modeling thresholds provide a conservative SIL analysis for projects with emissions below identified threshold levels. Project-specific modeling applicability thresholds are provided in the *Idaho Air Modeling Guideline* (DEQ 2013). These thresholds were based on assuring an ambient impact of less than the established SIL for specific pollutants and averaging periods. DEQ revised modeling applicability thresholds in 2021 as described in the revised DEQ *Air Modeling Guideline* (DEQ 2021). Modeling applicability for the SGP facility was not revised because the application was submitted prior to revision of the thresholds.

If total project-specific emission rate increases of a pollutant are below Level I Modeling Applicability Thresholds, then project-specific air impact analyses are not necessary for permitting. Use of Level II Modeling Applicability Thresholds is conditional, requiring DEQ approval. DEQ approval is based on dispersion-affecting characteristics of the emission sources such as stack height, stack gas exit velocity, stack gas temperature, distance from sources to ambient air, presence of elevated terrain, and potential exposure to sensitive public receptors.

For the SGP analyses, several modeling scenarios were considered to evaluate the worst-case air impacts from the SGP facility. The different modeling scenarios are discussed in Section 3.1.3. Table 4 provides a comparison between facility-wide maximum PTE for the highest-emitting scenario (W3) and modeling applicability thresholds. The short-term and long-term PTE emissions are equal to the sum of process and ancillary emissions and mining fugitive emissions. It is important to note that the process and ancillary source emissions remain the same for each modeling scenario discussed in Section 3.1.3.

Table 4. SITE-SPECIFIC CRITERIA POLLUTANT MODELING APPLICABILITY.

Source Category	Carbon Monoxide (CO)	Nitrogen Oxides (NOx)		$PM_{2.5}$[a]		PM_{10}[b]	Sulfur Dioxide (SO_2)		Lead (Pb)
	lb/hr[c]	ton/yr[d]	lb/hr	ton/yr	lb/hr	lb/hr	ton/yr	lb/hr	lb/month[e]
Process and ancillary	33.5	37.9	55.4	36.4	13.4	21.7	6.5	1.88	0.0437
Mining fugitive	1,742.0	17.1	46.8	98.9	22.5	224.7	0.03	0.09	--
Total	1,775.5	55.0	102.2	135.3	35.9	246.4	6.5	1.97	0.0437
Level I threshold	15.0	1.2	0.2	0.35	0.054	0.22	1.2	0.21	14.0
Modeling	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	No

REC 0643

PET 277

required									

a. Particulate matter with an aerodynamic diameter less than or equal to a nominal 2.5 micrometers.
b. Particulate matter with an aerodynamic diameter less than or equal to a nominal 10 micrometer.
c. Pounds per hour.
d. Tons per year.
e. Pounds per month.

As indicated in Table 4, the SGP facility-wide maximum PTE are greater than the respective Level I thresholds for all criteria pollutants and averaging periods except for Pb. Therefore, modeling is triggered for applicable averaging periods for CO, NOx, $PM_{2.5}$, PM_{10}, and SO_2. Modeling is not required for Pb. The use of Level II modeling thresholds was not approved by DEQ for this project.

Tables 5-7 list criteria pollutant emission rates used in the cumulative NAAQS impact analyses for the worst-case modeling scenarios. Significant Impact Level (SIL) analyses were not performed. Based on the magnitude of the facility-wide emissions and preliminary modeling analyses, it was determined that the impacts from the SGP emissions exceeded the SIL for most criteria pollutants. Therefore, SIL analyses were considered redundant and not performed for this report. Table 5 lists the source-specific modeled emission rates for 24-hour and annual $PM_{2.5}$ and 24-hour PM_{10} (worst-case modeling scenario: W5). Modeling scenario W5 was later removed as an allowable operational scenario as described in the submitted *TAP Addendum* and the *Modeling Review Attachment* to this memorandum. Air Sciences did not adjust the existing PM_{10} and $PM_{2.5}$ analyses for the removal of scenario W5 because NAAQS compliance was already confidently demonstrated with W5 included. Table 6 lists the source-specific modeled emission rates for 1-hour and 8-hour CO and annual NO_2 (worst-case modeling scenario: W1). Table 7 lists the source-specific modeled emission rates for 1-hour NO_2 and 1-hour and 3-hour SO_2 (worst-case modeling scenario: B1). Modeling scenarios are discussed in Section 3.1.3. For 1-, 3-, and 8-hour averaging times, hourly emission rates provided in pounds per hour were used. For 24-hour averaging time, daily emission rates provided in pounds per day were used. For the annual averaging time, annual emission rates provided in tons per year were used. All modeled emission rates in Tables 5-7 are listed in units of pounds per hour (lb/hr). The total modeled input emission rates (highest emission scenario) are listed in Table 8.

[a.] Combined process, ancillary, and fugitive emissions modeled. Fugitive emissions vary by pit scenario. Maximum pit scenario emissions are shown.

Ozone (O_3) differs from other criteria pollutants in that it is not typically emitted directly into the atmosphere. O_3 is formed in the atmosphere through reactions of VOCs, NOx, and sunlight. Atmospheric dispersion models used in stationary source air permitting analyses cannot be used to estimate O_3 impacts resulting from VOC and NOx emissions from an industrial facility. O_3 concentrations resulting from area-wide emissions are predicted by using more complex airshed models such as the Community Multi-Scale Air Quality (CMAQ) modeling system. Use of the CMAQ model is very resource-intensive and DEQ asserts that performing a CMAQ analysis for a particular permit application is not typically a reasonable or necessary requirement for air quality permitting.

Addressing secondary formation of O_3 within the context of permitting a new stationary source has been somewhat addressed in EPA regulation and policy. As stated in a letter from Gina McCarthy of EPA to Robert Ukeiley, acting on behalf of the Sierra Club (letter from Gina McCarthy, Assistant Administrator, United States Environmental Protection Agency, to Robert Ukeiley, January 4, 2012):

> *. . . footnote 1 to sections 51.166(I)(5)(I) of the EPA's regulations says the following: "No de minimis air quality level is provided for ozone. However, any net emission increase of 100 tons per year or more of volatile organic compounds or nitrogen oxides subject to PSD would be required to perform an ambient impact analysis, including the gathering of air quality data."*
>
> *"The EPA believes it unlikely a source emitting below these levels would contribute to such a violation of the 8-hour ozone NAAQS, but consultation with an EPA Regional Office should still be conducted in accordance with section 5.2.1.c. of Appendix W when reviewing an application for sources with emissions of these ozone precursors below 100 TPY."*

DEQ determined it was not appropriate or necessary to require a quantitative source-specific O_3 impact analysis because allowable emission estimates of VOCs and NOx are below the 100 tons/year threshold.

3.1.2 TAPs Modeling Applicability and Modeled Emission Rates

Source-specific applicability for TAP analyses and calculated TAP emission rates were reworked by Air Sciences and presented in the *TAP Addendum*, submitted in October 2021. DEQ's review of the *TAP Addendum* is presented in the *Modeling Review Attachment* of this memorandum.

REC 0649

PET 283

3.1.3 Modeling Scenarios

As discussed in Section 2.1, conventional open-pit methods will be used to extract ore and DR from three pits: YPP, HFP, and WEP, and legacy tailings from BT. Ore will be hauled to the crushing area, and the DR will be moved to four DRSF: Yellow Pine (YPDRSF), Hangar Flats (HFDRSF), West End (WEDRSF), and Fiddle (FDRSF). The SGP site layout provided later in Figure 4 shows these locations.

PRI plans for an up to three-year construction schedule to build mine site facilities and infrastructure, as well as the power transmission line, followed by 12 years of mining operations (i.e., LOM Years 1 through 12). Depending on the mine design and operating schedule, mining activity rates will vary temporally and spatially during the 12 years of mine production and operation. For example, ore production varies from approximately 6.8 MMton in LOM Year 1 (67% in YPP, 26% in WEP, and 7% in BT) to 9 MMton in LOM 3 (78% in YPP, 10% in BT, 7% in WEP, and 5% in HFP). Similarly, DR production varies from approximately 4.8 MMton in LOM Year 12 (100% in WEP) to 34 MMton in each of LOM Years 4 through 9, with varying distribution among the four DRSF for each LOM Year. The total material (ore and DR) production varies from approximately 12.5 MMton in LOM Year 12 to 42.7 MMton in LOM Year 4.

Similar to the material production, the distribution and hauling of DR to the four destinations (YPDRSF, HFDRSF, WEDRSF, FDRSF) also will vary for each LOM year. Depending on the material origin (pits and BT) and destination (crushing area and DRSF), material hauling distances also will vary for each LOM year.

Therefore, depending on material production rates and origin, DR destination, and hauling distances, mining emissions will vary spatially and temporally throughout the mine life. For permitting purposes, PRI used a maximum production rate of 180,000 tons of material (ore and/or DR) per day, for an annual production rate of 65.7 MMton/yr. This annual production rate is more than 50% higher than the estimated maximum total material production rate of 42.7 MMton/yr.

In order to allow PRI with operation flexibility and to capture variability in material origin and destination in the air quality analyses, several pit scenarios were developed for the SGP air quality analyses. Each pit scenario uses the maximum production rate of 180,000 ton/day in a single pit and uses a single material destination. Each pit has a dedicated ore scenario that assumes all material produced is ore and is hauled to the crusher area; and depending on mine design multiple DR destination scenarios each assuming all material produced is DR and is transported to a single DRSF. For example, most of the DR from HFP will be moved to HFDRSF and during LOM Years 2 through 10, but a fraction of this rock will be moved to FDRSF during LOM Years 3 and 8, and a fraction to YPDRSF during LOM Year 9. Therefore, in order to evaluate all hauling scenarios originating from HFP, the following four (one for ore hauling, three for DR hauling) HFP scenarios were modeled:

1. HFP Scenario 1 – 180,000 ton/day of ore produced and hauled to the crusher area
2. HFP Scenario 2 – 180,000 ton/day of DR produced and hauled to the FDRSF
3. HFP Scenario 3 – 180,000 ton/day of DR produced and hauled to the HFDRSF
4. HFP Scenario 4 – 180,000 ton/day of DR produced and hauled to the YPDRSF

Overall, 14 scenarios were modeled for $PM_{2.5}$ and PM_{10} analyses to cover all possible origin and destination combinations. Each modeling scenario included processing and ancillary source potential emissions. The multiple scenarios modeled for $PM_{2.5}$ and PM_{10} analyses are presented in Table 9. This table also shows the six origin/destination options that are not applicable to the SGP Project as denoted by "0 ton/day." These six scenarios are not feasible because the timing of the activity within the sequence of

REC 0650

PET 284

mine operations makes the scenarios logistically impossible. Also, Scenario W5 was eliminated after the February/March 2021 public comment period, as presented in the *TAP Addendum*.

Table 9. MODELING SCENARIOS FOR $PM_{2.5}$ AND PM_{10} ANALYSES.

Pit Scenario	Pit/Origin (ton/day)				Ore Destination (ton/day)	DR Destination (ton/day)			
	YPP	HFP	WEP	BT	STKP	FDRSF	HFDRSF	YPDRSF	WEDRSF
Y1	180,000	--	--	--	180,000	--	--	--	--
Y2	180,000	--	--	--	--	180,000	--	--	--

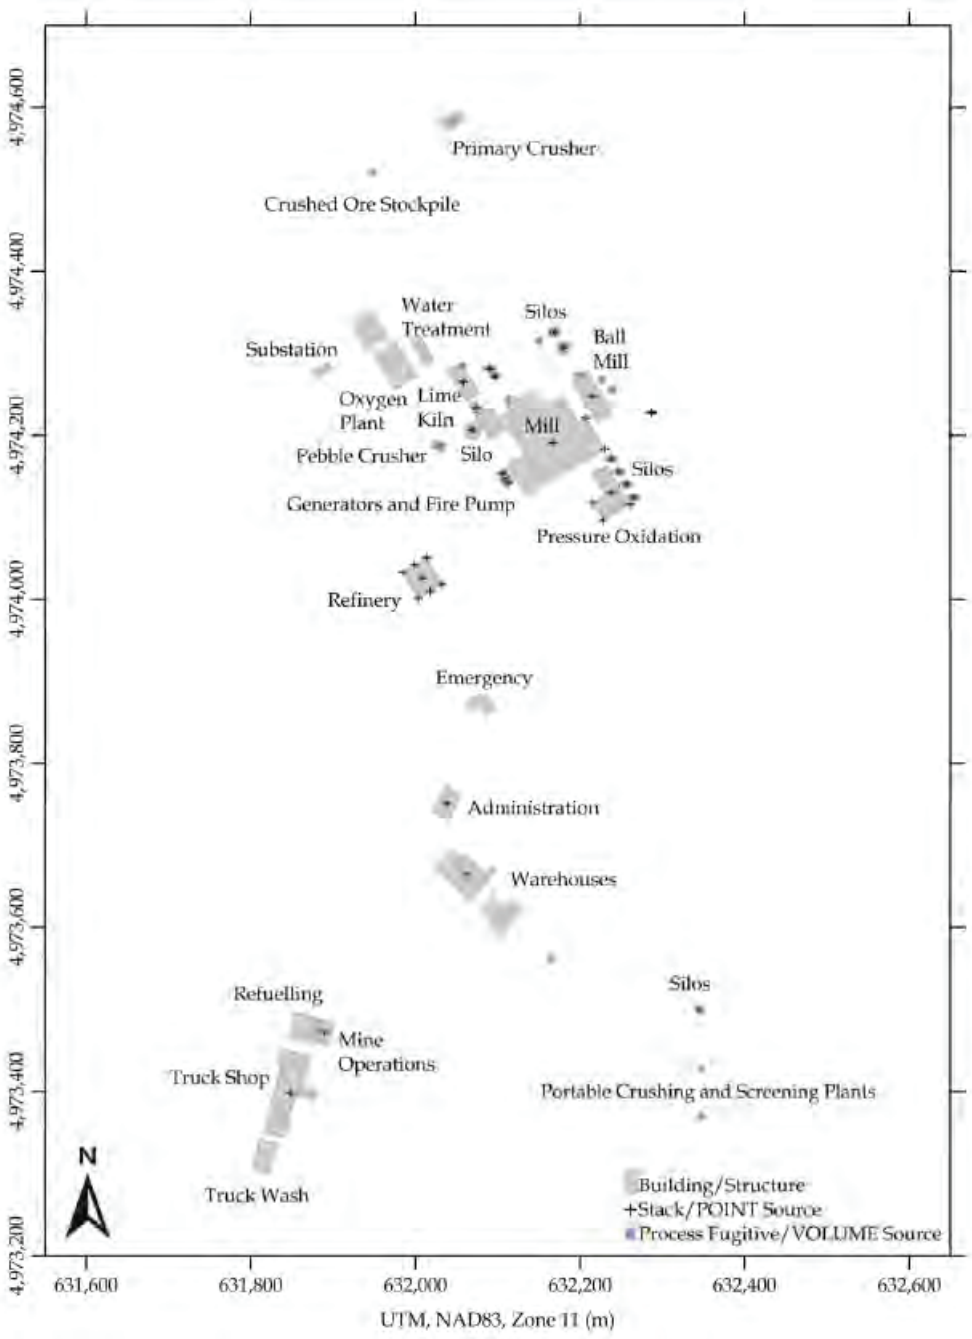
Y4	0	--	--	--	--	--	--	0	--
Y5	0	--	--	--	--	--	--	--	0
H1	--	180,000	--	--	180,000	--	--	--	--
H2	--	180,000	--	--	--	180,000	--	--	--
H3	--	180,000	--	--	--	--	180,000	--	--
H4	--	180,000	--	--	--	--	--	180,000	--
H5	--	0	--	--	--	--	--	--	0
W1	--	--	180,000	--	180,000	--	--	--	--
W2	--	--	180,000	--	--	180,000	--	--	--
W3	--	--	180,000	--	--	--	180,000	--	--
W4	--	--	180,000	--	--	--	--	180,000	--
W5	--	--	180,000	--	--	--	--	--	180,000
B1	--	--	--	180,000	180,000	--	--	--	--
B2	--	--	--	180,000	--	--	180,000	--	--
B3	--	--	--	0	--	0	--	--	--
B4	--	--	--	0	--	--	--	0	--
B5	--	--	--	0	--	--	--	--	0

Scenario Y4 is not applicable because the YPDRSF and the YPP are in the same area; therefore, the pit cannot be backfilled with development rock until after mining of the pit is completed. Scenarios Y5 and H5 are not applicable because the WEDRSF will only be utilized by the WEP because of its proximity; it is only accessible from the WEP. Scenarios B3, B4 and B5 are not applicable because the development rock from the BT will only be hauled to the HFDRSF because of its proximity. All other development rock storage facilities are significantly farther away from BT.



The fugitive CO, NO_2, and SO_2 emissions are limited to pits only, and they do not vary by ore and/or DR hauling and destinations. Therefore, for these pollutants, one scenario for each pit, including processing and ancillary source potential emissions, was modeled, i.e., scenarios Y1, H1, W1, and B1.

The TAP emissions are limited to processing and ancillary sources, so a single scenario was modeled for each applicable TAP analysis.

3.1.4 Processing, Refining, and Ancillary Sources

The processing, refining, and ancillary sources with exhaust stacks, such as baghouse-equipped sources, generators, process and building heaters, autoclave, retort, smelting furnace, carbon kiln, lime kiln, etc., were modeled as POINT sources. The process sources without exhaust stacks, such as material transfers, ore screening and crushing, etc., were modeled as VOLUME sources. A plot plan showing the processing and refining area buildings and sources is provided in Figure 3. Process and ancillary source model input parameters are provided later in Tables 13 and 14.

Figure 3. PROCESSING AND REFINING AREA BUILDING AND SOURCE LAYOUT.

3.1.5 Fugitive Sources: Blasting, Material Origin and Destination, and Underground Exploration Emissions

Blasting emissions were represented by a VOLUME source located inside a pit. Each material origin location (YPP, HFP, WEP, BT) was modeled as an AREA source and comprised appropriate emissions from drilling, material loading, dozing, and surface exploration. Ore destination (crusher area) was modeled as a VOLUME source and comprised ore unloading emissions. Each DR destination (FDRSF,

HFDRSF, YPDRSF, WEDRSF) was modeled as a VOLUME source comprising appropriate emissions from DR unloading, dozing, and wind erosion. Emissions from underground core sampling drilling (UGEXP) in the Scout prospect decline were represented by an AREA source characterized by the portal opening dimensions.

Model input physical characteristics for blasting and possible material origin and destination locations, and Scout portal are presented in Table 10. This table also shows the source type and associated dimensions for each of the modeled fugitive source/location. The VOLUME source dimensions for blasting provided in Table 10 were based on an estimated blast area. For the remaining AREA and VOLUME sources listed in Table 10, the dimensions were developed by reasonably fitting an equal-area rectangle within the actual footprint of each fugitive source. Blasting is not expected to occur in BT. However, blasting emissions were modeled in BT (BTBL) in order to streamline the permitting process.

Table 10. MODELED FUGITIVE ACTIVITY LOCATIONS.

Model ID	Activity Location	Type	Lateral Dimensions (m)	Emission Sources
YPP	Yellow Pine Pit	AREA	882 × 882	Drilling, loading, dozing, surface exploration
HFP	Hangar Flats Pit	AREA	491 × 491	Drilling, loading, dozing, surface exploration
WEP	West End Pit	AREA	376 × 376	Drilling, loading, dozing, surface exploration
BT	Bradley Tailings	AREA	820 × 420	Loading, dozing, wind erosion
YPPBL	Yellow Pine Pit (Blasting)	VOLUME	87 × 87	Blasting
HFPBL	Hangar Flats Pit (Blasting)	VOLUME	87 × 87	Blasting
WEPBL	West End Pit (Blasting)	VOLUME	87 × 87	Blasting
BTBL	Bradley Tailings (Blasting)	VOLUME	87 × 87	Blasting
STKP	PC Stockpile	VOLUME	229 × 229	Unloading, dozing, wind erosion
FDRSF	Fiddle DRSF	VOLUME	775 × 775	Unloading, dozing, wind erosion
HFDRSF	Hangar Flats DRSF	VOLUME	752 × 752	Unloading, dozing, wind erosion
YPDRSF	Yellow Pine DRSF	VOLUME	784 × 784	Unloading, dozing, wind erosion
WEDRSF	West End DRSF	VOLUME	533 × 533	Unloading, dozing, wind erosion
UGEXP	Scout Portal	AREA	4.9 × 4.9	Sample core drilling

The model input physical parameters for blasting, material origin and destination locations, and Scout portal are provided in Table 11.

Table 11. MODEL INPUT PARAMETERS FOR FUGITIVE ACTIVITY LOCATIONS.

Model ID	Base Elevation (m)	Release Height (m)	Initial Lateral Dispersion (m)	Initial Vertical Dispersion (m)
YPP	1,832.4	4.7	N/A	4.4
HFP	1,993.3	4.7	N/A	4.4
WEP	2,191.8	4.7	N/A	4.4
BT	2,011.7	4.7	N/A	4.4
YPPBL	1,717.2	15.0	20.2	7.0
HFPBL	1,890.6	15.0	20.2	7.0
WEPBL	1,994.0	15.0	20.2	7.0

BTBL	2,011.7	15.0	20.2	7.0
STKP	1,979.8	4.7	53.3	4.4
FDRSF	2,115.2	4.7	180.2	4.4
HFDRSF	2,079.8	4.7	174.8	4.4
YPDRSF	1,904.1	4.7	182.2	4.4
WEDRSF	2,376.5	4.7	124.1	4.4
UGEXP	2,018.0	0	N/A	0

The blasting physical parameters were developed from dimensions (provided in Table 10) based on blast area used in the emission calculation. The blasting release height is the midpoint of the blasting height (30 m).

The initial lateral and vertical dispersion dimensions for blasting were calculated per methods specified in (EPA 2018c) for a volume source not on or adjacent to a building, as:

$$Initial\ Lateral\ Dispesion = \frac{Width\ (87\ m)}{4.3}$$

$$Initial\ Vertical\ Dispesion = \frac{Height\ (30\ m)}{4.3}$$

For the pit and DRSF fugitive activity locations listed in Table 10, i.e., YPP, HFP, WEP, BT, FDRSF, HFDRSF, and WEDRSF, the release height was based on the haul truck height (weighted based on model-specific usage) and calculated using the recommendations provided in the Haul Road Workgroup Report (EPA 2012), as:

$$Release\ Height = \frac{Plume\ Top\ (Weighted\ Truck\ Height \times 1.7)}{2}$$

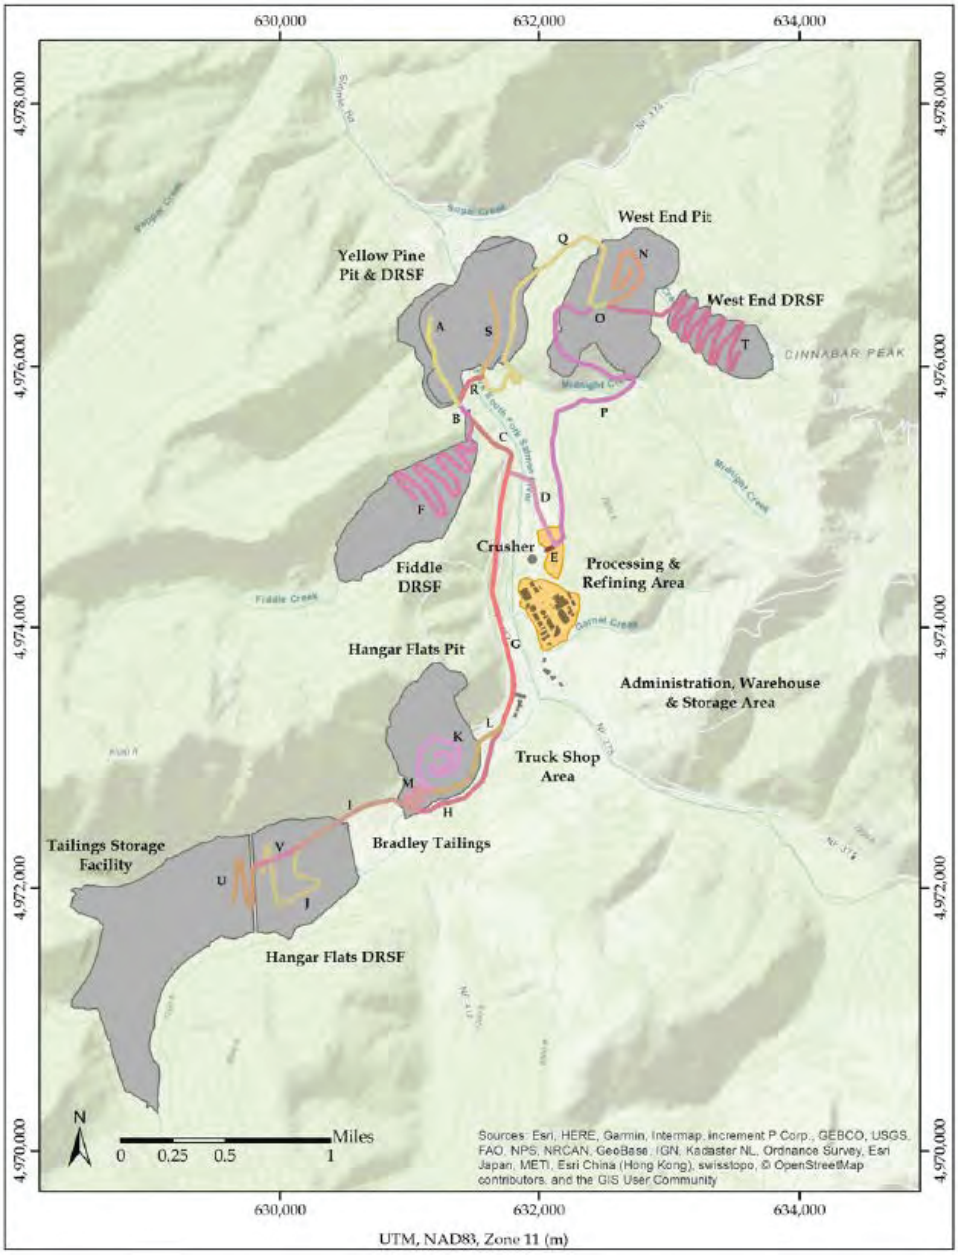
The applicable initial lateral dispersion for each VOLUME source was calculated from the respective shorter dimension and EPA-specified methods (EPA 2018c) (EPA 2016) as follows:

$$Initial\ Lateral\ Dispesion = \frac{Short\ Lateral\ Dimension}{2.15}$$

The applicable initial vertical dispersion for each AREA and VOLUME source was calculated from the respective vertical dimension and EPA-specified methods (EPA 2018c) (EPA 2016) as follows:

$$Initial\ Vertical\ Dispersion = \frac{Plume\ Top\ (Weighted\ Truck\ Height \times 1.7)}{2.15}$$

Scout portal was modeled as a surface-based AREA source with zero release height.



3.1.6 Fugitive Sources: Haul Roads

A representative haul road network for hauling material from inside the pit (or origin) to various destinations was developed for each pit scenario provided in Table 9. The haul road network is presented in Figure 4.

REC 0654

PET 288

Figure 4. HAUL ROAD NETWORK AND SECTIONS.

As shown in Figure 4, the haul road network was divided into 22 sections, A through V. Each section was further divided into multiple segments with a length equal to twice the adjusted haul road width of 32.5 m (26 m road width plus 6 m (EPA 2012)). Each of the segments was characterized as an individual VOLUME source in the model, with a release height of 4.75 m (weighted-average truck height times 1.7, divided by 2 (EPA 2012)), an initial lateral dispersion of 15.1 m (adjusted road width divided by 2.15 (EPA 2012)), and an initial vertical dispersion of 4.42 m (weighted-average top-of-plume height divided by 2.15 (EPA 2012)). Material hauling emissions associated with each origin-destination route were assigned to each segment along the route based on estimated total emissions along the route and traffic distribution along each section, as provided in Table 12 for the four HFP scenarios.

V	7	--	--	--	--

The top row in Table 12 shows the pit scenarios, and the next two rows show hauling route and the associated segment emission denominator (SED) used to distribute segment emissions along each route. The remainder of Table 12 presents the number of segments for each road section (shown in Figure 4) and the associated traffic distribution factor for each route. The emission distribution for each applicable segment is illustrated in the following example.

For route: HFP–STKP (Hangar Flats pit to crusher stockpile), Figure 4 shows that material from HFP will be hauled to the crusher area following the route along Sections K, L, G, and D. All (100%) of the ore from HFP will travel on each of these sections; therefore, each of these sections has a traffic distribution factor of 1.0 for this route.

The SED for each route is the sum-product of the number of segments and traffic distribution for the applicable sections. The SED for the HFP–STKP route is calculated as:

$$SED_{(HFP-STKP)} = (28 \times 1) + (16 \times 1) + (38 \times 1) + (14 \times 1) = 96$$

Emissions for each section-segment were estimated by dividing the total emissions along the route by its SED and multiplying by the section distribution factor. For example, the emission rate for each of the 28 segments along Section K was calculated as:

$$Emission\ Rate - Section\ K_{(Segments\ 1-28)} = \frac{Total\ Emissions_{(HFP-STKP)}}{96} \times 1$$

3.1.7 Fugitive Sources: Burntlog Route Access Road

The access road portion within the operations boundary was characterized by a series of LINE sources laid along the actual route. Emissions associated along this access road include dust emissions generated from travel of maintenance equipment, light-duty pickup trucks and buses used for employee, visitor, and contractor transportation, and heavy-duty trucks used for cargo and services transportation. These sources were assigned a release height of 3 m and an initial vertical dispersion of 2.8 m. These release parameters were based on an estimated average vehicle height of 3.5 m, which is representative of an overall approximation of anticipated vehicle heights (grader – 3.7 m, heavy-duty truck – 3.6 m, and pickup truck – 3.2 m) and the AREA source parameterization recommendations provided in the Haul Road Workgroup Report (EPA 2012). The AERMOD emission input units for AREA source are grams per meter square. The access road emissions were evenly distributed along the road by dividing the total access road emissions by its total area, i.e., the Burntlog Route section within the operations boundary (2,950 m) multiplied by the road width (6.1 m).

3.1.8 Emission Release Parameters

Table 13 lists the emission release parameters, including stack height, exhaust temperature, exhaust velocity, and stack diameter for SGP's process and ancillary point sources in metric units (English units are in parentheses). Table 14 lists the emission release parameters for SGP's process and ancillary volume sources in metric units (English units are in parentheses). Emission release parameters were based on information provided in the application. Justification for emission release parameters is summarized in the next section.

3.1.9 Emission Release Parameter Justification

Modeled Process and Ancillary Point Sources

The pneumatic transfer silo loadings and bin transfers (LS1L, MillS2L, ACS1L, ACS2L, ACS3L, ACS4L, PSL, CS1L, CS2L, LS6, LSBM, LS9, LSL) were modeled as POINT sources with a 3-foot bin vent above standard silo height as release height. Exit velocity was estimated using the standard stack diameter and flow rates for similar sources (NDEP 2019) or 0.001 meter per second for horizontal exhaust. These sources were modeled with ambient exhaust temperature.

For propane-fired process (Sb1, ACB, CKB, PV, HS) and building heaters (H1M, H2M, HM, HAC, HR, HA, HMO, HTS, HW), exhaust flow rates were calculated using EPA Method 9 with 3% oxygen content and 15% moisture content. Standard stack diameters were selected based on the heater rating. The process heaters were modeled with a 10-foot stack above the building, whereas the building heaters were modeled with a release height of 1 foot above the respective buildings.

Similar source exhaust temperature, flow, and diameter from (NDEP 2017) were used for refinery sources, including the carbon regeneration kiln (CKD), electrowinning cells (EW), mercury retort (MR),

REC 0661

PET 295

and induction furnace (MF). Each of these sources was modeled with a 10- foot stack above the refinery building.

For emergency generators (EDG1, EDG2, EDG3) and the fire pump (EDFP), the exhaust flow rates were calculated using EPA Method 9 with 9% oxygen content and 8% moisture content. Standard stack diameters were selected based on engine rating. Each engine was modeled with a 7-foot-high stack.

Antimony bagging (Sb2), autoclave (AC), lime kiln (LK) (common stack with kiln burner (LKC)), and lime crushing (LCR) were characterized with similar source parameters from (NDEP 2015b), (APT 2013), and (NDEP 2010). Each of these sources was modeled with a 10-foot stack above its respective building.

Release parameters for the process and ancillary point sources were appropriately documented and justified. DEQ's source-group analysis (Table 27 in Section 4.1.4) suggests that the process and ancillary point sources contribute a small amount to the modeled design concentrations.

Modeled Process and Ancillary Volume Sources

For the following VOLUME source characterization discussion, release height was estimated as half of the vertical length (for example, building height), initial vertical dispersion was calculated by dividing the vertical length by the applicable EPA-recommended constant (EPA 2018c) for a single VOLUME source (4.3), and initial lateral dispersion was determined using the lesser lateral dimension (for example, building width) divided by the applicable EPA-recommended constant (EPA 2018c) for the surface source or elevated source with a building (2.15).

The sources associated with the primary crusher building, including loader transfer (OC1), grizzly feeder (OC2), apron feeders (OC3, OC4), ore transfers (OC5, OC6), and primary crusher (OC7), were characterized by the primary crusher building dimensions: 128' high and 52.9' wide.

The stockpile height (71.6') and the conveyor width (3') were used to determine the VOLUME source parameters for the stockpile feed conveyor (OC8).

Tunnel exit dimensions (8' high and 8' wide) were used to estimate the VOLUME release parameters for the stockpile transfer points (OC9, OC10). The SAG mill feed conveyor transfer (OC11) was characterized by a building opening (4' high and 4' wide) at the mid-height (70') of the mill building.

Pebble crusher building dimensions (20' high and 32.7' wide) were used to characterize the pebble crusher-associated sources (OC12, OC13).

Silo/bin unloading sources (LS1U, Mill2SU, ACS1U, ACS2U, ACS3U, ACS42U, PSU) were characterized by a typical screw discharge feeder characteristic, i.e., 5' above the ground with a 1' diameter.

Aggregate transfer and handling sources (CS1U, CS2U, CAL, CAU, CM) were characterized by the aggregate stockpile dimensions: 20' high and 72.2' wide.

Each portable crushing and screening plant was characterized by typical portable crushing and screening plant dimensions: 14' high and 185' wide.

REC 0662

PET 296

Sources associated with limestone crushing (LS1, LS2, LS3, LS4, LS5) were characterized by the associated crusher building dimensions: 22.6’ high and 22.6’ wide.

The crushed limestone/pebble lime transfers (LS7, LS10, LSU) were characterized by a typical screw discharge to a conveyor characteristic, i.e., 5’ above the ground, 3’ drop, and a 1’ diameter.

The limestone ball mill feed discharge (LS8) was characterized by a building opening (4’ high and 4’ wide) at the mid-height (30’) of the ball mill building.
The limestone fines screening (LS11) was characterized by screen dimensions: 5’ drop and 8’ wide.

The limestone kiln feed (LS12) was characterized by a building opening (4’ high and 4’ wide) at the mid-height (70’) of the kiln building.

Model input source characterization for fugitive emissions is described in Sections 3.1.5 and 3.1.6. Fugitive activity locations and their respective dimensions are provided in Table 10 and associated release parameters are listed in Table 11.

Release parameters for the process and ancillary volume sources were appropriately documented and justified. DEQ’s source-group analysis (Table 27 in Section 4.1.4) suggests that the process and ancillary volume sources contribute a small amount to the modeled design concentrations.

3.2 Background Concentrations

Background concentrations are used if a cumulative NAAQS impact analysis is needed to demonstrate compliance with applicable NAAQS.

3.2.1 Onsite Particulate Monitoring

To establish background ambient air conditions for the SGP area, PRI developed an onsite monitoring program to collect site-specific meteorological parameters and determine ambient particulate matter ($PM_{2.5}$ and PM_{10}) concentrations at its Stibnite monitoring station.

In September 2015, PRI submitted the data collected at the Stibnite monitoring station for the period of November 2013 through June 2015 to DEQ. After reviewing the data and associated quality control procedures, DEQ concluded that the $PM_{2.5}$ and PM_{10} data collected at the Stibnite monitoring station satisfied the applicable regulatory requirements and approved the data to be used for background concentrations in the SGP air quality analyses (DEQ 2015). In its conclusions, DEQ recommended that the $PM_{2.5}$ and PM_{10} background concentrations should be based on calendar year 2014 instead of the complete dataset (November 2013 through June 2015).

DEQ-approved $PM_{2.5}$ and PM_{10} background concentrations, in units of micrograms per cubic meter ($\mu g/m^3$), are provided in Table 15. For 24-hour PM_{10}, the design value is the *second-highest* 24-hour average concentration in a given year. However, review of the Meteorological and Air Quality Data Summary for the SGP Monitoring Network (Perpetua Resources Idaho 2015) indicates that the DEQ-approved background for 24-hour PM_{10} (37.0 $\mu g/m^3$) is the *first-highest* 24-hour average concentration measured in 2014 (DEQ 2015). Therefore, using the first-high instead of the second-high as background adds a layer of conservatism to the cumulative NAAQS impact analyses for 24-hour PM_{10}.

REC 0663

PET 297

Table 15. DEQ-APPROVED $PM_{2.5}$ AND PM_{10} BACKGROUND CONCENTRATIONS FOR SGP.			
Pollutant	**Averaging Time**	**Background Concentration ($\mu g/m^3$)**	**Design Value Rank**
$PM_{2.5}$	1 year	3.5	Weighted average of quarterly means
	24 hours	15.0	98th percentile/8th high
PM_{10}	24 hours	37.0	Highest 1st high

3.2.2 Gaseous Pollutant Background Concentrations

With a few exceptions of very large facilities or facilities located in nonattainment areas, regulatory agencies do not require the collection of gaseous criteria pollutants, including CO, NOx (and/or nitrogen dioxide [NO_2]), O_3, and SO_2. For these gaseous pollutants, data collected at government-regulated monitoring stations located in settings similar to the project area in terms of terrain, land use, and proximity of emission sources are typically used to establish background concentrations.

To determine representative background concentrations of CO, NOx, O_3, and SO_2 for the SGP site, which is located in a remote rural area, the DEQ-maintained ambient monitoring network was reviewed by Air Sciences. This review revealed that DEQ only conducts limited trace monitoring for CO, NOx, O_3, and SO_2 in the Boise metropolitan area along the Interstate 84 corridor. Thus, the data collected at these monitors are exposed to high emissions from industrial, urban, and transportation sources (DEQ 2015a) (DEQ 2018). For this reason, the gaseous pollutant concentrations recorded at these urban monitoring locations were not considered to be representative of a rural area, like the SGP site.

The EPA-maintained monitoring stations (EPA 2018a) in Idaho and surrounding states also were reviewed by Air Sciences to determine representative gaseous pollutant background concentrations for the SGP site. This review also did not identify any representative monitoring station to establish background gaseous pollutant concentrations for the SGP site.

The DEQ-recommended (DEQ 2019) CO, NOx, O_3, and SO_2 background concentrations for the SGP air quality analyses in units of parts per billion (ppb) and $\mu g/m^3$, are provided in Table 16. These background concentrations were obtained from the Northwest International Air Quality Environmental Science and Technology Consortium (NW AIRQUEST; https://arcg.is/1jXmHH) online tool using the project site coordinates. These background air pollutant levels are based on regional-scale air pollution modeling of pollutants in Washington, Oregon, and Idaho, with modeling results adjusted according to available monitoring data.

Table 16. DEQ-RECOMMENDED GASEOUS POLLUTANT BACKGROUND CONCENTRATIONS FOR SGP.				
Pollutant	**Averaging Time**	**Background Concentration**		**Reference**
		(ppb)	**($\mu g/m^3$)**	
CO	8 hours	970	1,110	NW AIRQUEST, 2014-2017 design value

PET 298

3.2.3 Medium-Traffic Pollutant Background Concentrations

For additional information, background concentrations were obtained from NW AIRQUEST for the road section between mile markers 143 and 144 on Highway 55 passing through the town of McCall. This site (latitude 44.906° N, longitude 116.098° W) is approximately 38 miles west of the SGP. The annual average daily traffic count for this road section is over 10,000 vehicles per day. Table 17 provides the background concentrations for this medium-traffic site. Although these concentrations are not representative of the rural SGP area, they do provide additional information regarding the relative contribution of traffic emissions.

Table 17. MEDIUM-TRAFFIC BACKGROUND CONCENTRATIONS.

Pollutant	Averaging Time	Background Concentration		Reference
		(ppb)	($\mu g/m^3$)	
CO	8 hours	1,000	1,145	NW AIRQUEST, 2014-2017 design value, near McCall, ID (44.91°N, 116.10°W)
	1 hour	1,570	1,797	
NO_2	1 year	1.4	2.6	
	1 hour	7.6	14.3	
$PM_{2.5}$	1 year	--	5.1	
	24 hours	--	17.5	
PM_{10}	24 hours	--	60.1	
SO_2	3 hours	6.4	16.8	
	1 hour	4.7	12.3	

3.3 Impact Modeling Methodology

This section describes the modeling methods used by the applicant/consultant to demonstrate preconstruction compliance with applicable air quality standards.

3.3.1 General Overview of Impact Analyses

Air Sciences performed the project-specific air pollutant emission inventory and air impact analyses that were submitted with the application. The submitted information/analyses, in combination with results from DEQ's air impact analyses, demonstrate compliance with applicable air quality standards to DEQ's satisfaction, provided the facility is operated as described in the submitted application and in this memorandum.

Table 18 provides a brief description of parameters used in the modeling analyses.

Table 18. MODELING PARAMETERS.

Parameter	Description/Values	Documentation/Addition Description
General Facility Location	Stibnite, Idaho	The area is an attainment or unclassified area for all criteria pollutants.
Model	AERMOD	AERMOD with the PRIME downwash algorithm, version 19191.
Meteorological Data	Onsite and McCall, Idaho surface data; Boise, Idaho upper air data	See Section 3.3.5 of this memorandum for additional details of the meteorological data.
Terrain	Considered	1/3 arc second National Elevation Dataset (NED) was acquired from the USGS for the surrounding area. AERMAP version 18081 was used to process terrain elevation data for all buildings and receptors. See Section 3.3.6 for more details.
Building Downwash	Considered	Plume downwash was considered for the structures associated with the

		facility. BPIP-PRIME was used to evaluate building dimensions for consideration of downwash effects in AERMOD. See Section 3.3.7.
NOx Chemistry	Ozone Limiting Method	See Section 3.3.8.
Receptor Grid	**SIL Analysis** A SIL analysis was not performed.	
	Cumulative NAAQS Impact Analysis The selection of receptors for use in the cumulative NAAQS impact analysis is as follows (see Section 3.3.12):	
	Boundary	25-meter (m) spacing
	Grid 1	50-m spacing, 0.25 kilometers (km) out
	Grid 2	100-m spacing, 0.25 km to 1.25 km out
	Grid 3	500-m spacing, 1.25 km to 5 km out
	Grid 4	1,000-m spacing, 5 km to 10 km out
	Hotspot	25-m spacing, 200-m × 200-m around highest model impacts
	TAPs Analysis The receptor network used in the cumulative NAAQS impact analysis was also used in the TAPs analysis.	

3.3.2 Modeling Protocol

A modeling protocol for the SGP analyses was submitted to DEQ prior to the application, on May 30, 2019. The protocol was submitted by Brown and Caldwell on behalf of PRI. Conditional DEQ protocol approval was provided to Brown and Caldwell on June 27, 2019.

3.3.3 Modeling Methodology

Project-specific modeling and other required impact analyses were generally conducted using data and methods described in the *Idaho Air Quality Modeling Guideline* (DEQ 2013).

3.3.4 Model Selection

Idaho Air Rules Section 202.02 requires that estimates of ambient concentrations be based on air quality models specified in *Appendix W*. The refined, steady-state, multiple-source, Gaussian dispersion model AERMOD was promulgated as the replacement model for ISCST3 in December 2005. AERMOD retains the single straight-line trajectory of ISCST3, but it includes more advanced algorithms to assess turbulent mixing processes in the planetary boundary layer for both convective and stable stratified layers.

AERMOD version 19191 was used by Air Sciences for the modeling analyses to evaluate impacts of the facility. This version was the current version at the time the application was received by DEQ.

3.3.5 Meteorological Data

AERMOD requires an input of hourly meteorological data to estimate pollutant concentrations in ambient air resulting from modeled source emissions. These data are commonly obtained from National Weather Service (NWS) stations at airports throughout the state. Applicants select data from an airport site that is determined to be reasonably representative of the permitted site location. Collection of meteorological data from the permitted site is not typically required by DEQ for minor source permit applications. The collection of one year of onsite data is required for permitting projects subject to the Prevention of Significant Deterioration (PSD) program, which is triggered by larger non-fugitive emission quantities.

Site-specific hourly surface meteorological data were collected and used in air impact analyses for this project, as described in the submitted modeling report. These data were collected from January 1, 2014

REC 0666

PET 300

through December 31, 2014 at the Stibnite monitoring station. They were collected for analyses supporting an Environmental Impact Statement (EIS) and the Idaho DEQ minor source permit.

The site-specific surface data were supplemented with the twice-daily upper-air data (all levels) collected at the National Weather Service (NWS) station in Boise, Idaho (WBAN 24131).

These meteorological datasets were processed with the most recent version (19191) of the AERMOD meteorological pre-processor, AERMET, to produce AERMOD-input-ready hourly surface and profile meteorological files. The default option of adjusted surface friction velocity (ADJ_U*) and the Bulk Richardson (BULKRN) method for boundary layer parameter calculations was used for this meteorological data processing.

Additionally, an alternative meteorological dataset was processed without using the BULKRN method (NON-BULKRN). This alternate processing used the onsite and upper air datasets discussed above, supplemented with the cloud-cover data collected at the NWS station in McCall, Idaho (WBAN 94182).

Both processing methods (BULKRN and NON-BULKRN) are considered default for regulatory modeling analyses. EPA Region X Regional Modeling Contact, Jay McAlpine, PhD, was consulted for guidance on which data processing procedure to require for the analyses supporting the Idaho PTC. The BULKRN method was used for air impact analyses supporting the EIS after consultation with EPA, DEQ, and the US Forest Service. EPA recommended (June 18, 2019, email from Jay McAlpine, EPA, to Kevin Schilling, DEQ) using the BULKRN method since "use of the onsite data best fulfills the Guidance, and ensures consistency with the EIS, but this should be looked upon as technical advice only and not a requirement of the EPA."

Compliance with all NAAQS was easily demonstrated using meteorological data processed by the NON-BULKRN method; however, a small number of receptors showed 24-hour PM_{10} violations when the meteorological data processed with BULKRN method was used. DEQ performed a weight of evidence analyses (see Section 4.1.4 of this memorandum) to further evaluate the confidence of NAAQS compliance, using sensitivity analyses of various model input variables and the meteorological data processed using the BULKRN method.

AERMET requires the input of three surface boundary layer parameters: midday Bowen ratio (B_o), midday albedo (r), and surface roughness length (z_o). These parameters are dependent on the land use and vegetative cover of the area being evaluated. The EPA-recommended model, AERSURFACE, was used to estimate these surface parameters for the Stibnite meteorological data processing. AERSURFACE uses 1992 National Land Cover Data to determine these surface characteristics.

The determination of B_o is dependent on ambient moisture conditions (i.e., wet, average, or dry). For this purpose, historic 30-year (1985–2014) precipitation data from the Taylor Ranch station in Idaho (the closest station from which this type of data is available) were used.

The 70th and 30th percentile values estimated from the 30-year precipitation data were used to assign a moisture class to each calendar month per the following scheme: monthly precipitation greater than the 70th percentile was considered "wet"; between the 70th and 30th percentiles was considered "average"; and less than the 30th percentile was considered "dry." The monthly season and moisture classifications and estimated r and B_o for 2014 Stibnite meteorological data processing are presented in Table 19.

REC 0667

PET 301

Table 19. 2014 MONTHLY SEASON AND MOISTURE CLASSIFICATION, AND CALCULATED *r* AND B_o.							
Month	**Season**	***r***	**30-Year Precipitation Percentile (in)**		**2014 Precipitation (in)**	**Moisture Classification**	***Bo***
			30th	**70th**			
January	Winter	0.38	0.64	1.29	0.74	Average	0.50
February	Winter	0.38	0.40	0.81	0.99	Wet	0.50

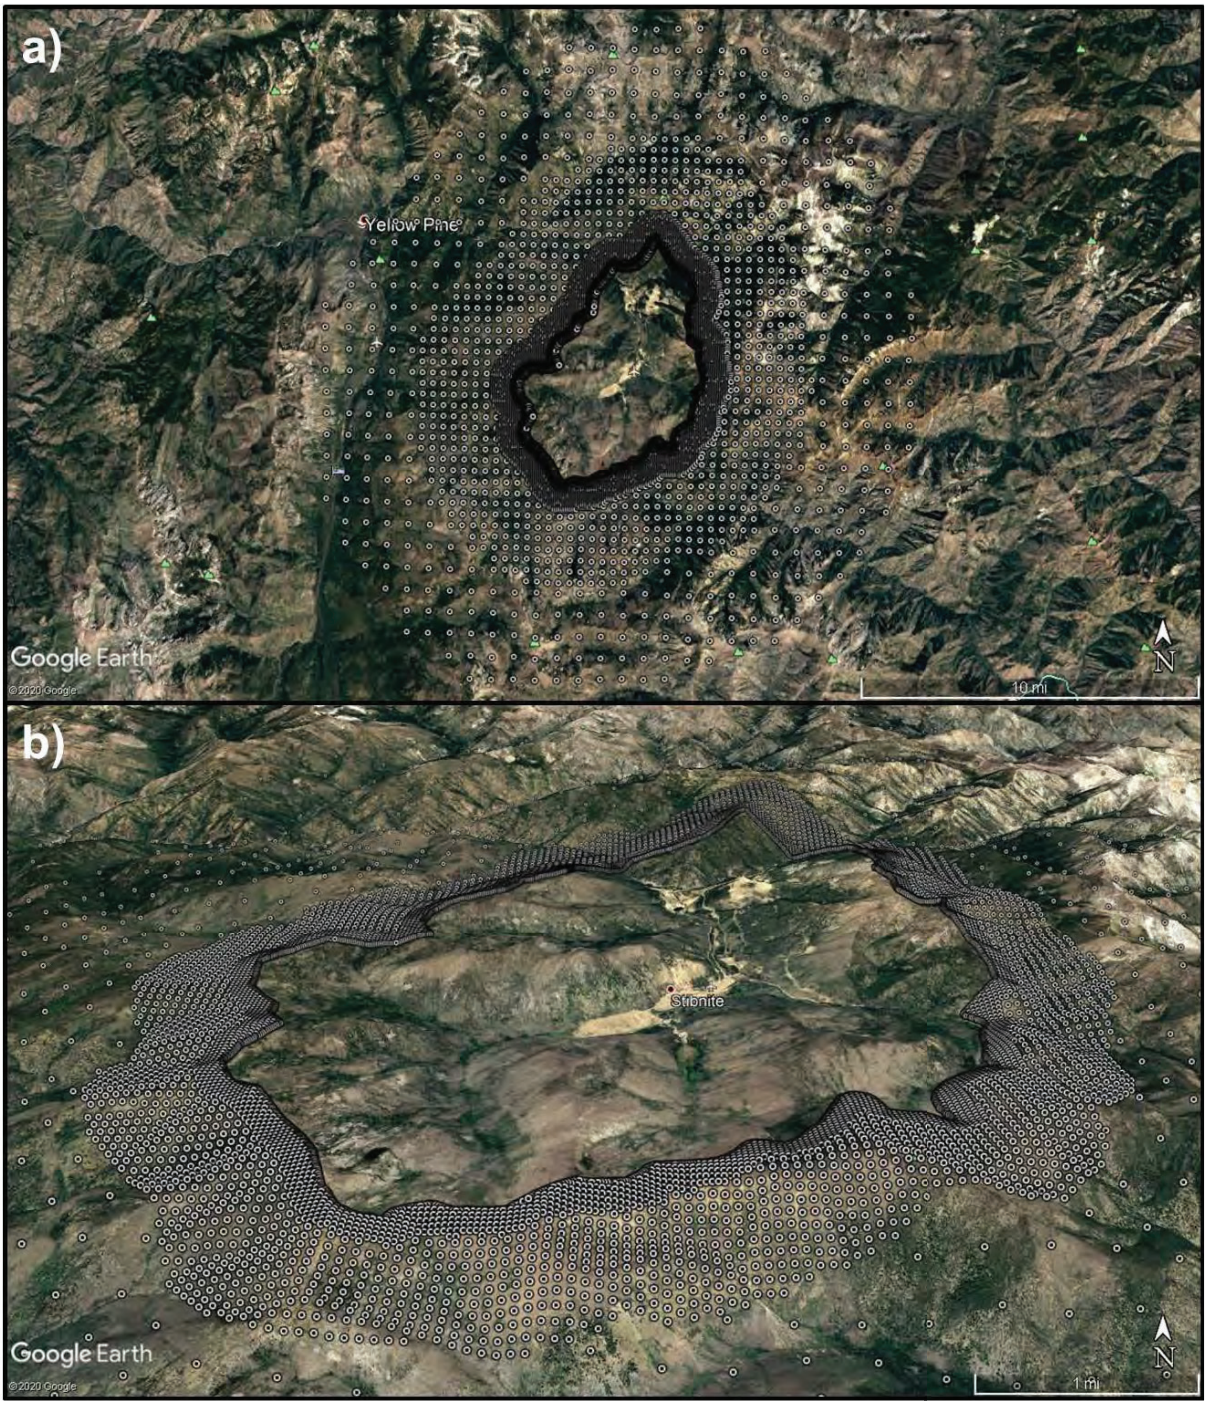
Met File Type: AERMET SFC
File: STIBNITE_2014U.SFC

Figure 6. METEOROLOGICAL STATION LOCATIONS FOR SGP MODELING.



3.3.6 Effects of Terrain on Modeled Impacts

Submitted ambient air impact analyses used terrain data extracted from United States Geological Survey (USGS) National Elevation Dataset (NED) files.

The terrain preprocessor AERMAP version 18081 was used by Air Sciences to extract the elevations from the NED files and assign them to receptors in the modeling domain in a format usable by AERMOD. AERMAP also determined the hill-height scale for each receptor. The hill-height scale is an

elevation value based on the surrounding terrain which has the greatest effect on that individual receptor. AERMOD uses those heights to evaluate whether the emission plume has sufficient energy to travel up and over the terrain or if the plume will travel around the terrain. Figure 7a depicts the full receptor grid used in the modeling analyses and Figure 7b illustrates a close-up of Figure 7a, overlaid on a terrain image from Google Earth.

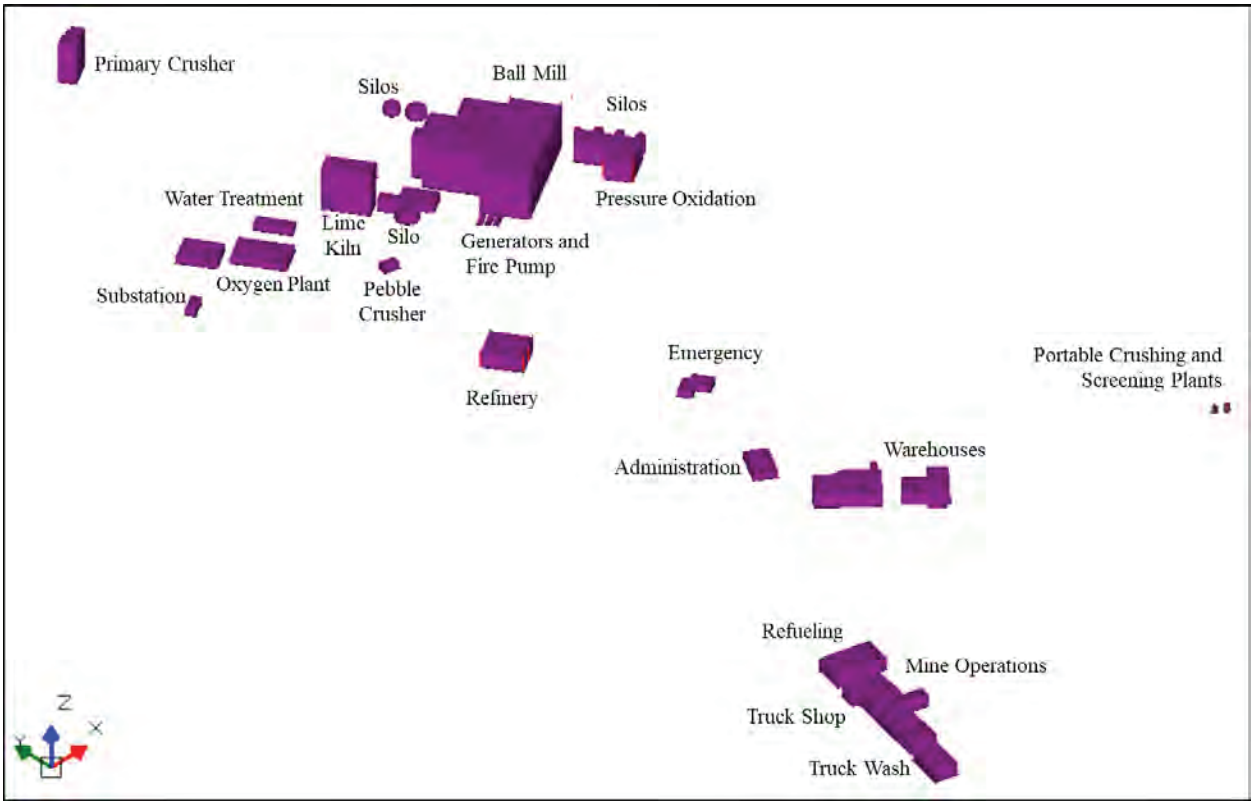


Figure 7. RECEPTOR GRID CENTERED AT THE SGP FACILITY.

3.3.7 Facility Layout and Downwash

Figure 3 shows the processing and refining area buildings and sources at the SGP facility. Figure 8 below depicts a three-dimensional view of Figure 3, as viewed from the southwest.

Figure 8. THREE-DIMENSIONAL VIEW OF PROCESSING AND REFINING AREA BUILDINGS AND SOURCES AT THE SGP FACILITY AS VIEWED FROM THE SOUTHWEST.

DEQ verified proper identification of the site location and the ambient air boundary by comparing a graphical representation of the modeling input file to aerial photographs on Google Earth (available at https://www.google.com/earth).

Potential downwash effects on emission plumes were accounted for in the model by using building dimensions and locations (locations of building corners, base elevation, and building heights). Dimensions and orientation of proposed buildings were used as input to the Building Profile Input Program for the Plume Rise Model Enhancements downwash algorithm (BPIP-PRIME version 04274) to calculate direction-specific dimensions and Good Engineering Practice (GEP) stack height information for input to AERMOD.

3.3.8 NOx Chemistry

The atmospheric chemistry of NO, NO_2, and O_3 complicates accurate prediction of NO_2 impacts resulting from NOx emissions. The conversion of NO to NO_2 can be conservatively addressed through the use of

several methods as outlined in a *2014 EPA NO_2 Modeling Clarification Memorandum* (EPA 2014). The guidance outlines a three-tiered approach:

- Tier 1 – assume full conversion of NO to NO_2 where total NOx emissions are modeled and modeled impacts are assumed to be 100 percent NO_2.
- Tier 2 – use an ambient ratio to adjust impacts from the Tier 1 analysis.
- Tier 3 – use a detailed screening method to account for $NO/NO_2/O_3$ chemistry such as the Ozone Limiting Method (OLM) or the Plume Volume Molar Ratio Method (PVMRM).

The default option of the Ozone Limiting Method (OLM), a third-tier method from 40 CFR 51, *Appendix W*, was used by Air Sciences to estimate the NO_2 1-hour and annual impacts for these analyses. The OLM method requires an input of in-stack NO_2/NOx ratio for each modeled source.

An in-depth literature review was conducted by Air Sciences to identify reasonable NO_2/NOx ratios for different combustion source categories. Based on this research, the NO_2/NOx ratio recommended for the heavy-duty diesel trucks in the California Air Pollution Control Officers Association (CAPCOA) Guidance Document (CAPCOA 2011) was selected for stationary diesel combustion sources. This NO_2/NOx ratio (11 percent) is conservatively higher than the diesel combustion NO_2/NOx ratio provided in the EPA ISR (In-Stack Ratio) database: 6 percent average, 9.8 percent maximum. The CAPCOA document and the EPA ISR database do not provide an NO_2/NOx ratio for propane boilers. The CAPCOA-recommended NO_2/NOx ratio for natural gas boilers was selected for the propane boilers. The natural gas boilers NO_2/NOx ratio is considered appropriate for the propane boilers because both are gaseous fuels with relatively similar combustion characteristics and are expected to have similar NO_2/NOx ratios. The NO_2/NOx ratio for blasting is based on blasting plume measurements provided in an Australian study (CSIRO 2008). The NO_2/NOx ratios used for the SGP NO_2 analyses are presented in Table 21.

Table 21. NO_2/NOx RATIOS.

Source Type	NO_2/NO_X Ratio	Reference
Blasting	0.036	Commonwealth Scientific and Industrial Research Organization (CSIRO 2008)
Diesel Engines	0.11	CAPCOA Guidance Document, heavy-duty diesel trucks (CAPCOA 2011)
Propane Heaters	0.10	CAPCOA Guidance Document, natural gas boilers (CAPCOA 2011)

DEQ performed a sensitivity analysis using a Tier 2 screening method (ARM2), which is more conservative than OLM, and found that the SGP facility is safely below the 1-hour and annual NO_2 NAAQS. Results are summarized in Section 4.1.3.

3.3.9 Particulate Deposition

For $PM_{2.5}$ and PM_{10} analyses, default particulate modeling methods, including deposition (Method 1, to account for depletion due to particulate settling), were used. To account for particulate settling, AERMOD requires the following source-specific variables:

1. Mass-mean aerodynamic particle diameter (PARTDIAM) for each particle size bin
2. Mass fraction (MASSFRAX) for each particle size bin
3. Particle density (PARTDENS) for each particle size bin

REC 0673

PET 307

A list of references that were used to develop the broad source category particle size bins and associated mass fractions was provided in the application. PRI (Perpetua Resources Idaho 2017b) provided the ore and DR material densities. The diesel and propane combustion particulate densities were adopted from technical literature (UMN 2002) and (Khalizov et al. 2012), respectively. Densities for the remaining materials were obtained from the Engineering Toolbox (https://www.engineeringtoolbox.com/density-materials-d_1652.html). An average density was used when a material-specific density range was available.

For sources that were aggregated and modeled as activity locations, deposition parameters were selected for the dominant source within the activity location. For open-pits (YPP, HFP, WEP), approximately 90% of emissions were associated with drilling; therefore, drilling deposition parameters were assigned to these sources. Similarly, emissions from dozing accounted for over 70% of emissions in the DRSF (FDRSF, HFDRSF, WEDRSF) and BT; therefore, these sources were assigned deposition parameters based on a dozing particulate profile.

The deposition parameters including mass fractions, mass mean diameters, and densities for the different source categories/groups are provided in Table 22.

Table 22. DEPOSITION PARAMETERS BY SOURCE CATEGORY.

Source Category	Parameter	PM_{10}				$PM_{2.5}$	
		Bin 1	Bin 2	Bin 3	Bin 4	Bin 1	Bin 2

	Mass Fraction (Kiln)	0.49	0.51	--	--	1.00	--
	Mass Fraction (Ball Mill)	0.36	0.64	--	--	1.00	--
	Mass Mean Diameter (µm)	2.50	10.00	--	--	2.50	--
	Density (g/cm^3)	1.09	1.09	--	--	1.09	--
Blasting and Drilling	Bin Upper Diameter (µm)	2.50	10.00	--	--	2.50	--
	Mass Fraction	0.06	0.94	--	--	1.00	--
	Mass Mean Diameter (µm)	2.50	10.00	--	--	2.50	--
	Density (g/cm^3) (Ore or DR)	Pit-specific, see Table 23.					
Dozing	Bin Upper Diameter (µm)	2.50	10.00	--	--	2.50	--
	Mass Fraction	0.55	0.45	--	--	1.00	--
	Mass Mean Diameter (µm)	2.50	10.00	--	--	2.50	--
	Density (g/cm^3) (DR)	Pit-specific, see Table 23.					

In order to account for variability in ore and DR densities for different pits, pit-specific densities were used for the ore and DR for each modeling scenario, with the following exception – for haul roads, access roads, and portable crushers, the average DR density from YPP, HFP, and WEP was used. Note that the BT density was excluded from those sources because the BT material will not be used for roads or construction. The pit-specific ore and DR densities are provided in Table 23.

Table 23. PIT-SPECIFIC ORE AND DEVELOPMENT ROCK DENSITIES FOR DEPOSITION.		
Pit	**Material**	**Density (g/cm^3)**
YPP	Ore	2.59
BT	Ore	2.00
HFP	Ore	2.59
WEP	Ore	2.68
YPP	DR	2.48
BT	DR	2.00
HFP	DR	2.34
WEP	DR	2.57
Average (YPP,HFP, WEP)	DR	2.46

3.3.10 Ambient Air Boundary

Ambient air is defined in Section 006 of the Idaho Air Rules as "that portion of the atmosphere, external to buildings, to which the general public has access."

PRI will legally control the SGP, an active industrial site where mining activities will occur, such as heavy equipment operation. Most areas of the mine will require strict safety protocols and controlled access. PRI has established an operations boundary to identify the area where public access will be excluded. Public access inside the operations boundary will be restricted for the life of the mine by physical barriers at points of potential access, including the current Stibnite Road point of entry and proposed site access via the Burntlog Route, as well as natural features of the landscape that prevent access. Consistent with the guidance provided in the EPA's draft revised policy on ambient air (EPA 2018b), public access control will include the following measures:

- Primary Access Points: The Stibnite Road (north) and Burntlog Route (south) access points will include locked gates. Guard shacks will be located at each gate to monitor all vehicle ingress/egress. Each gate also will include appropriate adjacent barriers (i.e., fencing, bollards, boulders, or other barriers) to prevent any vehicle from circumventing the gate and gaining site access. These primary access points are also controlled by adjacent natural features, such as streams and creeks, steep topography, and areas of thick vegetation and undergrowth that serve as natural barriers or impediments to access.

- Secondary Access Points: Other potential access points, such as secondary roadways and trails, will include posted signs warning the public against entry into the site. At these locations, boulders will be placed across the trail and at an appropriate width adjacent to the trail to prevent any vehicle from circumventing the barrier. These secondary access points also incorporate adjacent natural features, such as streams and creeks, steep topography, and areas of thick vegetation and undergrowth that serve as natural barriers or impediments to access. Some mine features, such as the TSF and process plant areas, will include perimeter fencing.

- Surveillance: PRI security personnel will routinely patrol mine facilities and roadways for unauthorized individuals. In addition, all onsite personnel will be trained on the necessity of restricting public access to areas within the operations boundary. Any suspected trespassing by unauthorized individuals will be reported immediately to security, and trespassers will be escorted off the site.

In response to comments from local community citizens, PRI will manage an access route to provide the general public with limited access through the SGP site between Stibnite Road at Sugar Creek and Thunder Mountain Road at Meadow Creek (shown in Figure 2). This route will be managed in accordance with the Stibnite Road Access Management Plan which is summarized as follows:

The proposed Stibnite Road access route through the SGP site is meant to provide controlled through-site access that is safe, provides travel-time comparable to current conditions and is consistent with the United States Forest Service travel management plan. The Stibnite Road access route extends from the north entry point southward to the Administration, Warehouse and Storage Area. Continuing southward, the Stibnite Road access route incorporates the Burntlog access road segment that occurs within the operations area and extends to the south entry point as shown on Figure 2. PRI has the legal authority to control access to the Stibnite Road access route and would provide seasonal (non-winter conditions) access only. At the discretion of PRI, additional access controls may occur during various phases of construction, during mine operations that present potential safely hazards such as blasting, due to

REC 0676

PET 310

inclement weather, or under any other circumstances that may present a threat to the protection of public or employee health and safety. PRI has the legal and practical ability to enforce its control over roadway access and to monitor traffic passing through the SGP site. Signage will be placed at the North Security Gate (near the bridge over Sugar Creek) and the South Security Gate (near the Stibnite Lodge) to provide information to travelers, and guard shacks will be located at each gate to monitor all vehicle ingress/egress. Persons wishing to traverse the SGP site on the Stibnite Road access route will be required to check in at the security gate to receive a safety briefing and to alert mine staff of their presence. Travelers will be required to check out upon exiting the site to ensure passage through the site in a safe and timely manner. Travelers will not be allowed to stop or loiter while traveling though the operations area. Along its full length, the Stibnite Road access route would have appropriate signage to direct travelers and would be separated from mine haul roads and areas of mine operations by fencing, berms, or gates to prevent travelers from straying from the route. When possible and to the degree practicable, anticipated public access restrictions will be communicated to the public in a timely manner so that they may plan appropriately. Receptors on the Stibnite Road access route were not included in the SGP air quality analyses as this road is not considered ambient air.

The worker housing facility will be located within the project operations boundary, near the south access security gate. This housing facility will be used strictly for accommodating employees, contractors, and official visitors, and it will not be accessible to the general public. Therefore, the atmosphere over the land occupied by the worker housing facility is not considered ambient air, and receptors were not placed at this location for the air quality analyses.

The operations boundary, shown in Figure 2 above and Figure 9 below, was used to define the ambient air boundary for air dispersion modeling purposes.

3.3.11 Nearby Co-Contributing Sources

If impacts of neighboring emission sources on receptors showing a significant impact from the sources subject to the permitting action are not adequately accounted for by the background concentration used, then emissions from those sources must be modeled. The nearest significant permitted facility to SGP is Tamarack Mill, located more than 75 kilometers (km) west. This facility is located too far away to cause a significant concentration gradient along the periphery of the SGP and was therefore not included in the cumulative impact analyses for SGP.

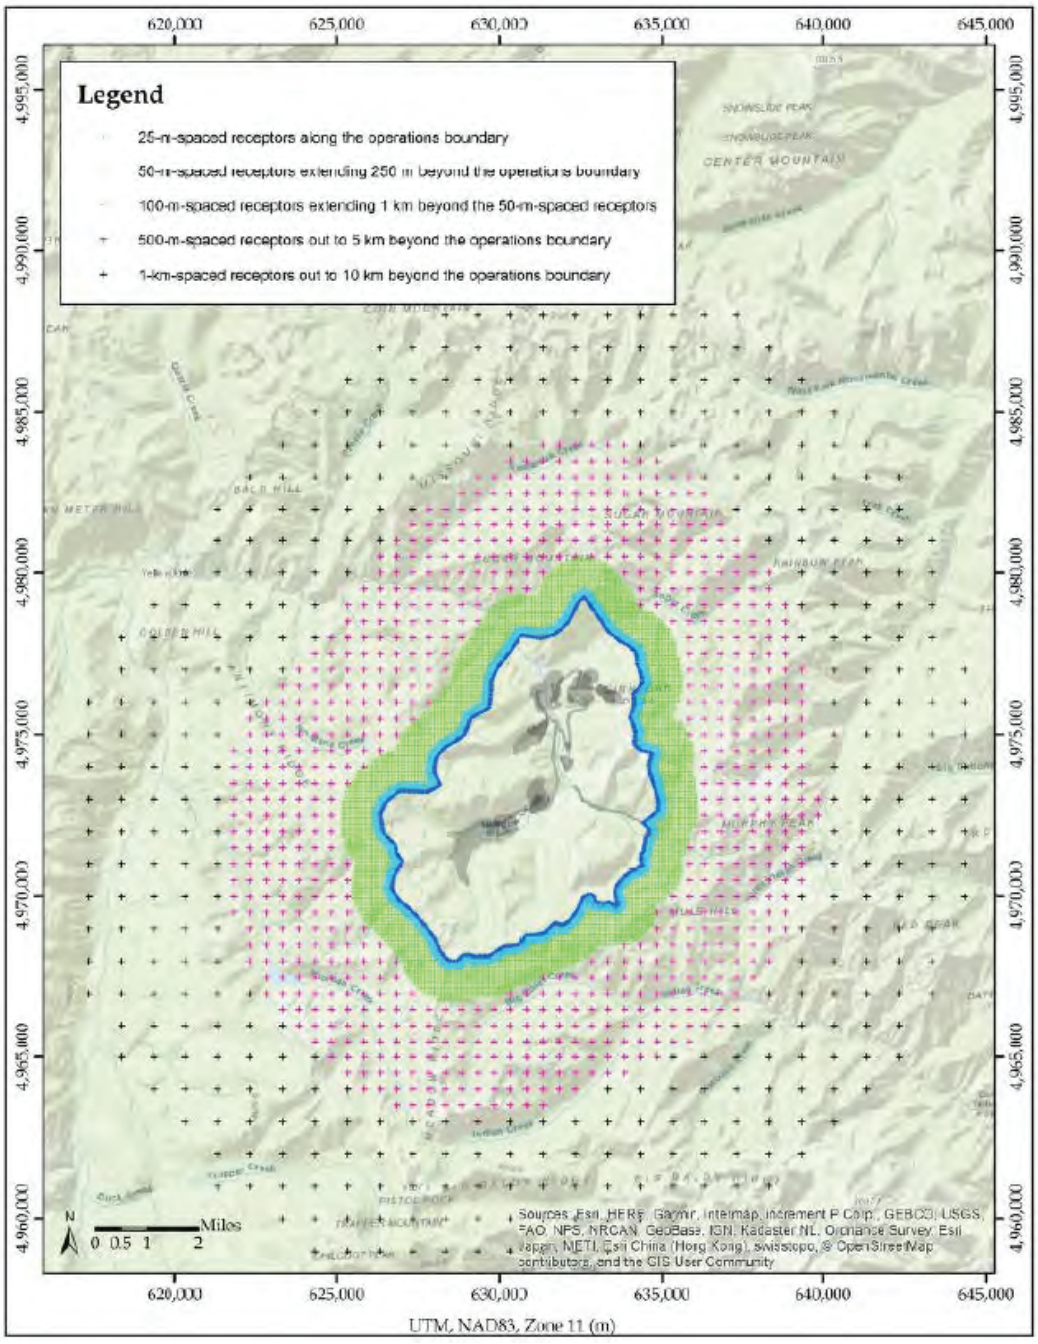
3.3.12 Receptor Network

DEQ determined that the receptor grid used in the submitted modeling analyses was adequate to resolve maximum modeled impacts.

The SGP air quality analyses were performed using the following receptor spacing and extents (Table 18):

- 25-m-spaced receptors placed along the ambient air boundary;
- 50-m-spaced receptors extending 250 m beyond the ambient air boundary;
- 100-m-spaced receptors extending 1 km beyond the 50-m-spaced receptors;
- 500-m-spaced receptors extending 5 km beyond the ambient air boundary; and
- 1-km-spaced receptors extending 10 km beyond the ambient air boundary.

In addition, each highest modeled impact was evaluated further by performing a hot-spot analysis using a finer 25-m-spacing receptor grid. The modeling receptor grid is shown below in Figure 9. The full grid,



REC 0677

PET 311

along with the fenceline receptors, includes a total of 9,631 receptors. A SIL analysis was not conducted. The full receptor grid was used in the cumulative NAAQS impact and TAPs impact analyses.

The receptor grid used in the submitted modeling analyses met the minimum recommendations specified in the *Idaho Air Quality Modeling Guideline* (DEQ 2013), and DEQ determined that the receptor network was effective in reasonably assuring compliance with applicable air quality standards at all ambient air locations.

PET 312

3.3.13 Good Engineering Practice Stack Height

An allowable good engineering practice (GEP) stack height may be established using the following equation in accordance with Idaho Air Rules Section 512.03.b:

H = S + 1.5L, where:

H = good engineering practice stack height measured from the ground-level elevation at the base of the stack.

S = height of the nearby structure(s) measured from the ground-level elevation at the base of the stack.

L = lesser dimension, height or projected width, of the nearby structure.

Sources from the SGP facility are below GEP stack height. Therefore, consideration of downwash caused by nearby buildings was required.

4.0 NAAQS and TAPs Impact Modeling Results

4.1 Results for NAAQS Analyses

4.1.1 Significant Impact Level Analyses

A SIL analysis was not performed for the SGP project.

4.1.2 Cumulative NAAQS Impact Analyses

Table 24 provides results (highest of 14 scenarios) for the cumulative NAAQS impact analysis. It provides the model-predicted maximum design concentration (including the hot-spot analyses) and the associated modeling scenario, the background concentration, and the estimated total concentration (SGP impact plus background) for each pollutant-averaging time combination. A comparison of the estimated total concentrations with the applicable NAAQS is also provided in this table. For each pollutant and averaging period, two modeled design concentrations are listed, each corresponding to the meteorological data processed with (BULKRN) and without (NON-BULKRN, grey shading) the Bulk Richardson method.

Table 24. RESULTS FOR CUMULATIVE NAAQS IMPACT ANALYSES.

Pollutant	Averaging Time	Max. Conc.[a] (µg/m^3)[b]	Model Scenario	Back. Conc.[c] (µg/m^3)	Total Conc.[d] (µg/m^3)	NAAQS (µg/m^3)	Percent of NAAQS
Carbon monoxide	8 hours	6,218[e]	W1	1,110	7,328	10,000	73.3%
		3,516[f]	W1		4,626		46.3%
	1 hour	17,054	W1	1,740	18,794	40,000	47.0%
		9,467	W1		11,207		28.0%
Nitrogen dioxide	1 year	2.3	W1	0.9	3.2	100	3.2%
		1.4	W1		2.3		2.3%
	1 hour	116.7	B1	4.3	121.0	188	64.4%
		111.0	W1		115.3		61.3%

$PM_{2.5}$[g]	1 year	7.7	W5	3.5	11.2	12	93.3%
		4.2	W5		7.7		64.2%
	24 hours	18.6	W5	15.0	33.6	35	96.0%
		11.0	W5		26.0		74.3%
PM_{10}[h]	24 hours	121.5	W5	37.0[i]	158.5	150	105.7%[j]
		75.7	W5		112.7		75.1%

		1.2	B1		18.0		1.4%
	1 hour	3.2	B1	12.3	15.5	196	7.9%
		2.7	B1		15.0		7.7%

a. Max. Conc. = maximum modeled design concentration.
b. Micrograms per cubic meter.
c. Back. Conc. = background concentration.
d. Total Conc. = total (modeled + background) concentration.
e. The first Max. Conc. value for each pollutant and averaging time represents results using the BULKRN meteorological data.
f. The second (grey-shaded) Max. Conc. value for each pollutant and averaging time represents results using the NON-BULKRN meteorological data.
g. Particulate matter with an aerodynamic diameter less than or equal to a nominal 2.5 micrometers.
h. Particulate matter with an aerodynamic diameter less than or equal to a nominal 10 micrometers.
i. For 24-hour PM_{10}, the design value is the *second-highest* 24-hour average concentration in a given year. However, the background value that was used in the modeling analyses represents the *first-highest* 24-hour average concentration measured in 2014. Therefore, using a larger background concentration adds a layer of conservatism to the calculated total impact for 24-hour PM_{10}.
j. Results for 24-hour PM_{10} with meteorological data processed using BULKRN show up to five hotspot receptors that exceed NAAQS. Refer to Section 4.1.4 of this modeling memo for a weight-of-evidence analysis demonstrating NAAQS compliance.

Table 24 shows that modeled concentrations derived using the BULKRN meteorological data are higher than the NON-BULKRN dataset. It also shows that the total (modeled + background) concentrations from the SGP cumulative impact analyses do not exceed the applicable NAAQS, except for when the BULKRN meteorological data are used in modeling 24-hour PM_{10} (total concentration is 105.7% of the 24-hour PM_{10} NAAQS).

PM_{10} modeling with the meteorological dataset processed with the BULKRN method shows up to five hotspot receptors for three modeling scenarios (W1, W3, and W5) with slight exceedance of NAAQS. Scenario W5 is the worst-case scenario, with a maximum total concentration of 158.5 $\mu g/m^3$ which exceeds the NAAQS of 150 $\mu g/m^3$. A weight-of-evidence analysis demonstrating PM_{10} NAAQS compliance is presented in Section 4.1.4 of this modeling memo.

The locations of the maximum impacts for each pollutant and averaging time are illustrated in Figure 10. The results presented in this figure include the hot-spot analyses conducted for each applicable pollutant-averaging time combination. For $PM_{2.5}$ and PM_{10}, the alternate meteorological data (NON-BULKRN) were used.

Modeling for ozone and secondary $PM_{2.5}$ were not performed for this minor stationary source. These analyses are typically associated with applications for major stationary sources. Nonetheless, taking the ratio of the VOC, NOx, and SO_2 emissions from the SGP facility by the emissions and resulting concentrations of O_3 and secondary $PM_{2.5}$ from EPA's modeled emission rates for precursors (MERPs) guidance yields estimated O_3 and secondary $PM_{2.5}$ concentrations of less than 1 ppb of O_3 and less than 0.1 $\mu g/m^3$ of $PM_{2.5}$ (24-hour and annual) for the SGP. These estimated concentrations have a negligible effect on compliance demonstration with the NAAQS.

REC 0680

PET 314

Figure 10. SGP CUMULATIVE IMPACTS (µg/m^3) AND LOCATIONS.

Higher background concentrations from McCall that include medium-traffic emissions provided in Section 3.2.3 were then combined with the SGP model-predicted maximum design concentrations to provide an additional level of conservatism in demonstrating compliance. These results are shown in Table 25. For $PM_{2.5}$ and PM_{10}, the alternate meteorological data (NON-BULKRN) were used. For the rest of the criteria pollutants, the BULKRN meteorological data were used.

4.1.3 DEQ's Sensitivity Analyses for 1-hour and Annual NO_2

DEQ performed a sensitivity analysis for 1-hour and annual NO_2 using a Tier 2 (ARM2) screening method. Minimum and maximum NO_2/NOx ratios of 0.5 and 0.9, respectively, were used. Results from DEQ's cumulative NAAQS impact analyses, summarized below in Table 26, indicate that the SGP facility is safely below the 1-hour and annual NO_2 NAAQS even when using a more conservative NO_2 screening method.

4.1.4 DEQ's Weight-of-Evidence Analyses for 24-hour PM_{10}

This section describes a weight-of-evidence analysis that provides additional analytical information to evaluate the degree of NAAQS compliance confidence for 24-hour PM_{10}. NAAQS compliance was demonstrated in the submitted application using meteorological data processed with an EPA-approved method using regional cloud cover to calculate stability parameters rather than site-specific monitored solar radiation and measured temperature differences with height. Both methods are considered default for regulatory purposes, and modeling using this dataset shows that the facility is well below NAAQS.

REC 0682

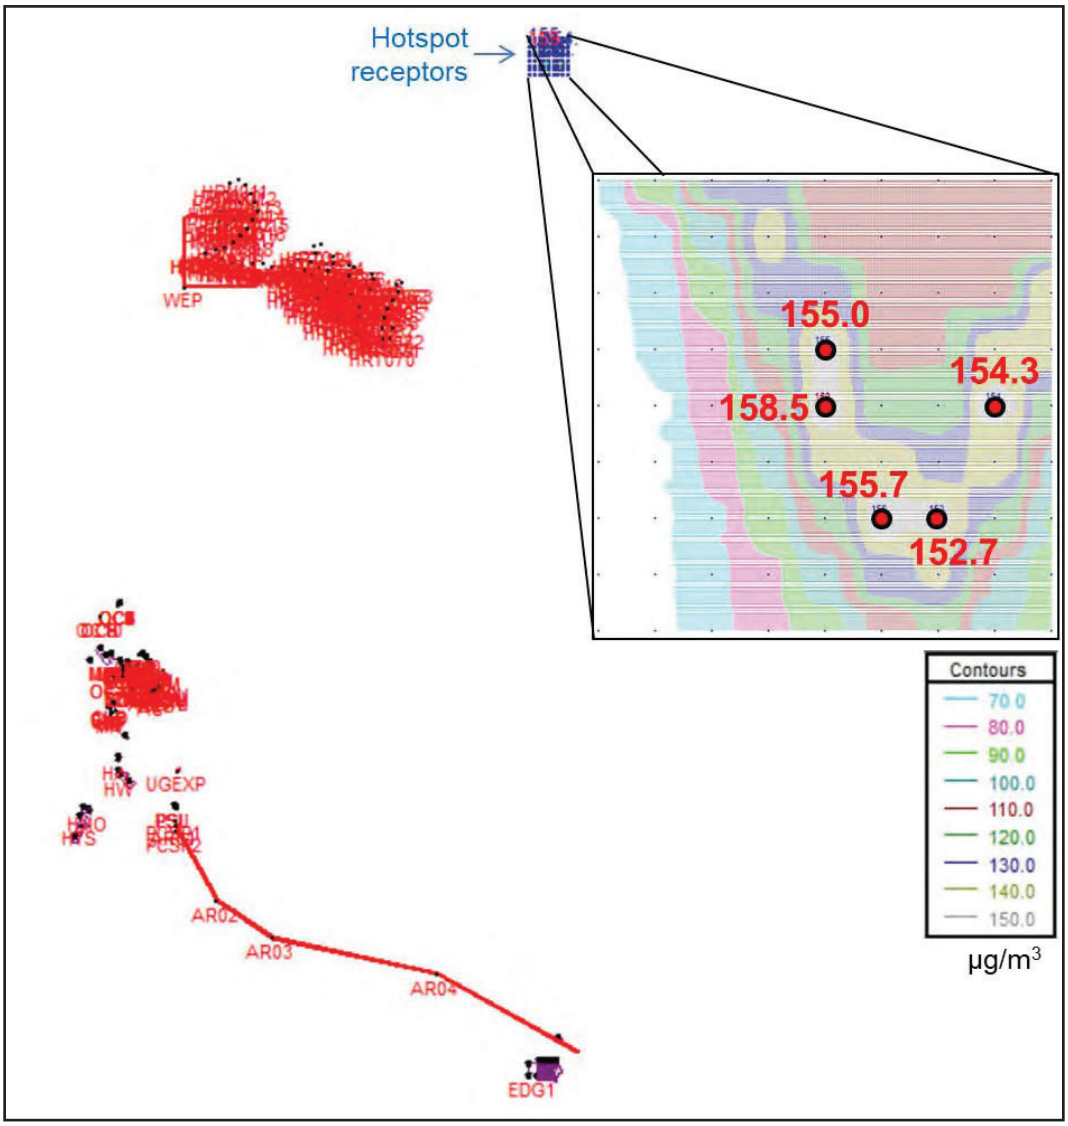
PET 316

As described in Section 4.1.2, PM_{10} modeling with meteorological dataset processed using the site-specific BULKRN method shows up to five hotspot receptors for Scenario W5 (the highest PM_{10} modeling scenario) that exceed NAAQS (150 µg/m^3). The hotspot receptors have a 25-meter grid spacing. Hotspot receptors that exceed 24-hour PM_{10} NAAQS have total (modeled + background) concentrations of 152.7, 154.3, 155.0, 155.7, and 158.5 µg/m^3. Locations of these receptors are illustrated in Figure 11. Figure 12 shows these receptors overlaid on Google Earth. As noted in Section 3.2.1 of this modeling memorandum, the design value for 24-hour PM_{10} is the *second-highest* 24-hour average concentration in a given year. However, the background value that was used in the modeling analyses (37.0 µg/m^3) represents the *first-highest* 24-hour average concentration measured in 2014. Therefore, using a larger background concentration adds another layer of conservatism to the calculated total impact for 24-hour PM_{10}. If the *second-highest* 24-hour average concentration (34.0 µg/m^3) were used in the modeling analyses, the number of receptors that exceed the 24-hour PM_{10} NAAQS is reduced from five to four.

REC 0683

PET 317

Figure 11. HOTSPOT RECEPTORS THAT EXCEED 24-HOUR PM_{10} NAAQS (SCENARIO W5, BULKRN METEOROLOGICAL DATA).



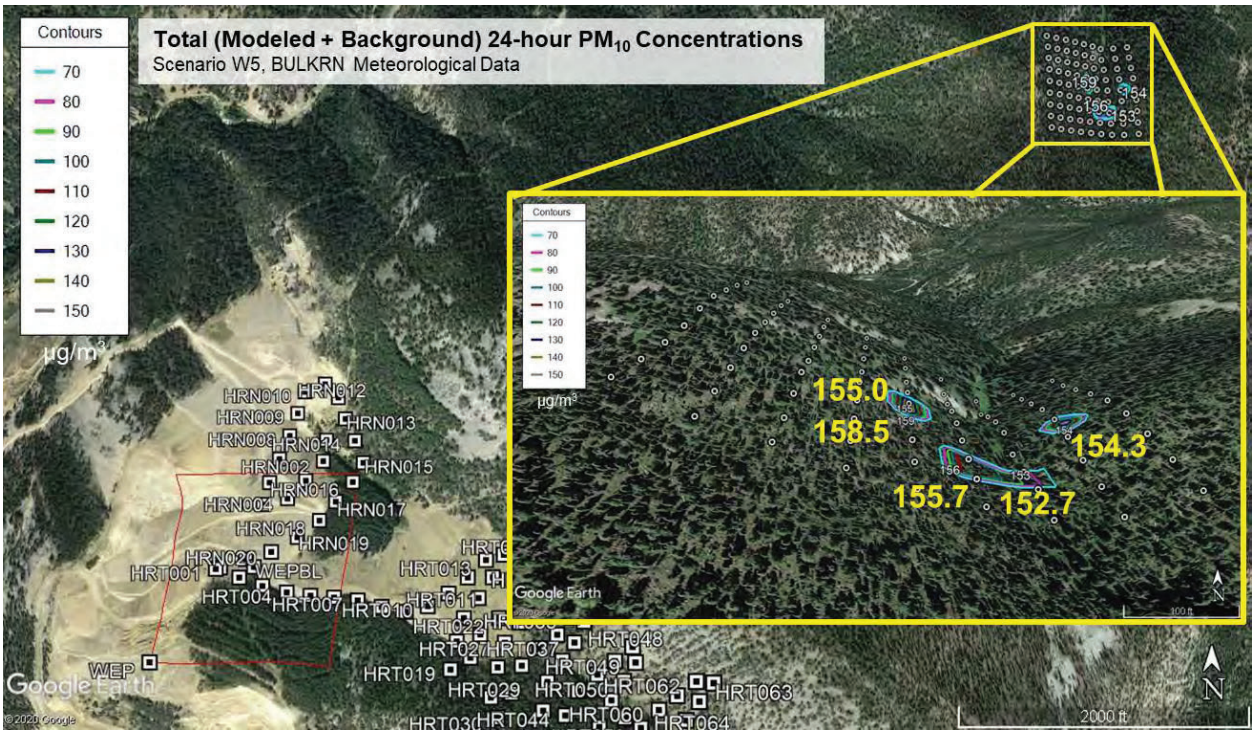


Figure 12. HOTSPOT RECEPTORS THAT EXCEED 24-HOUR PM_{10} NAAQS, OVERLAID ON GOOGLE EARTH IMAGE (SCENARIO W5, BULKRN METEOROLOGICAL DATA).

Figures 11 and 12 show that the modeled PM_{10} NAAQS exceedances are located northeast of the SGP facility. These receptors are located 2 km away from the center of the West End Pit (WEP). The AERMOD output files indicate that all modeled violations occur during winter (all modeled violations occur on December 23, 2014). Data provided in the SGP baseline study (Perpetua Resources Idaho 2017a) specify an average snow depth of 21-68 inches and an average precipitation of 6.0 inches at the project site during this period. Therefore, fugitive road dust emissions during high-modeled impact hours could be overestimated.

DEQ performed a source-group analysis (Table 27) which indicates that emissions from the WEP and the Haul Road (HR) are the largest contributors to the maximum modeled PM_{10} design concentrations. For comparison, source-group analyses using the NON-BULKRN meteorological data are also listed in Table 27.

Table 27. SOURCE-GROUP ANALYSES FOR 24-HOUR PM_{10} (SCENARIO W5).

Emission Source Group	Modeled Design Concentration (µg/m³)[a]	
	BULKRN	NON-BULKRN
ALL	121.5	75.7
West End Pit (WEP)	89.3	24.5

Process & Ancillary Volume Sources	0.20	0.29

[a] Micrograms per cubic meter.

The six source groups listed in Table 27 that are related to mining activity and emissions (WEP, WEPBL, WEDRSF, HR, ACCRD, UGEXP) were examined further. Table 28 lists the daily modeled PM_{10} emissions (in pounds per day [lb/day]), grouped according to mining activity. Key assumptions for calculating the daily emissions are also listed in this table. Total modeled PM_{10} emission from mining activity for Scenario W5 is 3,336.76 lb/day. The contribution from each source group is listed in the second column of Table 28, and a pie chart is illustrated in Figure 13.

Table 28. KEY ASSUMPTIONS FOR CALCULATING DAILY MINING ACTIVITY EMISSIONS FOR 24-HOUR PM_{10} (SCENARIO W5).

Mining Activity	Emissions (lb/day)[a]
WEP (West End Pit)	**885.54**
Open Pit Drilling	
• Blasting 180,000 tons of material (DR) per day • Drilling 1,200 holes per day	811.20
Material Loading	
• Blasting 180,000 tons of material (DR) per day	18.00
Dozing	
• Dozers operating 144 hours per day • Surface material silt content of 6.9% • Material moisture content of 7.9%	54.20
Surface Exploration	
• Total wet drilling holes of 700 divided by 14 years • 50 holes per year	2.15

[a.] Pounds per day.

Figure 13. PIE CHART FOR DAILY MODELED PM_{10} EMISSIONS FROM MINING ACTIVITY (SCENARIO W5).

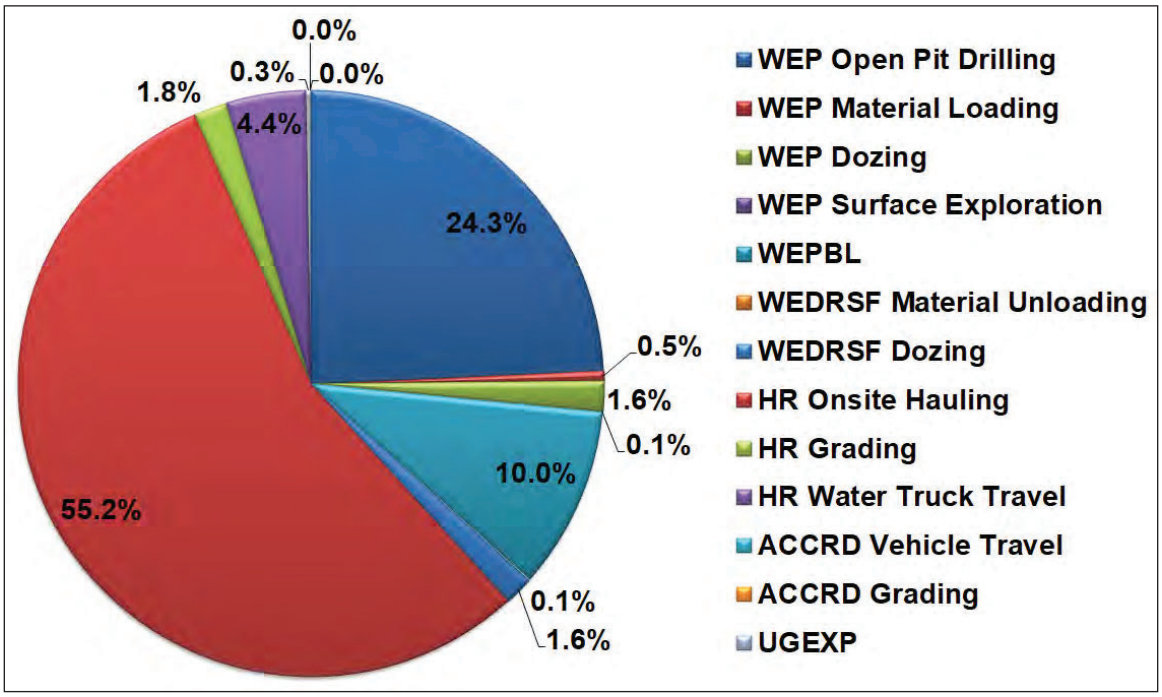

Figure 13 shows that onsite hauling on haul roads ("HR Onsite Hauling") accounts for 55.2% of the total daily PM_{10} emissions. Open pit drilling at the WEP ("WEP Open Pit Drilling") and blasting ("WEPBL") account for 24.3% and 10.0% of the daily PM_{10} emissions, respectively. Therefore, it is not surprising that HR, WEP, and WEPBL are associated with the highest modeled design concentrations in Table 27.

Table 29 shows the ten highest-ranked modeled 24-hour PM_{10} impacts from each emission source group. Note that for 24-hour PM_{10}, the design value is the *second-highest* 24-hour average concentration in a given year. Therefore, the second-high modeled value for source group ALL (121.5 $\mu g/m^3$) was summed

with the background concentration for comparison to NAAQS. The calculated total impact (modeled design value + background concentration) is conservative because the background value that was used in the cumulative NAAQS impact analyses (37.0 µg/m^3) represents the *first-highest* 24-hour average concentration measured in 2014.

Table 29. TEN HIGHEST-RANKED MODELED 24-HOUR PM_{10} IMPACTS IN µg/m^3 FROM DIFFERENT SOURCE GROUPS (SCENARIO W5, BULKRN METEOROLOGICAL DATA).

g. UGEXP = Underground Exploration.
h. PRCSPT = Process & Ancillary Point Sources.
i. PRCSVOL = Process & Ancillary Volume Sources.

Given a background of 37.0 µg/m^3 and a NAAQS of 150 µg/m^3, the critical modeled concentration threshold for any 24-hour PM_{10} NAAQS violation is therefore 113.0 µg/m^3. Table 29 shows that the third-high modeled value for source group ALL (113.4 µg/m^3) barely exceeds NAAQS. Fourth-high (and lower-ranked) modeled impacts, when added to the background concentration, are below NAAQS.

As discussed earlier in this section, HR Onsite Hauling, WEP Open Pit Drilling, and WEP Blasting are the three largest components of the total daily PM_{10} emissions. Therefore, it is not surprising that HR, WEP, and WEPBL are associated with the highest modeled concentrations among all source groups.

To investigate the potential culpability of each source group to the modeled 24-hour PM_{10} NAAQS violation, DEQ performed a culpability analysis using the MAXIFILE output option in AERMOD. The MAXIFILE option provides the receptor location and date of an impact. DEQ performed two MAXIFILE runs. In the first MAXIFILE simulation, the model was run using source group ALL. A threshold value (113.0 µg/m^3) equal to the NAAQS minus background was set. The output file provided a list of the receptors where the NAAQS is exceeded. In the second MAXIFILE simulation, the model was run using only the receptors identified by the first MAXIFILE run. Source groups were included in the second modeling simulation. A threshold value equal to the 24-hour PM_{10} SIL (5.0 µg/m^3) was set. The output file provided a date stamp for any day when a source group exceeds the SIL and potentially contributes to a violation of the NAAQS. A significant contribution to a NAAQS violation would be predicted to occur if the date stamps for source group ALL (from the first MAXIFILE run) and for a specific source group (from the second MAXIFILE run) matched.

DEQ's culpability analyses confirm that emission source groups HR and WEP are culpable for the 24-hour PM_{10} NAAQS exceedances. The date stamps indicate NAAQS violations during the winter season (January 6, January 15, and December 23). We show next that when modeled emissions are more-closely

REC 0688

PET 322

representative of typical daily mining production rates for a high-production period (everything else held constant), the SGP facility is able to demonstrate compliance with 24-hour PM_{10} NAAQS at those few receptors showing a potential violation when using meteorological data processed with the BULKRN method. We also discuss next the implication of NAAQS violations occurring during the winter season.

As listed in Table 28, PM_{10} modeling simulation for Scenario W5 was based on a mining production rate of 180,000 ton/day of development rock. This corresponds to 65,700,000 ton/year, which is more conservative than the expected peak production rate of 42,692,000 ton/year (116,964 ton/day). To investigate the effect of a lower modeled mining production rate on design value concentrations, DEQ performed a modeling simulation ("DEQ Run 1") where mining production rate was assumed to be 120,000 ton/day instead of 180,000 ton/day, but all other model variables were held constant. This adjustment lowered the modeled daily emission rates for WEP, WEDRSF, and HR, which are summarized in Table 30. Because the modeled emission rates were lower, the modeled design concentrations were also lower. Results for DEQ's sensitivity analyses are summarized in Table 31.

Table 30. DAILY MINING ACTIVITY EMISSIONS USED IN DEQ'S SENSITIVITY ANALYSES FOR 24-HOUR PM_{10} (SCENARIO W5).

Mining Activity	Emissions (lb/day)[a]

c. Back. Conc. = background concentration.
d. Total Conc. = total (modeled + background) concentration.
e. Particulate matter with an aerodynamic diameter less than or equal to a nominal 10 micrometers.
f. DEQ Run 1: mining production rate was modeled at 120,000 ton/day instead of 180,000 ton/day. Everything else was held constant.
g. For 24-hour PM_{10}, the design value is the *second-highest* 24-hour average concentration in a given year. However, the background value that was used in the modeling analyses represents the *first-highest* 24-hour average concentration measured in 2014. Therefore, using a larger background concentration adds a layer of conservatism to the calculated total impact for 24-hour PM_{10}.

Maximum modeled concentration for "DEQ Run 1", when summed with the background concentration, is lower than NAAQS thereby demonstrating NAAQS compliance. Total (modeled + background) concentrations for all hotspot receptors are depicted in Figure 14; maximum total impact is depicted by the red circle. The SGP facility complies with the 24-hour PM_{10} NAAQS when daily mining production rates closer to a more typical daily rate for a high-production period are used in the model, instead of a very conservative mining production rate, even when using site-specific BULKRN meteorological data.

Figure 14. RESULTS FOR DEQ'S SENSITIVITY ANALYSES SHOWING TOTAL (MODELED + BACKGROUND) 24-HOUR PM_{10} CONCENTRATIONS AT HOTSPOT RECEPTORS (SCENARIO W5, BULKRN METEOROLOGICAL DATA).

Meteorological data processing with and without BULKRN are considered acceptable by EPA. However, the BULKRN meteorological data yielded higher modeled design values for the SGP facility than the meteorological data processed without the BULKRN method. DEQ's analyses suggest that when daily mining production rates closer to a more typical daily rate for a high-production period are used (everything else held constant), the SGP facility is able to demonstrate compliance with 24-hour PM_{10} NAAQS at those few receptors showing a potential violation when using meteorological data processed with the BULKRN method.

Maximum modeled design value 24-hour PM_{10} impacts, even with the use of more reasonably expected daily production rates, are still just under the 150 $\mu g/m^3$ NAAQS. As noted earlier in this section, these high values were observed during the winter season. During this period, not only are fugitive emissions minimized because of the higher moisture content of material handled or driven over, but background concentrations in such remote areas are generally much lower because of the absence of wildfires and dust-generating sources.

To summarize, DEQ considered the following assumptions and results in its weight-of-evidence analyses:

a. All modeled impacts are below NAAQS for meteorological data with stability parameters calculated by regional cloud cover data.
b. Modeled impacts over the 24-hour PM_{10} NAAQS using BULKRN meteorological data are limited to a small area and limited period of time.
c. Modeled 24-hour PM_{10} NAAQS exceedances are limited to the winter season, where emissions and background levels are likely overestimated.
d. The model assumes maximum allowable operations/emissions.
e. The model assumes minimum allowable controls on emissions. The permit would require at least 93% control of maximum potential fugitive emissions, but the fugitive emissions may in fact be controlled by more than that, especially during winter and periods of precipitation.
f. Finally, 24-hour PM_{10} background concentrations represent the maximum 1st high (instead of the maximum 2nd high) which is on the higher end of the distribution.

DEQ's weight-of-evidence analyses show that, considering all the collective conservative layers of the modeling analyses, modeling efforts using both site-specific and alternative meteorological datasets show acceptable impacts. DEQ is highly confident that operation of the SGP will not cause or contribute to a violation of NAAQS. This is based on: (1) the submitted application materials and analyses; (2) DEQ's supplemental analyses; and (3) the assumption that the facility is constructed and operated as described in the application and limited by the PTC.

PRI later determined that the West End Development Rock Storage Facility will not be constructed. This change eliminated Scenario W5 as a potential operating scenario. Scenario W3 is now the scenario producing the highest modeled impacts, and NAAQS compliance is easily demonstrated when using temporally varying background PM_{10} values, which were obtained from onsite monitoring data. Results are presented in the *Modeling Review Attachment* to this memorandum.

4.1.5 DEQ's Sensitivity Analyses for a Lower Fugitive Road Dust Control Efficiency

Fugitive particulate emissions from roadways were estimated by the applicant to be controlled above 93%, which is an aggressive level of control. The high level of emission control was needed to demonstrate compliance with NAAQS. To investigate the effect of lower unpaved road emission control efficiency, DEQ performed a modeling simulation ("DEQ Run 2") where the control efficiency was set to

REC 0691

PET 325

90%. The daily mining production rate was assumed to be 120,000 ton/day instead of 180,000 ton/day, but everything else was held constant. These adjustments lowered the daily modeled emission rates for WEP and WEDRSF, but increased the daily modeled emission rate for HR and the Access Road (ACCRD) (Table 32). Five receptors exceed the 24-hour PM_{10} NAAQS. Figure 15 shows the locations of these receptors.

Table 32. DAILY MINING ACTIVITY EMISSIONS USED IN DEQ'S SENSITIVITY ANALYSES FOR 24-HOUR PM_{10} (SCENARIO W5).

REC 0692

PET 326

Figure 15. RESULTS FOR DEQ'S SENSITIVITY ANALYSES SHOWING HOTSPOT RECEPTORS THAT EXCEED 24-HOUR PM_{10} NAAQS, ASSUMING MINING PRODUCTION RATE OF 120,000 TONS PER DAY AND FUGITIVE ROAD DUST CONTROL EFFICIENCY OF 90% (SCENARIO W5, BULKRN METEOROLOGICAL DATA).

DEQ's sensitivity analyses suggest that a few hotspot receptors exceed the 24-hour PM_{10} NAAQS when the unpaved road control efficiency falls below 93% and the meteorological data processed with the BULKRN method is used. When the meteorological data processed without the BULKRN method is used, all the hotspot receptors demonstrate compliance with NAAQS at a 90% control efficiency and at both examined production levels:

- maximum impact at 120,000 ton per day: 73.9 $\mu g/m^3$ + 37.0 $\mu g/m^3$ = 110.9 $\mu g/m^3$.
- maximum impact at 180,000 ton per day: 84.6 $\mu g/m^3$ + 37.0 $\mu g/m^3$ = 121.6 $\mu g/m^3$.

While using alternative meteorological data processed without the BULKRN method safely demonstrates

compliance with NAAQS, using site-specific BULKRN meteorological data does not. Therefore, DEQ's modeling team recommends that the permit require an aggressive implementation of measures to achieve above 93% control efficiency for fugitive particulate emissions from roadways.

4.2 Results for TAPs Impact Analyses

TAP analyses were extensively refined after the February/March public comment period, as described in the *TAP Addendum* submitted by Perpetua. DEQ's review of the *TAP Addendum* is provided in the DEQ *Modeling Review Attachment* to this memorandum.

5.0 Conclusions

The information submitted with the PTC application (including the *TAP Addendum*), combined with DEQ's air impact analyses and the assumption that the facility is constructed and operated as described in the application and limited by the PTC, demonstrated to DEQ's satisfaction that emissions from the Stibnite Gold Project in Valley County, Idaho will not cause or significantly contribute to a violation of any applicable ambient air quality standard or TAP increment.

TAPs Addendum Modeling Review Attachment

1.0 Introduction and Summary

Perpetua Resources Idaho, Inc. (PRI) submitted the *Stibnite Gold Project (SGP) Permit to Construct Application TAP Addendum* (*TAP Addendum*), prepared by Air Sciences Inc. (Air Sciences) and submitted to DEQ on October 5, 2021. The TAP Addendum reassessed source applicability to Toxic Air Pollutant (TAP) permitting requirements, refined TAPs regulatory methods to demonstrate compliance with applicable TAP increments, revised and/or refined operations and operational parameters affecting TAP emissions, and refined TAP air impact analyses. The revisions and refinements made for the TAP Addendum also reduced PM_{10} and $PM_{2.5}$ emissions, and this effect is presented in this *TAPs Addendum Modeling Review Attachment* (*Modeling Review Attachment*).

2.0 Scope of TAPs Addendum

DEQ reevaluated TAPs compliance regulatory interpretations and impact assessment methods following the second public comment period of February 18, 2021, through March 19, 2021. Areas of revision in response to issues identified after the public comment period included:

- Revising source-specific TAP impact assessment applicability, primarily identifying what sources can be excluded because they are "covered" or "addressed" by a National Emissions Standard for Hazardous Air Pollutants (NESHAP) or New Source Performance Standard (NSPS).
- Refining regulatory methods used to demonstrate compliance with TAP increments.
- Refining TAP emission calculation methods and dispersion-affecting parameters.
- Reassessing TAP impacts resulting from revised and/or refined methods and data.
- Providing a best-estimate of actual TAP emissions that will occur from operation of the mine, and then comparing this to maximum permit-allowable emissions.

PRI and Air Sciences, PRI's permitting consultant, submitted the *TAP Addendum* on October 5, 2021.

3.0 Revised NESHAP/NSPS TAP Exclusion

DEQ and PRI reevaluated TAP source applicability after the second public comment period in response to expressed concerns regarding sources excluded as per *Idaho Air Rules* Section 210.20 (excluding sources that are "covered" or "addressed" by a NESHAP). TAP applicability is explained in greater detail in the main body of the DEQ Statement of Basis. As a result of the reevaluation, some additional sources were included in the TAP impact modeling analyses that were not previously. TAP sources from gold mining that were modeled in the final TAP analyses included: drilling, blasting, excavating, hauling, prill silos, rock dumps and storage piles, and tailings.

Air Sciences consulted with DEQ to refine TAP compliance demonstration methods from what was originally submitted in the application. The refinement was primarily needed to show compliance with the

arsenic Acceptable Ambient Concentration of a Carcinogen (AACC). The revised methods are described in the submitted *TAP Addendum* and this DEQ *Modeling Review Attachment*.

4.0 TAPs Refined Compliance Demonstration Approach

PRI, in consultation with DEQ, used a highly refined TAPs analysis approach to demonstrate compliance with applicable TAP increments. This approach involved the following:

- AACC Adjustment for Toxic Air Pollutant Reasonably Available Control Technology (T-RACT) Utilization.
- TAP Emission Averaging Period.
- AACC Adjustment for the Operational Life of the Mine.

4.1 AACC Adjustment for T-RACT Utilization

Idaho Air Rules Section 210.12 allows TAP impacts of 10 times the AACC if the application demonstrates that T-RACT is used for the TAP emission sources. This represents a life-time cancer risk of 1-in-100,000. An adjustment cannot be made for non-carcinogenic TAPs listed in *Idaho Air Rules* Section 585.

Review of the T-RACT demonstration is performed by the DEQ permit writer and is described in the main body of the DEQ Statement of Basis.

4.2 TAP Emission Averaging Period

Annual average emissions of carcinogenic TAPs are typically used in the dispersion model to estimate maximum annual impacts. PRI refined the analyses by using source-specific emission rates that are representative of a 5-year averaging period. This approach is appropriate because carcinogenic impacts are of concern from a long-term exposure basis.

4.3 AACC Adjustment for the Operational Life of the Mine

AACCs were established based on a 1-in-1,000,000 cancer risk over a 70-year lifetime, as stated in *Idaho Air Rules* Section 006.125:

> ***Toxic Air Pollutant Carcinogenic Increments****. Those ambient air quality increments based on the probability of developing excess cancers over a seventy (70) year lifetime exposure to one (1) microgram per cubic meter (1 ug/m3) of a given carcinogen and expressed in terms of a screening emission level or an acceptable ambient concentration for a carcinogenic toxic air pollutant. They are listed in Section 586.*

PRI indicated the maximum life-of-mine will be 16 years. Life-time exposures to carcinogenic TAPs were refined by multiplying the maximum modeled annual impact by a ratio of 16/70. Section 5.7 of this *Modeling Review Attachment* provides more details on this adjustment for the project.

5.0 Refined TAP Emission Estimates and Modeling Methods/Parameters

This section describes changes made to TAP emission estimates and to methods/parameters used in the impact modeling analyses.

5.1 Operational Adjustments

PRI and Air Sciences proposed and committed to several operational adjustments to reduce actual and estimated TAP emissions:

- Installing and operating dust collection systems on drilling rigs (determined to be T-RACT).
- Capping the haul roads that are outside of the pits and development rock storage facilities (DRSFs) with clean (lower levels of arsenic) development rock (determined to be T-RACT).
- Eliminating the West End Development Rock Storage Facility, which eliminated the highest-emitting operational scenario W5.
- Limiting long-term mining production to an average of 135,000 tons/day for a 5-year rolling average.
- Constructing the Burntlog access road with offsite materials containing "background" levels of arsenic.
- Updating the bulldozing emission factor using the SGP site-specific silt content.

5.2 General Modeling Methods and Parameters

Modeling methods and parameters used in TAP impact analyses presented in the *TAP Addendum* are largely identical to those used in the previously submitted application. These include the air dispersion model used, meteorological data, terrain, building downwash, ambient air boundary, and receptors. TAP modeling was conducted for the 14 operational modeling scenarios, consistent with the NAAQS analyses. Modeling Scenario W5 was eliminated from the arsenic modeling, as discussed in Section 5.8 of this *Modeling Review Attachment*.

The meteorological dataset processed using McCall, Idaho, cloud cover data was used for analyses in the *TAP Addendum*. Impacts were not assessed using the dataset processed using the Bulk Richardson (BULKRN) method for boundary layer parameter calculations. EPA considers both methods to be acceptable. Although modeled impacts tend to be somewhat larger when using meteorological data processed by the BULKRN method, DEQ contends that the impact analyses are still largely conservative compared to actual impacts anticipated. Conservative aspects include: continual operation of the worst-case operational scenario; operation at maximum allowable rates for the averaging period; no reduction in winter-time emissions from fugitive sources, accounting for emission suppression effects of increased moisture.

5.3 TAP Modeling Applicability

Table 1 provides a comparison between applicable facility-wide maximum potential TAP emissions for the highest-emitting scenario (W3) and TAP screening emission levels (ELs) from *Idaho Air Rules* Sections 585 (for non-carcinogens) and 586 (for carcinogens). Note that TAPs also classified as HAPs

emitted from sources "addressed" or "covered" by NSPS or NESHAP were not required to be evaluated for compliance with TAP increments in accordance with *Idaho Air Rules* Section 210.20. Furthermore, PRI has determined that the West End Development Rock Storage Facility will not be constructed. This change eliminated Modeling Scenario W5 (the highest-emitting scenario described in the main body of the DEQ *Modeling Review Memorandum*) as a potential operating scenario. After eliminating Modeling Scenario W5, it was determined that Modeling Scenario W3 is the highest-emitting scenario for all TAPs.

Table 1. TAP MODELING APPLICABILITY DETERMINATION (HIGHEST-EMITTING MODELING SCENARIO: W3).

a. Total HAP/TAP emissions for EL evaluation from mining (i.e., pits, blasting, haul roads, stockpiles and DRSF, tailings storage facility, access road, and underground exploration) and leaching. Emissions from sources covered/addressed by NSPS/NESHAP are not included in the evaluation for modeling applicability.

b. Total HAP/TAP emissions for EL evaluation from processing and production (i.e., ore processing [crushers and transfer, prill silos], ore concentration and refining [autoclave, electrowinning cells and pregnant solution tank, retort, furnace, carbon kiln], process heating [POX boiler, carbon regeneration kiln, propane vaporizer, solution heater], lime production [limestone crushers, screens, mill, transfers, lime kiln, kiln feed, lime mill, pebble lime silo, lime silos, lime mill crushing], aggregate production [portable crushers, screens, transfers], concrete production [central mixer, cement silos, aggregate bin], HVAC [heaters], emergency power [emergency generators, fire pump], fuel storage [gasoline fuel and tanks]). Emissions from sources covered/addressed by NSPS/NESHAP are not included in the evaluation for modeling applicability.

c. Non-carcinogenic EL from *Idaho Air Rules* Section 585.

d. Carcinogenic EL from *Idaho Air Rules* Section 586.

Table 1 shows that the SGP facility-wide potential TAP emissions exceed the respective EL for arsenic, beryllium, cadmium, cyanide, formaldehyde, manganese, nickel, phosphorus, aluminum, barium, calcium carbonate, calcium oxide, iron, sulfuric acid, thallium, and vanadium. Therefore, modeling was required for these 16 TAPs (11 non-carcinogenic and five carcinogenic TAPs) to demonstrate compliance with Acceptable Ambient Concentrations of Non-Carcinogens (AACs) and AACCs.

5.4 TAP Modeled Emission Rates

Table 2 lists the source-specific modeled emission rates for all 11 non-carcinogenic TAPs that required modeling (worst-case modeling scenario for all non-carcinogenic TAPs: W5). Table 3 lists the source-specific modeled emission rates for all five carcinogenic TAPs that required modeling (worst-case impacts for arsenic are associated with modeling scenario W2; worst-case impacts for all other carcinogenic TAPs are associated with modeling scenario W1). Note that all source-specific emission rates listed in Tables 2 and 3 were extracted by DEQ's modeling staff from the submitted modeling input files.

The total modeled emission rates for all non-carcinogenic TAPs are equal to the total facility-wide HAP/TAP emissions as stated in the permitting emissions inventory (excluding sources addressed by NSPS/NESHAP), evaluated at 180,000 T/day (see last two rows of Table 2). However, for carcinogenic TAPs, modeling was performed using an emission inventory that included T-RACT controls, long-term mining production limits, and other emission inventory refinements, as described in Section 4.0 of this *Modeling Review Attachment* (see last three rows of Table 3).

Table 2. MODELED EMISSION RATES FOR NON-CARCINOGENIC TAPS (WORST-CASE MODELING SCENARIOS).

a. Aluminum (worst-case modeling scenario: W5).
b. Pounds per hour.
c. Barium (worst-case modeling scenario: W5).
d. Calcium carbonate (worst-case modeling scenario: W5).
e. Calcium oxide (worst-case modeling scenario: W5).
f. Cyanide (worst-case modeling scenario: W5).
g. Iron (worst-case modeling scenario: W5).
h. Manganese (worst-case modeling scenario: W5).
i. Phosphorus (worst-case modeling scenario: W5).
j. Sulfuric acid (worst-case modeling scenario: W5).
k. Thallium (worst-case modeling scenario: W5).
l. Vanadium (worst-case modeling scenario: W5).
m. The Haul Road was represented in the model as a series of volume sources. The emission rates listed in this table represent each individual volume source.
n. Total emission rates at 180,000 tons per day were derived from Worksheet "TblA" in the emission inventory dated October 5, 2021. The total emission rates in this row represent all facility-wide HAP/TAP emission sources from mining, leaching, and processing and production (excluding emissions from sources "addressed" or "covered" by NSPS/NESHAP).

a. Arsenic (worst-case modeling scenario: W2).
b. Pounds per hour.
c. Beryllium (worst-case modeling scenario: W1).
d. Cadmium (worst-case modeling scenario: W1).
e. Formaldehyde (worst-case modeling scenario: W1).
f. Nickel (worst-case modeling scenario: W1).
g. The Haul Road was represented in the model as a series of volume sources. The emission rates listed in this table represent each individual volume source.
h. Total T-RACT emission rates – calculated based on T-RACT controls, long-term mining production limits, and other emission inventory refinements, as described in Section 4.0 of this *Modeling Review Attachment* – are derived from Tables B-W2 (for Arsenic) and B-W1 (for Beryllium, Cadmium, Formaldehyde, and Nickel) in Appendix B of the *TAP Addendum*.
i. Total emission rates at 180,000 tons per day were derived from Worksheet "TblA" in the emission inventory dated October 5, 2021. The total emission rates in this row represent all facility-wide HAP/TAP emission sources from mining, leaching, and processing and production (excluding emissions from sources "addressed" or "covered" by NSPS/NESHAP).

5.5 Cyanide Modeling Emission Source Parameters

Modeling analyses for cyanide introduced two new emission sources that were not previously evaluated by DEQ: tailings storage facility (model ID: TSF) and mill tanks (model ID: MILLTANKS).

1. The tailings storage facility was modeled by Air Sciences as a surface-based (zero release height above ground-level and zero initial vertical dimension) AREA source. The easterly and northerly lengths were calculated as square-root of the TSF area (easterly length = northerly length = $\sqrt{1{,}338{,}158\ square\ meters}$ = 1,157 meters).

2. The mill tanks were grouped and modeled by Air Sciences as a single VOLUME source. The tanks sit on the ground, so the release height was set to the average tank height of 12.2 meters (40 feet). The initial lateral dispersion (σ_y) was calculated as the equivalent diameter of the combined (18) tank area divided by the single VOLUME source coefficient of 4.3:

REC 0707

$$\sigma_{y(MILLTANKS)} = \frac{Equivalent\ diameter}{4.3} = \frac{\sqrt{\Sigma(d)^2}}{4.3} = 42.8\ feet$$

The individual tank diameters (d) are: two tanks at 40 feet, four tanks at 52 feet, six tanks at 54 feet, and six tanks at 20 feet.

DEQ typically requires that tailings storage facilities be modeled as an AREAPOLY source with an outline that follows the contour of the emission source, and that mill tanks be represented in the model as individual volume sources; but, given that the maximum modeled concentration for cyanide is safely below the AAC (0.08%), DEQ's modeling team accepted the modeling analysis submitted by Air Sciences and concluded that it confidently demonstrates that the cyanide AAC will not be exceeded.

5.6 Deposition Modeling

Air Sciences applied particle deposition algorithms in the impact modeling for particulate TAPs. The particulate deposition parameters used in the NAAQS compliance analysis were derived for PM_{10} and $PM_{2.5}$ (see Tables 22 and 23 in the main body of the DEQ *Modeling Review Memorandum*). Dust-related metal TAP emissions include total particulates (all size fractions of particulate matter [PM] up to PM_{30}). Therefore, the deposition parameters for PM were calculated using the same methodology and EPA references used for PM_{10} and $PM_{2.5}$ in the NAAQS compliance demonstration analyses. The PM deposition parameters are provided below in Table 4. The same density values were used as in the previous TAPs modeling analysis. However, an additional deposition characterization bin was added to better handle deposition of 10 µm to 30 µm particulates; mass fractions were adjusted accordingly.

Table 4. PARTICULATE MATTER DEPOSITION PARAMETERS BY SOURCE CATEGORY.

5.7 Carcinogenic TAP Modeling Lifetime Exposure Adjustment

Maximum modeled concentrations for carcinogenic TAPs were adjusted to account for the life-of-mine production limits, which affects the lifetime exposure.

PRI evaluated the highest modeled annual carcinogenic TAP concentration from each of the 14 modeling scenarios for lifetime exposure as follows:

$$Lifetime\ exposure\ \left(\frac{\mu g}{m^3}\right) = \frac{Highest\ annual\ concentration\ \left(\frac{\mu g}{m^3}\right) \times 16\ (mine\ operation\ years)}{70\ (years, lifetime\ exposure)}$$

This equation assumes that the highest annual concentration from the 14 modeling scenarios is repeated for 16 years of mining operation. This was then averaged over 70 years to calculate the 70-year lifetime exposure.

PRI and Air Sciences contend that calculating lifetime exposure based on 16 years of mining operation is conservative. The annual emissions for carcinogenic TAP modeling are based on 135,000 tons/day (see Section 5.1 of this *Modeling Review Attachment*) and 365 days per year. Over 16 years, this equates to a potential mining production of 788.4 million tons:

$$\frac{135{,}000\ \left(\frac{tons}{day}\right) \times 365\ \left(\frac{days}{year}\right) \times 16\ years}{1{,}000{,}000\ \left(\frac{tons}{million\ ton}\right)} = 788.4\ million\ tons$$

The actual life-of-mine total production as described in the SGP *Refined Proposed Action* (*ModPRO2*) mine plan is only 402.86 million tons (Perpetua 2021), which is 51.1% of the potential life-of-mine production represented in the above equation and related emission evaluations.

5.8 Arsenic Compliance Demonstration for Modeling Scenarios W1-W4

To demonstrate compliance with the AACC for arsenic, PRI applied two additional operating limitations:

- The removal of Modeling Scenario W5 as a potential operating scenario
- Limiting the West End Pit's life-of-mine potential mining production to 50% of the total life-of-mine potential mining production of 788.4 million tons: 50% * 788.4 million tons = 394.2 million tons

PRI has determined that the West End Development Rock Storage Facility (DRSF) will not be constructed. This change eliminated Modeling Scenario W5 from the arsenic modeling evaluation. The remaining four West End Pit modeling scenarios (W1–W4) are evaluated using the 70-year lifetime exposure equation from Section 5.7 and adjusting for the proposed West End Pit life-of-mine production limit of 50% of the total production as follows:

$$LifeExpose_{Wi,j,n} = \left[\left(WEPExpose_{Wi,n}\right)(50\%) + \left(nonWEPExpose_{Sj,n}\right)(50\%)\right]\left[\frac{16\ year\ LOM}{70\ year\ exposure}\right]$$

where:

W*i*	=	West End Pit scenario, where *i* = 1 to 4.
S*j*	=	non West End Pit scenario, where *j* = B1, B2, H1, H2, H3, H4, Y1, Y2, and Y3.
n	=	specific receptor.
$LifeExpose_{Wi,j,n}$	=	lifetime exposure in µg/m^3 for West End Pit scenario *i*, non West End Pit scenario *j*, at receptor *n*.
$WEPExpose_{Wi,n}$	=	annual maximum impact in µg/m^3 for West End Pit scenario *i* at receptor *n*.
$nonWEPExpose_{Sj,n}$	=	annual maximum impact in µg/m^3 for non West End Pit scenario *j* at receptor *n*.
16 year LOM	=	maximum life-of-mine.
70 year exposure	=	Lifetime exposure used for development of AACCs in *Idaho Air Rules*.

The above equation was used to calculate the lifetime arsenic exposure from the West End Pit scenarios (W1–W4) on a receptor-by-receptor basis. Combining the concentrations from Modeling Scenarios W1–W4 with the highest concentration from the remaining non-West End Pit scenarios (B1, B2, H1, H2, H3, H4, Y1, Y2, or Y3) conservatively ensures that the maximum potential impacts from applicable sources are evaluated and remain below AACCs.

PRI contends that calculating lifetime arsenic exposure based on the proposed West End Pit life-of-mine production limit of 50% of the total production is conservative. The actual life-of-mine total production from the West End Pit as described in the ModPRO2 mine plan is only 198.26 million tons (Perpetua 2021), which is 50.3% of the proposed West End Pit life-of-mine production limit of 394.2 million tons.

6.0 Impact Results

TAP impact analysis results, as submitted in the *TAP Addendum* and as further assessed by DEQ, are discussed in this section. The effect of various operational refinements also reduced PM_{10} and $PM_{2.5}$ impacts, and this is discussed in Section 6.2.

6.1 TAP Impact Analyses Results

This section describes the revised TAP impact analyses and demonstrates that applicable TAP emissions resulting from operation of the SGP will not result in increased impacts that exceed AACs or AACCs.

6.1.1 Modeling Non-Carcinogenic TAPs

The non-carcinogenic TAPs subject to impact modeling requirements to demonstrate compliance with AACs of *Idaho Air Rules* Section 585 were modeled at the emission levels shown in Table 1 above. The maximum 24-hour modeled concentration for each of the 14 modeling scenarios demonstrates compliance with the applicable AAC, as summarized below in Table 5. PRI elected to include Scenario W5 in the modeling analysis for non-carcinogenic TAPs. Figure 1 illustrates the locations of the maximum impacts for each non-carcinogenic TAP.

REC 0712

PET 346

Figure 1. SGP NON-CARCINOGENIC MAXIMUM TAP IMPACT LOCATIONS.

6.1.2 Modeling Carcinogenic TAPs

The carcinogenic TAPs subject to impact modeling requirements to demonstrate compliance with AACCs of *Idaho Air Rules* Section 586 were modeled using an emission inventory that includes the T-RACT controls, long-term mining production limits, and other emission inventory refinements, as described in Section 4.0 and 5.0 of this *Modeling Review Attachment*.

The maximum modeled impact for each of the 14 modeling scenarios demonstrated compliance with the T-RACT AACC, as summarized below in Table 6. The SGP maximum concentrations were adjusted to account for the life-of-mine production limits, which affect the lifetime exposure, and to account for the elimination of Modeling Scenario W5. See Sections 5.7 and 5.8 of this *Modeling Review Attachment* for more detail. The locations of the maximum impacts for each carcinogenic TAP are presented in Figure 2. Arsenic concentrations are considerably lower in areas away from the location of maximum impact as shown in Figure 3.

Table 6. RESULTS FOR TAPS IMPACT ANALYSES FOR CARCINOGENIC TAPS.

Toxic Air Pollutant	Averaging Time	Maximum Modeled Lifetime Exposure Concentration ($\mu g/m^3$)[a,b]	Model Scenario	AACC[c] ($\mu g/m^3$)	T-RACT[d] AACC	Percent of T-RACT AACC

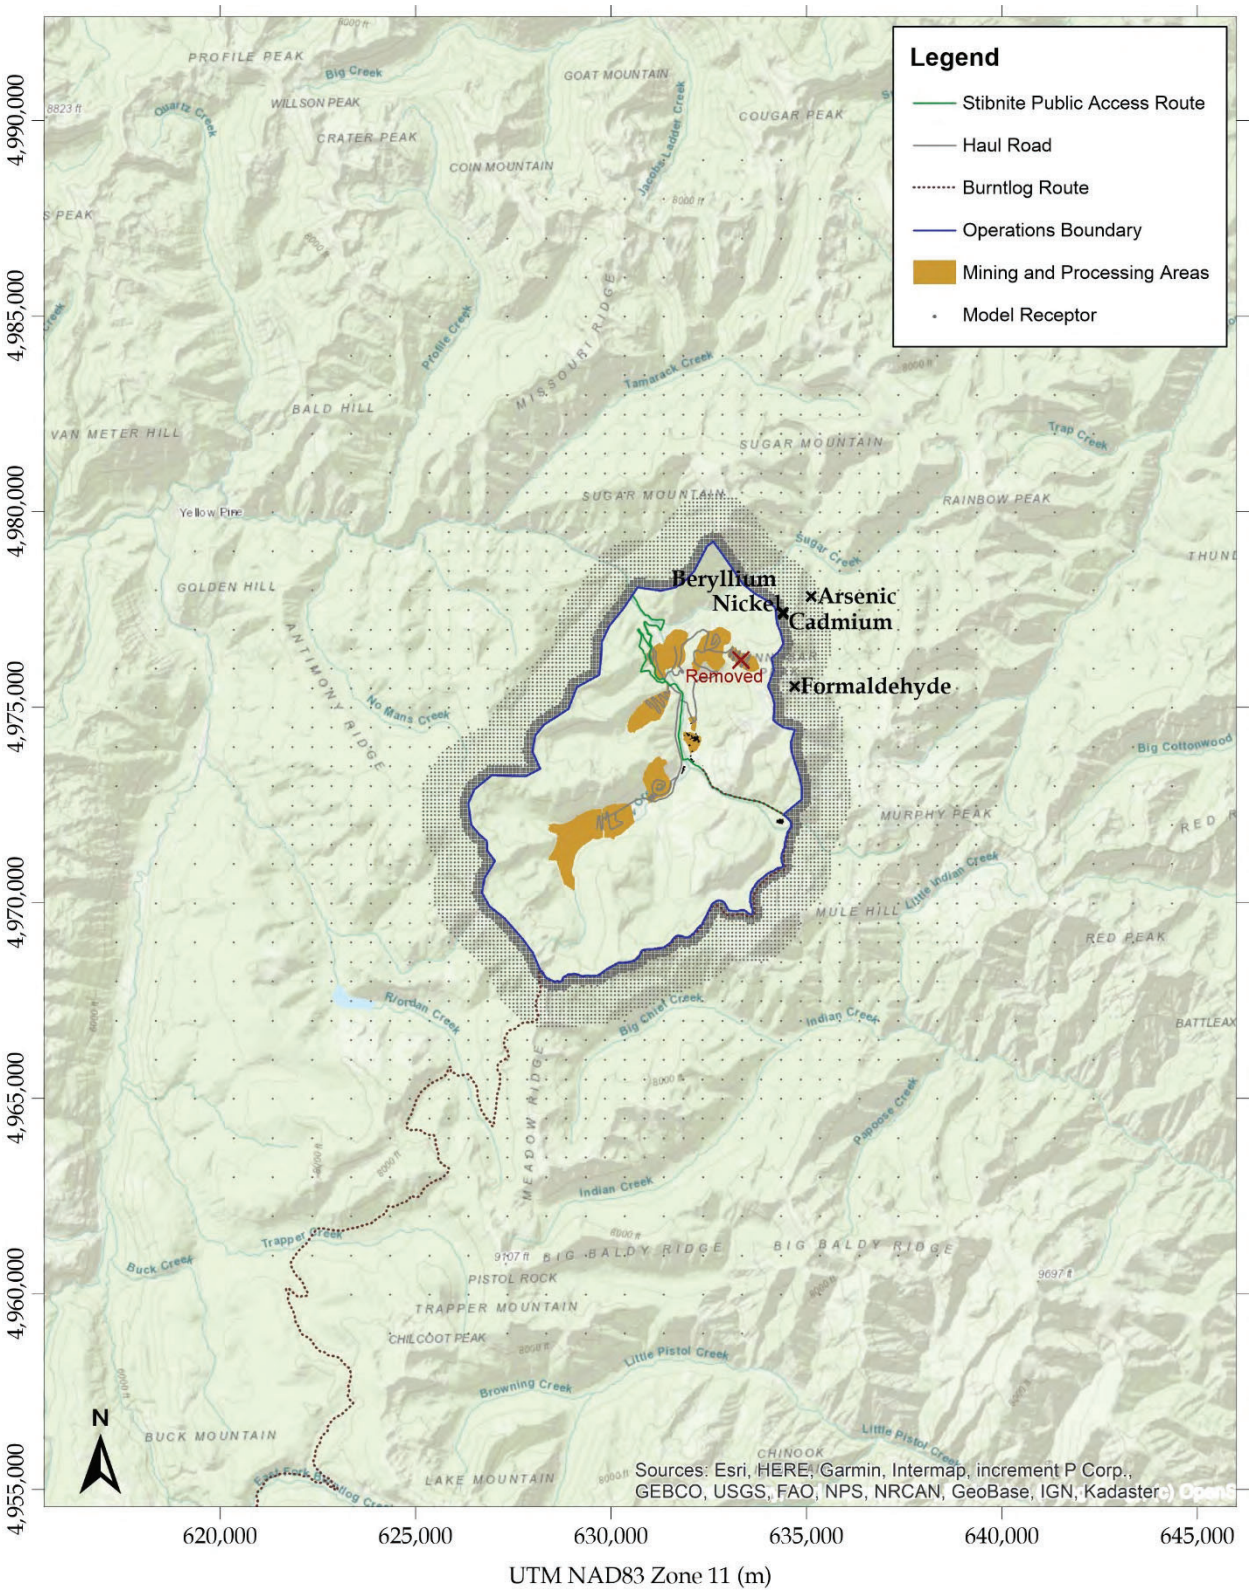
c. Acceptable Ambient Concentration of a Carcinogenic TAP.
d. Toxic Air Pollutant Reasonably Available Control Technology allows the AACCs to be increased by a factor of ten per *Idaho Air Rules* Section 210.12(b).

Figure 2. SGP CARCINOGENIC MAXIMUM TAP IMPACT LOCATIONS.



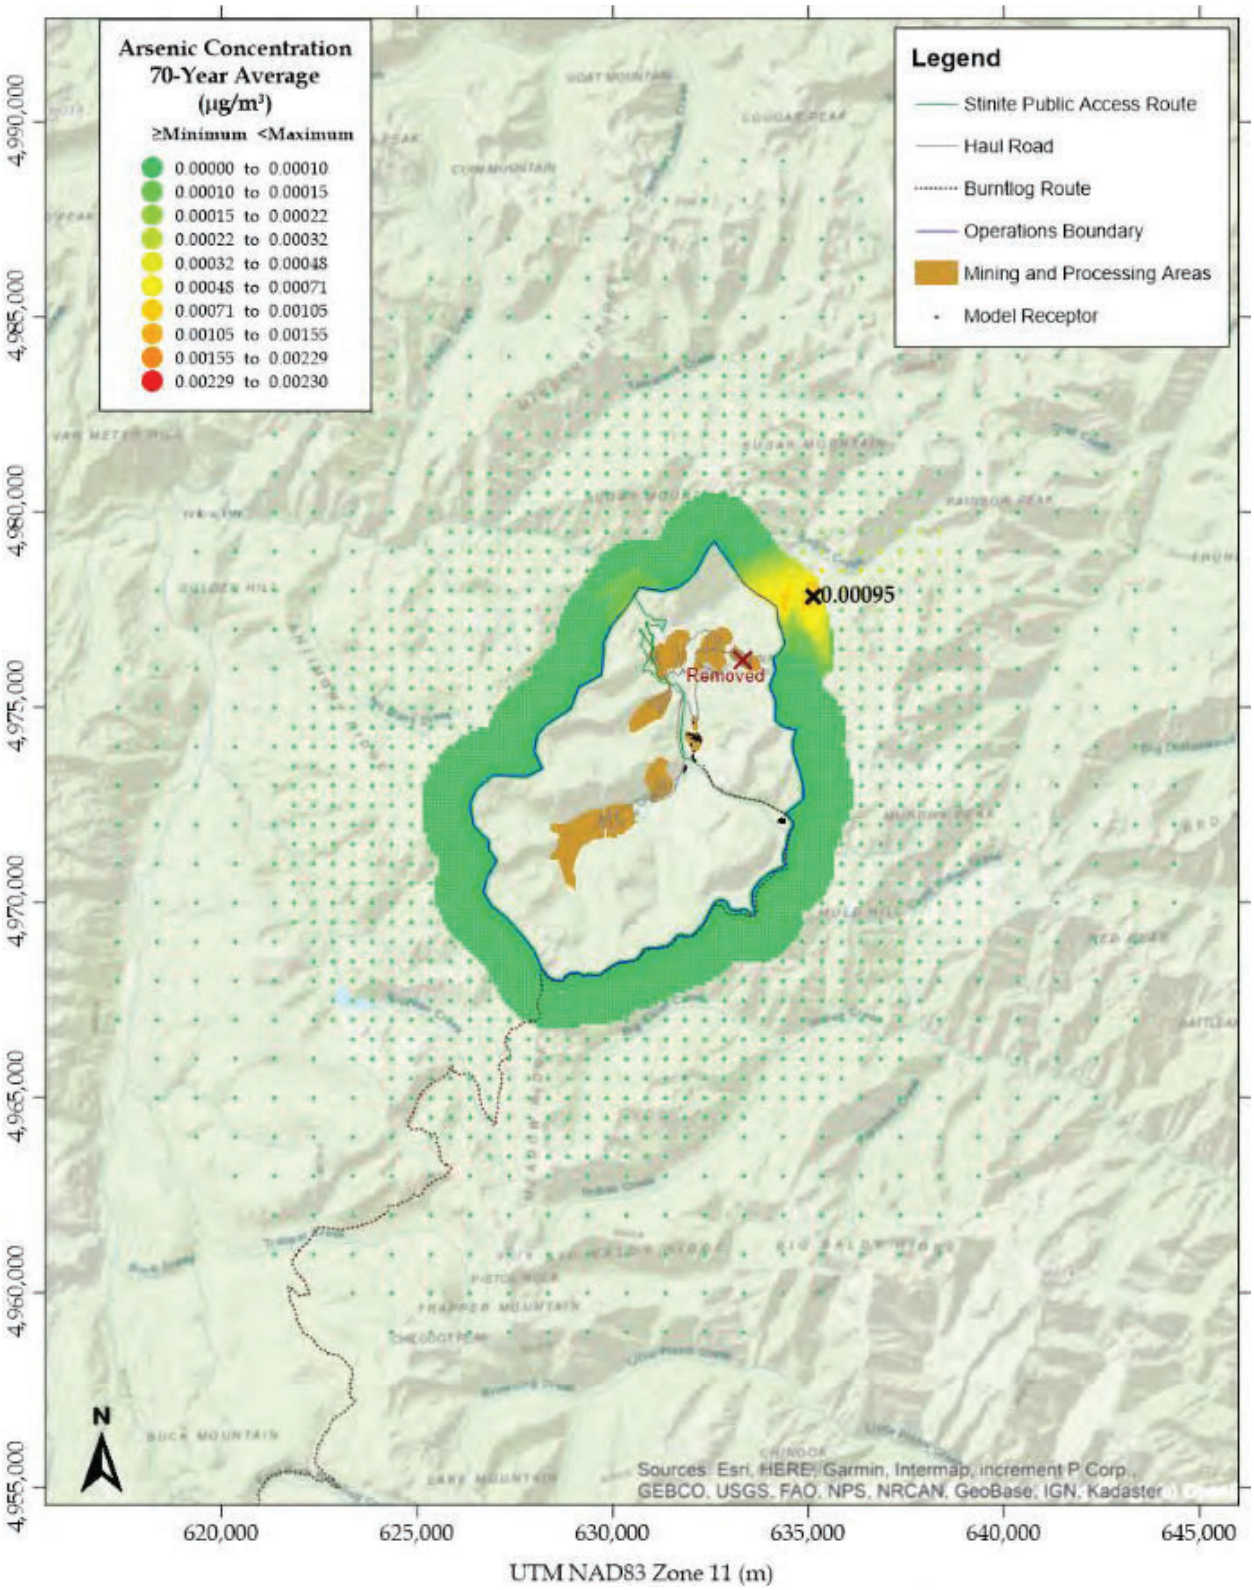


Figure 3. SGP CONTOURS OF LIFETIME ARSENIC IMPACTS.

6.2 Effect of Changes to Modeled PM_{10} Results

PRI has determined that the West End Development Rock Storage Facility will not be constructed. This change eliminated Modeling Scenario W5 as a potential operating scenario. In Section 4.1.4 in the main body of the DEQ *Modeling Review Memorandum*, DEQ identified PM_{10} NAAQS exceedances at four hotspot receptors when using the BULKRN meteorological dataset for Modeling Scenario W5 (the highest PM_{10} impact modeling scenario). When Modeling Scenario W5 is removed, the highest modeled impacts are predicted to occur for Modeling Scenario W3, which represents the transport of development rock from the West End Pit to the Hangar Flats Development Rock Storage Facility.

Table 7 presents results for the cumulative NAAQS impact analyses for Scenario W3. Results still exceed the 24-hour PM_{10} NAAQS even when Modeling Scenario W5 is eliminated. However, there is only one hotspot receptor exceeding NAAQS. The modeled violation is also predicted to occur during winter. This is a critical consideration because during winter, not only are fugitive emissions minimized because of the higher moisture content of material handled or driven over, but background concentrations in such remote areas are also generally much lower because of the absence of wildfires and dust-generating sources.

Table 7 also lists the results when using temporally varying backgrounds, instead of a single-value background, in the cumulative NAAQS impact analysis (using the "SEASON" and "MONTH" options in AERMOD). The highest daily average PM_{10} concentrations measured at Stibnite for every season and month in 2014 were used as inputs in the model. Table 7 shows that the SGP facility ***safely*** demonstrates compliance with the 24-hour PM_{10} NAAQS when temporally varying backgrounds (both seasonal and monthly) are used instead of the single-value background. Summing modeled design values with a single-value background that is on the upper end of the distribution results in a very conservative estimate of total impacts. DEQ strongly believes that using temporally varying backgrounds that respect seasonality is appropriate for the SGP facility, and that using the highest value in the period interval is very conservative.

TABLE 7. RESULTS FOR 24-HOUR PM_{10} CUMULATIVE NAAQS IMPACT ANALYSES FOR MODELING SCENARIO W3.

Backgrounds Scenario	Max. Conc.[a] (µg/m³)[b]	Model Scenario	Back. Conc.[c] (µg/m³)	Total Conc.[d] (µg/m³)	NAAQS (µg/m³)	Percent of NAAQS
Single-Value Background	116.9	W3	34.0	150.9[e]	150	100.6%
Seasonally Varying Backgrounds	123.5[f]	W3	*Seasonal*	123.5[f]		82.3%
Monthly Varying Backgrounds	123.5[f]	W3	*Monthly*	123.5[f]		82.3%

a. Max. Conc. = maximum modeled design concentration.
b. Micrograms per cubic meter.
c. Back. Conc. = background concentration.
d. Total Conc. = total (modeled + background) concentration.
e. One hotspot receptor exceeds NAAQS.
f. The maximum modeled design concentration already incorporates the seasonal and monthly background values.

The time series plot in Figure 4 and the box-and-whiskers plot in Figure 5 illustrate the variability in daily average PM_{10} concentrations collected at the Stibnite Site in 2014. Figures 4 and 5 confirm that the highest concentrations from the modeled and monitored datasets do ***not*** occur simultaneously. Highest modeled impacts are predicted to occur during winter while the highest background concentrations were measured at Stibnite during summer. Therefore, the summation method, where total impacts are

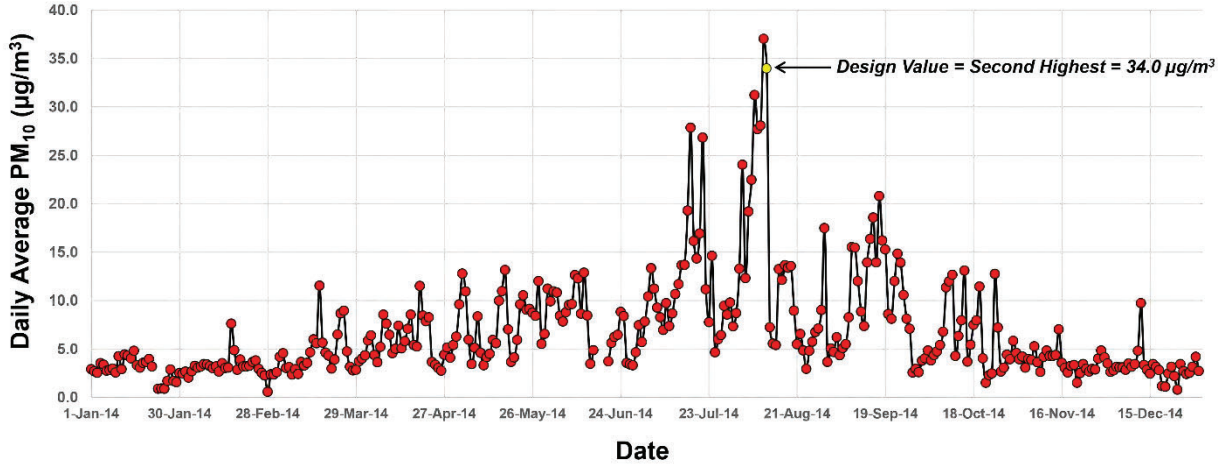
REC 0717

PET 351

calculated by summing modeled design values with a background concentration that is also consistent in form with the regulatory design value, results in a very conservative estimate of the total impact for comparison to NAAQS. DEQ concludes that use of temporally varying (i.e., seasonal and monthly) backgrounds for SGP is justified. DEQ is highly confident that operation of the SGP will not cause or contribute to a violation of NAAQS.

PM_{10} and $PM_{2.5}$ NAAQS compliance was previously demonstrated prior to refinements and adjustments proposed in the submitted *TAP Addendum*. The main body of the DEQ *Modeling Review Memorandum* discussed and considered results from both modeling with meteorological data processed using the BULKRN method and modeling with data processed using cloud cover data, and DEQ concluded that NAAQS compliance was demonstrated with a high degree of confidence. The adjustments and refinements described in the *TAP Addendum* further increase DEQ's confidence in NAAQS compliance.

Figure 4. TIME SERIES OF DAILY AVERAGE PM_{10} CONCENTRATIONS MEASURED AT STIBNITE IN 2014.



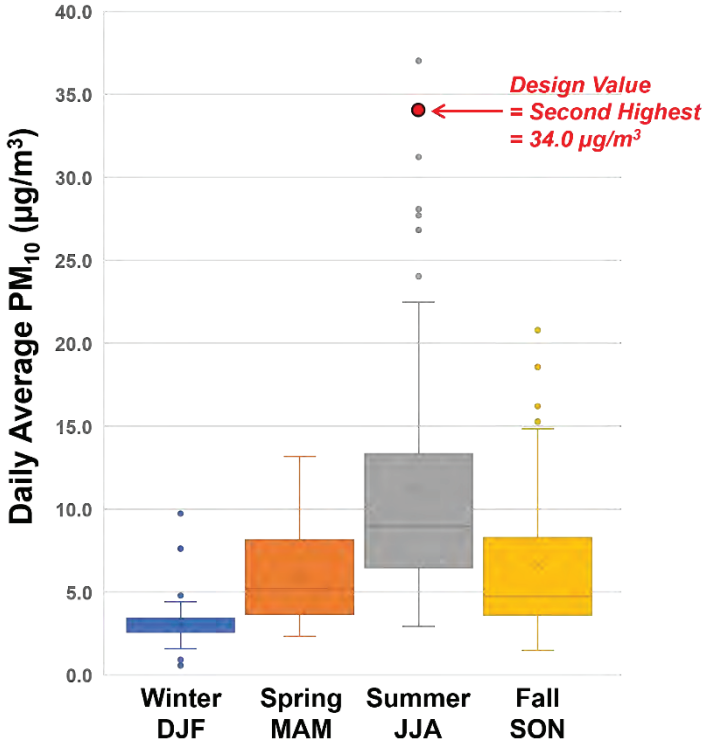


Figure 5. BOX-AND-WHISKERS PLOT FOR SEASONAL PM_{10} BACKGROUND CONCENTRATIONS MEASURED AT STIBNITE IN 2014.

In Figure 5 the middle line of each box represents the median. The "x" in the box represents the mean. The bottom and the top lines of the box represent the 1st quartile (25th percentile) and the 3rd quartile (75th percentile), respectively. The whiskers extend to the minimum and maximum values not considered outliers. Outliers are plotted individually.

7.0 Conclusions

This section provides conclusions of the *TAP Addendum* and DEQ's review of the *TAP Addendum*.

7.1 Conclusions of Revised TAP Analyses

The revised and refined TAP analyses:

- Revised TAP-applicable sources at the SGP facility.
- Proposed additional emission control measure and adjusted operations to reduce TAP emissions.
- Refined the approach used to demonstrate compliance with TAP regulations.

The submitted application, with the adjustments and refinements to analyses as described in the *TAP Addendum*, demonstrated to DEQ's satisfaction that the emissions of applicable TAPs will not result in impacts to ambient air that exceed TAP increments of *Idaho Air Rules* Section 585 and 586.

7.2 Effects of Adjustments/Revisions on NAAQS Compliance Demonstrations

The submitted application, prior to the *TAP Addendum*, demonstrated compliance with NAAQS to DEQ's satisfaction; and the operational measures proposed in the *TAP Addendum* will only further reduce estimated emissions. Eliminating Modeling Scenario W5 impacts, with the elimination of the West End Development Rock Storage Facility, affects the 24-hour PM_{10} impact modeling analysis for SGP. Modeling Scenario W3 is now the scenario producing the highest modeled impacts, and NAAQS compliance is easily demonstrated when using temporally varying background PM_{10} values, which were obtained from onsite monitoring data.

7.3 Conservatism of Permitting Analyses

Emissions and locations from which emissions occur are highly dynamic at mining facilities. This presents unique challenges for permit development because permits must include limits and operational requirements that ensure air quality standards are not violated. Permitting rules require that air impacts be assessed using maximum potential emissions as limited by either the capacity of the unit/operation or as limited by enforceable permit provisions. A permit where actual emissions are nearly representative of maximum allowable emissions, through imposing permit limits, would be exceedingly complex and require overly burdensome monitoring and record-keeping requirements. To avoid this, applicants typically calculate allowable emissions and perform impact analyses based on simplistic operational scenarios that largely overstate emissions estimated to occur from the facility.

PRI and Air Sciences have asserted that the submitted emission estimates, operational scenarios, and air impact analyses associated with the permit application greatly overstate best-estimated values. This point is evident when comparing the permit application materials and analyses with those presented in ModPRO2, PRI's revised mine plan and associated impacts. ModPRO2 is used in support of the Environmental Impact Statement (EIS).

Perpetua. 2021. "ModPRO2 Mine Plan." *File: Midas Stibnite Mine Plan and Equipment Schedule (10Feb21).xlsx.* Email from R. McCluskey, Perpetua Resources Inc., to E. Memon, Air Sciences Inc., February 11.

APPENDIX C – FACILITY DRAFT COMMENTS

The following comments were received from the facility on August 3 and 13, 2020:

Editorial proposed changes were provided in a redlined version of the draft permit. Each non-editorial proposed change was addressed in the following comments. DEQ agreed with and incorporated the redlined editorial corrections that were not individually addressed in the following (non-editorial) comments below.

Facility Comment #1: Condition 1.2, Table 1.1, and Condition 3.2, Table 3.1: Please remove the control efficiency values listed for haul roads (93.3%) and enclosures (80%). It appears that these percentages are provided for descriptive purposes only. As such, this information would more appropriately be provided in the Statement of Basis only. In addition, it does not appear that Idaho mining PTCs typically contain control efficiency values for fugitive sources. Alternatively, the following language may be added to Condition 1.2, "Control equipment information and maximum process rate information is provided for information only unless also included in specific enforceable permit conditions."

DEQ Response:

Permit Conditions 1.2 and 3.2 were revised for clarification to include a statement that the information in the tables is provided for informational purposes.

Proposed control efficiencies were left unchanged. Although control efficiencies are included for informational purposes, this information serves as an important reference when observing and characterizing emissions as required by the permit. The specified control efficiencies were relied upon in estimating and modeling emissions and are one of many important parameters which form the basis of this permit.

Facility Comment #2: Condition 1.2, Table 1.1, Hauling, and Condition 2.5, 2nd and 17th Bullets: Please remove the Maximum Process Rate of "490,000 mi/mo" and related monitoring obligation. The mining excavation rate is already limited to 180,000 T/day, which directly impacts vehicle miles traveled. At this limit, all hauling scenarios were modeled to capture the maximum-case hauling distances, which included a hauling mileage of 16,415 mi/day (492,465 mi/30 days or 508,880 mi/31 days). The maximum-case mileage far exceeds the peak production total actual annual hauling mileage of 1.4 million mi/yr (116,700 mi/mo). Therefore, a mileage limit is not necessary to limit emissions, and recording miles daily adds unnecessary and burdensome monitoring.

DEQ Response:

Permit Conditions 1.2 and 2.6 (renumbered) were revised to remove the explicit mileage limit. As supported by the emission estimates, hauling operations and associated emissions are constrained by the daily production limit and the proposed vehicle fleet characteristics.

Although all conditions that affect roadway conditions should be considered when determining water and suppressant application rates and frequency, it is left to the permittee to determine and define within the FDCP the site-specific parameters most critical to ensuring successful control of fugitive emissions. An effective FDCP will require active monitoring on the part of the permittee to determine the appropriate frequencies and amounts of water and dust suppressant applications sufficient to achieve the target 93.3% reduction in haul road emissions. Monitoring of vehicle mileage is one option that may need to be considered.

Facility Comment #3:

Condition 1.2, Table 1.1, Prill Silos, and Conditions 3.8 and 3.17: Please revise the Maximum Process Rate of "608/month" to "200 T/day." The daily rate was used for the 24- hour PM_{10} and 24-hour $PM_{2.5}$ modeling. See Appendix B, pages 11, 12, and 15 of the June 23, 2020, PTC Application (Application). No other criteria pollutants or toxic air pollutants (TAP) are emitted by these insignificant sources. The Application also requested a 7,300 T/yr limit. However, it has come to our attention that an annual limit of 9,000 T/yr is needed. This change has essentially no effect on the annual emission inventory for annual $PM_{2.5}$ modeling. The $PM_{2.5}$ emission change from increasing the annual throughput from 7,300 T/yr to 9,000 T/yr (an increase of 0.00005 g/s) is less than five-thousandth of a percent of the total $PM_{2.5}$ emissions.

DEQ Response:

Permit Condition 1.2 was revised to reflect the requested daily and annual rates.

Annual emission estimates were updated in the statement of basis to reflect the increase in annual silo material loading and unloading rates from 7,300 to 9,000 T/yr. Based on a supplemental modeling analysis performed by DEQ, in which the Prill Silos Loading (PSL) and Prill Silos Unloading (PSU) were each modeled with adjusted annual $PM_{2.5}$ emission rates, the model impacts reported did not change.

Facility Comment #4:

Condition 1.2, Table 1.1, Autoclave (AC) and Electrowinning Cells: Please remove "and as limited by Subpart EEEEEEE" from the Maximum Process Rate. Subpart EEEEEEE does not contain any process rate limits. This subpart only provides emission limits, and control and monitoring requirements as noted in Condition 4.2, Table 4.1, and Conditions 4.18 and 4.19.

DEQ Response:

Permit Condition 1.2 was updated as requested to remove references to Subpart EEEEEEE. As indicated, process emissions rather than process maximum rates are limited by this subpart.

Because federally-applicable requirements will be explicitly incorporated into the required Tier I permit, high-level references and incorporation by reference were considered sufficient within the PTC.

Facility Comment #5:

Condition 1.2, Table 1.1, POX Boiler, and Condition 4.4: Please replace the Maximum Process Rate of "1 hr/day and 30 hr/yr" with "operation is limited to AC start-up only." The boiler is used only for starting up the AC. Once the AC is running, the boiler is turned off; however, a start-up will be longer than 1 hour. AC start-ups are expected to require up to 10 hours of POX Boiler firing, and there may be as many as three start-ups per year. Limiting operation only to start-up provides flexibility and reflects the proposed operating scenario. Midas will continue to monitor boiler operating hours during AC start-up, per Condition 4.17.

DEQ Response:
Permit Condition 1.2 was updated as requested to reflect operation during autoclave startup only. Based on a supplemental modeling analysis performed by DEQ, operation as described does not change reported model impacts.

Facility Comment #6:

Condition 1.2, Table 1.1, PFR Shaft Lime Kiln Combustion: Please replace "20.5" with "22.0 MMBtu/hr." See page 93 of the Application.

DEQ Response:

Permit Condition 1.2 was updated to reflect the correct heat input capacity for the Parallel Flow Regenerative Shaft Kiln.

Facility Comment #7:

Condition 1.2, Table 1.1, SAG Mill and AC Lime Silos: The Maximum Process Rate of "169 T/day and 52,337 T/yr" only applies to LS-L/U, LK, and LCR. The SAG Mill and AC Lime Silos (6 storage silos) have a combined Maximum Process Rate of 70,000 T/yr of lime.

DEQ Response:

Permit Condition 1.2 was revised to reflect the correct maximum process rates, including the combined daily and annual loading and unloading rates from all six silos.

Facility Comment #8:

Condition 1.2, Table 1.1, Concrete Production, and Condition 5.8: Please replace the Maximum Process Rate of "80 T/day and 60,000 T/yr (cement + aggregate)" with "2,480 T/day and 560,000 T/yr of (cement + aggregate)." See page 47 of the Application. Also, the Central Mixer capacity is 120 T/hr (20 T/hr of cement plus 100 T/hr of aggregate).

DEQ Response:

Permit Condition 1.2 was revised to reflect the correct maximum daily and annual process rates, when considering both cement and aggregate inputs.

Facility Comment #9:

Condition 1.2, Table 1.1, Concrete Production, Central Mixer Loading, and Conditions 5.1 and 5.2: Please revise the control description to match the control options listed in AP-42 and the Application (page 7 and Appendix B page 11).

DEQ Response:

Permit Condition 1.2 was revised to reflect the variety of control equipment options described in AP-42 that were considered in the development of emission factors for central mix plants.

Facility Comment #10:

Condition 2.4: Please replace the facility-wide inspection frequency with "monthly." A monthly inspection rate is typical for large mining operations and consistent with other Idaho mining PTCs.

DEQ Response:

For clarification, this frequency was revised from once each shift to once every 12 hours. Daily inspection was considered reasonable and adequate based on the size and scale of proposed ore processing, ore concentration and refining operations. A frequency of once every 12 hours ensures that both daytime and nighttime operations will be observed, to confirm that sufficient fugitive dust control measures are applied as assumed in demonstrations of compliance with NAAQS on a 24-hour basis. Frequent inspection of fugitive sources, in particular haul roads from which the contribution to $PM_{10}/PM_{2.5}$ modeled impacts was greatest, is necessary to ensure that the target 93.3% reduction in haul road emissions is consistently achieved.

Facility Comment #11:

Condition 2.5, 1st Paragraph: IDAPA 58.01.01.799 applies to nonmetallic mineral processing plants. Thus, clarifying language should be added: "IDAPA 58.01.01.799 applies to fugitive dust sources at the limestone crushing plant and aggregate production plant."

DEQ Response:

Permit Condition 2.6 (renumbered) was updated to clarify that IDAPA 58.01.01.799 specifies best management practices specifically applicable to emission sources at the lime production and aggregate production plants.

Although the requirements in this rule are specific to these sources, the FDCP is to address the control of fugitive emissions from all fugitive sources (facility-wide). Additional discussion is also provided below (response to Comment #14).

Facility Comment #12:

Condition 2.5, 1st Bullet: Please replace "to 20 miles per hour or lower if appropriate" with "in accordance with the FDCP." The Application did not propose a 20 miles per hour speed limit, and certain haul road sections may be driven at higher speeds while emissions are minimized.

DEQ Response:

Permit Condition 2.6 was revised to remove the explicit vehicle speed limit. As supported by the emission estimates, hauling operations and associated emissions are constrained by the daily production limit and the proposed vehicle fleet characteristics.

Although all conditions that affect roadway conditions should be considered in controlling emissions, it is left to the permittee to determine safe and appropriate vehicle speeds onsite, and to define these site-specific parameters within the FDCP to ensure successful control of fugitive emissions. An effective FDCP will require active monitoring on the part of the permittee to ensure that the target 93.3% reduction in haul road emissions is achieved. Monitoring to ensure that appropriate vehicle speeds are observed is one option that may need to be considered.

Facility Comment #13:

Condition 2.5, 2nd Bullet: Please remove this bullet as discussed in Condition 1.2, Table 1.1, Hauling, above.

DEQ Response:

Permit Condition 2.6 was revised to remove the explicit mileage limit as discussed above (response to Comment #2).

Facility Comment #14:

Condition 2.5; 3rd, 4th, 5th, 7th, 13th, 15th Bullets: Each of these bullets require some action if fugitive PM emissions are observed to exceed 20% or leaving a roadway in the case of haul roads. However, the periods that trigger corrective action in these bullets are inconsistent with each other. IDAPA 58.01.01.650 does not impose a trigger for action, other than the requirement to take reasonable precautions. While the visible emissions rule IDAPA 58.01.01.625 does not suit fugitive emission observations, for comparison, that rule states, "for a period or periods aggregating more than ***three*** minutes in any 60-minute period." The Draft Permit states, "for a period or periods aggregating more than ***one*** minute in any 60- minute period." If IDEQ prefers to establish a threshold for dust mitigation action, then the following period would be acceptable to Midas Gold:

- Whenever visible fugitive PM emissions exceed 20% for more than two consecutive minutes (4th, 5th, 7th bullets)
- Whenever visible fugitive PM emissions are observed leaving a roadway for more than two consecutive minutes (3rd bullet). Note that this would also apply to the 13th and 15th bullets, but Midas Gold is proposing to remove these conditions.

DEQ Response:

Permit Condition 2.6 was revised and Permit Condition 2.5 added to clarify the intended requirements. The FDCP applies facility-wide to all fugitive emission sources, and while IDAPA 58.01.01.799 includes requirements specific to the lime production and aggregate production plants, it was considered reasonable to apply best management practices for haul roads on a facility-wide basis.

Control strategy triggers specific to unpaved haul roads, transfer points, screening operations, crushers, grinding mills, and building vents are specified in IDAPA 58.01.01.799 – Nonmetallic Mineral Processing Plant Fugitive Dust Best Management Practice. A progressive control strategy is outlined wherein when defined triggers are exceeded, successive control strategies are employed until fugitive dust control is achieved.

Although these requirements are specifically applicable to the lime production and aggregate production plants as noted, in the case of haul roads, it was considered that the emission sources dedicated to nonmetallic and metallic mineral processing and to mining operations are similar enough in practice to justify applying the haul road control strategy trigger to all such hauling operations (facility-wide). Similar to the responses above, compliance with such reasonable precautions helps to ensure conservatism in estimates of emissions from unpaved roadways and to justify the aggressive dust control efficiencies applied to these estimates.

To distinguish it as a requirement separate from recommended control strategies, the control trigger level was separated into a new permit condition (Permit Condition 2.5), and Permit Conditions 2.4 and 2.6 were updated as appropriate to reference the new permit condition.

Facility Comment #15:

Condition 2.5, 4th Bullet: Please add language to address upstream water sprays that provide downstream control via moisture carryover.

DEQ Response:

Permit Condition 2.6 (renumbered) was revised to clarify that water sprays provide moisture carryover for downstream control.

Facility Comment #16:

Condition 2.5, 6th Bullet: There are no plans to apply water or chemical to the "mine working face." Please revise to, "Apply appropriate dust control at the initial point of material handling to suppress dust throughout the material handling process, as necessary."

DEQ Response:

Permit Condition 2.6 (renumbered) was revised as requested to remove the example control measure. Although this specific example of a reasonable control measure was removed and use of this measure may not be planned, it remains the responsibility of the permittee to implement reasonable precautions as necessary to prevent fugitive emissions (Permit Condition 2.1).

Facility Comment #17:

Condition 2.5, 13th Bullet: Please remove "Whenever visible fugitive PM emissions are observed leaving a roadway during inspection or valid complaint (Permit Condition 2.3), the adequacy of water and dust suppressant application rates should be evaluated." These requirements are already addressed elsewhere:

- The Condition 2.5, 3rd bullet addresses the dust mitigation action whenever visible PM emissions are observed leaving a roadway.
- The Condition 2.5, 20th bullet addresses the periodic evaluation of the FDCP, including dust suppressant application rates.
- The Condition 2.3 addresses valid complaints.

DEQ Response:

Permit Condition 2.6 (renumbered) was revised and Permit Condition 2.5 added. Trigger levels for dust mitigation were revised as discussed above (response to Comment #14). Annual evaluation was considered adequate as minimum frequency for formal evaluation of the FDCP to ensure timely incorporation of updates, and requirements to respond to citizen complaints were adequately addressed in Permit Condition 2.3, and these permit conditions were revised accordingly. Control measures utilized in response to any fugitive dust complaints received (e.g., any change to dust suppressant application rates) over the annual period should be taken into consideration during each such evaluation.

Facility Comment #18:

Condition 2.5, 14th Bullet: Please remove this bullet. Chemical suppressant application will be based on the manufacturer's recommendations and periodic inspections of fugitive dust, not atmospheric conditions.

DEQ Response:

Permit Condition 2.6 (renumbered) was revised as requested to remove the specific requirement to evaluate ambient temperature, humidity and wind speed conditions onsite.

Although all conditions that affect roadway conditions should be considered when determining water and suppressant application rates and frequency, it is left to the permittee to determine and define within the FDCP the site-specific parameters most critical to ensuring successful control of fugitive emissions. An effective FDCP will require active monitoring on the part of the permittee to determine the appropriate frequencies and amounts of water and dust suppressant applications sufficient to achieve the target 93.3% reduction in haul road emissions. Monitoring of ambient conditions may need to be considered.

Facility Comment #19:

Condition 2.5, 15th Bullet: Please remove this bullet, as it is a repeat of the 2nd sentence of the 13th bullet.

DEQ Response:

Permit Condition 2.6 (renumbered) was revised as requested to remove this bullet. Trigger levels were separated into a new permit condition and annual evaluation of the FDCP required as discussed above (responses to Comments #14 and #17).

Facility Comment #20:

Condition 2.5, 17th Bullet: Please remove this bullet as discussed in Condition 1.2, Table 1.1, Hauling, above.

DEQ Response:

Permit Condition 2.6 (renumbered) was revised as requested to remove the explicit mileage limit and associated monitoring as discussed above (response to Comment #2). Although monitoring of mileage is no longer required by the permit, active monitoring of conditions affecting haul roads should be considered when determining appropriate water and suppressant application rates.

Facility Comment #21:

Condition 2.5, 18th Bullet: Please remove this bullet as the 10th bullet already requires that "Chemical dust suppressants shall be applied consistent with manufacturer's instructions and recommendations" and the 16th bullet already requires that "At least once per day during operation, monitor and record the frequency of application and application rates for water and suppressant controls."

DEQ Response:

Permit Condition 2.6 (renumbered) was revised as requested to remove requirements for water spray calibration inspection beyond compliance with manufacturer's specifications. Adequacy of fugitive dust controls and associated equipment calibrations shall be determined by inspection at least once per day.

In addition, due to the similarity of the 16th bullet referenced above and Permit Condition 2.2, these were both combined by moving the daily frequency requirement into Permit Condition 2.2 and removal of this bullet.

Facility Comment #22:

Condition 2.5, 20th Bullet: Please add "and evaluate effectiveness of practices including dust suppressant application rates."

DEQ Response:

Permit Condition 2.6 (renumbered) was revised as requested to add the language referencing evaluation of the effectiveness of practices.

Facility Comment #23:

Condition 2.5, 20th Bullet: Please replace "every six-months" with "every year." Annual review is more typical for the mining industry. Also, it does not appear that Idaho mining PTCs typically require a six-month review of FDCPs.

DEQ Response:

Permit Condition 2.6 (renumbered) was revised as requested to require annual evaluation of the FDCP as discussed above (response to Comment #17)

Facility Comment #24:

Condition 2.9: Please replace "each shift" with "each month" and add "including any stack, vent, or functionally equivalent opening" after "potential sources of visible emissions" to clarify which sources are subject to this condition. It does not appear that Idaho mining PTCs typically contain a visible emission inspection frequency for each shift.

DEQ Response:

Permit Condition 2.10 (renumbered) was reduced to a frequency of once per day from once per shift to facilitate inspection of point sources during daylight hours. As discussed above (response to Comment #10), monthly inspection was considered insufficient due to the continuous nature of operations (24 hours per day, 7 days per week).

Facility Comment #25:

Condition 2.11: Please revise "and 22" to "and knowledgeable of procedures of Method 22" language to reflect that there is no certification for Method 22.

DEQ Response:

Permit Condition 2.12 (renumbered) was revised as requested to clarify that the certification requirement applies only to Method 9.

Facility Comment #26:

Condition 2.21, NSPS 40 CFR 60, Subpart LL: Please remove "OC8." Conveyor drops to stockpiles are not subject to Subpart LL.

DEQ Response:

Permit Condition 2.22 (renumbered) was revised as requested to remove reference to the coarse ore stockpile feed transfer to stockpile (OC8).

Conveyor belt transfer points subject to Subpart LL as defined in 40 CFR 60.381 do not include where the metallic mineral is transferred to a stockpile.

Facility Comment #27:

Condition 2.23: Please add the citation "40 CFR 70.3(c)(2)" to specify that the Tier I operating permit is required only for the emission units that cause the source to be subject to the part 70 program.

DEQ Response:

The citation in Permit Condition 2.24 (renumbered) was abbreviated to reflect only IDAPA 58.01.01.313.01.b. Procedures and requirements for Tier I Operating Permits are established in IDAPA 58.01.01.300–399, and the appropriate reference was cited in incorporating the deadline to apply for a Tier I operating permit. All underlying PTC conditions in this permit, for all emission sources comprising the facility, will be incorporated into the Tier I operating permit.

Facility Comment #28:

Condition 2.24, Table 2.1, Pollutant: Please replace "PM" with "PM_{10}" as this is the pollutant that is required to be tested in the Draft Permit (Condition 4.3).

DEQ Response:

Permit Condition 2.25 (renumbered) was revised to reflect the correct pollutant (PM_{10}) as limited by the permit.

Facility Comment #29:

Condition 2.24, Table 2.1, Test Method: Please add Method 201A for PM_{10}.

DEQ Response:

Permit Condition 2.25 (renumbered) was revised as requested to include reference to approved EPA Reference Method 201A for measurement of PM_{10} emissions.

Facility Comment #30:

Condition 2.24, Table 2.1, Additional Requirements: Please revise the PM Additional Requirements to: "Particulate matter (PM) including condensable PM as defined in IDAPA 58.01.01.006, with an aerodynamic diameter less than or equal to a nominal 10 micrometers for PM_{10}, and less than or equal to a nominal 2.5 micrometers for $PM_{2.5}$" to make it consistent with the rest of the Draft Permit.

DEQ Response:

Permit Condition 2.25 (renumbered) was revised as requested to include the complete descriptions for $PM_{2.5}$ and PM_{10}.

Facility Comment #31:

Condition 3.2, Table 3.1: Please revise as discussed in Condition 1.2, Table 1.1, above.

DEQ Response:

Permit Conditions 1.2 and 3.2 were revised for clarification to include a statement that the information in the tables is provided for informational purposes, as discussed above (response to Comment #1).

Facility Comment #32:

Condition 3.8 and 3.17: Please revise as discussed in Condition 1.2, Table 1.1, Prill Silos, above.

DEQ Response:

Permit Condition 3.8 and 3.16 (renumbered) were revised as requested to reflect the proposed daily and annual rates, as discussed above (response to Comment #3).

Facility Comment #33:

Condition 3.11: Please remove this condition. The crushers will be controlled by water sprays. No emission control credit was taken for the buildings, which will likely have door and vent openings.

DEQ Response:

Permit Conditions 3.10 (renumbered) and 5.11 were revised to remove the requirement to enclose these processes within a building. Consistent with the controls identified in Table 3.1 and Table 5.1, only credit for the use of water spray and moisture carryover controls were relied upon for reductions within emission estimates for these processes.

Facility Comment #34:

Condition 4.2, Table 4.1: Please revise as follows:

- Carbon bed pressure drop is a maximum limit (O&M)
- Carbon bed inlet gas temperature is a maximum limit (Subpart EEEEEEE)
- Baghouse pressure is a maximum limit (O&M)

DEQ Response:

Permit Condition 4.2 was revised to reflect the corrections noted for these monitoring parameters.

Facility Comment #35:

Condition 4.3, Table 4.2: Please remove footnote (c) from NO_x, CO, VOC, and SO_2 as there is no testing required for these pollutants.

DEQ Response:

No change was made to the permit. This standard footnote is applied generally to all pound-per-hour emission limits. Although source testing was not required in the permit for NO_x, CO, VOC, and SO_2 emissions from ore concentration and refining process equipment, it remains that credible evidence can be used to show compliance or noncompliance with these established emission limits, and alteration or removal is not supported.

Facility Comment #36:

Condition 4.4: Please revise as discussed in Condition 1.2, Table 1.1, POX Boiler, above.

DEQ Response:

Permit Condition 4.4 was revised as requested to limit operation of the POX Boiler to autoclave start-up operation only.

Facility Comment #37:

Condition 4.11 through 4.16: Please remove "and in accordance with IDAPA 58.01.01.210.21." The rule states, "Additional procedures and requirements to demonstrate and ensure actual and continuing compliance may be required by the Department in the permit to construct." Conditions 4.11 through 4.16 establish procedures or requirements regarding compliance, and therefore it is not necessary to cite this rule. Including the citation suggests that there are more requirements than stated in the PTC, but any additional requirements are to be in the PTC according to the rule text.

DEQ Response:

Permit Conditions 4.11 through 4.16 were revised as requested to remove reference to Section 210.21. These citations were replaced with the correct citation of Section 210.08.c, consistent with establishing TAP emission limits.

Permit Condition 4.11 through 4.16 were revised, with Section 210.21 citations replaced with the correct citation of Section 210.08.c, consistent with establishing emission limits when controlled ambient concentrations is used to demonstrate preconstruction compliance with TAP AAC or AACC.

Facility Comment #38:

Condition 4.28: Please add carbon filter monitoring requirements.

DEQ Response:

Permit Condition 4.28 was revised as requested to add monitoring of inlet gas stream temperature and pressure drop across the carbon filter to ensure compliance with O&M specifications.

Facility Comment #39:

Conditions 5.1 and 5.2: Please revise as discussed in Condition 1.2, Table 1.1, Concrete Production, Central Mixer Loading, above.

DEQ Response:

Permit Conditions 5.1 and 5.2 were revised to reflect the variety of control equipment options described in AP-42 that were considered in the development of emission factors for central mix plants, as discussed above (response to Comment #9).

Facility Comment #40:

Condition 5.3: Please remove footnote (c) as there are no testing requirements for these pollutants.

DEQ Response:

No change was made to the permit. This standard footnote is applied generally to all pound-per-hour emission limits even if testing is not required, as discussed above (response to Comment #35).

Facility Comment #41:

Condition 5.8: Please revise as discussed in Condition 1.2, Table 1.1, Concrete Production, above.

DEQ Response:

Permit Condition 5.8 was revised to reflect the correct maximum daily and annual process rates, as discussed above (response to Comment #8).

Facility Comment #42:

Condition 5.11: Please remove this condition. The crushers will be controlled by water sprays. No emission control credit was taken for the building, which will likely have openings.

DEQ Response:

Permit Condition 5.11 was revised as requested to remove the requirement to enclose these processes within a building, as discussed above (response to Comment #33).

Facility Comments in Redlined Permit and DEQ Response:

In addition to the comments specifically addressed above, many of the remaining recommended corrections identified and descriptive language suggested in the redlined permit were incorporated (except as noted in the comments above), with minor editorial changes made for clarification. One noted exception concerns the lime, aggregate, and concrete production plant emission limits in Table 5.2. An effort was made to separately identify each activity and to establish the limits consistent with the emission estimates provided in the emissions inventory for each.

Facility Comments in Redlined Statement of Basis and DEQ Response:

In addition to the comments specifically addressed above, many of the remaining recommended corrections identified and descriptive language suggested in the redlined statement of basis were also incorporated (except as noted in the comments above), with minor editorial changes made for clarification. There were a few exceptions noted:

- Discussion of facility classification (comments relating to "synthetic minor" and "natural minor") was left to the appropriate "Facility Classification" section. Where concerns were noted, a reference to this section was included.
- Language addressing any conflict with federal NSPS/NESHAP requirements was not included in the "Toxic Air Pollutant Emissions" section, as it was addressed elsewhere in the appropriate "Permit Conditions Review" section.
- Although an updated Access Management Plan is required by the permit, the initial and relevant Stibnite Road Access Management Plan was retained for reference and appended to this statement of basis.
- The source ID corrections were removed from the "NSPS Applicability" section and were left for explicit identification in the permit (Permit Condition 2.22).
- As discussed above, although applicable requirements are cited, the scope and intent of the FDCP is to address the control of emissions from all fugitive emission sources facility-wide. And although the permit does not include requirements to enclose processes within buildings as requested, this is still recommended where prudent to do so.

Facility Comments in Redlined Modeling Review Memorandum:

The recommended corrections identified and descriptive language suggested in the redlined modeling review memorandum were also incorporated, with minor editorial changes made for clarification. Results from a culpability analysis were also added. There were a few exceptions noted pertaining to the following suggested verbiage for Section 4.1.5:

"DEQ's sensitivity analyses suggest that a few hotspot receptors exceed the 24-hour PM_{10} NAAQS when the unpaved road control efficiency falls below 93% and the meteorological data processed with the BULKRN method is used. However, all the hotspot receptors demonstrate compliance with NAAQS at a 90% control efficiency when using the meteorological data processed without the BULKRN method, and at both examined production levels:

- *maximum impact at 120,000 ton per day – 73.9 $\mu g/m^3$ + 37.0 $\mu g/m^3$ = 110.9 $\mu g/m^3$.*
- *maximum impact 180,000 ton per day – 84.6 $\mu g/m^3$ + 37.0 $\mu g/m^3$ = 121.6 $\mu g/m^3$.*

As previously stated, meteorological data processing with and without BULKRN are both considered acceptable regulatory options by EPA. Therefore, this demonstrates that emissions resulting from a lower unpaved road control efficiency (even potentially less than 90%) do not cause or contribute to a NAAQS violation. Nonetheless, the permit requires an aggressive implementation of measures to control fugitive particulate emissions from roadways."

DEQ Response:

DEQ disagrees with the suggested modification. Because meteorological data processing with and without BULKRN are both considered acceptable regulatory options by EPA, an argument can be made that modeling

simulations using both meteorological datasets (especially for site-specific BULKRN meteorological data) must demonstrate compliance with NAAQS. Furthermore, EPA recommended using data processed with the BULKRN method since it utilizes more of the site-specific data collected. DEQ's sensitivity analyses suggest that 93.3% control efficiency is a very critical assumption for demonstrating 24-hour PM_{10} NAAQS compliance when using the BULKRN meteorological data and when modeled emissions are more-closely representative of typical daily mining production rates for a high-production period. Therefore, DEQ's modeling team maintains that this critical assumption (above 93.3% control efficiency for unpaved road dust) needs to be highlighted in Section 4.1.5 of the modeling memo. DEQ ***strongly disagrees*** with the facility's comment that "emissions resulting from a lower unpaved road control efficiency (even potentially less than 90%) do not cause or contribute to a NAAQS violation."

The highlighted discussion in Section 4.1.5 now reads:

"DEQ's sensitivity analyses suggest that a few hotspot receptors exceed the 24-hour PM_{10} NAAQS when the unpaved road control efficiency falls below 93% and the meteorological data processed with the BULKRN method is used. When the meteorological data processed without the BULKRN method is used, all the hotspot receptors demonstrate compliance with NAAQS at a 90% control efficiency and at both examined production levels:

- *maximum impact at 120,000 ton per day: 73.9 $\mu g/m^3$ + 37.0 $\mu g/m^3$ = 110.9 $\mu g/m^3$.*
- *maximum impact at 180,000 ton per day: 84.6 $\mu g/m^3$ + 37.0 $\mu g/m^3$ = 121.6 $\mu g/m^3$.*

While using alternative meteorological data processed without the BULKRN method safely demonstrates compliance with NAAQS, using site-specific BULKRN meteorological data does not. Therefore, DEQ's modeling team recommends that the permit require an aggressive implementation of measures to achieve above 93% control efficiency for fugitive particulate emissions from roadways."

In addition to the changes enumerated above, DEQ performed a culpability analysis for 24-hour PM_{10}. Results for the culpability analyses are added in Section 4.1.4 of the modeling memo (all succeeding table numbers have been updated):

"Table 30 shows the ten highest-ranked modeled 24-hour PM_{10} impacts from each emission source group. Note that for 24-hour PM_{10}, the design value is the second-highest 24-hour average concentration in a given year. Therefore, the second-high modeled value for source group ALL (121.5 $\mu g/m^3$) was summed with the background concentration for comparison to NAAQS.

Table 30. TEN HIGHEST-RANKED MODELED 24-HOUR PM_{10} IMPACTS IN $\mu g/m^3$ FROM DIFFERENT SOURCE GROUPS (SCENARIO W5, BULKRN METEOROLOGICAL DATA).

10TH	99.8	71.2	1.23	0.76	41.8	2.56E-03	0	0.15	0.08

a. ALL = all emission sources
b. WEP = West End Pit
c. WEPBL = West End Pit Blasting
d. WEDRSF = West End Pit Development Rock Storage Facility
e. HR = Haul Road
f. ACCRD = Access Road
g. UGEXP = Underground Exploration
h. PRCSPT = Process & Ancillary Point Sources
i. PRCSVOL = Process & Ancillary Volume Sources

Given a background of 37.0 µg/m^3 and a NAAQS of 150 µg/m^3, the critical modeled concentration threshold for any 24-hour PM_{10} NAAQS violation is therefore 113.0 µg/m^3. Table 30 shows that the third-high modeled value for source group ALL (113.4 µg/m^3) barely exceeds NAAQS. Fourth-high (and lower-ranked) modeled impacts, when added to the background concentration, are below NAAQS.

As discussed earlier in this section, HR Onsite Hauling, WEP Open Pit Drilling, and WEP Blasting are the three largest components of the total daily PM_{10} emissions. Therefore, it is not surprising that HR, WEP, and WEPBL are associated with the highest modeled concentrations among all source groups.

To investigate the potential culpability of each source group to the modeled 24-hour PM_{10} NAAQS violation, DEQ performed a culpability analysis using the MAXIFILE output option in AERMOD. The MAXIFILE option provides the receptor location and date of an impact. DEQ performed two MAXIFILE runs. In the first MAXIFILE simulation, the model was run using source group ALL. A threshold value (113.0 µg/m^3) equal to the NAAQS minus background was set. The output file provided a list of the receptors where the NAAQS is exceeded. In the second MAXIFILE simulation, the model was run using only the receptors identified by the first MAXIFILE run. Source groups were included in the second modeling simulation. A threshold value equal to the 24-hour PM_{10} SIL (5.0 µg/m^3) was set. The output file provided a date stamp for any day when a source group exceeds the SIL and potentially contributes to a violation of the NAAQS. A significant contribution to a NAAQS violation would be predicted to occur if the date stamps for source group ALL (from the first MAXIFILE run) and for a specific source group (from the second MAXIFILE run) matched.

DEQ's culpability analyses confirm that emission source groups HR and WEP are culpable for the 24-hour PM_{10} NAAQS exceedances. The date stamps indicate NAAQS violations during the winter season (January 6, January 15, and December 23). We show next that when modeled emissions are more-closely representative of typical daily mining production rates for a high-production period (everything else held constant), the SGP facility is able to demonstrate compliance with 24-hour PM_{10} NAAQS at those few receptors showing a potential violation when using meteorological data processed with the BULKRN method. We also discuss next the implication of NAAQS violations occurring during the winter season."

Air Quality

PERMIT TO CONSTRUCT

Permittee	Midas Gold Idaho, Inc.
Permit Number	P-2019.0047
Project ID	62288
Facility ID	085-00011
Facility Location	Forest Service Roads NF-374 and NF-412 Stibnite, Idaho 83611

Permit Authority

This permit (a) is issued according to the "Rules for the Control of Air Pollution in Idaho" (Rules), IDAPA 58.01.01.200–228; (b) pertains only to emissions of air contaminants regulated by the State of Idaho and to the sources specifically allowed to be constructed or modified by this permit; (c) has been granted on the basis of design information presented with the application; (d) does not affect the title of the premises upon which the equipment is to be located; (e) does not release the permittee from any liability for any loss due to damage to person or property caused by, resulting from, or arising out of the design, installation, maintenance, or operation of the proposed equipment; (f) does not release the permittee from compliance with other applicable federal, state, tribal, or local laws, regulations, or ordinances; and (g) in no manner implies or suggests that the Idaho Department of Environmental Quality (DEQ) or its officers, agents, or employees assume any liability, directly or indirectly, for any loss due to damage to person or property caused by, resulting from, or arising out of design, installation, maintenance, or operation of the proposed equipment. Changes in design, equipment, or operations may be considered a modification subject to DEQ review in accordance with IDAPA 58.01.01.200–228.

Date Issued DRAFT July 14, 2020

1 Permit Scope

Purpose

1.1 This is an initial permit to construct (PTC) for ore processing, ore concentration and refining, and ancillary equipment at the Stibnite Gold Project (SGP).

Regulated Sources

1.2 Table 1.1 lists all sources of regulated emissions in this permit.

Table 1.1 Regulated Sources

Source ID No.	Source	Control Equipment	Maximum Process Rate
Mining			
	Drilling activities	Reasonable control and Fugitive Dust Control Plan (FDCP)	1,200 holes/day
	Blasting activities	Reasonable control & FDCP	2 blasts/day
	Excavating and hauling activities	Reasonable control & FDCP – Chemical suppression and water sprays ~~Control efficiency: 93.3% for PM/PM_{10}~~ (haul roads)	180,000 T/day and ~~490,000 mi/mo (combined mileage of all haul trucks)~~
Ore Processing			
OC1	~~Conveyor~~ Loader Transfer of Ore to Grizzly	Reasonable control & FDCP – Water sprays and moisture carryover	25,000 T/day
OC2	~~Conveyor~~ Grizzly to Apron Feeder		
OC3	Conveyor – Apron Feeder to Dribble		
OC4	Conveyor – Apron Feeder to Grizzly		
OC5	Conveyor – Dribble to Grizzly		
OC6	~~Conveyor~~ Grizzly to Primary Crusher or Coarse Ore Stockpile Feed		
OC7	Primary Crusher	Reasonable control & FDCP – Water sprays and moisture carryover	
OC8	Conveyor – Coarse Ore Stockpile Feed Transfer to Stockpile		
OC9	~~Conveyor~~ Stockpile Transfer to Reclaim Conveyors	Reasonable control & FDCP – Below-grade of storage piles ~~Control efficiency: 80% for PM/PM_{10}~~	27,600 T/day
OC10	Conveyor – Reclaim Conveyors to Feed Conveyor		
OC11	Conveyor – Feed Transfer to	Reasonable control & FDCP – Enclosure ~~Control efficiency: 80% for PM/PM_{10}~~	
OC12	Pebble Crusher	Reasonable control & FDCP – Water sprays and moisture carryover	
OC13	~~Conveyor~~ Pebble Discharge to Feed		
PS	(2) Prill Silos #1-2 Maximum capacity: 100 T (each)	Loading – None Unloading – None	~~608 T/month~~200 T/day; 9,000 T/yr (combined)

Source ID No.	Source	Control Equipment	Maximum Process Rate
Ore Concentration and Refining			
AC	Autoclave (AC)	Wet Scrubber (WS1)	6,960 T/day ~~, and as limited by Subpart EEEEEEE~~
EW	Electrowinning Cells and Pregnant Solution Tank	Shared Carbon Filter (CA2) Type: sulfur-impregnated activated carbon Form: granulated	100 gpm ~~, and as limited by Subpart EEEEEEE~~
MR	Mercury Retort	Condenser Carbon Filter (CA3) Type: sulfur-impregnated activated carbon Form: granulated	1,000 lb/batch and 21 T/yr
MF	Induction Melting Furnace	Baghouse (BH2) Carbon Filter (CA4) Type: sulfur-impregnated activated carbon Form: granulated	
CKD	Carbon Regeneration Kiln (Drum)	Wet Scrubber (WS2) Carbon Filter (CA1) Type: sulfur-impregnated activated carbon Form: granulated	7.2 T/day
Sb2	Antimony Bagging	Baghouse (BH1)	108 T/day, or as limited by source testing
Process Heating			
Sb1	Sb Dryer Maximum capacity: 2.72 MMBtu/hr Fuel: propane	None	not applicable (n/a)
ACB	POX Boiler Maximum capacity: 17 MMBtu/hr Fuel: propane	None	~~1 hr/day and 30 hr/yr~~ operation is limited to AC startup only
CKB	Carbon Regeneration Kiln (Burners) Maximum capacity: 2.255 MMBtu/hr Fuel: propane	None	n/a
PV	Propane Vaporizer Maximum capacity: 0.1 MMBtu/hr Fuel: propane	None	n/a
HS	Strip Circuit Solution Heater Maximum capacity: 5 MMBtu/hr Fuel: propane	None	n/a
LKC	PFR Shaft Lime Kiln Combustion Maximum capacity: ~~20.5~~22.0 MMBtu/hr (each) Fuel: propane	None	n/a

Source ID No.	Source	Control Equipment	Maximum Process Rate
Lime Production			
LS1	~~Conveyor~~ Limestone transfer to Primary Crusher Hopper	None	1,130 T/day
LS2	~~SAG Mill~~ Primary Crusher Maximum capacity: 1,130 T/day	None	
LS3	Primary Screen	None	
LS4	~~SAG Mill~~ Secondary Crusher	None	
LS5	Secondary Screen	None	
LS6	Conveyor – Limestone to Ball Mill Feed Bin	None	
LSBM	Limestone Ball Mill	Baghouse (BH3)	
LS7	Conveyor – Limestone to Ball Mill Feed	None	
LS8	Conveyor – Ball Mill Feed to Ball Mill	None	
LS9	Conveyor – Limestone to Kiln Feed Bin	None	267 T/day
LS10	Conveyor – Limestone to Lime Kiln Feed	None	
LS11	Fines Screen	None	
LS12	Conveyor – Kiln Feed to PFR Shaft Lime Kiln	None	
LS-L/U	Bucket Elevator – Pebble Lime Silo Loading	Loading – Bin Vent Filter	169 T/day and 52,377 T/yr
	Pebble Lime Silo discharge to Lime Slaker	Unloading – Wet Scrubber (WS3)	
LK	Parallel Flow Regenerative Shaft Kiln	Baghouse (BH4)	
LCR	Lime Mill Crusher	Baghouse (BH5)	
LS1-L/U	Lime Silo #1 Maximum capacity: 250 T/day	Loading – Bin Vent Filter Unloading – None	70,000 T/yr (combined)
MillS2-L/U	Lime Silo #2 Maximum capacity: 250 T/day	Loading – Bin Vent Filter Unloading – None	
ACS1	AC Lime Silo #1 Maximum capacity: 1,000 T/day	Loading – Bin Vent Filter Unloading – None	
ACS2	AC Lime Silo #2 Maximum capacity: 1,000 T/day	Loading – Bin Vent Filter Unloading – None	
ACS3	AC Lime Silo #3 Maximum capacity: 1,000 T/day	Loading – Bin Vent Filter Unloading – None	
ACS4	AC Lime Silo #4 Maximum capacity: 500 T/day	Loading – Bin Vent Filter Unloading – None	

Source ID No.	Source	Control Equipment	Maximum Process Rate
Aggregate Production			
PCSP1	Portable Crushing and Screening Plant 1 Crushers, screens, and conveyors	Reasonable control & FDCP – water sprays and moisture carryover	2,000 T/day (aggregate)
PCSP2	Portable Crushing and Screening Plant 2 Crushers, screens, and conveyors	Reasonable control & FDCP – water sprays and moisture carryover	2,000 T/day (aggregate)
Concrete Production			
CM	Central Mixer Loading Maximum capacity: 120 T/hr	Reasonable control & FDCP – ~~Water sprays and moisture carryover, and~~ Controls may ~~also~~ include water sprays, enclosures, hoods, curtains, shrouds, movable and telescoping chutes, central duct collection systems, etc.	~~80~~ 2,480 T/day and 560,000 T/yr (cement + aggregate)
CS1-L/U	Cement/Shotcrete Silo #1 Maximum capacity: 80 T	Loading – Bin Vent Filter Unloading – None	
CS2-L/U	Cement/Shotcrete Silo #2 Maximum capacity: 80 T	Loading – Bin Vent Filter Unloading – None	
CA-L/U	Aggregate Bin Maximum capacity: 2,400 T	Loading – None Unloading – None	
Heating, Ventilation, and Air Conditioning (HVAC)			
H1M	Mine Air Heater #1 Maximum capacity: 4 MMBtu/hr Fuel: propane	None	n/a
H2M	Mine Air Heater #2 Maximum capacity: 4 MMBtu/hr Fuel: propane	None	n/a
HM	(4) Mill HVAC Heaters #1-4 Maximum capacity: 1.0 MMBtu/hr (each) Fuel: propane	None	n/a
HAC	Autoclave HVAC Heater Maximum capacity: 0.25 MMBtu/hr Fuel: propane	None	n/a
HR	Refinery HVAC Heater Maximum capacity: 0.25 MMBtu/hr Fuel: propane	None	n/a
HA	Admin HVAC Heater Maximum capacity: 0.25 MMBtu/hr Fuel: propane	None	n/a
HMO	(2) Mine Ops. HVAC Heaters Maximum capacity: 0.25 MMBtu/hr (each) Fuel: propane	None	n/a
HTS	(2) Truck Shop HVAC Heaters Maximum capacity: 1.0 MMBtu/hr (each) Fuel: propane	None	n/a
HW	(3) Warehouse HVAC Heaters Maximum capacity: 1.0 MMBtu/hr (each) Fuel: propane	None	n/a

Source ID No.	Source	Control Equipment	Maximum Process Rate
Emergency Power Generation and Fire Suppression			
EDG1	Camp Emergency Generator Date of construction: 2007 or later Maximum capacity: 1,000 bkW Maximum operation: 100 hr/yr (non-emergency) Fuel: ultra-low sulfur diesel (ULSD) Displacement: <10 L/cyl	EPA Tier 2 technologies	1 hr/day and 100 hr/yr
EDG2	Plant Emergency Generator #1 Date of construction: 2007 or later Maximum capacity: 1,000 bkW Maximum operation: 100 hr/yr (non-emergency) Fuel: ULSD Displacement: <10 L/cyl	EPA Tier 2 technologies	1 hr/day and 100 hr/yr
EDG3	Plant Emergency Generator #2 Date of construction: 2007 or later Maximum capacity: 1,000 bkW Maximum operation: 100 hr/yr (non-emergency) Fuel: ULSD Displacement: <10 L/cyl	EPA Tier 2 technologies	1 hr/day and 100 hr/yr
EDFP	Mill Fire Pump Date of construction: 2009 or later Maximum capacity: 200 bkW Maximum operation: 100 hr/yr (non-emergency) Fuel: ULSD Displacement: <10 L/cyl	None	1 hr/day and 100 hr/yr
Fuel Storage			
TG1–TG2	Mine Site Gasoline Tanks (#1 through #2) Maximum capacity: 5,000 gal each	Lids or other appropriate closure with gasketed seal and submerged filling	<100,000 gal/mo
TD3–TD10	Mine Site Diesel Tanks (#3 through #10)	Lids or other appropriate closure	n/a

REC 0740

PET 374

2 Facility-Wide

Fugitive Dust

2.1 All reasonable precautions shall be taken to prevent particulate matter from becoming airborne in accordance with IDAPA 58.01.01.650-651. In determining what is reasonable, consideration will be given to factors such as the proximity of dust-emitting operations to human habitations and/or activities and atmospheric conditions which might affect the movement of PM. Some of the reasonable precautions include, but are not limited to, the following:

- Use, where practical, of water or chemicals for control of dust in the demolition of existing buildings or structures, construction operations, the grading of roads, or the clearing of land.
- Application, where practical, of asphalt, oil, water, or suitable chemicals to, or covering of dirt roads, material stockpiles, and other surfaces which can create dust.
- Installation and use, where practical, of hoods, fans, and fabric filters or equivalent systems to enclose and vent the handling of dusty materials. Adequate containment methods should be employed during sandblasting or other operations.
- Covering, when practical, open-bodied trucks transporting materials likely to give rise to airborne dusts.
- Paving of roadways and their maintenance in a clean condition, where practical.
- Prompt removal of earth or other stored material from streets, where practical.

2.2 The permittee shall monitor and maintain records of the frequency and the methods used (e.g., water, chemical dust suppressants) to reasonably control fugitive dust emissions.

2.3 The permittee shall maintain records of all fugitive dust complaints received. The permittee shall take appropriate corrective action as expeditiously as practicable after receipt of a valid complaint. The records shall include, at a minimum, the date that each complaint was received and a description of the following: the complaint, the permittee's assessment of the validity of the complaint, any corrective action taken, and the date the corrective action was taken.

2.4 The permittee shall conduct a facility-wide inspection of potential sources of fugitive emissions (e.g., stockpiles, transfer points, etc.) identified in the Fugitive Dust Control Plan (FDCP) at least once per ~~shift~~ month during daylight hours and under normal operating conditions to ensure that the methods used to reasonably control fugitive dust emissions are effective. If emissions are not being reasonably controlled, the permittee shall take corrective action as expeditiously as practicable. The permittee shall maintain records of the results of each fugitive dust emissions inspection. The records shall include, at a minimum, the date of each inspection and a description of the following: the permittee's assessment of the conditions existing at the time fugitive emissions were present (if observed), any corrective action taken in response to the fugitive dust emissions, and the date the corrective action was taken.

2.5 The permittee shall develop and maintain a Fugitive Dust Control Plan (FDCP) to ensure compliance with fugitive dust requirements (Permit Conditions 2.1–2.4) and fugitive dust best management practices in accordance with IDAPA 58.01.01.799. IDAPA 58.01.01.799 applies to fugitive dust sources at the limestone crushing plant and aggregate production plant. The permittee shall comply with the FDCP at all times. The requirements specified in the FDCP shall be incorporated by reference to this permit and shall be enforceable permit conditions. At a minimum, the FDCP shall contain a list of all potential sources of fugitive dust emissions, and a list of reasonable precautions to minimize fugitive dust emissions (Permit Condition 2.1), ~~and requirements to~~such as:

- Post and limit the maximum speed of haul trucks ~~to 20 miles per hour or lower if appropriate~~in accordance with the FDCP. Signs shall be posted along the haul route and placed so they are visible to vehicles entering and leaving the site of operations.
- ~~Limit vehicle miles traveled from all haul trucks (combined) to less than 490,000 miles per month.~~
- Apply water or suitable dust suppressant chemicals (e.g., magnesium chloride, calcium chloride) to disturbed areas, haul roads, equipment staging areas, parking areas, and storage piles during the dry season and at other times as necessary to control fugitive dust. Water ~~and~~ or dust suppressant should be applied to a haul road consistent with industry standards and whenever visible fugitive PM emissions are observed leaving a roadway for more than two consecutive minutes.~~a period or periods aggregating more than one minute in any 60-minute period.~~
- Apply water or suitable dust suppressant whenever visible fugitive PM emissions exceed 20% for more than two consecutive minutes from any transfer point, screening operation, or crushing operation identified in the FDCP and at other times as necessary to control fugitive dust. Transfer points include points where material (e.g., ore and rock, lime, aggregate, cement, etc.) is transferred to or from a belt conveyor, conveying system, bucket elevator, screening operation, or stockpile. Controls shall include manual water spray capability or installing, operating, and maintaining water spray bars at transfer points to wet the material for downstream control; moisture carryover. Controls shall also include limiting drop heights in truck loading, front-end loader dumping, and conveying operations to ensure a homogeneous flow of material.
- Apply water or suitable dust suppressant whenever visible fugitive PM emissions from wind erosion of any stockpile exceeds 20% opacity for more than two consecutive minutes~~a period or periods aggregating more than one minute in any 60-minute period~~, and at other times as necessary to control fugitive dust. Water may need to be applied to storage piles before and during truck loading, and when stockpiled ore and waste rock is not processed promptly in order to avoid drying and becoming airborne. Stockpile height should be limited to limit disturbance.
- Apply appropriate dust control at the initial point of material handling~~, such as the mine working face,~~ to suppress dust throughout the material handling process as necessary.
- Apply appropriate dust control whenever visible fugitive PM emissions exceed 20% for more than two consecutive minutes from any grinding mill building vent~~ or capture system stack~~.
- Apply crushed gravel to haul roads, equipment staging areas, and other areas as necessary to limit migration of fine sediment.
- Install wind fences or barriers around, place below grade, or enclose all storage piles, parking areas, and equipment staging areas as necessary to control fugitive dust. This is required for

the Stockpile Transfer to Reclaim Conveyors (OC9), Reclaim Conveyors to Feed Conveyor (OC10), and Feed Transfer to conveyor (OC11).

- Develop specific criteria to determine when and what type of dust suppressant must be applied, and appropriate suppressant application rates. Chemical dust suppressants shall be applied consistent with manufacturer's instructions and recommendations.
- Develop specific criteria to determine when water must be applied, and appropriate water application rates.
- Develop and implement precautionary measures to address high-wind events, such as when average (sustained) wind speed is forecast to exceed 25 miles per hour.
- At least ~~twice~~ once per ~~day~~ month while haul trucks are transporting ore and/or rock, inspect active haul routes for visible fugitive PM emissions using the specified method and procedures (Permit Condition 2.4). ~~Whenever visible fugitive PM emissions are observed leaving a roadway during inspection or valid complaint (Permit Condition 2.3), the adequacy of water and dust suppressant application rates should be evaluated.~~
- ~~At least once per day during operation, monitor and record criteria relied upon to determine water and suppressant application rates and frequency, such as temperature, humidity, and wind speed.~~
-
- , monitor and record the frequency of application and application rates for water and suppressant controls.
- ~~Each month, monitor and record haul truck vehicle miles traveled.~~
- ~~At least once every six months, inspect each water and suppressant spray calibration to ensure adequate coverage and delivery rate and to ensure operation in accordance with manufacturer's recommendations.~~
- Provide training/orientation to all relevant employees regarding FDCP requirements, including the necessity of restricting public access. Visible emissions evaluations shall be conducted by the permittee's ~~own~~ employees who~~m~~ are certified visible emission observers.
- , evaluate FDCP requirements to identify additional requirements and evaluate effectiveness of practices, including dust suppressant application rates, as appropriate.

2.6 The permittee shall develop and maintain an Access Management Plan (AMP) that identifies the facility boundary and all primary and secondary access points, and clearly specifies measures used to discourage public access to the facility. The permittee shall comply with the measures identified in the AMP at all times. The measures specified in the AMP shall be incorporated by reference to this permit and shall be enforceable permit conditions. At a minimum, the AMP shall include requirements to:

- Observe all primary access points to the facility in an effort to discourage public access. Onsite personnel shall be available for this purpose during active mining and mineral processing operations. Public access to the facility may be monitored by the use of security escort vehicles or manned guardhouses, or sufficiently precluded by the use of locked gates, barriers, or equivalent measures. Primary access points include the North and South Security Gates.
- Post warning signs and periodically patrol secondary access points to the facility in an effort to discourage public access. Onsite personnel shall be available for this purpose. Plans shall

be described in the AMP, including identifying the access points monitored, the frequency of patrol, and measures employed to discourage access (e.g., locked gates, barriers, natural features, etc.). Secondary access points include secondary roadways and trails traversing the facility.

2.7 Copies of the FDCP and AMP shall be submitted to DEQ within 60 days of permit issuance at the address provided (Permit Condition 2.25), and shall remain onsite at all times. Any changes to the FDCP or the AMP shall be submitted to DEQ for review and comment within 15 days of the change.

Visible Emission

2.8 The permittee shall not discharge any air pollutant to the atmosphere from any point of emission for a period or periods aggregating more than three minutes in any 60-minute period which is greater than 20% opacity as determined by the test methods and procedures contained in IDAPA 58.01.01.625. These provisions shall not apply when the presence of uncombined water, nitrogen oxides, and/or chlorine gas is the only reason for the failure of the emission to comply with this permit condition.

2.9 The permittee shall conduct a facility-wide inspection of potential point sources of visible emissions; including any stack, vent, or functionally equivalent opening; each ~~shift~~month, during daylight hours and under normal operating conditions. Sources that are monitored using a continuous opacity monitoring system (COMS) are not required to comply with this permit condition. The inspection shall consist of a see/no see evaluation for each potential source of visible emissions. If any visible emissions are present from any point of emission, the permittee shall either:

- Take appropriate corrective action as expeditiously as practicable to eliminate the visible emissions. Within 24 hours of the initial see/no see evaluation and after the corrective action, the permittee shall conduct a see/no see evaluation of the emissions point in question. If the visible emissions are not eliminated, the permittee shall comply with the following; or
- Perform a Method 9 opacity test in accordance with the procedures outlined in IDAPA 58.01.01.625. A minimum of 30 observations shall be recorded when conducting the opacity test. If opacity is greater than 20% for a period or periods aggregating more than three minutes in any 60-minute period, the permittee shall take all necessary corrective action and report the exceedance in the annual compliance certification and in accordance with IDAPA 58.01.01.130-136.

2.10 The permittee shall maintain records of the results of each visible emission inspection and each opacity test when conducted. The records shall include, at a minimum, the date and results of each inspection and test and a description of the following: the permittee's assessment of the conditions existing at the time visible emissions are present (if observed), any corrective action taken in response to the visible emissions, and the date corrective action was taken.

2.11 The permittee shall have a certified opacity reader onsite at all times during operation of any regulated sources (in Table 1.1). The reader shall be certified in using the test methods and procedures of EPA Reference Methods 9 and ~~22~~knowledgeable of Method 22 procedures.

Process Weight

2.12 The permittee shall not emit PM to the atmosphere from any process or process equipment in excess of the amount shown by the equations in IDAPA 58.01.01.700-703.

- The ore processing; ore concentration and refining; lime production; aggregate production; concrete production; and process heating equipment (identified in Table 1.1) are process equipment as defined in IDAPA 58.01.01.006.

Odor

2.13 The permittee shall not allow, suffer, cause, or permit the emission of odorous gases, liquids, or solids into the atmosphere in such quantities as to cause air pollution in accordance with IDAPA 58.01.01.776.01.

2.14 The permittee shall maintain records of all odor complaints received. If the complaint has merit, the permittee shall take appropriate corrective action as expeditiously as practicable. The records shall include, at a minimum, the date that each complaint was received and a description of the following: the complaint, the permittee's assessment of the validity of the complaint, any corrective action taken, and the date the corrective action was taken.

Fuels

2.15 The permittee shall not sell, distribute, use, or make available for use any distillate fuel oil containing more than the following percentages of sulfur, in accordance with IDAPA 58.01.01.725:

- ASTM Grade 1 fuel oil - 0.3% by weight.
- ASTM Grade 2 fuel oil - 0.5% by weight.

2.16 The permittee shall maintain documentation of supplier verification of fuel oil sulfur content on an as-received basis to ensure compliance with fuel specifications (Permit Condition 2.15).

2.17 The maximum ~~combined~~ throughput of gasoline to the Gasoline Tanks (TG1, TG2) shall not exceed 100,000 gallons per month (gal/mo).

2.18 After startup, each month the permittee shall maintain records demonstrating compliance with gasoline throughput limits, by tracking either amounts loaded or amounts dispensed from each Gasoline Tank.

O&M Manual

2.19 Within 60 days after startup of any process equipment (Permit Condition 2.12), the permittee shall develop and maintain an Operation and Maintenance (O&M) manual to ensure compliance with emission limits (Permit Conditions 2.8, 2.12, 4.3, and 0) and the control equipment maintenance and operation general provision (Permit Condition 7.2). The O&M manual shall be a permittee-developed document based upon, but independent from, manufacturer-supplied operating manuals. The permittee shall operate control equipment in accordance with the O&M manual at all times. The requirements in the O&M manual shall be incorporated by reference to this permit and shall be enforceable permit conditions. At a minimum, the O&M manual shall include the following for all (Table 1.1):

- Identify the manufacturer, model, date of manufacture, and maximum capacity (as-built) for each regulated emission source assigned a source ID, and for each control device in the service of ore concentration and refining, lime production, and concrete production (in Table 1.1). For each wet scrubber, carbon filter, baghouse and bin vent filter cartridge control device, a copy of the vendor-supplied performance guarantee shall be included. For each engine, a copy of the EPA tier certification shall be included.
- Establish operating ranges for control equipment, based on manufacturer specifications and conditions measured during performance testing;

- Minimum pressure drop across each wet scrubber
- Minimum recirculation flow rate for each wet scrubber
- Maximum inlet gas stream temperature to each carbon filter
- ~~Minimum~~ Maximum pressure drop across each carbon filter
- Maximum pressure drop across each baghouse
- Minimum coolant flow rate in the mercury retort condenser

- Describe the procedures for proper operation, startup, and shutdown of control equipment, based on manufacturer specifications.
- Describe the schedule and procedures for routine inspection (Permit Condition 2.9), maintenance, repair, and replacement of control equipment.
  - See-no-see visible emissions inspection of each wet scrubber, carbon filter, baghouse, and bin vent shall be conducted at least once per month.
  - , the drum lining of the carbon regeneration kiln shall be visually inspected for structural damage and cracks.
  - The dates, times, and results from each inspection (as required by Permit Condition 2.10), corrective action, maintenance, repair, and replacement of control equipment shall be recorded at least once per month.
  - The replacement dates for each baghouse and bin vent filter cartridge and for each activated carbon filter medium shall be recorded ~~at least once per month~~for each replacement. For cartridges, records shall include the manufacturer and model. For carbon filters, records shall include the manufacturer, type, and form of medium added. Records shall also include any changes in supplier and other relevant information.
  - All carbon filter beds ~~from the mercury retort~~ shall be disposed of in an acceptable manner in compliance with all applicable state rules and federal regulations.
- Describe the schedule and procedures for corrective action that will be taken if visible emissions are present from wet scrubber (WS1, WS2, WS3), carbon filter (CA1, CA2, CA3, CA4), baghouse (BH1, BH2, BH3, BH4, BH5), or bin vent filter (LS, LS1, MillS2, ACS1, ACS2, ACS3, ACS4, CS1, CS2) control equipment at any time. Procedures should include how to determine whether filter cartridges are ruptured or are not appropriately secured in place, and how to determine whether the wet scrubber, condenser, and carbon filters are operating properly.
- Describe each monitoring device and methodology used to measure weights of materials to demonstrate compliance with each material throughput limit (Permit Conditions 3.5–3.8, 4.5–4.10, and 5.4–5.8). Procedures for proper installation, calibration, and maintenance shall be included.

2.20 ~~Copies of the~~ The O&M manual shall be submitted to DEQ within 60 days after initial startup of any ore processing, ore concentration and refining, lime production, or aggregate production emission source regulated by this permit (as identified in Table 1.1) at the address provided (Permit Condition 2.25), and shall remain onsite at all times. Any changes to the O&M manual shall be submitted to DEQ for review and comment within 15 days of the change.

Incorporation of Federal Requirements

2.21 Unless expressly provided otherwise, any reference in this permit to any document identified in IDAPA 58.01.01.107.03 shall constitute the full incorporation into this permit of that document for the purposes of the reference, including any notes and appendices therein. Documents include, but are not limited to:

- Standards of Performance for New Stationary Sources (NSPS) 40 CFR 60, Subpart A – General Provisions.
- NSPS 40 CFR 60, Subpart LL – Standards of Performance for Metallic Mineral Processing Plants. Each crusher (OC7, OC12), conveyor belt transfer point (~~OC1~~OC1–OC6, ~~OC8~~OC8–OC11, OC13), and truck unloading station (OC1) is an affected facility.
- NSPS 40 CFR 60, Subpart OOO – Standards of Performance for Nonmetallic Mineral Processing Plants. Each crusher (LS2, LS4), grinding mill (LSBM~~, OC12~~), screening operation (LS3, LS5, LS11), belt conveyor (LS6–LS10, LS12), and storage bin (LS1) is an affected facility.
- NSPS 40 CFR 60, Subpart IIII – Standards of Performance for Stationary Compression Ignition Internal Combustion Engines. Each emergency generator engine and fire pump (EDG1, EDG2, EDG3, and EDFP) is an affected facility.
- National Emission Standards for Hazardous Air Pollutants for Source Categories (NESHAP) 40 CFR 63, Subpart A – General Provisions.
- NESHAP 40 CFR 63, Subpart EEEEEEE – National Emission Standards for Hazardous Air Pollutants: Gold Mine Ore Processing and Production Area Source Category. The collection of ore pretreatment processes including the autoclave (AC) and the carbon process including the carbon regeneration kiln (CKD), the electrowinning cells and pregnant solution tank (EW), the mercury retort (MR), and the induction melting furnace (MF) are affected facilities.
- NESHAP 40 CFR 63, Subpart ZZZZ – National Emission Standards for Hazardous Air Pollutants for Stationary Reciprocating Internal Combustion Engines (RICE). Each emergency generator engine and fire pump (EDG1, EDG2, EDG3, and EDFP) is an affected facility.
- NESHAP 40 CFR 63, Subpart CCCCCC – National Emission Standards for Hazardous Air Pollutants for Source Category: Gasoline Dispensing Facilities. Each gasoline fuel storage tank (TG1, TG2) is an affected facility.

2.22 For permit conditions referencing or cited in accordance with any document incorporated by reference (including permit conditions identified as NSPS or NESHAP), should there be any conflict between the requirements of the permit condition and the requirements of the document, the requirements of the document shall govern, including any amendments to that regulation.

2.23 In accordance with IDAPA 58.01.01.313.01.b., 40 CFR 70.3(c)(2), and 40 CFR 63.11640(d), the permittee shall submit a complete application to DEQ at the address provided (Permit Condition 2.25) for an initial Tier I operating permit within 12 months of becoming a Tier I source.

Test Methods

2.24 Except as otherwise specified in this permit and in IDAPA 58.01.01.157.02, when testing is required the following test methods shall be used to measure pollutant emissions.

Table 2.1 Test Methods

Pollutant		Test Method	Additional Requirements
H_2SO_4		EPA Method 8	
PM_{10}		EPA Method 5 and 201A, and 202	PM, including condensable particulate as defined in IDAPA 58.01.01.006~~.~~, with an aerodynamic diameter less than or equal to a nominal 10 micrometers for PM_{10}, and less than or equal to a nominal 2.5 micrometers for $PM_{2.5}$.
Opacity	point	EPA Method 9	For NSPS and NESHAP sources, use IDAPA 58.01.01.625 and Method 9. For other sources, use IDAPA 58.01.01.625 only.
	fugitive	EPA Method 22	Visible fugitive PM.

Notifications

2.25 All requests, reports, applications, submittals, certifications, and other communications required by this permit shall be submitted to:

Air Quality Permit Compliance
Department of Environmental Quality

1445 N. Orchard St.
Boise, Idaho 83706

phone: (208) 373-0550
fax: (208) 373-0287

3 Mining and Ore Processing

3.1 Process Description

Conventional open-pit mining methods including drilling, blasting, excavating, and hauling will be used to extract ore and waste rock, termed development rock (DR). Hydraulic shovels and front-end loaders will be used to load ore and DR into haul trucks. DR will be used for construction, restoration, and backfilling, or hauled to dedicated development rock storage facilities (DRSF). Approximately 340 million tons of DR will be handled over the life of the mine.

The SGP will include three years of pre-mining development and construction activities, followed by an operating mine life of approximately 12 years. Mining will occur in three open pits: Yellow Pine Pit (YPP), Hangar Flats pit (HFP), and West End pit (WEP). Legacy tailings from the Meadow Creek valley (Bradley Tailings [BT]) will also be reclaimed and reprocessed. Surface exploration drilling will occur within the pits and underground within the Scout Prospect decline.

Ore will be hauled to the primary crusher area, where it will be fed directly into the crusher dump pocket or stockpiled. The ore crushing plant will be designed to operate at a maximum rate of 25,000 tons per calendar day (T/day). Approximately 100 million tons of ore will be mined from the three pits over the life of the project.

The metal-recovery process from ore will include conventional crushing and grinding, followed by froth-flotation circuits that will generate separate gold-silver and antimony-silver concentrates. The antimony-silver concentrate will be shipped offsite for refining, whereas additional onsite processing of the gold-silver concentrate will include pressure oxidation, carbon-in-leach circuits, and refining processes to recover gold and minor amounts of silver. The finely ground leftover ore material from the mineral-recovery process, termed tailings, will be neutralized, thickened, and transported via a pipeline to the tailings storage facility (TSF).

3.2 Control Device Descriptions

Table 3.1 Mining and Ore Processing Control Equipment

Emission Sources	Control Devices
Excavating and hauling activities	Chemical suppression and water sprays ~~Control efficiency: 93.3% for PM/PM_{10}~~ (haul roads)
Loader Transfer of Ore to Grizzly	Water sprays and moisture carryover
Grizzly to Apron Feeder	
Apron Feeder to Dribble	
Apron Feeder to Grizzly	
Dribble to Grizzly	
Grizzly to Primary Crusher or Coarse Ore Stockpile Feed	
Primary Crusher	Water sprays and moisture carryover
Coarse Ore Stockpile Feed Transfer to Stockpile	
Stockpile Transfer to Reclaim Conveyors	Below-grade of storage piles ~~Control efficiency: 80% for PM/PM_{10}~~
Reclaim Conveyors to Feed Conveyor	
Feed Transfer to	Enclosure ~~Control efficiency: 80% for PM/PM_{10}~~
Pebble Crusher	Water sprays and moisture carryover
Pebble Discharge to Feed	
(2) Prill Silos #1-2 Maximum capacity: 100 T (each)	None

Operating Limits

3.3 Drilling Limits

The permittee shall drill no more than 1,200 blast holes per day.

3.4 Blasting Limits

The permittee shall complete no more than 2 blasting operations per day.

3.5 Hauling and Excavating Limits

The permittee shall haul no more than 180,000 tons of ore and rock per day.

3.6 Primary Crusher Limit

The permittee shall process ore as the raw material in the primary crusher, and the maximum input to the primary crusher shall not exceed 25,000 T/day.

3.7 Pebble Crusher Limit

The permittee shall process ore as the raw material, and the maximum input to the pebble crusher shall not exceed 27,600 T/day.

3.8 Prill Loading Limit

The permittee shall not load in excess of ~~608 tons per month (T/mo)~~200 T/day nor 9,000 T/yr of prill (ammonium nitrate) to the prill silos.

3.9 Mining and Ore Processing Dust Control

The permittee shall control emissions from mining and ore processing emission sources (Table 3.1) in accordance with the Fugitive Dust Control Plan.

3.10 Ore Processing Equipment Water Sprays

The permittee shall install, maintain, and operate water sprays in accordance with the O&M manual (Permit Condition 2.19) to control PM emissions from each ore processing crusher and conveyor. Water sprays shall operate at all times when this equipment is operated to ensure compliance with Fugitive Dust requirements (Permit Conditions 2.1–2.5).

3.11 ~~Building Enclosures~~

~~The Primary Crusher (OC7) shall be fully enclosed within a building (Primary Crusher Building).~~

~~The Pebble Crusher (OC12) shall be fully enclosed within a building (Pebble Crusher Building).~~

Monitoring and Recordkeeping Requirements

3.12 Drilling Limits Monitoring

The permittee shall monitor and record the number of blast holes drilled per calendar day.

3.13 Blasting Limits Monitoring

The permittee shall monitor and record the number of blasting operations completed each calendar day.

3.14 Hauling and Excavating Limit Monitoring

The permittee shall monitor and record the amount of ore and rock transported on haul trucks each calendar day. The devices and methodologies used to measure weights shall be identified in O&M Manual.

3.15 Primary Crusher Limit Monitoring

The permittee shall monitor and record the tons of ore input to the crusher each calendar day (T/day). The devices and methodologies used to measure weights shall be identified in O&M Manual.

3.16 Pebble Crusher Limit Monitoring

The permittee shall monitor and record the tons of ore input to the pebble crusher each calendar day (T/day). The devices and methodologies used to measure weights shall be identified in O&M Manual.

3.17 Prill Loading Limit Monitoring

The permittee shall monitor and record the amount of prill loaded to the prill silos each calendar day (T/day). Annual material loading shall be determined by summing the monthly loading over the previous consecutive 12-month period. The devices and methodologies used to measure weights shall be identified in O&M Manual.

4 Ore Concentration and Refining

4.1 Process Description

The autoclave is a pressure oxidation (POX) vessel used to ~~extract gold from~~oxidize gold-silver concentrate at elevated temperature and pressure, in the presence of oxygen. Upon exiting the autoclave, the slurry is cooled in flash vessels, neutralized using lime and caustic soda prior to being sent to the vat leaching circuit for gold and silver recovery. ~~The autoclave discharges to flash vessels and a wet scrubber (WS1).~~ A dilute sodium cyanide solution is added to the leach tanks to dissolve the gold and silver from the ore.~~Slurry discharge from the flash vessels processes through basic ferric sulfate (BFS) re-leach tanks to stabilize the solids. The concentrate is then conditioned with lime before cyanide leaching.~~ Leached "pulp" is sent to multistage carbon-in-pulp (CIP) and/or carbon-in-leach (CIL) tanks, where gold is recovered via adsorption onto activated carbon~~carbon filters~~. The autoclave is located in the POX Building and the exhaust from autoclave passes through a wet scrubber (WS1).

~~Carbon filters~~Carbon loaded with gold ~~are~~ is removed and washed with acid, then stripped with a caustic solution. This mineral-bearing solution is sent to the electrowinning cells and pregnant solution tank (EW). The EW cells remove the gold from the solution by plating it onto cathodes consisting of stainless-steel plates with steel wool. The EW cell exhaust passes through a carbon adsorption column (CA2), where ~~any~~ remaining mercury vapor is adsorbed onto sulfur-impregnated activated carbon (SIAC) ~~before being emitted to the atmosphere~~. The stripped ~~carbon filters~~carbon must be periodically regenerated in the carbon regeneration kiln. Exhaust from the carbon regeneration kiln passes through a carbon adsorption bed (CA1), where ~~any~~ mercury is adsorbed onto SIAC ~~before being emitted to the atmosphere~~.

Gold concentrate is loaded into the mercury retort, where it is heated under vacuum to drive off mercury. The mercury retort exhaust passes through a shell-and-tube condenser to cool the exhaust and condense the mercury vapor into a liquid, which is collected by the mercury trap. The exhaust passes through a carbon adsorption column (CA3), where ~~any~~ remaining vapor mercury is adsorbed onto ~~sulfur-impregnated activated carbon (~~SIAC~~) before being emitted to the atmosphere~~.

After retorting, the gold concentrate is transferred to the electric induction melting furnace. Only retorted concentrate is melted in the furnace. The exhaust passes through a carbon adsorption column (CA4), where ~~any~~ remaining mercury vapor is adsorbed onto SIAC ~~before being emitted to the atmosphere~~. The electrowinning cells and pregnant solution tank, carbon regeneration kiln, mercury retort, and induction melting furnace are located in the Refinery Building.

4.2 Control Device Descriptions

Table 4.1 Ore Concentration and Refining Equipment Descriptions

Lime Production Plant Emissions Unit / Processes	Control Devices	Emission Points
Autoclave	Wet Scrubber (WS1) Minimum pressure drop and minimum recirculation flow rate monitoring established in accordance with Subpart EEEEEEE	Autoclave Wet Scrubber Stack
Electrowinning Cells and Pregnant Solution Tank	Shared Carbon Filter (CA2) ~~Minimum~~ Maximum Maximum pressure drop monitoring~~and~~ established in accordance with O&M ~~minimum~~ Maximum inlet gas stream temperature monitoring established in accordance with Subpart EEEEEEE	Electrowinning Cells and Pregnant Solution Tank Shared Carbon Filter Stack
Mercury Retort	Condenser Minimum coolant flow rate monitoring established in accordance with O&M Carbon Filter (CA3) Maximum Maximum pressure drop monitoring established in accordance with O&M Maximum inlet gas stream temperature monitoring established in accordance with Subpart EEEEEEE	Mercury Retort Carbon Filter Stack
Induction Melting Furnace	Baghouse (BH2) Maximum~~Minimum~~ pressure drop monitoring established in accordance with O&M Carbon Filter (CA4) Maximum Maximum pressure drop monitoring established in accordance with O&M Maximum inlet gas stream temperature monitoring established in accordance with Subpart EEEEEEE	Induction Melting Furnace Carbon Filter Stack
Carbon Regeneration Kiln	Wet Scrubber (WS2) Minimum pressure drop and minimum recirculation flow rate monitoring established in accordance with O&M Carbon Filter (CA1) Maximum Maximum pressure drop monitoring established in accordance with O&M Maximum inlet gas stream temperature monitoring established in accordance with Subpart EEEEEEE	Carbon Regeneration Kiln Carbon Filter Stack
Antimony Bagging	Baghouse (BH1) Maximum ~~Minimum~~ pressure drop monitoring established in accordance with O&M	Antimony Bagging Baghouse Stack

Emission Limits

4.3 Ore Concentration and Refining Equipment Emission Limits

Emissions from ore concentration and refining equipment stacks shall not exceed any corresponding emission rate limits (Table 4.2~~Table 4.1~~).

Table 4.2 Ore Concentration and Refining Emissions Limits [a]

Source Description	PM / PM_{10} / $PM_{2.5}$ [b]	NO_x	CO	VOC	SO_2	H_2SO_4
	lb/hr [c]	lb/hr ~~(c)~~	lb/hr ~~(c)~~	lb/hr ~~(c)~~	lb/hr ~~(c)~~	lb/hr [c]
Autoclave (AC)	5.08				0.65	2.03
Carbon regeneration kiln (CKD~~, CKB~~)	~~0.44~~0.42	0.01	0.12	0.11		
Antimony Bagging (Sb2)	0.12					
Electrowinning cells and pregnant solution tank (EW)	0.07					
Mercury retort (MR)	0.01 [d]					
Induction melting furnace (MF)	2.84					

a) In absence of any other credible evidence, compliance is ensured by complying with permit operating, monitoring, and recordkeeping requirements.
b) Particulate matter (PM) including condensable PM as defined in IDAPA 58.01.01.006, with an aerodynamic diameter less than or equal to a nominal 10 micrometers for PM_{10}, and less than or equal to a nominal 2.5 micrometers for $PM_{2.5}$.
c) Pounds per hour, as determined by a test method prescribed by IDAPA 58.01.01.157, EPA reference test method, continuous emission monitoring system (CEMS) data, or DEQ-approved alternative.
d) For this emission limit, compliance may be demonstrated as measurement below detection limits, when addressed as part of a performance test protocol that is approved by DEQ.

Operating Limits

4.4 POX Boiler Operation

Operation of the POX Boiler shall be limited to the autoclave strat-up operation only~~not exceed 1 hour per calendar day and 30 hours per consecutive 12-month period~~.

4.5 Autoclave Input

The permittee shall process ore concentrate as the raw material in the autoclave, and the maximum input to the autoclave shall not exceed 6,960 T/day.

4.6 Mercury Retort Input

The permittee shall process precious metal concentrate as the raw material in the mercury retort, and the maximum input to the mercury retort shall not exceed 1,000 pounds per batch (lb/batch) and 21 T/yr.

Precious metal concentrate includes material loaded with precious metals produced by electrowinning, flotation and gravity separation, and other gold concentration or precipitation processes; and material collected from the wash-down of equipment and surfaces contacted with precious metals that have been concentrated through these concentration methods.

4.7 Induction Melting Furnace Input

The permittee shall process retorted concentrate as the raw material in the induction melting furnace, and the input to the induction melting furnace shall not exceed 1,000 lb/batch, and 21 T/yr. Retorted concentrate includes precious metal concentrate that has been retorted and dust collected from the baghouse and fume hood of the induction melting furnace.

4.8 Carbon Regeneration Kiln Input

The permittee shall process carbon filters as the raw material in the carbon regeneration kiln, and the maximum input to the carbon regeneration kiln shall not exceed 7.2 T/day.

4.9 Electrowinning Cells and Pregnant Solution Tank Throughput

The permittee shall process ~~ore and ore concentrate~~mineral-bearing solution as the raw materials in the electrowinning cells and pregnant solution tank, and the maximum throughput for the electrowinning cells and pregnant solution tank shall not exceed 100 gallons per minute (gpm).

4.10 Antimony Bagging Input

The maximum throughput through the antimony bagging process shall not exceed 108 T/day, or the maximum throughput established during performance testing when addressed as part of a performance test protocol that is approved by DEQ (Permit Condition 4.30).

4.11 Autoclave Wet Scrubber

The permittee shall install, maintain, and operate a wet scrubber (WS1) in accordance with the O&M manual (Permit Condition 2.19) and manufacturer's specifications. All emissions from the autoclave shall be ducted to the wet scrubber at all times to ensure compliance with autoclave emission limits (Table 4.2)~~ and in accordance with IDAPA 58.01.01.210.21~~.

4.12 Electrowinning Cells and Pregnant Solution Tank Shared Carbon Filter

The permittee shall install, maintain, and operate a carbon filter (CA2) in accordance with the O&M manual (Permit Condition 2.19) and consistent with manufacturer's recommendations. All emissions from the electrowinning cells and pregnant solution tank shall be ducted to a carbon filter at all times to ensure compliance with electrowinning cells and pregnant solution tank emission limits (Table 4.2)~~ and in accordance with IDAPA 58.01.01.210.21~~.

4.13 Mercury Retort Condenser and Carbon Filter

The permittee shall install, maintain, and operate a condenser and carbon filter (CA3) in series in accordance with the O&M manual (Permit Condition 2.19) and manufacturer's recommendations. All emissions from the mercury retort (MR) shall be ducted to the condenser and activated carbon filter at all times to ensure compliance with mercury retort emission limits (Table 4.2~~Table 4.1~~) ~~and in accordance with IDAPA 58.01.01.210.21~~.

- The MR shall be fully enclosed in the refinery building.
- The air pressure within the MR shall be maintained lower than the room air pressure such that air flows into the MR at all times when the MR is operating. The MR door shall be kept closed at all times during operation.
- The permittee shall not operate the MR unless the chilled water condenser is operating, carbon filter in place, and the condenser coolant flow rate~~exhaust gas temperature~~ is maintained within the range specified in the O&M manual.
- The condenser and carbon filter shall be maintained and operated in accordance with the O&M manual.
- All liquid mercury captured from the MR shall be stored in closed containers

4.14 Induction Melting Furnace Baghouse and Carbon Filter

The permittee shall install, maintain, and operate a baghouse (BH2) and carbon filter (CA4) in series in accordance with the O&M manual (Permit Condition 2.19) and manufacturer's recommendations. All emissions from the induction melting furnace shall be ducted to the baghouse and carbon filter at all times during operation to ensure compliance with induction melting furnace emission limits (Table 4.2)~~ and in accordance with IDAPA 58.01.01.210.21~~.

4.15 Carbon Regeneration Kiln Wet Scrubber and Carbon Filter

The permittee shall install, maintain, and operate a wet scrubber (WS2) and carbon filter (CA1) in series in accordance with the O&M manual (Permit Condition 2.19) and consistent with manufacturer's recommendations. All emissions from the carbon regeneration kiln shall be ducted to the wet scrubber and a carbon filter at all times to ensure compliance with carbon regeneration kiln drum emission limits (Table 4.2~~Table 4.1~~) ~~and in accordance with IDAPA 58.01.01.210.21~~.

4.16 Antimony Bagging Baghouse

The permittee shall install, maintain, and operate a baghouse (BH1) in accordance with the O&M manual (Permit Condition 2.19) and consistent with manufacturer's recommendations. All emissions from antimony bagging shall be ducted to the baghouse at all times to ensure compliance with antimony bagging emission limits (Table 4.2~~Table 4.1~~) ~~and in accordance with IDAPA 58.01.01.210.21~~.

Monitoring and Recordkeeping

4.17 POX Boiler Operation Monitoring

Each calendar month, the permittee shall monitor and record the operating hours of the POX Boiler, in hours per calendar month and in hours per consecutive 12-month period ~~to demonstrate with the POX Boiler Operation limits~~.

4.18 Autoclave Input Monitoring

Each day, the permittee shall monitor and record the material input to the autoclave in tons per day (T/day) to demonstrate compliance with the autoclave input limit. The devices and methodologies used to measure weights shall be identified in O&M Manual, and the device shall be installed in accordance with the requirements of NESHAP Subpart EEEEEEE.

4.19 Mercury Retort Input Monitoring

Each day, the permittee shall monitor and record the material input to the mercury retort in pounds per day (lb/day) to demonstrate compliance with the daily mercury retort input limit. ~~The devices and methodologies used to measure weights shall be identified in O&M Manual.~~The device and methodologies used to measure weights shall be in accordance with the requirements of NESHAP Subpart EEEEEEE.

Each month, the permittee shall monitor and record the material input to the mercury retort in tons per month (T/mo) and in tons per year (T/yr) to demonstrate compliance with the annual mercury retort input limit. Annual material input shall be determined by summing the monthly input over the previous consecutive 12-month period.

4.20 Induction Melting Furnace Input Monitoring

Each day, the permittee shall monitor and record the material input to the induction melting furnace in lb/day to demonstrate compliance with the daily induction melting furnace input limit. The devices and methodologies used to measure weights shall be identified in O&M Manual.

Each month, the permittee shall monitor and record the material input to the induction melting furnace in T/mo and in T/yr to demonstrate compliance with the annual induction melting furnace input limit. Annual material input shall be determined by summing the monthly input over the previous consecutive 12-month period.

4.21 Carbon Regeneration Kiln Input Monitoring

Each day, the permittee shall monitor and record the material input to the carbon regeneration kiln in tons per day (T/day) to demonstrate compliance with the carbon regeneration kiln input limit. The devices and methodologies used to measure weights shall be identified in O&M Manual.

4.22 Electrowinning Cells and Pregnant Solution Tank Throughput Monitoring

Each day, the permittee shall monitor and record the material throughput in the electrowinning cells and pregnant solution tank in gallons per minute (gpm) to demonstrate compliance with the Electrowinning Cells and Pregnant Solution Tank Throughput limit. The devices and methodologies used to measure weights shall be identified in O&M Manual. ~~The device shall be installed in accordance with the requirements of NESHAP Subpart EEEEEEE.~~

4.23 Antimony Bagging Input Monitoring

Each day, the permittee shall monitor and record the material input to antimony bagging operations in tons per day (T/day) to demonstrate compliance with the antimony bagging input limit. The devices and methodologies used to measure weights shall be identified in O&M Manual.

4.24 Autoclave Wet Scrubber Monitoring

The permittee shall install, calibrate, maintain, and operate a device for monitoring the recirculation flow rate in the autoclave wet scrubber, and the pressure drop across the autoclave wet scrubber.

At least once per shift, the permittee shall monitor and record the recirculation flow rate and the pressure drop across the autoclave wet scrubber to ensure compliance with O&M specifications.

4.25 Electrowinning Cells and Pregnant Solution Tank Shared Carbon Filter Monitoring

The permittee shall install, calibrate, maintain, and operate a device for monitoring the inlet gas stream temperature to the carbon filter, and the maximum pressure drop across the carbon filter.

At least once per shift, the permittee shall monitor and record the inlet gas stream temperature and maximum pressure drop across the carbon filter for the electrowinning cells and pregnant solution tank to ensure compliance with O&M specifications.

4.26 Mercury Retort Condenser and Carbon Filter Monitoring

The permittee shall install, calibrate, maintain, and operate a device for monitoring the coolant flow rate in the condenser, a device for monitoring the inlet gas temperature to the carbon filter, maximum pressure drop across the carbon filter, and a device for monitoring the difference between the pressure inside the MR and the air pressure in the room.

At least once per shift, the permittee shall monitor and record the coolant flow rate to the condenser, and the inlet gas stream temperature and maximum pressure drop across the carbon filter for the mercury retort to ensure compliance with O&M specifications.

4.27 Induction Melting Furnace Baghouse and Carbon Filter Monitoring

The permittee shall install, calibrate, maintain, and operate a device for monitoring the pressure drop across the induction melting furnace baghouse, the inlet gas stream temperature to the carbon filter, and the maximum pressure drop across the carbon filter.

At least once per shift, the permittee shall monitor and record the pressure drop across the induction melting furnace baghouse, and the inlet gas stream temperature and maximum pressure drop across the carbon filter for the induction melting furnace to ensure compliance with O&M specifications.

4.28 Carbon Regeneration Kiln Wet Scrubber and Carbon Filter Monitoring

The permittee shall install, calibrate, maintain, and operate a device for monitoring the recirculation flow rate in the carbon regeneration kiln wet scrubber, ~~and~~ the pressure drop across the carbon regeneration kiln wet scrubber, the inlet gas stream temperature to the carbon filter, and the maximum pressure drop across the carbon filter.

At least once per shift, the permittee shall monitor and record the recirculation flow rate and the pressure drop across the carbon regeneration kiln wet scrubber, and the inlet gas stream temperature and maximum pressure drop across the carbon filter to ensure compliance with O&M specifications.

4.29 Antimony Bagging Baghouse Monitoring

The permittee shall install, calibrate, maintain, and operate a device for monitoring the pressure drop across the antimony bagging baghouse. At least once per shift, the permittee shall monitor and record the pressure drop across the antimony bagging baghouse to ensure compliance with O&M specifications.

Testing

4.30 Ore Concentration and Refining Equipment Performance Tests

Within 180 days after initial startup, performance testing shall be conducted to demonstrate compliance with the following Ore Concentration and Refining Equipment Emission Limits. The permittee shall conduct three separate test runs for each performance test using the appropriate test method (Permit Condition 2.24). The source test shall be conducted under "worst-case normal" conditions as required by IDAPA 58.01.01.157 and the General Provisions of this permit, and the source test report shall contain documentation that the test was conducted under these conditions.

- PM_{10} and H_2SO_4 in lb/hr from the Autoclave Wet Scrubber Stack
- PM_{10} in lb/hr from the Carbon Regeneration Kiln Carbon Filter Stack
- PM_{10} in lb/hr from the Antimony Bagging Baghouse Stack
- PM_{10} in lb/hr from the Electrowinning Cells and Pregnant Solution Tank Shared Carbon Filter Stack
- PM_{10} in lb/hr from the Mercury Retort Carbon Filter Stack

- PM_{10} in lb/hr from the Induction Melting Furnace Carbon Filter Stack

4.31 Ore Concentration and Refining Equipment Performance Tests Monitoring

The permittee shall monitor and record the following during each performance test:

- Material input rates for all ore concentration and refining process equipment (Permit Conditions 4.18, 4.19, 4.20, ~~and~~ 4.21, 4.22, and 4.23) during each test run, in tons.
- Control equipment monitoring relevant to the stack tested (Permit Condition 4.24, 4.25, 4.26, 4.27, 4.28, or 4.29), measured at least once ~~every 15 minutes~~ during each test run.
- The visible emissions observed for the stack tested during each test run, using the methods specified in IDAPA 58.01.01.625 (Permit Condition 2.8).

5 Lime, Aggregate, and Concrete Production

5.1 Process Description

The lime, aggregate, and cement batch plants produce raw materials necessary for mining and ore concentration and refining operations. Lime is used in ~~the lime slaking mill~~ore processing for pH control. Aggregate and cement are used in concrete production, with aggregate also used in road construction.

Lime production consists of a ~~central mix batch~~limestone crushing, screening, and grinding plant and lime storage silos. The ~~central mix batch plant~~limestone grinding process utilizes ~~water sprays and moisture carryover~~a baghouse to reduce emissions during processing. Each storage silo has a bin vent filter used to reduce PM emissions during silo loading.

Aggregate production consists of two portable crushing and screening plants ~~batch plant~~ and aggregate and cement storage silos. Each portable crushing and screening plant utilizes water sprays and moisture carryover to reduce emissions during processing. Each storage silo has a bin vent filter used to reduce PM emissions during silo loading.

Concrete production consists of a central mix batch plant and ~~lime~~ cement storage silos. The central mix batch plant utilizes controls that controls may include water sprays, enclosures, hoods, curtains, shrouds, movable and telescoping chutes, central duct collection systems, etc. to reduce PM emissions during processing. Each storage silo has a bin vent filter used to reduce PM emissions during silo loading.

5.2 Control Device Descriptions

Table 5.1 Lime, Aggregate, and Concrete Production Equipment Descriptions

Lime Production Plant Emissions Unit / Processes	Control Devices	Emission Points
~~Central Mix Loading~~	~~Water sprays and moisture carryover, and may also include enclosures, hoods, curtains, shrouds, movable and telescoping chutes, central duct collection systems, etc.~~	~~Fugitive~~
AC Lime Silo #1, AC Lime Silo #2, AC Lime Silo #3, and AC Lime Silo #4 loading	Bin vent filters	AC Lime Silo #1 Stack, AC Lime Silo #2 Stack, AC Lime Silo #3 Stack, and AC Lime Silo #4 Stack
unloading	None	Fugitive

Aggregate Production Plant Emissions Unit / Processes	Control Devices	
Portable Crushing and Screening Plant 1 Crushers, screens, and conveyors	Water sprays and moisture carryover	Fugitive
Portable Crushing and Screening Plant 2 Crushers, screens, and conveyors	Water sprays and moisture carryover	Fugitive
Concrete Production Plant Emissions Unit / Processes	**Control Devices**	
Central Mix	Controls Controls may include water sprays, enclosures, hoods, curtains, shrouds, movable and telescoping chutes, central duct collection systems, etc.	Fugitive
Aggregate bin loading/unloading	None	~~Aggregate Bin Stack~~Fugitive
Cement/Shotcrete Silo #1 and Silo #2 loading	Bin vent filters	Cement/Shotcrete Silo #1 Stack, and Cement/Shotcrete Silo #2 Stack
unloading	None	Fugitive

Emission Limits

5.3 Lime, Aggregate, and Concrete Production Emission Limits

Emissions from the lime production plant stacks shall not exceed any emission rate limit in the following table.

Table 5.2 Lime, Aggregate, and Concrete Production Plant Emission Limits [a]

Source Description	PM [b] lb/hr [c]	PM_{10} [b] lb/hr [c]	$PM_{2.5}$ [b] lb/hr [c]	NO_x lb/hr [c]	CO lb/hr [c]	VOC lb/hr [c]	SO_2 lb/hr [c]
Lime Production							
Parallel Flow Regenerative Shaft Kiln (LK, LKC)	1.07	1.07	1.07	~~4.61~~4.82	~~4.85~~4.98	~~0.18~~0.19	~~0.37~~0.39
Limestone Ball Mill (LSBM)	1.90	1.60	0.57				
Lime Mill Crusher (LCR)	0.28	0.24	0.09				
~~Lime Mill screens and conveyors (LS2, LS4, LS3, LS5, LS11, LS1, LS6–LS10, LS12)~~	~~3.66~~	~~1.34~~	~~0.20~~				
Mill Lime Silo loading and unloading (LS1, MillS2)	~~0.06~~0.31	~~0.02~~0.15	~~0.01~~0.02				
AC Lime Silo loading and unloading (ACS1, ACS2, ACS3, ACS4)	~~0.12~~0.86	~~0.04~~0.39	~~0.01~~0.06				
Pebble Lime Silo loading (LS-L)	0.01	0.01	0.01				
Pebble Lime Silo unloading (LS-U)	0.001	0.001	0.001				
Crushers, screens, conveyors ~~, silo unloading (LSBM, LCR,~~ LS1– LS12)	~~6.00~~3.81	~~3.22~~1.39	~~0.87~~0.21				
Aggregate Production							
Portable Crushing and Screening Plant 1	0.63	0.23	0.03				
Portable Crushing and Screening Plant 2	0.63	0.23	0.03				
Concrete Production							
Central Mix Plant (CM, CS1, CS2, CA)	2.10	0.94	0.14				

a) In absence of any other credible evidence, compliance is ensured by complying with permit operating, monitoring, and recordkeeping requirements.

b) Particulate matter (PM) including condensable PM as defined in IDAPA 58.01.01.006 , with an aerodynamic diameter less than or equal to a nominal 10 micrometers for PM_{10}, and less than or equal to a nominal 2.5 micrometers for $PM_{2.5}$.

c) ~~Pounds per hour, as determined by a test method prescribed by IDAPA 58.01.01.157, EPA reference test method, continuous emission monitoring system (CEMS) data, or DEQ approved alternative.~~

Operating Requirements

5.4 Primary Crusher Limit

The permittee shall process limestone as the raw material, and the maximum input to the ~~Semi-Autogenous Grinding (SAG) Mill~~ Primary Crusher shall not exceed 1,130 T/day.

5.5 Parallel Flow Regenerative Kiln Limit

The permittee shall process lime~~stone~~ as the raw material in the Parallel Flow Regenerative Kiln. The maximum output from the kiln shall not exceed 169 T/day and 52,377 T/yr.

5.6 Portable Crushing and Screening Plant 1 Input Limit

The permittee shall process aggregate as the raw material, and the maximum input to the Portable Crushing and Screening Plant 1 shall not exceed 2,000 tons per calendar day.

5.7 Portable Crushing and Screening Plant 2 Input Limit

The permittee shall process aggregate as the raw material, and the maximum input to the Portable Crushing and Screening Plant 2 shall not exceed 2,000 tons per calendar day.

5.8 Central Mix Input Limit

The permittee shall process cement and aggregate as the raw materials, and the maximum input to the central mix plant shall not exceed ~~80~~ 2,480 tons per calendar day and 5560,000 tons per 12-month period.

5.9 Lime, Aggregate, and Concrete Production Dust Control

The permittee shall control emissions from lime production, aggregate production, and concrete production emission sources (Table 5.1) in accordance with the Fugitive Dust Control Plan.

5.10 Portable Crushing and Screening Plant Water Sprays

The permittee shall install, maintain, and operate water sprays in accordance with the O&M manual (Permit Condition 2.19) to control PM emissions from each portable crushing and screening plant ~~and from Central Mix loading~~. Water sprays shall operate at all times when this equipment is operated to ensure compliance with Fugitive Dust requirements (Permit Conditions 2.1–2.5)

5.11 ~~Building Enclosures~~

~~The Limestone Ball Mill (LSBM) shall be fully enclosed within a building (Ball Mill Building) and all emissions from the limestone ball mill shall be ducted to the baghouse at all times to ensure compliance with limestone ball mill emission limits (Table 5.2).~~

~~The Lime Mill Crusher (LCR) shall be fully enclosed within a building (Lime Kiln Discharge Crusher Building) and all emissions from the lime mill crusher shall be ducted to the baghouse at all times to ensure compliance with lime mill crusher emission limits (Table 5.2).~~

5.12 Parallel Flow Regenerative Kiln Baghouse

The permittee shall install, operate, and maintain a baghouse system (BH4) in accordance with the O&M manual (Permit Condition 2.19) and consistent with manufacturer's recommendations. All emissions from the parallel flow regenerative kiln shall be ducted to the baghouse at all times to ensure compliance with parallel flow regenerative emission limits.

5.13 Limestone Ball Mill Baghouse

The permittee shall install, operate, and maintain a baghouse system (BH3) in accordance with the O&M manual (Permit Condition 2.19) and consistent with manufacturer's recommendations. All emissions from the limestone ball mill kiln shall be ducted to the baghouse at all times to ensure compliance with parallel flow regenerative emission limits (Table 5.2).

5.14 Lime Mill Crusher Baghouse

The permittee shall install, operate, and maintain a baghouse (BH5) in accordance with the O&M manual (Permit Condition 2.19) and consistent with manufacturer's recommendations.

5.15 Pebble Lime Silo Wet Scrubber

The permittee shall install, operate, and maintain a wet scrubber on the Pebble Lime Silo discharge (LS) in accordance with the O&M manual (Permit Condition 2.19) and consistent with manufacturer's recommendations. All emissions during discharge from the Pebble Lime Silo shall be ducted to the wet scrubber to ensure compliance with pebble lime silo emission limits (Table 5.2).

5.16 Silo Bin Vent Filters

The permittee shall install, operate, and maintain a bin vent filter on each silo (LS1, MillS2, ACS1, ACS2, ACS3, ACS4, LS, CS1, CS2) in accordance with the O&M manual (Permit Condition 2.19) and consistent with manufacturer's recommendations. All emissions during loading of each silo shall be ducted to the corresponding bin vent filter to ensure compliance with corresponding silo emission limits (Table 5.2).

Monitoring and Recordkeeping Requirements

5.17 Primary Crusher Monitoring

Each day, the permittee shall monitor and record the material input to the Primary Crusher in tons per calendar (T/day) to demonstrate compliance with the daily Primary Crusher Limit. The devices and methodologies used to measure weights shall be identified in O&M Manual.

5.18 Parallel Flow Regenerative Kiln Limit Monitoring

Each day, the permittee shall monitor and record the material output from the Parallel Flow Regenerative Kiln in tons per calendar day (T/day) to demonstrate compliance with the daily Parallel Flow Regenerative Kiln Limits. The devices and methodologies used to measure weights shall be identified in O&M Manual.

Each month, the permittee shall calculate and record the material output from the Parallel Flow Regenerative Kiln in tons per calendar month (T/mo) and in tons per consecutive 12-month period (T/yr) to demonstrate compliance with the annual Parallel Flow Regenerative Kiln Limit. Annual material output shall be determined by summing the monthly output over the previous consecutive 12-month period.

5.19 Portable Crushing and Screening Plant 1 Input Limit Monitoring

Each day, the permittee shall monitor and record the material input to the Portable Crushing and Screening Plant 1 plant in tons per calendar day (T/day) to demonstrate compliance with the daily Portable Crushing and Screening Plant 1 Input Limit. The devices and methodologies used to measure weights shall be identified in O&M Manual.

5.20 Portable Crushing and Screening Plant 2 Input Limit Monitoring

Each day, the permittee shall monitor and record the material input to the Portable Crushing and Screening Plant 2 plant in tons per calendar day (T/day) to demonstrate compliance with the daily Portable Crushing and Screening Plant 2 Input Limit. The devices and methodologies used to measure weights shall be identified in O&M Manual.

5.21 Central Mix Input Limit Monitoring

Each day, the permittee shall monitor and record the material input to the Central Mix Plant in tons per calendar day (T/day) to demonstrate compliance with the daily Central Mix Input Limit. The devices and methodologies used to measure weights shall be identified in O&M Manual.

Each month, the permittee shall calculate and record the material input to the central mix plant in tons per calendar month (T/mo) and in tons per consecutive 12-month period (T/yr) to demonstrate compliance with the annual Central Mix Input Limit. Annual material input shall be determined by summing the monthly input over the previous consecutive 12-month period.

5.22 Parallel Flow Regenerative Kiln Baghouse Monitoring

The permittee shall install, calibrate, maintain, and operate a device for monitoring the pressure drop across the parallel flow regenerative kiln baghouse. At least once per shift, the permittee shall monitor and record the pressure drop across the parallel flow regenerative kiln baghouse to demonstrate compliance with O&M specifications.

5.23 Limestone Ball Mill Baghouse Monitoring

The permittee shall install, calibrate, maintain, and operate a device for monitoring the pressure drop across the limestone ball mill baghouse. At least once per shift, the permittee shall monitor and record the pressure drop across the limestone ball mill kiln baghouse to demonstrate compliance with O&M specifications.

5.24 Lime Mill Crusher Baghouse Monitoring

The permittee shall install, calibrate, maintain, and operate a device for monitoring the pressure drop across the lime mill crusher baghouse. At least once per shift, the permittee shall monitor and record the pressure drop across the lime mill crusher kiln baghouse to demonstrate compliance with O&M specifications.

5.25 Pebble Lime Silo Wet Scrubber Monitoring

The permittee shall install, calibrate, maintain, and operate a device for monitoring the recirculation flow rate in the pebble lime silo wet scrubber, and the pressure drop across the pebble lime silo wet scrubber. At least once per shift, the permittee shall monitor and record the recirculation flow rate and the pressure drop across the pebble lime silo wet scrubber to demonstrate compliance with O&M specifications.

6 Engines

6.1 Process Description

Stationary internal combustion engines (ICE) for emergency power generation and fire suppression are essential to ensure safety and uninterrupted essential operations in case of unforeseen power failures or emergency situations. Portable diesel-fired light plant engines provide supplemental lighting as needed; these are not regulated by this permit and will be operated as nonroad engines defined in 40 CFR 1068.30.

6.2 Emergency Generator and Fire Pump Engine Operation

Operation of each emergency generator engine (EDG1, EDG2, EDG3) and each fire pump engine (EDFP) shall not exceed 1 hour per calendar day and 100 hours per consecutive 12-month period for non-emergency purposes.

6.3 Emergency Generator and Fire Pump Engine Operation Monitoring

Each calendar month, the permittee shall monitor and record the non-emergency operating hours of each emergency generator and fire pump engine, in hours per calendar month and in hours per consecutive 12-month period to demonstrate compliance with the emergency generator and fire pump engine operation limit.

6.4 Engines Subject to Regulation Notification

With the exception of the emergency generator and fire pump engines (identified in Table 1.1) and engines used to propel vehicles, notification shall be provided to DEQ if an engine (including any previously operated as a nonroad engine) will be operated onsite at a specific location beyond 12 months, and no longer meets criteria for regulation as a nonroad engine. Notification shall be provided as soon as practicable in advance of exceeding 12 months of operation at a single location and within 30 days after the engine ceases to meet the definition of nonroad engine in 40 CFR 1068.30.

- A nonroad engine may include engines that are portable or transportable, meaning designed to be and capable of being carried or moved from one location to another (e.g., portable light plant engines). Indicia of transportability include, but are not limited to, wheels, skids, carrying handles, dolly, trailer, or platform.
- A portable or transportable internal combustion engine is not a nonroad engine if it remains or will remain at a location for more than 12 consecutive months, or a shorter period of time for an engine located at a seasonal source. A location is any single site at a building, structure, facility, or installation. Any engines (or engine) that replace(s) an engine at a location and is intended to perform the same or similar function as the engine(s) replaced are included in calculating the consecutive time period. Permitting requirements and emission standards may become applicable when an engine becomes a stationary source.

7 General Provisions

General Compliance

7.1 The permittee has a continuing duty to comply with all terms and conditions of this permit. All emissions authorized herein shall be consistent with the terms and conditions of this permit and the "Rules for the Control of Air Pollution in Idaho." The emissions of any pollutant in excess of the limitations specified herein, or noncompliance with any other condition or limitation contained in this permit, shall constitute a violation of this permit, the "Rules for the Control of Air Pollution in Idaho," and the Environmental Protection and Health Act (Idaho Code §39-101, et seq).

[Idaho Code §39-101, et seq.]

7.2 The permittee shall at all times (except as provided in the "Rules for the Control of Air Pollution in Idaho") maintain in good working order and operate as efficiently as practicable all treatment or control facilities or systems installed or used to achieve compliance with the terms and conditions of this permit and other applicable Idaho laws for the control of air pollution.

[IDAPA 58.01.01.211, 5/1/94]

7.3 Nothing in this permit is intended to relieve or exempt the permittee from the responsibility to comply with all applicable local, state, or federal statutes, rules, and regulations.

[IDAPA 58.01.01.212.01, 5/1/94]

Inspection and Entry

7.4 Upon presentation of credentials, the permittee shall allow DEQ or an authorized representative of DEQ to do the following:

- Enter upon the permittee's premises where an emissions source is located, emissions-related activity is conducted, or where records are kept under conditions of this permit;
- Have access to and copy, at reasonable times, any records that are kept under the conditions of this permit;
- Inspect at reasonable times any facilities, equipment (including monitoring and air pollution control equipment), practices, or operations regulated or required under this permit; and
- As authorized by the Idaho Environmental Protection and Health Act, sample or monitor, at reasonable times, substances or parameters for the purpose of determining or ensuring compliance with this permit or applicable requirements.

[Idaho Code §39-108]

Construction and Operation Notification

7.5 This permit shall expire if construction has not begun within two years of its issue date, or if construction is suspended for one year.

[IDAPA 58.01.01.211.02, 5/1/94]

7.6 The permittee shall furnish DEQ written notifications as follows:

- A notification of the date of initiation of construction, within five working days after occurrence; except in the case where pre-permit construction approval has been granted then notification shall be made within five working days after occurrence or within five working days after permit issuance whichever is later;
- A notification of the date of any suspension of construction, if such suspension lasts for one year or more; and

- A notification of the initial date of achieving the maximum production rate, within five working days after occurrence - production rate and date.

[IDAPA 58.01.01.211.01, 5/1/94]

- A notification of the anticipated date of initial start-up of the stationary source or facility not more than sixty days or less than thirty days prior to such date; and
- A notification of the actual date of initial start-up of the stationary source or facility within fifteen days after such date.

[IDAPA 58.01.01.211.03, 5/1/94]

Performance Testing

7.7 If performance testing (air emissions source test) is required by this permit, the permittee shall provide notice of intent to test to DEQ at least 15 days prior to the scheduled test date or shorter time period as approved by DEQ. DEQ may, at its option, have an observer present at any emissions tests conducted on a source. DEQ requests that such testing not be performed on weekends or state holidays.

7.8 All performance testing shall be conducted in accordance with the procedures in IDAPA 58.01.01.157. Without prior DEQ approval, any alternative testing is conducted solely at the permittee's risk. If the permittee fails to obtain prior written approval by DEQ for any testing deviations, DEQ may determine that the testing does not satisfy the testing requirements. Therefore, at least 30 days prior to conducting any performance test, the permittee is encouraged to submit a performance test protocol to DEQ for approval. The written protocol shall include a description of the test method(s) to be used, an explanation of any or unusual circumstances regarding the proposed test, and the proposed test schedule for conducting and reporting the test.

7.9 Within 60 days following the date in which a performance test required by this permit is concluded, the permittee shall submit to DEQ a performance test report. The report shall include a description of the process, identification of the test method(s) used, equipment used, all process operating data collected during the test period, and test results, as well as raw test data and associated documentation, including any approved test protocol.

[IDAPA 58.01.01.157, 4/5/00 and 4/11/15]

Monitoring and Recordkeeping

7.10 The permittee shall maintain sufficient records to ensure compliance with all of the terms and conditions of this permit. Monitoring records shall include, but not be limited to, the following: (a) the date, place, and times of sampling or measurements; (b) the date analyses were performed; (c) the company or entity that performed the analyses; (d) the analytical techniques or methods used; (e) the results of such analyses; and (f) the operating conditions existing at the time of sampling or measurement. All monitoring records and support information shall be retained for a period of at least five years from the date of the monitoring sample, measurement, report, or application. Supporting information includes, but is not limited to, all calibration and maintenance records, all original strip-chart recordings for continuous monitoring instrumentation, and copies of all reports required by this permit. All records required to be maintained by this permit shall be made available in either hard copy or electronic format to DEQ representatives upon request.

[IDAPA 58.01.01.211, 5/1/94]

Excess Emissions

7.11 The permittee shall comply with the procedures and requirements of IDAPA 58.01.01.130–136 for excess emissions due to start-up, shut-down, scheduled maintenance, safety measures, upsets, and breakdowns.

[IDAPA 58.01.01.130–136, 4/5/00]

Certification

7.12 All documents submitted to DEQ—including, but not limited to, records, monitoring data, supporting information, requests for confidential treatment, testing reports, or compliance certification—shall contain a certification by a responsible official. The certification shall state that, based on information and belief formed after reasonable inquiry, the statements and information in the document(s) are true, accurate, and complete.

[IDAPA 58.01.01.123, 5/1/94]

False Statements

7.13 No person shall knowingly make any false statement, representation, or certification in any form, notice, or report required under this permit or any applicable rule or order in force pursuant thereto.

[IDAPA 58.01.01.125, 3/23/98]

Tampering

7.14 No person shall knowingly render inaccurate any monitoring device or method required under this permit or any applicable rule or order in force pursuant thereto.

[IDAPA 58.01.01.126, 3/23/98]

Transferability

7.15 This permit is transferable in accordance with procedures listed in IDAPA 58.01.01.209.06.

[IDAPA 58.01.01.209.06, 4/11/06]

Severability

7.16 The provisions of this permit are severable, and if any provision of this permit to any circumstance is held invalid, the application of such provision to other circumstances, and the remainder of this permit, shall not be affected thereby.

[IDAPA 58.01.01.211, 5/1/94]

Statement of Basis

Permit to Construct No. P-2019.0047
Project ID 62288

Midas Gold Idaho, Inc.
Stibnite, Idaho

Facility ID 085-00011

Draft for Facility Review

July 14, 2020
Morrie Lewis
Permit Writer

The purpose of this Statement of Basis is to satisfy the requirements of IDAPA 58.01.01.et seq, Rules for the Control of Air Pollution in Idaho, for issuing air permits.

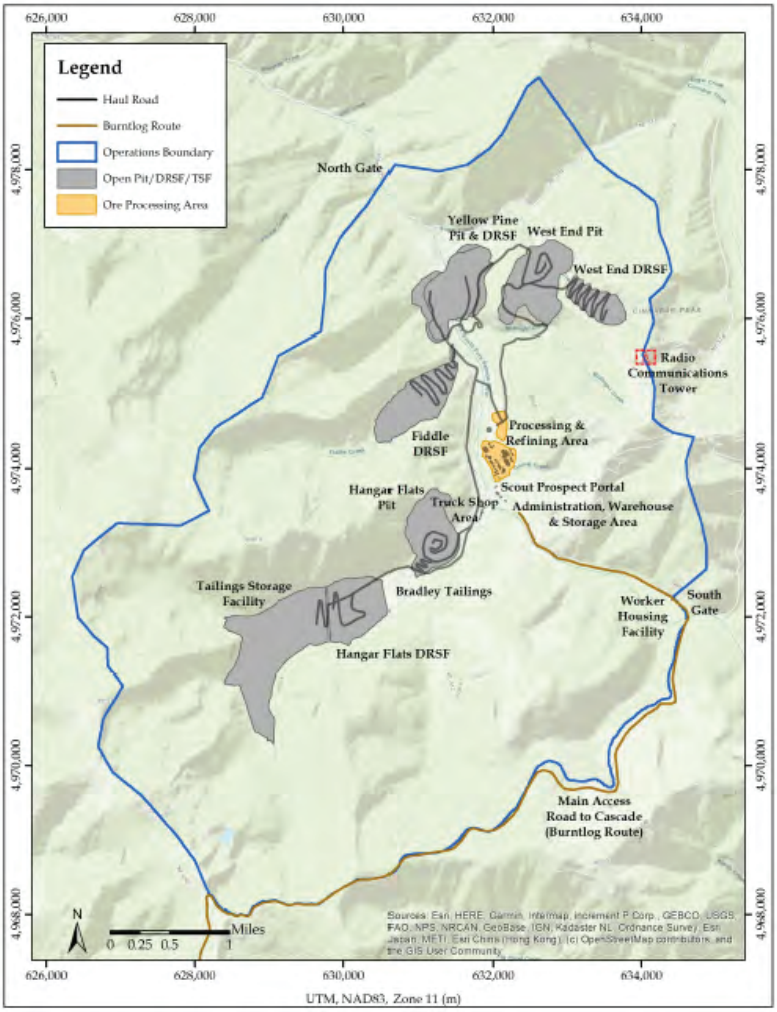
ACRONYMS, UNITS, AND CHEMICAL NOMENCLATURE

AAC	acceptable ambient concentrations
AACC	acceptable ambient concentrations for carcinogens
acfm	actual cubic feet per minute
ANFO	ammonium nitrate/fuel oil
ASTM	American Society for Testing and Materials
bkW	brake kilowatt
BT	Bradley Tailings
Btu	British thermal units
CAA	Clean Air Act
CAM	Compliance Assurance Monitoring
CAS No.	Chemical Abstracts Service registry number
CEMS	continuous emission monitoring systems
cfm	cubic feet per minute
CFR	Code of Federal Regulations
CI	compression ignition
CMS	continuous monitoring systems
CO	carbon monoxide
CO_2	carbon dioxide
CO_2e	CO_2 equivalent emissions
COMS	continuous opacity monitoring systems
DEQ	Department of Environmental Quality
DR	development rock
DRSF	development rock storage facilities
dscf	dry standard cubic feet
EF	emission factors
EL	screening emission levels
EPA	U.S. Environmental Protection Agency
FDCP	Fugitive Dust Control Plan
FDRSF	Fiddle Development Rock Storage Facility
GACT	Generally Available Control Technology
gpm	gallons per minute
gr	grains (1 lb = 7,000 grains)
H_2SO_4	Sulfuric Acid gas
HAP	hazardous air pollutants
HFDRSF	Hangar Flats Development Rock Storage Facility
HFP	Hangar Flats Pit
Hg	mercury
hp	horsepower
hr/yr	hours per consecutive 12-calendar-month period
HVAC	heating, ventilation, and air conditioning
ICE	internal combustion engines
IDAPA	a numbering designation for all administrative rules in Idaho promulgated in accordance with the Idaho Administrative Procedures Act
km	kilometers
lb/hr	pounds per hour
lb/qtr	pound per quarter
LMP	lime manufacturing plant
Midas Gold	Midas Gold Idaho, Inc.
MACT	Maximum Achievable Control Technology
MMBtu	million British thermal units
MMscf	million standard cubic feet

NAAQS	National Ambient Air Quality Standard
NESHAP	National Emission Standards for Hazardous Air Pollutants
NF	National Forest System road
NO_2	nitrogen dioxide
NO_x	oxides of nitrogen
NSPS	New Source Performance Standards
NSR	New Source Review
O&M	operation and maintenance
O_2	oxygen
PAH	polycyclic aromatic hydrocarbons
Pb	lead
PM	particulate matter
$PM_{2.5}$	particulate matter with an aerodynamic diameter less than or equal to a nominal 2.5 micrometers
PM_{10}	particulate matter with an aerodynamic diameter less than or equal to a nominal 10 micrometers
POM	polycyclic organic matter
POX	pressure oxidation
ppm	parts per million
PSD	Prevention of Significant Deterioration
PTC	permit to construct
PTE	potential to emit
PW	process weight rate
RICE	reciprocating internal combustion engines
Rules	*Rules for the Control of Air Pollution in Idaho*
SAG	semi-autogenous grinding
scf	standard cubic feet
SCL	significant contribution limits
SGP	Stibnite Gold Project
SIP	State Implementation Plan
SM	synthetic minor
SM80	synthetic minor facility with emissions greater than or equal to 80% of a major source threshold
SO_2	sulfur dioxide
STKP	crusher stockpile
T/day	tons per calendar day
T/hr	tons per hour
T/yr	tons per consecutive 12-calendar-month period
TAP	toxic air pollutants
TSF	tailings storage facility
ULSD	ultra-low sulfur diesel
U.S.C.	United States Code
VOC	volatile organic compounds
WEDRSF	West End Development Rock Storage Facility
WEP	West End pit
YPDRSF	Yellow Pine Development Rock Storage Facility
YPP	Yellow Pine Pit
$\mu g/m^3$	micrograms per cubic meter

REC 0773

PET 407



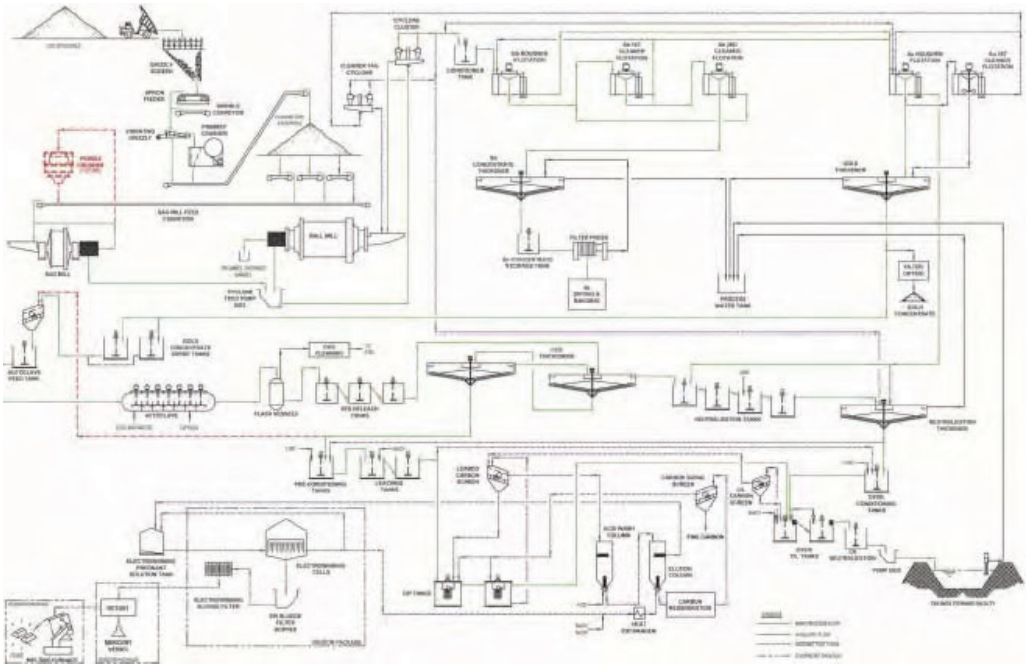
FACILITY INFORMATION

Description

Midas Gold Idaho, Inc. (Midas Gold) proposes to construct and operate the Stibnite Gold Project (SGP), consisting of conventional open-pit mining, ore preparation, and gold extraction operations.

SGP is to be located in Valley County at the intersection Forest Service roads NF-374 and NF-412 (Stibnite Road), approximately 10 miles east of Yellow Pine. The proposed Burntlog Route access road will provide year-round access to the site. The project comprises a combination of public national forest and private lands. The mining operations boundary within which public access will be excluded is defined in Figure 1. This operations boundary also defines the ambient air boundary used in all ambient air quality impact analyses.

Figure 1 PROJECT AREA OF OPERATIONS



SGP will require the construction of significant infrastructure, including a power transmission line, a primary mine site access road, onsite haul roads, an ore processing facility, onsite workspaces, employee housing and recreation, water storage and distribution facilities, and sewage disposal facilities.

Conventional open-pit mining methods including drilling, blasting, excavating, and hauling will be used to extract ore and waste rock, termed development rock (DR). Hydraulic shovels and front-end loaders will be used to load ore and DR into haul trucks. DR will be used for construction, restoration, and backfilling, or hauled to the dedicated development rock storage facilities (DRSF). Approximately 340 million tons of DR will be handled over the life of the mine.

The SGP will include three years of pre-mining development and construction activities, followed by an operating mine life of approximately 12 years. Mining will occur in three open pits: Yellow Pine Pit (YPP), Hangar Flats pit (HFP), and West End pit (WEP). Although there will be overlap in mine development construction and operations, the general sequence of mining will be the YPP deposit, followed by the HFP and WEP deposits. Legacy tailings from the Meadow Creek valley (Bradley Tailings [BT]) will also be reclaimed and reprocessed during the initial project schedule. Surface exploration drilling will occur within the pits and within the Scout Prospect decline (underground exploration) throughout the mine operation period. Restoration and reclamation of other legacy mining features will occur prior to mining, throughout the life of the mine, and as part of the mine closure.

Figure 2 DIAGRAM OF PROCESS FLOWS

Ore will be hauled to the primary crusher area, where it will be fed directly into the crusher dump pocket or stockpiled. The ore crushing plant will be designed to operate at a maximum rate of 25,000 tons per calendar day (T/day). Approximately 100 million tons of ore will be mined from the three pits over the life of the project. The metal-recovery process from ore will include conventional crushing and grinding, followed by froth-flotation circuits that will generate separate gold-silver and antimony-silver concentrates. The antimony-silver concentrate will be shipped offsite for refining, whereas additional onsite processing of the gold-silver concentrate will include pressure oxidation, carbon-in-leach circuits, and refining processes to recover gold and minor amounts of silver. The finely ground leftover ore material from the mineral-recovery process, termed tailings, will be neutralized, thickened, and transported via a pipeline to the tailings storage facility (TSF). A diagram of ore processing and ore concentration and refining process flows is provided in Figure 2.

Permitting History

This is the initial PTC for a new facility, thus there is no permitting history.

Application Scope

This permit is the initial PTC for this facility.

The applicant has proposed to conduct mining operations and to install and operate ore processing, ore concentration and refining, and ancillary equipment:

- Drilling, blasting, excavating, and hauling operations;
- Ore processing operations (OC1–OC13, PS);
- Ore concentration and refining operations (AC, EW, MR, MF, CKD, Sb2);
- Process heating (Sb1, ACB, CKB, PV, HS, LKC);
- Lime production operations (LS1–LS12, LSBM, LS-L/U, LK, LCR, LS1-L/U, MillS2-L/U, ACS1–ACS4);
- Aggregate production operations (PCSP1, PCSP2);
- Concrete production operations (CM; CS1–CS2-L/U, CA-L/U);
- Heating, Ventilation, and Air Conditioning heaters (H1M–H2M, HM, HAC, HR, HA, HMO, HTS, HW);
- Emergency generator engines (EDG1–EDG3, EDFP); and
- Fuel storage (TG1–TG2, TD3—TD10).

Application Chronology

August 20, 2019	DEQ received an application and an application fee.
August 29 – September 13, 2019	DEQ provided an opportunity to request a public comment period on the application and proposed permitting action.
September 19, 2019	DEQ determined that the application was incomplete.
October 4, 2019	DEQ received a preliminary response and supplemental information from the applicant, including a request to delegate authority of responsible official.
October 9, 2019	DEQ approved the request to delegate authority of responsible official.
October 15, 2019	DEQ met with the applicant to review and discuss the preliminary response.
October 22, 2019	DEQ determined that the application remained incomplete while the applicant prepared a response to remaining items previously identified

	(9/19/19), and included a summary of recommendations provided at the meeting (10/15/19).
November 8, 2019	DEQ requested additional information from the applicant via email, relating to items previously identified (9/19/19).
November 27, 2019	DEQ received supplemental information from the applicant, including a revised application with updated emission inventories and modeling analyses.
December 24, 2019	DEQ determined that the application was incomplete.
February 5, 2020	DEQ received supplemental information from the applicant, including a revised application with updated emission inventories and modeling analyses.
March 6, 2019	DEQ determined that the application was incomplete.
April 15, 2020	DEQ received supplemental information from the applicant, including updated modeling analyses.
May 15, 2020	DEQ determined that the application was complete.
July 6, 2020	DEQ made available the draft permit and statement of basis for peer and regional office review.
July 14, 2020	DEQ made available the draft permit and statement of basis for applicant review.
Month XX – Month XX, 2020	DEQ provided a public comment period on the proposed action.
Month XX, 2020	DEQ received the permit processing fee.
DRAFT	DEQ issued the final permit and statement of basis.

TECHNICAL ANALYSIS

Emissions Units and Control Equipment

Table 1 EMISSIONS UNIT AND CONTROL EQUIPMENT INFORMATION

Information presented in Table 1 is for information purposes only and is unenforceable unless included in another permit condition.

Comment [A1]: Please update as per comments provided on the draft PTC.

Source ID No.	Source	Control Equipment	Maximum Process Rate
Mining			
	Drilling activities	Reasonable control and Fugitive Dust Control Plan (FDCP)	1,200 holes/day
	Blasting activities	Reasonable control & FDCP	2 blasts/day
	Excavating and hauling activities	Reasonable control & FDCP – Chemical suppression and water sprays Control efficiency: 93.3% for PM/PM_{10} (haul roads)	180,000 T/day and 490,000 mi/mo (combined mileage of all haul trucks)
Ore Processing			
OC1	Conveyor – Loader Transfer of Ore to Grizzly	Reasonable control & FDCP – Water sprays and moisture carryover	25,000 T/day
OC2	Conveyor – Grizzly to Apron Feeder		
OC3	Conveyor – Apron Feeder to Dribble		
OC4	Conveyor – Apron Feeder to Grizzly		
OC5	Conveyor – Dribble to Grizzly		
OC6	Conveyor – Grizzly to Primary Crusher or Coarse Ore Stockpile Feed		
OC7	Primary Crusher	Reasonable control & FDCP – Water sprays and moisture carryover	
OC8	Conveyor – Coarse Ore Stockpile Feed Transfer to Stockpile		
OC9	Conveyor – Stockpile Transfer to Reclaim Conveyors	Reasonable control & FDCP – Below-grade storage piles Control efficiency: 80% for PM/PM_{10}	27,600 T/day
OC10	Conveyor – Reclaim Conveyors to SAG Mill Feed Conveyor		
OC11	Conveyor – SAG Mill Feed Transfer to SAG Mill	Reasonable control & FDCP – Enclosure Control efficiency: 80% for PM/PM_{10}	
OC12	Pebble Crusher	Reasonable control & FDCP – Water sprays and moisture carryover	
OC13	Conveyor – Pebble Discharge to SAG Mill Feed		
PS	(2) Prill Silos #1-2 Maximum capacity: 100 T (each)	Loading – None Unloading – None	608 T/month (combined)
Ore Concentration and Refining			
AC	Autoclave (AC)	Wet Scrubber (WS1)	6,960 T/day, and as limited by Subpart EEEEEEE
EW	Electrowinning Cells and Pregnant Solution Tank	Shared Carbon Filter (CA2) Type: sulfur-impregnated activated carbon Form: granulated	100 gpm, and as limited by Subpart EEEEEEE
MR	Mercury Retort	Condenser Carbon Filter (CA3) Type: sulfur-impregnated activated carbon Form: granulated	1,000 lb/batch and 21 T/yr
MF	Induction Melting Furnace	Baghouse (BH2) Carbon Filter (CA4) Type: sulfur-impregnated activated carbon Form: granulated	
CKD	Carbon Regeneration Kiln (Drum)	Wet Scrubber (WS2) Carbon Filter (CA1) Type: sulfur-impregnated activated carbon Form: granulated	7.2 T/day
Sb2	Antimony Bagging	Baghouse (BH1)	108 T/day, or as limited by source testing

Source ID No.	Source	Control Equipment	Maximum Process Rate
Lime Production			
LS1	Conveyor – Limestone to Primary Crusher Hopper	None	1,130 T/day
LS2	SAG Mill Primary Crusher Maximum capacity: 1,130 T/day	None	
LS3	Primary Screen	None	
LS4	SAG Mill Secondary Crusher	None	
LS5	Secondary Screen	None	
LS6	Conveyor – Limestone to Ball Mill Feed Bin	None	
LSBM	Limestone Ball Mill	Baghouse (BH3)	
LS7	Conveyor – Limestone to Ball Mill Feed	None	
LS8	Conveyor – Ball Mill Feed to Ball Mill	None	
LS9	Conveyor – Limestone to Kiln Feed Bin	None	267 T/day
LS10	Conveyor – Limestone to Lime Kiln Feed	None	
LS11	Fines Screen	None	
LS12	Conveyor – Kiln Feed to PFR Shaft Lime Kiln	None	
LS-L/U	Bucket Elevator – Pebble Lime Silo Loading	Loading – Bin Vent Filter	169 T/day and 52,377 T/yr
	Pebble Lime Silo discharge to Lime Slaker	Unloading – Wet Scrubber (WS3)	
LK	Parallel Flow Regenerative Shaft Kiln	Baghouse (BH4)	
LCR	Lime Mill Crusher	Baghouse (BH5)	
LS1-L/U	SAG Mill Lime Silo #1 Maximum capacity: 250 T	Loading – Bin Vent Filter Unloading – None	
MillS2-L/U	SAG Mill Lime Silo #2 Maximum capacity: 250 T	Loading – Bin Vent Filter Unloading – None	
ACS1	AC Lime Silo #1 Maximum capacity: 1,000 T	Loading – Bin Vent Filter Unloading – None	
ACS2	AC Lime Silo #2 Maximum capacity: 1,000 T	Loading – Bin Vent Filter Unloading – None	
ACS3	AC Lime Silo #3 Maximum capacity: 1,000 T	Loading – Bin Vent Filter Unloading – None	
ACS4	AC Lime Silo #4 Maximum capacity: 500 T	Loading – Bin Vent Filter Unloading – None	

Source ID No.	Source	Control Equipment	Maximum Process Rate
Aggregate Production			
PCSP1	Portable Crushing and Screening Plant 1 Crushers, screens, and conveyors	Reasonable control & FDCP – water sprays and moisture carryover	2,000 T/day (aggregate)
PCSP2	Portable Crushing and Screening Plant 2 Crushers, screens, and conveyors	Reasonable control & FDCP – water sprays and moisture carryover	2,000 T/day (aggregate)
Concrete Production			
CM	Central Mixer Loading Maximum capacity: 20 T/hr	Reasonable control & FDCP – Water sprays and moisture carryover, and may also include enclosures, hoods, curtains, shrouds, movable and telescoping chutes, central duct collection systems, etc.	80 T/day and 60,000 T/yr (cement + aggregate)
CS1-L/U	Cement/Shotcrete Silo #1 Maximum capacity: 80 T	Loading – Bin Vent Filter Unloading – None	
CS2-L/U	Cement/Shotcrete Silo #2 Maximum capacity: 80 T	Loading – Bin Vent Filter Unloading – None	
CA-L/U	Aggregate Bin Maximum capacity: 2,400 T	Loading – None Unloading – None	
Process Heating			
Sb1	Sb Dryer Maximum capacity: 2.72 MMBtu/hr Fuel: propane	None	not applicable (n/a)
ACB	POX Boiler Maximum capacity: 17 MMBtu/hr Fuel: propane	None	1 hr/day and 30 hr/yr
CKB	Carbon Regeneration Kiln (Burners) Maximum capacity: 2.255 MMBtu/hr Fuel: propane	None	n/a
PV	Propane Vaporizer Maximum capacity: 0.1 MMBtu/hr Fuel: propane	None	n/a
HS	Strip Circuit Solution Heater Maximum capacity: 5 MMBtu/hr Fuel: propane	None	n/a
LKC	PFR Shaft Lime Kiln Combustion Maximum capacity: 20.5 MMBtu/hr (each) Fuel: propane	None	n/a

Source ID No.	Source	Control Equipment	Maximum Process Rate
Heating, Ventilation, and Air Conditioning (HVAC)			
H1M	Mine Air Heater #1 Maximum capacity: 4 MMBtu/hr Fuel: propane	None	n/a
H2M	Mine Air Heater #2 Maximum capacity: 4 MMBtu/hr Fuel: propane	None	n/a
HM	(4) Mill HVAC Heaters #1-4 Maximum capacity: 1.0 MMBtu/hr (each) Fuel: propane	None	n/a
HAC	Autoclave HVAC Heater Maximum capacity: 0.25 MMBtu/hr Fuel: propane	None	n/a
HR	Refinery HVAC Heater Maximum capacity: 0.25 MMBtu/hr Fuel: propane	None	n/a
HA	Admin HVAC Heater Maximum capacity: 0.25 MMBtu/hr Fuel: propane	None	n/a
HMO	(2) Mine Ops. HVAC Heaters Maximum capacity: 0.25 MMBtu/hr (each) Fuel: propane	None	n/a
HTS	(2) Truck Shop HVAC Heaters Maximum capacity: 1.0 MMBtu/hr (each) Fuel: propane	None	n/a
HW	(3) Warehouse HVAC Heaters Maximum capacity: 1.0 MMBtu/hr (each) Fuel: propane	None	n/a

Source ID No.	Source	Control Equipment	Maximum Process Rate
Emergency Power Generation and Fire Suppression			
EDG1	Camp Emergency Generator Date of construction: 2007 or later Maximum capacity: 1,000 bkW Maximum operation: 100 hr/yr (non-emergency) Fuel: ultra-low sulfur diesel (ULSD) Displacement: <10 L/cyl	EPA Tier 2 technologies	1 hr/day and 100 hr/yr
EDG2	Plant Emergency Generator #1 Date of construction: 2007 or later Maximum capacity: 1,000 bkW Maximum operation: 100 hr/yr (non-emergency) Fuel: ULSD Displacement: <10 L/cyl	EPA Tier 2 technologies	1 hr/day and 100 hr/yr
EDG3	Plant Emergency Generator #2 Date of construction: 2007 or later Maximum capacity: 1,000 bkW Maximum operation: 100 hr/yr (non-emergency) Fuel: ULSD Displacement: <10 L/cyl	EPA Tier 2 technologies	1 hr/day and 100 hr/yr
EDFP	Mill Fire Pump Date of construction: 2009 or later Maximum capacity: 200 bkW Maximum operation: 100 hr/yr Fuel: ULSD Displacement: <10 L/cyl	None	1 hr/day and 100 hr/yr
Fuel Storage			
TG1–TG2	Mine Site Gasoline Tanks (#1 through #2) Maximum capacity: 5,000 gal each	Lids or other appropriate closure with gasketed seal and submerged filling	<100,000 gal/mo
TD3–TD10	Mine Site Diesel Tanks (#3 through #10)	Lids or other appropriate closure	n/a

REC 0782

PET 416

Emissions Inventories

Potential to Emit

IDAPA 58.01.01 defines Potential to Emit (PTE) as the maximum capacity of a facility or stationary source to emit an air pollutant under its physical and operational design. Any physical or operational limitation on the capacity of the facility or source to emit an air pollutant, including air pollution control equipment and restrictions on hours of operation or on the type or amount of material combusted, stored or processed, shall be treated as part of its design if the limitation or the effect it would have on emissions is state or federally enforceable. Secondary emissions did not count in determining the PTE of a facility or stationary source.

Using this definition of PTE, an emissions inventory was developed for the SGP (see Appendix A). Emissions estimates of criteria pollutant and hazardous air pollutant (HAP) PTE were based on project-specific activity rates (e.g., continuous operation with the exception of the POX Boiler and emergency generator engines, design production rates, material haul rates, blasting agent usage rates, etc.), process design (e.g., open-pit mining, electrowinning cells and pregnant solution tank plating, parallel flow regenerative lime production, central mix concrete production, haul fleet, etc.), emission abatement techniques (e.g., dust suppressant, carbon filter, wet scrubber, baghouse, and bin vent filtration control equipment), material characteristics (e.g., moisture content, road silt content, haul route distances, etc.), site conditions (onsite meteorological data, precipitation, etc.), and emission factors based on AP-42,[1] representative source test emissions data, and representative emission limits. Estimated emissions from the autoclave and the carbon regeneration kiln relied on emissions data from representative source test emissions data, scaled to the proposed equipment capacity. Estimated emissions from fuel storage tanks relied on TANKS[2] emission estimation software and projected annual gasoline and ULSD usage rates. Estimated emissions from the emergency generator engines relied on the use of certified engine emission factors.

Uncontrolled PTE

Using the definition of PTE, uncontrolled PTE is then defined as the maximum capacity of a facility or stationary source to emit an air pollutant under its physical and operational design. Any physical or operational limitation on the capacity of the facility or source to emit an air pollutant, including air pollution control equipment and restrictions on hours of operation or on the type or amount of material combusted, stored or processed, shall **not** be treated as part of its design **since** the limitation or the effect it would have on emissions **is not** state or federally enforceable.

The uncontrolled PTE is used to determine if a facility is a "synthetic minor" source of emissions. Synthetic minor sources are facilities that have an uncontrolled PTE for regulated air pollutants or HAP above an applicable major source threshold without permit limits. Based on the uncontrolled PTE shown in Table 2 below and the emissions inventory in Appendix A, Midas Gold will be a "synthetic minor" source of PM, PM_{10}, and $PM_{2.5}$ emissions for new source review and Title V permitting purposes. The uncontrolled PTE for other criteria pollutants and for HAP emissions confirm Midas Gold will be a natural minor source of these emissions.

[1] Compilation of Air Pollutant Emission Factors, AP-42, Volume I, Fifth Edition (AP-42), Section 1.3 –Fuel Oil Combustion, 1.4 –Natural Gas Combustion, 1.5 – LPG Combustion, 3.2 – Natural Gas-Fired Reciprocating Engines, 3.3 – Gasoline and Diesel Industrial Engines, 3.4 – Large Stationary Diesel and All Stationary Dual-Fuel Engines, 8.3 – Ammonium Nitrate, 11.9 – Western Surface Coal Mining, 11.12 – Concrete Batching, 11.17 – Lime Manufacturing, 11.19 – Construction and Aggregate Processing, 13.2 – Fugitive Dust Sources, and 13.3 – Explosives Detonation, Office of Air Quality Planning and Standards Office of Air and Radiation (OAQPS), EPA, updated as of August 2011.

[2] TANKS Storage Tank Emissions Calculation Software Version 4.09D, OAQPS, EPA, released October 5, 2006.

For Midas Gold, uncontrolled PTE was based upon a worst-case for operation of the facility of continuous operation at proposed maximum material throughput and fuel input rates (Table 1), without consideration of control equipment. For batch operations, the number of operations necessary to achieve the proposed daily throughput rates was assumed in estimating emissions (~~LS-L/U, EW,~~ MR, MF~~, CKD, MF, Sb2, ACB, CM~~). Silo loading and unloading operations were assumed to occur at most once per day (LS1-L/U, MillS2-L/U, LS1-L/U, Mill2S-L/U, LS-L/U, PS-L/U, ACS1–ACS4-L/U, PS-L/U, CS1–CS2-L/U, CA-L/U). Fuel storage was based on estimated facility-wide fuel usage rates (TG1, TG2 and TD3-TD10). For the purposes of maintenance and testing, emergency power generation operations were assumed to occur 1 hour per day and 100 hours per year (EDG1–EDG3, EDFP). With the exception of the POX Boiler operated at 1 hour per day of simultaneous operation with the autoclave ~~(at full boiler and autoclave capacity) and 30 hours per year, continuous operation at~~ maximum fuel input rates was assumed for all process heating and HVAC equipment.

Comment [A2]: Please see related comments provided on the draft PTC.

The following table presents the uncontrolled PTE for regulated air pollutants as submitted by the applicant and verified by DEQ staff. See Appendix A for a detailed presentation of the calculations and the assumptions used to determine emissions for each source.

Pre-Project PTE

Pre-project PTE is used to establish the change in emissions at a facility as a result of this project. Because this is a new facility, pre-project emissions are set to zero for all criteria pollutants.

Post-Project PTE

For existing sources, the Post-project PTE is used to establish the change in emissions at a facility and to determine the facility's classification as a result of this project. Post-project PTE includes all permit limits resulting from this project. Midas Gold is a new source, so the post-project PTE is equivalent to the PTE presented in the emissions inventory at Appendix A.

In addition to assuming continuous operation of the facility at the proposed material throughput and fuel input rates, post-project emissions estimates account for the use of baghouse and bin vent filtration, wet scrubber systems, carbon filter systems, water sprays and moisture carryover, and any other control equipment or methods as defined in the Fugitive Dust Control Plan (FDCP).

A variety of factors impact emissions from unpaved roadways, and it was recognized that accurate determination of site-specific parameters characterizing road conditions and vehicle traffic was critical to estimating particulate matter emissions and ambient air impacts. Midas Gold provided site-specific information to support parameters such as silt content, mean vehicle weight, and dust suppressant control efficiencies, and provided an analysis evaluating the conservatism of the resulting emission factor (AP-42).[3] To ensure operation consistent with these parameters and to reasonably control fugitive emissions, compliance with requirements identified in the FDCP is required by the permit. Further discussion of the sensitivity of predicted air quality impacts is provided in the Ambient Air Quality Impact Analyses section.

The following table presents the post-project PTE for criteria pollutants from all emissions units at the facility as determined by DEQ staff, confirming source status as a "synthetic minor" source.. See Appendix A for a detailed presentation of the calculations of these emissions for each emissions unit.

a) Controlled average emission rate in tons per year is an annual average, based on the proposed annual operating scenarios and annual limits.

b) Estimated emissions from the "W3" scenario resulted in the most emissions across most activities, with the exception of material load/unload and wind erosion activities, which occurred in the Y1, H1, W1, and B1 scenarios. Totals reported are for the "W3" scenario.

Fourteen operational scenarios were evaluated by the applicant and verified by DEQ in order to estimate maximum hourly, daily, and annual potential emissions from sources. These scenarios encompassed all feasible origin and destination location combinations for locating ore and development rock. A summary of these scenarios is provided in Table 5. Although drilling, blasting, excavating, and hauling activities are not expected to be confined to a single scenario in practice, emissions in each scenario were conservatively estimated at the maximum daily proposed processing rate (180,000 of ore and rock) to allow for maximum operational flexibility, and to evaluate potential air quality impacts. Scenarios having the greatest potential emissions (i.e., the top seven) were those with the longest origin-to-destination distances, which resulted in increased emissions evident in onsite hauling and material loading and unloading activities. Consequently, the W3 scenario having the maximum origin-to-destination distance (16,415 daily vehicle miles traveled) is representative of maximum potential emissions.

There are numerous sources of fugitive dust emissions at the facility, including drilling and blasting activities, crushing and ore handling equipment, ore and rock storage piles, and unpaved roadways. Calculated at maximum daily processing rates, emissions from these sources would tend to be conservatively estimated. But it is also recognized that uncertainties exist in some of the emission factors used, and that predicted modeled impacts may be sensitive to emissions from such sources. In particular, it may prove challenging to consistently and continuously achieve the targeted level of fugitive dust control for emissions from traffic on unpaved roadways, with over 55 miles of haul truck routes within the mining operations boundary, a fleet of 32 haul trucks weighing between 37 and 357 tons, and a targeted dust control efficiency of 93.3% accomplished by application of both dust suppressant and water controls. Based on this, and the scale of operations, a detailed Fugitive Dust Control Plan (FDCP) was required (Permit Conditions 2.5). It is noted that Midas Gold projected actual annual production at approximately 42.7 million T/yr, or 65% of the permitted annual production limit of 65.7 million T/yr (Permit Condition 3.5), and that as a result actual emissions are expected to be lower than presented.

a) Where ore and rock origin and destination locations as depicted in Figure 1 are abbreviated as follows:
YPP = Yellow Pine Pit, HFP = Hangar Flats pit, WEP = West End pit, BT = Bradley Tailings, STKP = Primary Crusher Stockpile, FDRSF = Fiddle DRSF, HFDRSF = Hangar Flats DRSF, YPDRSF = Yellow Pine DRSF, WEDRSF = West End DRSF, and DRSF = development rock storage facilities.

Change in PTE

For existing source, t~~T~~he change in facility-wide PTE is used to determine if a public comment period may be required and to determine the processing fee per IDAPA 58.01.01.225. The following table presents the facility-wide change in the potential to emit for criteria pollutants which for a new source equals the post project PTE.

Comment [A3]: Footnote (a) is missing.

Toxic Air Pollutant Emissions

A summary of the estimated PTE for emissions increase of non-carcinogenic and carcinogenic toxic air pollutants (TAP) is provided in the following table. Toxic air pollutants (TAP) also classified as hazardous air pollutants (HAP) emitted from sources regulated by National Emission Standards for Hazardous Air Pollutants (NESHAP) were estimated by the applicant. These regulated HAP emissions ~~, but~~ were not required to be evaluated~~included in the evaluation~~ for compliance with TAP increments, in accordance with IDAPA 58.01.01.210.20. Affected sources subject to ~~applicable to~~ Subpart EEEEEEE, Subpart CCCCCC, and Subpart ZZZZ are identified in the incorporation of federal requirements condition (Permit Condition 2.21) and in the MACT/GACT Applicability (40 CFR 63) section. In the event there is a conflict between Permit Condition 2.21 and the listed Subparts in determining applicability, the federal applicability requirements shall apply.

Toxic Air Pollutants	Emissions (lb/hr)				Screening Emission Level [e]		Exceeds Screening Level? (Y/N)
	Propane Combustion (a)	Material Handling (b)	Fugitive Mining (c)	Total TAP (d)	Non-Carcinogenic (lb/hr)	Carcinogenic (lb/hr)	
Sulfuric Acid		2.03E+0		2.03E+0	6.70E-2		**Yes**
Thallium		5.88E-5		5.88E-5	7.00E-3		No
Uranium		5.88E-5		5.88E-5	1.30E-2		No
Vanadium	1.52E-4			1.52E-4	3.00E-3		No
Zinc	1.92E-3			1.92E-3	6.67E-1		No

a) TAP from propane combustion.
b) TAP from material processing.
c) Fugitive TAP from mining activities.
d) Total TAP from all regulated sources and activities. Does not include TAP addressed by NESHAP in accordance with IDAPA 58.01.01.210.20.
e) Non-carcinogenic and carcinogenic screening emission levels (EL) from IDAPA 58.01.01.585-586.
f) Polycyclic aromatic hydrocarbons (PAH) as defined in IDAPA 58.01.01.586.
g) Polycyclic organic matter (POM) as defined in IDAPA 58.01.01.586.

Some of the screening levels ~~changes in emissions rates~~ for non-carcinogenic and carcinogenic TAP were exceeded as a result of this project, triggering modeling. Modeling was required for antimony and sulfuric acid (H_2SO_4) because the 24-hour average non-carcinogenic screening emission levels (EL) in IDAPA 58.01.01.585 were exceeded. Modeling was required for arsenic, cadmium, formaldehyde, and nickel because the annual average carcinogenic EL in IDAPA 58.01.01.586 were exceeded.

Ambient Air Quality Impact Analyses

The applicant has demonstrated preconstruction compliance to DEQ's satisfaction that emissions from this facility will not cause nor significantly contribute to a violation of any ambient air quality standard. The applicant has also demonstrated preconstruction compliance to DEQ's satisfaction that the emissions increase due to this permitting action will not exceed any acceptable ambient concentration (AAC) or acceptable ambient concentration for carcinogens (AACC) for toxic air pollutants (TAP). A summary of the Ambient Air Impact Analysis for TAP is provided in Appendix A.

As presented in the modeling memorandum in Appendix B, the estimated emission rates of PM_{10}, $PM_{2.5}$, SO_2, CO, NO_x, and certain TAP from this project exceeded applicable screening emission levels (EL) and published DEQ modeling thresholds established in IDAPA 58.01.01.585-586 and in the State of Idaho Air Quality Modeling Guideline.[4] Refer to the Emissions Inventories section for additional information concerning the emissions inventories.

Facility-wide emission rate~~s~~ of lead (Pb) ~~and SO_2 were~~was determined to be below the "below regulatory concern" (BRC) threshold level of less than 10% of the "significant" emission rate defined in IDAPA 58.01.01.006 (i.e., less than 0.06 ~~and 4.0 T/yr, respectively~~), and therefore modeling was not required. ~~CO facility-wide emission rates were below published DEQ modeling thresholds, and therefore modeling was not required.~~[5]

[4] Criteria pollutant thresholds in Table 2, State of Idaho Guideline for Performing Air Quality Impact Analyses, Doc ID AQ-011 (September 2013), September 2013, criteria pollutant BRC thresholds as provided in IDAPA 58.01.01.221.01, and DEQ guidance pertaining to BRC (2009ACF12).

[5] Criteria pollutant thresholds in Table 2, State of Idaho Guideline for Performing Air Quality Impact Analyses, Doc ID AQ-011 (September 2013), September 2013, criteria pollutant BRC thresholds as provided in IDAPA 58.01.01.221.01, and DEQ guidance pertaining to BRC (2009ACF12).

With the exception of antimony, arsenic, cadmium, formaldehyde, nickel, and sulfuric acid, estimated emission increases of non-carcinogenic and carcinogenic TAP demonstrated preconstruction compliance with TAP standards, in accordance with IDAPA 58.01.01.210.07 using controlled average emission rates. Modeling analyses conducted in the development of TAP rules supports that if controlled average emission rates do not exceed applicable screening emission levels (EL) in IDAPA 58.01.01.585–586, controlled ambient concentrations are expected to be below the applicable acceptable ambient concentration (AAC/AACC).

Estimated emission increases of antimony, arsenic, cadmium, formaldehyde, nickel, and sulfuric acid demonstrated preconstruction compliance with TAP standards in accordance with IDAPA 58.01.01.210.08 for controlled ambient concentrations. Modeling analyses demonstrated preconstruction compliance with the acceptable ambient concentrations for these non-carcinogens (AAC) and carcinogens (AACC) in IDAPA 58.01.01.585–586. Emission limits consistent with modeled TAP emission rates were established in accordance with IDAPA 58.01.01.210.08. Emission limits (Permit Condition 4.3), operational and material throughput limits (Permit Conditions 3.3–3.8, 4.4–4.10, and 5.4–5.8), fugitive dust control requirements (Permit Conditions 2.1–2.7), and control equipment requirements (Permit Conditions 2.5, 3.9–3.11, 4.11–4.16, and 5.9–5.16) were established to limit nickel, antimony, arsenic, cadmium, formaldehyde, nickel, and sulfuric acid TAP emissions in accordance with IDAPA 58.01.01.210.08.c, to limit Pb to BRC, and to limit PM, PM_{10} ,and $PM_{2.5}$ below the emission rates relied upon in the NAAQS evaluation of ambient air impacts in the modeling analyses.

The applicant has demonstrated preconstruction compliance to DEQ's satisfaction that emissions from this facility will not cause nor significantly contribute to a violation of any ambient air quality standard. The applicant has also demonstrated preconstruction compliance to DEQ's satisfaction that the emissions increase due to this permitting action will not exceed any acceptable ambient concentration (AAC) or acceptable ambient concentration for carcinogens (AACC) for toxic air pollutants (TAP). A summary of the Ambient Air Impact Analysis for TAP is provided in Appendix A.

It was recognized that accurately defining the mining operations boundary and controlling public access within that boundary was critical to estimating ambient air impacts. Midas Gold identified site-specific access control measures used to define the mining operations boundary.[6] To ensure operation consistent with these measures, compliance with requirements identified in an Access Management Plan (AMP) is required (Permit Condition 2.6)~~; the proposed plan is include in Appendix E~~.

An ambient air quality impact analyses document has been crafted by DEQ based on a review of the modeling analysis submitted in the application. That document is part of the final permit package for this permitting action (refer to Appendix B). Refer to the Emissions Inventories section and Appendix A for additional information concerning development of the emissions inventories.

Comment [A4]: GLOBAL: Please update the permit condition references as per comments provided on the draft PTC.

Comment [A5]: Please verify this reference. Appendix A to this report is Emission Inventories.

Comment [A6]: A new AMP will be developed per the requirements of Condition 2.6.

[6] Appendix A – Model Parameter / Assumption / Data Level of Conservatism IDEQ Forms, Stibnite Gold Project Permit to Construct Application, Midas Gold, revised February 5, 2020 (2020AAG1078).

REGULATORY ANALYSIS

Attainment Designation (40 CFR 81.313)

The facility is located in Valley County, which is designated as attainment or unclassifiable for $PM_{2.5}$, PM_{10}, SO_2, NO_2, CO, and Ozone. Refer to 40 CFR 81.313 for additional information.

Facility Classification

The AIRS/AFS facility classification codes are as follows:

For HAP (hazardous air pollutants) only:

A = Use when any one HAP has permitted emissions > 10 T/yr or if the aggregate of all HAP (Total HAP) has permitted emissions > 25 T/yr.

SM80 = Use if a synthetic minor (uncontrolled HAP emissions are > 10 T/yr or if the aggregate of all uncontrolled HAP (Total HAP) emissions are > 25 T/yr and permitted emissions fall below applicable major source thresholds) and the permit sets limits > 8 T/yr of a single HAP or ≥ 20 T/yr of Total HAP.

SM = Use if a synthetic minor (uncontrolled HAP emissions are > 10 T/yr or if the aggregate of all uncontrolled HAP (Total HAP) emissions are > 25 T/yr and permitted emissions fall below applicable major source thresholds) and the permit sets limits < 8 T/yr of a single HAP and/or < 20 T/yr of Total HAP.

B = Use when the potential to emit (i.e. uncontrolled emissions and permitted emissions) are below the 10 and 25 T/yr HAP major source thresholds.

UNK = Class is unknown.

For All Other Pollutants:

A = Use when permitted emissions of a pollutant are > 100 T/yr.

SM80 = Use if a synthetic minor for the applicable pollutant (uncontrolled emissions are > 100 T/yr and permitted emissions fall below 100 T/yr) and permitted emissions of the pollutant are ≥ 80 T/yr.

SM = Use if a synthetic minor for the applicable pollutant (uncontrolled emissions are > 100 T/yr and permitted emissions fall below 100 T/yr) and permitted emissions of the pollutant are < 80 T/yr.

B = Use when the potential to emit (i.e. uncontrolled emissions and permitted emissions) are below the 100 T/yr major source threshold.

UNK = Class is unknown.

Table 8 REGULATED AIR POLLUTANT FACILITY CLASSIFICATION

Pollutant	Uncontrolled PTE (T/yr)	Permitted PTE (T/yr)	Relevant ~~Major Source~~ Thresholds (T/yr)	AIRS/AFS Classification
PM	565	87.3	**100**	SM80
PM_{10}	342	56.3	**100**	SM
$PM_{2.5}$	169	36.4	**100**	SM
SO_2	6.48	6.5	**100**	B
NO_x	37.85	37.9	**100**	B
CO	30.45	30.5	**100**	B
VOC	4.78	4.8	**100**	B
HAP (single)	0.97	0.97	**10**	B
Total HAP	1.80	1.80	**25**	B

Comment [A7]: Major source is not a defined term in IDAPA. Could confuse reader since for PSD major source threshold is 250 TPY

Permit to Construct (IDAPA 58.01.01.201)

The permittee has requested that a PTC be issued to the facility for the proposed new emission sources. Therefore, a permit to construct is required in accordance with IDAPA 58.01.01.220~~0~~1. This permitting action was processed in accordance with the procedures of IDAPA 58.01.01.200-228.

Comment [A8]: 220 is for PTC exemptions.

Tier II Operating Permit (IDAPA 58.01.01.401)

IDAPA 58.01.01.401 ..... Tier II Operating Permit

The application was submitted for a permit to construct (refer to the Permit to Construct (IDAPA 58.01.01.201) section), and an optional Tier II operating permit has not been requested. Therefore, the procedures of IDAPA 58.01.01.400–410 were not applicable to this permitting action.

Particulate Matter – New Equipment Process Weight Limitations (IDAPA 58.01.01.701)

IDAPA 58.01.01.701 ..... Particulate Matter – New Equipment Process Weight Limitations

IDAPA 58.01.01.700 through 703 set PM emission limits for process equipment based on when the piece of equipment commenced operation and the piece of equipment's process weight (PW) in pounds per hour (lb/hr). IDAPA 58.01.01.701 establishes PM emission limits for equipment that commenced operation on or after October 1, 1979.

For equipment commencing operation on or after October 1, 1979, the PM allowable emission rate (E) is based on one of the following equations:

IDAPA 58.01.01.701.01.a: If PW is < 9,250 lb/hr; $E = 0.045\ (PW)^{0.60}$

IDAPA 58.01.01.701.01.b: If PW is ≥ 9,250 lb/hr; $E = 1.10\ (PW)^{0.25}$

For the new ore processing, ore concentration and refining, lime production, aggregate production, and concrete production equipment sources (Table 1) emissions (E) were calculated at the proposed maximum throughput rates (Table 1), and estimated emissions from all sources demonstrated compliance with this requirement. Compliance with operational and material throughput limits (Permit Conditions 3.3–3.8, 4.4–4.10, and 5.4–5.8) and control equipment requirements (Permit Conditions 2.5, 3.9–3.11, 4.11–4.16, and 5.9–5.16) assure compliance with this standard, resulting in much lower emission rates.

Mercury Emission Standard for New or Modified Sources

IDAPA 58.01.01.215..... Mercury Emission Standard for New or Modified Sources

IDAPA 58.01.01.215 sets requirements for mercury emissions. No owner or operator may commence construction or modification of a stationary source or facility that results in an increase in annual potential emissions of mercury of 25 pounds or more unless a PTC is obtained and Mercury Best Available Control Technology (MBACT) determined. For this standard, fugitive emissions shall not be included in a determination of applicability, and new or modified stationary sources within a source category subject to NESHAP 40 CFR 63 are exempt. As identified in the MACT/GACT Applicability (40 CFR 63) section, sources addressed by NESHAP 40 CFR 63, Subpart EEEEEEE (AC, EW, MR, MF, CKD), Subpart ZZZZ (EDG1, EDG2, EDG3, and EDFP), and Subpart CCCCCC (TG1, TG2) were exempt from this standard. Emissions from drilling, blasting, material handling (excavating), roadways (hauling), dozing, grading, storage piles, and other fugitive and mobile emission sources were also exempt from this standard.

Mercury emissions from the applicable process sources (non-fugitive and non-NESHAP) were estimated to be less than 0.2 pounds per year (lb/yr), below the level at which MBACT review is required.

Title V Classification (IDAPA 58.01.01.300, 40 CFR Part 70)

IDAPA 58.01.01.301..... Requirement to Obtain Tier I Operating Permit

Any source subject to 40 CFR 63, Subpart EEEEEEE is a Tier I source as defined in IDAPA 58.01.01.006.122.c. In accordance with IDAPA 58.01.01.313.01.b., 40 CFR 70.3(c)(2), and 40 CFR 63.11640(d), the permittee must submit a complete application to DEQ for an initial Tier I operating permit within 12 months of becoming a Tier I source.

Midas Gold has committed to applying for a Tier I permit. Detailed federal regulatory applicability were provided in the PTC application, and specific federally-applicable requirements will be incorporated into the Tier I. Refer to the NSPS Applicability (40 CFR 60), NESHAP Applicability (40 CFR 61), and MACT/GACT Applicability (40 CFR 63) sections below for additional information regarding applicable requirements.

Post-project facility-wide emissions from this facility do not have a PTE greater than 100 tons per year for criteria pollutants or 10 tons per year for any one HAP or 25 tons per year for all HAP combined as demonstrated previously in the Emissions Inventories section of this analysis. Although not a major facility as defined in IDAPA 58.01.01.008.10, any source subject to 40 CFR 63, Subpart EEEEEEE is a Tier I source as defined in IDAPA 58.01.01.006.122.c. In accordance with IDAPA 58.01.01.313.01.b., 40 CFR 70.3(c)(2), and 40 CFR 63.11640(d), the permittee must submit a complete application to DEQ for an initial Tier I operating permit within 12 months of becoming a Tier I source. Refer to the NESHAP Applicability (40 CFR 61) section for additional discussion of Subpart EEEEEEE applicability.

Permit Condition 2.23 incorporates the requirement to obtain a Tier I permit in accordance with IDAPA 58.01.01.313.01.b., 40 CFR 70.3(c)(2), and 40 CFR 63.11640(d).

Comment [A9]: Added to specify that the Tier I operating permit is required only for the emission units that cause the source to be subject to the part 70 program.

PSD Classification (40 CFR 52.21)

40 CFR 52.21 ..... Prevention of Significant Deterioration of Air Quality

The facility is not a major stationary source as defined in 40 CFR 52.21(b)(1), nor is it undergoing any physical change at a stationary source not otherwise qualifying under paragraph 40 CFR 52.21(b)(1) as a major stationary source which would constitute a major stationary source by itself as defined in 40 CFR 52. PSD requirements were therefore not applicable to this permitting action in accordance with 40 CFR 52.21(a)(2).

The facility includes a lime manufacturing plant (LMP) that uses a Parallel Flow Regenerative Shaft Kiln (LK, LKC) to produce lime product from limestone by calcination, which is a designated facility as defined in 40 CFR 52.21(b)(1)(i)(a). For each criteria pollutant, LMP emissions do not exceed 100 T/yr and facility-wide emissions do not exceed 250 T/yr.

NSPS Applicability (40 CFR 60)

The project emissions units were reviewed for NSPS applicability. ~~The permittee has affected facilities subject to the following New Source Performance Standards (NSPS).~~ The POX Boiler (ACB) meets the definition of process heater rather than steam generating unit, and the use of a rotary lime kiln has not been proposed in the production of lime; therefore Subpart Dc and Subpart HH are not applicable. Applicability determinations and regulatory analyses are provided below.

- Standards of Performance for New Stationary Sources (NSPS) 40 CFR 60, Subpart A – General Provisions. DEQ is delegated this Subpart.
- NSPS 40 CFR 60, Subpart LL – Standards of Performance for Metallic Mineral Processing Plants. DEQ is delegated this Subpart. Each crusher (OC7, OC12), conveyor belt transfer point (OC1–OC6, OC8–OC11, OC13), and truck unloading station is an affected facility.
- NSPS 40 CFR 60, Subpart OOO – Standards of Performance for Nonmetallic Mineral Processing Plants. DEQ is delegated this Subpart. Each crusher (LS2, LS4), grinding mill (LSBM, OC12), screening operation (LS3, LS5, LS11), belt conveyor (LS6–LS10, LS12), and storage bin is an affected facility.
- NSPS 40 CFR 60, Subpart IIII – Standards of Performance for Stationary Compression Ignition Internal Combustion Engines. DEQ is delegated this Subpart. Each emergency generator engine and fire pump (EDG1, EDG2, EDG3, and EDFP) is an affected facility.

Comment [A10]: Please update the source IDs as per comments provided on the draft PTC.

40 CFR 60, Subpart A ..... General Provisions

§60.1 ..... Applicability

(a) Except as provided in subparts B and C, the provisions of this part apply to the owner or operator of any stationary source which contains an affected facility, the construction or modification of which is commenced after the date of publication in this part of any standard (or, if earlier, the date of publication of any proposed standard) applicable to that facility.

(b) Any new or revised standard of performance promulgated pursuant to section 111(b) of the Act shall apply to the owner or operator of any stationary source which contains an affected facility, the construction or modification of which is commenced after the date of publication in this part of such new or revised standard (or, if earlier, the date of publication of any proposed standard) applicable to that facility.

Because the permittee will own or operate NSPS affected facilities, which have been proposed to commence construction after the date of publication of the relevant applicable NSPS standards (as listed above), general provisions in Subpart A are applicable.

40 CFR 60, Subpart A is incorporated by reference into Permit Condition 2.23, and specific applicable requirements will be incorporated into the Tier I operating permit.

40 CFR 60, Subpart Dc ..... Standards of Performance for Small Industrial-Commercial-Institutional Steam Generating Units

§60.40c ..... Applicability and delegation of authority.

(a) Except as provided in paragraphs (d), (e), (f), and (g) of this section, the affected facility to which this subpart applies is each steam generating unit for which construction, modification, or reconstruction is commenced after June 9, 1989 and that has a maximum design heat input capacity of 29 megawatts (MW) (100 million British thermal units per hour (MMBtu/h)) or less, but greater than or equal to 2.9 MW (10 MMBtu/h).

§60.41c ..... Definitions.

As used in this subpart, all terms not defined herein shall have the meaning given them in the Clean Air Act and in subpart A of this part.

...

Heat input *means heat derived from combustion of fuel in a steam generating unit and does not include the heat derived from preheated combustion air, recirculated flue gases, or exhaust gases from other sources (such as stationary gas turbines, internal combustion engines, and kilns).*

Heat transfer medium *means any material that is used to transfer heat from one point to another point.*

...

Process heater *means a device that is primarily used to heat a material to initiate or promote a chemical reaction in which the material participates as a reactant or catalyst.*

...

Steam generating unit *means a device that combusts any fuel and produces steam or heats water or heats any heat transfer medium. This term includes any duct burner that combusts fuel and is part of a combined cycle system. This term does not include process heaters as defined in this subpart.*

Although the Pressure Oxidation Boiler (POX Boiler) is between 10 and 100 MMBtu/hr in design heat input capacity (17 MMBtu/hr) and is proposed for construction after June 9, 1989, it meets the definition of process heater rather than steam generating unit, and therefore is not applicable to this subpart. The POX Boiler (ACB) is a device used to directly heat ore material via steam injection into the autoclave, to promote chemical oxidation reactions in which the heated ore participates as a reactant. DEQ is delegated this Subpart.

40 CFR 60, Subpart HH..... Standards of Performance for Lime Manufacturing Plants

§60.340..... Applicability and designation of affected facility.

(a) The provisions of this subpart are applicable to each rotary lime kiln used in the manufacture of lime.

(b) The provisions of this subpart are not applicable to facilities used in the manufacture of lime at kraft pulp mills.

(c) Any facility under paragraph (a) of this section that commences construction or modification after May 3, 1977, is subject to the requirements of this subpart.

§60.341..... Definitions.

As used in this subpart, all terms not defined herein shall have the same meaning given them in the Act and in the General Provisions.

(a) Lime manufacturing plant *means any plant which uses a rotary lime kiln to produce lime product from limestone by calcination.*

(b) Lime product *means the product of the calcination process including, but not limited to, calcitic lime, dolomitic lime, and dead-burned dolomite.*

(c) Positive-pressure fabric filter *means a fabric filter with the fans on the upstream side of the filter bags.*

(d) Rotary lime kiln *means a unit with an inclined rotating drum that is used to produce a lime product from limestone by calcination.*

(e) Stone feed *means limestone feedstock and mill scale or other iron oxide additives that become part of the product.*

The use of a rotary lime kiln has not been proposed in the production of lime, and therefore the requirements of Subpart HH are not applicable. DEQ is delegated this Subpart.

40 CFR 60, Subpart LL ..... Standards of Performance for Metallic Mineral Processing Plants

§60.380 ..... Applicability and designation of affected facility.

(a) The provisions of this subpart are applicable to the following affected facilities in metallic mineral processing plants: Each crusher and screen in open-pit mines; each crusher, screen, bucket elevator, conveyor belt transfer point, thermal dryer, product packaging station, storage bin, enclosed storage area, truck loading station, truck unloading station, railcar loading station, and railcar unloading station at the mill or concentrator with the following exceptions. All facilities located in underground mines are exempted from the provisions of this subpart. At uranium ore processing plants, all facilities subsequent to and including the beneficiation of uranium ore are exempted from the provisions of this subpart.

(b) An affected facility under paragraph (a) of this section that commences construction or modification after August 24, 1982, is subject to the requirements of this part.

Because the permittee will own or operate a metallic mineral processing plant with a crusher at an open-pit mine; with crushers, conveyor belt transfer points, and truck unloading stations at the mill or concentrator; and because these are proposed to commence construction after August 24, 1982, requirements in Subpart LL are applicable.

40 CFR 60, Subpart LL is incorporated by reference into Permit Condition 2.23, and specific applicable requirements will be incorporated into the Tier I operating permit.

40 CFR 60, Subpart OOO ..... Standards of Performance for Nonmetallic Mineral Processing Plants

§60.670 ..... Applicability and designation of affected facility.

(a)(1) Except as provided in paragraphs (a)(2), (b), (c), and (d) of this section, the provisions of this subpart are applicable to the following affected facilities in fixed or portable nonmetallic mineral processing plants: each crusher, grinding mill, screening operation, bucket elevator, belt conveyor, bagging operation, storage bin, enclosed truck or railcar loading station. Also, crushers and grinding mills at hot mix asphalt facilities that reduce the size of nonmetallic minerals embedded in recycled asphalt pavement and subsequent affected facilities up to, but not including, the first storage silo or bin are subject to the provisions of this subpart.

(2) The provisions of this subpart do not apply to the following operations: All facilities located in underground mines; plants without crushers or grinding mills above ground; and wet material processing operations (as defined in §60.671).

(b) An affected facility that is subject to the provisions of subparts F or I of this part or that follows in the plant process any facility subject to the provisions of subparts F or I of this part is not subject to the provisions of this subpart.

(c) Facilities at the following plants are not subject to the provisions of this subpart:

(1) Fixed sand and gravel plants and crushed stone plants with capacities, as defined in §60.671, of 23 megagrams per hour (25 tons per hour) or less;

(2) Portable sand and gravel plants and crushed stone plants with capacities, as defined in §60.671, of 136 megagrams per hour (150 tons per hour) or less; and

(3) Common clay plants and pumice plants with capacities, as defined in §60.671, of 9 megagrams per hour (10 tons per hour) or less.

(d)(1) When an existing facility is replaced by a piece of equipment of equal or smaller size, as defined in §60.671, having the same function as the existing facility, and there is no increase in the amount of emissions, the new facility is exempt from the provisions of §§60.672, 60.674, and 60.675 except as provided for in paragraph (d)(3) of this section.

(2) An owner or operator complying with paragraph (d)(1) of this section shall submit the information required in §60.676(a).

(3) An owner or operator replacing all existing facilities in a production line with new facilities does not qualify for the exemption described in paragraph (d)(1) of this section and must comply with the provisions of §§60.672, 60.674 and 60.675.

(e) An affected facility under paragraph (a) of this section that commences construction, modification, or reconstruction after August 31, 1983, is subject to the requirements of this part.

(f) Table 1 of this subpart specifies the provisions of subpart A of this part 60 that do not apply to owners and operators of affected facilities subject to this subpart or that apply with certain exceptions.

Because the project contains crushers, grinding mills, screening operations, belt conveyors, and storage bins in a fixed or portable nonmetallic mineral processing plant, which are proposed to commence construction after August 31, 1983, requirements in Subpart OOO are applicable. The portable crushing and screening plants (PCSP1, PCSP2) will be rated at below 150 tons per hour (T/hr), and are therefore not subject to the provisions of Subpart OOO.

40 CFR 60, Subpart OOO is incorporated by reference into Permit Condition 2.212~~.23~~, and specific applicable requirements will be incorporated into the Tier I operating permit.

40 CFR 60, Subpart IIII..... Standards of Performance for ~~Nonmetallic Mineral Processing Plants~~Stationary Compression Ignition Internal Combustion Engines

§60.4200..... Am I subject to this subpart?

(a) The provisions of this subpart are applicable to manufacturers, owners, and operators of stationary compression ignition (CI) internal combustion engines (ICE) and other persons as specified in paragraphs (a)(1) through (4) of this section. For the purposes of this subpart, the date that construction commences is the date the engine is ordered by the owner or operator.

(1) Manufacturers of stationary CI ICE with a displacement of less than 30 liters per cylinder where the model year is:

(i) 2007 or later, for engines that are not fire pump engines;

(ii) The model year listed in Table 3 to this subpart or later model year, for fire pump engines.

(2) Owners and operators of stationary CI ICE that commence construction after July 11, 2005, where the stationary CI ICE are:

(i) Manufactured after April 1, 2006, and are not fire pump engines, or

(ii) Manufactured as a certified National Fire Protection Association (NFPA) fire pump engine after July 1, 2006.

(3) Owners and operators of any stationary CI ICE that are modified or reconstructed after July 11, 2005 and any person that modifies or reconstructs any stationary CI ICE after July 11, 2005.

(4) The provisions of §60.4208 of this subpart are applicable to all owners and operators of stationary CI ICE that commence construction after July 11, 2005.

(b) The provisions of this subpart are not applicable to stationary CI ICE being tested at a stationary CI ICE test cell/stand.

(c) If you are an owner or operator of an area source subject to this subpart, you are exempt from the obligation to obtain a permit under 40 CFR part 70 or 40 CFR part 71, provided you are not required to obtain a permit under 40 CFR 70.3(a) or 40 CFR 71.3(a) for a reason other than your status as an area source under this subpart. Notwithstanding the previous sentence, you must continue to comply with the provisions of this subpart applicable to area sources.

(d) Stationary CI ICE may be eligible for exemption from the requirements of this subpart as described in 40 CFR part 1068, subpart C (or the exemptions described in 40 CFR part 89, subpart J and 40 CFR part 94, subpart J, for engines that would need to be certified to standards in those parts), except that owners and operators, as well as manufacturers, may be eligible to request an exemption for national security.

(e) Owners and operators of facilities with CI ICE that are acting as temporary replacement units and that are located at a stationary source for less than 1 year and that have been properly certified as meeting the standards that would be applicable to such engine under the appropriate nonroad engine provisions, are not required to meet any other provisions under this subpart with regard to such engines.

Because the permittee will own or operate compression ignition (CI) internal combustion engines (ICE) which are proposed to commence construction after July 11, 2005 and which will be ordered after April 1, 2006 for the emergency generator engines, and which will be ordered after July 1, 2006 for the fire pump engine, requirements in Subpart IIII are applicable. The permittee has not requested or qualified for exemption pursuant to §60.4200(b), (d), or (e).

40 CFR 60, Subpart IIII is incorporated by reference into Permit Condition 2.23, and specific applicable requirements will be incorporated into the Tier I operating permit.

NESHAP Applicability (40 CFR 61)

The facility is not subject to any NESHAP requirements in 40 CFR 61.

MACT/GACT Applicability (40 CFR 63)

The permittee has proposed to operate as a minor source of hazardous air pollutant (HAP) emissions, and has affected facilities subject to the following National Emission Standards for Hazardous Air Pollutants (NESHAP). The lime manufacturing plant is proposed at an area source of HAP, and therefore is not applicable to Subpart AAAAA. Applicability determinations and regulatory analyses are provided below.

- National Emission Standards for Hazardous Air Pollutants for Source Categories (NESHAP) 40 CFR 63, Subpart A – General Provisions. DEQ is delegated this Subpart for Tier I sources.
- NESHAP 40 CFR 63, Subpart ZZZZ – National Emission Standards for Hazardous Air Pollutants for Stationary Reciprocating Internal Combustion Engines (RICE). DEQ is delegated this Subpart. The emergency generator and fire pump engines (EDG1, EDG2, EDG3, and EDFP) are affected sources.
- NESHAP 40 CFR 63, Subpart CCCCCC – National Emission Standards for Hazardous Air Pollutants for Source Category: Gasoline Dispensing Facilities. DEQ is delegated this Subpart for Tier I sources. The gasoline fuel storage tanks (TG1, TG2) are affected sources.
- NESHAP 40 CFR 63, Subpart EEEEEEE – National Emission Standards for Hazardous Air Pollutants: Gold Mine Ore Processing and Production Area Source Category. DEQ is delegated this Subpart for Tier I sources. The collection of ore pretreatment processes and the carbon process with mercury retort are affected sources. Ore pretreatment processes include the autoclave (AC). Carbon processes with mercury retort include the electrowinning cells and pregnant solution tank (EW), the mercury retort (MR), induction melting furnace (MF), and the carbon regeneration kiln (CKD).

40 CFR 63, Subpart A ..... General Provisions

§63.1 ..... Applicability.

(a) General. *(1) Terms used throughout this part are defined in §63.2 or in the Clean Air Act (Act) as amended in 1990, except that individual subparts of this part may include specific definitions in addition to or that supersede definitions in §63.2.*

(2) This part contains national emission standards for hazardous air pollutants (NESHAP) established pursuant to section 112 of the Act as amended November 15, 1990. These standards regulate specific categories of stationary sources that emit (or have the potential to emit) one or more hazardous air pollutants listed in this part pursuant to section 112(b) of the Act. This section explains the applicability of such standards to sources affected by them. The standards in this part are independent of NESHAP contained in 40 CFR part 61. The NESHAP in part 61 promulgated by signature of the Administrator before November 15, 1990 (i.e., the date of enactment of the Clean Air Act Amendments of 1990) remain in effect until they are amended, if appropriate, and added to this part.

(3) No emission standard or other requirement established under this part shall be interpreted, construed, or applied to diminish or replace the requirements of a more stringent emission limitation or other applicable requirement established by the Administrator pursuant to other authority of the Act (section 111, part C or D or any other authority of this Act), or a standard issued under State authority. The Administrator may specify in a specific standard under this part that facilities subject to other provisions under the Act need only comply with the provisions of that standard.

(4)(i) Each relevant standard in this part 63 must identify explicitly whether each provision in this subpart A is or is not included in such relevant standard.

(ii) If a relevant part 63 standard incorporates the requirements of 40 CFR part 60, part 61 or other part 63 standards, the relevant part 63 standard must identify explicitly the applicability of each corresponding part 60, part 61, or other part 63 subpart A (General) provision.

(iii) The General Provisions in this subpart A do not apply to regulations developed pursuant to section 112(r) of the amended Act, unless otherwise specified in those regulations.

…

(b) Initial applicability determination for this part*. (1) The provisions of this part apply to the owner or operator of any stationary source that—*

(i) Emits or has the potential to emit any hazardous air pollutant listed in or pursuant to section 112(b) of the Act; and

(ii) Is subject to any standard, limitation, prohibition, or other federally enforceable requirement established pursuant to this part.

(2) [Reserved]

(3) An owner or operator of a stationary source who is in the relevant source category and who determines that the source is not subject to a relevant standard or other requirement established under this part must keep a record as specified in §63.10(b)(3).

Because the permittee will own or operate stationary sources that emit HAP which are subject to standards, limitations, prohibitions, or other federally-enforceable requirements established pursuant to NESHAP, provisions in Subpart A are applicable.

40 CFR 63, Subpart A is incorporated by reference into Permit Condition 2.23, and specific applicable requirements will be incorporated into the Tier I operating permit.

40 CFR 63, Subpart ZZZZ..... ~~*General Provisions*~~*National Emissions Standards for Hazardous Air Pollutants for Stationary Reciprocating Internal Combustion Engines*

§63.6580..... *What is the purpose of subpart ZZZZ?*

Subpart ZZZZ establishes national emission limitations and operating limitations for hazardous air pollutants (HAP) emitted from stationary reciprocating internal combustion engines (RICE) located at major and area sources of HAP emissions. This subpart also establishes requirements to demonstrate initial and continuous compliance with the emission limitations and operating limitations.

§63.6585..... *Am I subject to this subpart?*

You are subject to this subpart if you own or operate a stationary RICE at a major or area source of HAP emissions, except if the stationary RICE is being tested at a stationary RICE test cell/stand.

(a) A stationary RICE is any internal combustion engine which uses reciprocating motion to convert heat energy into mechanical work and which is not mobile. Stationary RICE differ from mobile RICE in that a stationary RICE is not a non-road engine as defined at 40 CFR 1068.30, and is not used to propel a motor vehicle or a vehicle used solely for competition.

(b) A major source of HAP emissions is a plant site that emits or has the potential to emit any single HAP at a rate of 10 tons (9.07 megagrams) or more per year or any combination of HAP at a rate of 25 tons (22.68 megagrams) or more per year, except that for oil and gas production facilities, a major source of HAP emissions is determined for each surface site.

(c) An area source of HAP emissions is a source that is not a major source.

(d) If you are an owner or operator of an area source subject to this subpart, your status as an entity subject to a standard or other requirements under this subpart does not subject you to the obligation to obtain a permit under 40 CFR part 70 or 71, provided you are not required to obtain a permit under 40 CFR 70.3(a) or 40 CFR 71.3(a) for a reason other than your status as an area source under this subpart. Notwithstanding the previous sentence, you must continue to comply with the provisions of this subpart as applicable.

(e) If you are an owner or operator of a stationary RICE used for national security purposes, you may be eligible to request an exemption from the requirements of this subpart as described in 40 CFR part 1068, subpart C.

(f) The emergency stationary RICE listed in paragraphs (f)(1) through (3) of this section are not subject to this subpart. The stationary RICE must meet the definition of an emergency stationary RICE in §63.6675, which includes operating according to the provisions specified in §63.6640(f).

(1) Existing residential emergency stationary RICE located at an area source of HAP emissions that do not operate or are not contractually obligated to be available for more than 15 hours per calendar year for the purposes specified in §63.6640(f)(2)(ii) and (iii) and that do not operate for the purpose specified in §63.6640(f)(4)(ii).

(2) Existing commercial emergency stationary RICE located at an area source of HAP emissions that do not operate or are not contractually obligated to be available for more than 15 hours per calendar year for the purposes specified in §63.6640(f)(2)(ii) and (iii) and that do not operate for the purpose specified in §63.6640(f)(4)(ii).

(3) Existing institutional emergency stationary RICE located at an area source of HAP emissions that do not operate or are not contractually obligated to be available for more than 15 hours per calendar year for the purposes specified in §63.6640(f)(2)(ii) and (iii) and that do not operate for the purpose specified in §63.6640(f)(4)(ii).

Because the permittee will own or operate stationary RICE at an area source of HAP which are subject to standards, limitations, prohibitions, or other federally-enforceable requirements established pursuant to NESHAP, requirements in Subpart ZZZZ are applicable.

40 CFR 63, Subpart ZZZZ is incorporated by reference into Permit Condition 2.23, and specific applicable requirements will be incorporated into the Tier I operating permit.

40 CFR 63, Subpart AAAAA..... ~~General Provisions~~National Emission Standards for Hazardous Air Pollutants for Lime Manufacturing Plants

§63.7080..... What is the purpose of this subpart?

This subpart establishes national emission standards for hazardous air pollutants (NESHAP) for lime manufacturing plants. This subpart also establishes requirements to demonstrate initial and continuous compliance with the emission limitations.

§63.7081..... Am I subject to this subpart?

(a) You are subject to this subpart if you own or operate a lime manufacturing plant (LMP) that is a major source, or that is located at, or is part of, a major source of hazardous air pollutant (HAP) emissions, unless the LMP is located at a kraft pulp mill, soda pulp mill, sulfite pulp mill, beet sugar manufacturing plant, or only processes sludge containing calcium carbonate from water softening processes.

(1) An LMP is an establishment engaged in the manufacture of lime product (calcium oxide, calcium oxide with magnesium oxide, or dead burned dolomite) by calcination of limestone, dolomite, shells or other calcareous substances.

(2) A major source of HAP is a plant site that emits or has the potential to emit any single HAP at a rate of 9.07 megagrams (10 tons) or more per year or any combination of HAP at a rate of 22.68 megagrams (25 tons) or more per year from all emission sources at the plant site.

(b) [Reserved]

§63.7143..... What definitions apply to this subpart?

Terms used in this subpart are defined in the Clean Air Act, in §63.2, and in this section as follows:

...

Lime manufacturing plant (LMP) *means any plant which uses a lime kiln to produce lime product from limestone or other calcareous material by calcination.*

Lime product *means the product of the lime kiln calcination process including, calcitic lime, dolomitic lime, and dead-burned dolomite.*

Limestone *means the material comprised primarily of calcium carbonate (referred to sometimes as calcitic or high calcium limestone), magnesium carbonate, and/or the double carbonate of both calcium and magnesium (referred to sometimes as dolomitic limestone or dolomite).*

...

The lime manufacturing plant is proposed at an area source of HAP, and therefore is not subject to this Subpart.

40 CFR 60, Subpart CCCCCC..... ~~General Provisions~~National Emission Standards for Hazardous Air Pollutants for Source Category: Gasoline Dispensing Facilities

§63.11110..... What is the purpose of this subpart?

This subpart establishes national emission limitations and management practices for hazardous air pollutants (HAP) emitted from the loading of gasoline storage tanks at gasoline dispensing facilities (GDF). This subpart also establishes requirements to demonstrate compliance with the emission limitations and management practices.

§63.11111..... Am I subject to the requirements in this subpart?

(a) The affected source to which this subpart applies is each GDF that is located at an area source. The affected source includes each gasoline cargo tank during the delivery of product to a GDF and also includes each storage tank.

(b) If your GDF has a monthly throughput of less than 10,000 gallons of gasoline, you must comply with the requirements in §63.11116.

(c) If your GDF has a monthly throughput of 10,000 gallons of gasoline or more, you must comply with the requirements in §63.11117.

(d) If your GDF has a monthly throughput of 100,000 gallons of gasoline or more, you must comply with the requirements in §63.11118.

(e) An affected source shall, upon request by the Administrator, demonstrate that their monthly throughput is less than the 10,000-gallon or the 100,000-gallon threshold level, as applicable. For new or reconstructed affected sources, as specified in §63.11112(b) and (c), recordkeeping to document monthly throughput must begin upon startup of the affected source. For existing sources, as specified in §63.11112(d), recordkeeping to document monthly throughput must begin on January 10, 2008. For existing sources that are subject to this subpart only because they load gasoline into fuel tanks other than those in motor vehicles, as defined in §63.11132, recordkeeping to document monthly throughput must begin on January 24, 2011. Records required under this paragraph shall be kept for a period of 5 years.

(f) If you are an owner or operator of affected sources, as defined in paragraph (a) of this section, you are not required to obtain a permit under 40 CFR part 70 or 40 CFR part 71 as a result of being subject to this subpart. However, you must still apply for and obtain a permit under 40 CFR part 70 or 40 CFR part 71 if you meet one or more of the applicability criteria found in 40 CFR 70.3(a) and (b) or 40 CFR 71.3(a) and (b).

(g) The loading of aviation gasoline into storage tanks at airports, and the subsequent transfer of aviation gasoline within the airport, is not subject to this subpart.

(h) Monthly throughput is the total volume of gasoline loaded into, or dispensed from, all the gasoline storage tanks located at a single affected GDF. If an area source has two or more GDF at separate locations within the area source, each GDF is treated as a separate affected source.

(i) If your affected source's throughput ever exceeds an applicable throughput threshold, the affected source will remain subject to the requirements for sources above the threshold, even if the affected source throughput later falls below the applicable throughput threshold.

(j) The dispensing of gasoline from a fixed gasoline storage tank at a GDF into a portable gasoline tank for the on-site delivery and subsequent dispensing of the gasoline into the fuel tank of a motor vehicle or other gasoline-fueled engine or equipment used within the area source is only subject to §63.11116 of this subpart.

(k) For any affected source subject to the provisions of this subpart and another Federal rule, you may elect to comply only with the more stringent provisions of the applicable subparts. You must consider all provisions of the rules, including monitoring, recordkeeping, and reporting. You must identify the affected source and provisions with which you will comply in your Notification of Compliance Status required under §63.11124. You also must demonstrate in your Notification of Compliance Status that each provision with which you will comply is at least as stringent as the otherwise applicable requirements in this subpart. You are responsible for making accurate determinations concerning the more stringent provisions, and noncompliance with this rule is not excused if it is later determined that your determination was in error, and, as a result, you are violating this subpart. Compliance with this rule is your responsibility and the Notification of Compliance Status does not alter or affect that responsibility.

§63.11132 ..... What definitions apply to this subpart?

As used in this subpart, all terms not defined herein shall have the meaning given them in the Clean Air Act (CAA), or in subparts A and BBBBBB of this part. For purposes of this subpart, definitions in this section supersede definitions in other parts or subparts.

Dual-point vapor balance system *means a type of vapor balance system in which the storage tank is equipped with an entry port for a gasoline fill pipe and a separate exit port for a vapor connection.*

Gasoline *means any petroleum distillate or petroleum distillate/alcohol blend having a Reid vapor pressure of 27.6 kilopascals or greater, which is used as a fuel for internal combustion engines.*

Gasoline cargo tank *means a delivery tank truck or railcar which is loading or unloading gasoline, or which has loaded or unloaded gasoline on the immediately previous load.*

Gasoline dispensing facility (GDF) *means any stationary facility which dispenses gasoline into the fuel tank of a motor vehicle, motor vehicle engine, nonroad vehicle, or nonroad engine, including a nonroad vehicle or nonroad engine used solely for competition. These facilities include, but are not limited to, facilities that dispense gasoline into on- and off-road, street, or highway motor vehicles, lawn equipment, boats, test engines, landscaping equipment, generators, pumps, and other gasoline-fueled engines and equipment.*

Monthly throughput *means the total volume of gasoline that is loaded into, or dispensed from, all gasoline storage tanks at each GDF during a month. Monthly throughput is calculated by summing the volume of gasoline loaded into, or dispensed from, all gasoline storage tanks at each GDF during the current day, plus the total volume of gasoline loaded into, or dispensed from, all gasoline storage tanks at each GDF during the previous 364 days, and then dividing that sum by 12.*

Motor vehicle *means any self-propelled vehicle designed for transporting persons or property on a street or highway.*

Nonroad engine *means an internal combustion engine (including the fuel system) that is not used in a motor vehicle or a vehicle used solely for competition, or that is not subject to standards promulgated under section 7411 of this title or section 7521 of this title.*

Nonroad vehicle *means a vehicle that is powered by a nonroad engine, and that is not a motor vehicle or a vehicle used solely for competition.*

Submerged filling *means, for the purposes of this subpart, the filling of a gasoline storage tank through a submerged fill pipe whose discharge is no more than the applicable distance specified in §63.11117(b) from the bottom of the tank. Bottom filling of gasoline storage tanks is included in this definition.*

Vapor balance system *means a combination of pipes and hoses that create a closed system between the vapor spaces of an unloading gasoline cargo tank and a receiving storage tank such that vapors displaced from the storage tank are transferred to the gasoline cargo tank being unloaded.*

Vapor-tight *means equipment that allows no loss of vapors. Compliance with vapor-tight requirements can be determined by checking to ensure that the concentration at a potential leak source is not equal to or greater than 100 percent of the Lower Explosive Limit when measured with a combustible gas detector, calibrated with propane, at a distance of 1 inch from the source.*

Vapor-tight gasoline cargo tank *means a gasoline cargo tank which has demonstrated within the 12 preceding months that it meets the annual certification test requirements in §63.11092(f) of this part.*

Because the permittee will own or operate a gasoline dispensing facility (GDF) at an area source of HAP, requirements in Subpart CCCCCC are applicable. Because the permittee has committed to loading and dispensing of less than 100,000 gallons of gasoline per month (gal/mo), the requirements of 40 CFR 63.11117 will become applicable in accordance with 40 CFR 63.11111(b) and (c). Gasoline loading and dispensing is limited by Permit Condition 2.17 to avoid requirements applicable to GDF exceeding 100,000 gal/mo, and requires recordkeeping in accordance with 40 CFR 63.11111(e).

40 CFR 63, Subpart CCCCCC is incorporated by reference into Permit Condition 2.23, and specific applicable requirements will be incorporated into the Tier I operating permit.

40 CFR 63, Subpart EEEEEEE..... National Emission Standards for Hazardous Air Pollutants: Gold Mine Ore Processing and Production Area Source Category

§40 CFR 63.11640..... Am I subject to this subpart?

(a) You are subject to this subpart if you own or operate a gold mine ore processing and production facility as defined in §63.11651, that is an area source.

(b) This subpart applies to each new or existing affected source. The affected sources are each collection of "ore pretreatment processes" at a gold mine ore processing and production facility, each collection of "carbon processes with mercury retorts" at a gold mine ore processing and production facility, each collection of "carbon processes without mercury retorts" at a gold mine ore processing and production facility, and each collection of "non-carbon concentrate processes" at a gold mine ore processing and production facility, as defined in §63.11651.

(1) An affected source is existing if you commenced construction or reconstruction of the affected source on or before April 28, 2010.

(2) An affected source is new if you commenced construction or reconstruction of the affected source after April 28, 2010.

(c) This subpart does not apply to research and development facilities, as defined in section 112(c)(7) of the Clean Air Act (CAA).

(d) If you own or operate a source subject to this subpart, you must have or you must obtain a permit under 40 CFR part 70 or 40 CFR part 71.

§40 CFR 63.11651..... What definitions apply to this subpart?

Terms used in this subpart are defined in the Clean Air Act, in §63.2, and in this section as follows:

Autoclave *means a pressure oxidation vessel that is used to treat gold ores (primarily sulfide refractory ore) and involves pumping a slurry of milled ore into the vessel which is highly pressurized with oxygen and heated to temperatures of approximately 350° to 430 °F.*

Calomel-based mercury control system *means a mercury emissions control system that uses scrubbers to remove mercury from the gas stream of a roaster or combination of roasters by complexing the mercury from the gas stream with mercuric chloride to form mercurous chloride (calomel). These scrubbers are also referred to as "mercury scrubbers."*

Carbon adsorber *means a control device consisting of a single fixed carbon bed, multiple carbon beds or columns, carbon filter packs or modules, and other variations that uses activated carbon to remove pollutants from a gas stream.*

Carbon kiln *means a kiln or furnace where carbon is regenerated by heating, usually in the presence of steam, after the gold has been stripped from the carbon.*

Carbon processes with mercury retorts *means the affected source that includes carbon kilns, preg tanks, electrowinning cells, mercury retorts, and melt furnaces at gold mine ore processing and production facilities that use activated carbon, or resins that can be used as a substitute for activated carbon, to recover (adsorb) gold from the pregnant cyanide solution.*

Carbon processes without mercury retorts *means the affected source that includes carbon kilns, preg tanks, electrowinning cells, and melt furnaces, but has no retorts, at gold mine ore processing and production facilities that use activated carbon, or resins that can be used as a substitute for activated carbon, to recover (adsorb) gold from the pregnant cyanide solution.*

Concentrate *means the sludge-like material that is loaded with gold along with various other metals (such as silver, copper, and mercury) and various other substances, that is produced by electrowinning, the Merrill-Crowe process, flotation and gravity separation processes. Concentrate is measured as the input to mercury retorts, or for facilities without mercury retorts, as the input to melt furnaces before any drying takes place. For facilities without mercury retorts or melt furnaces, concentrate is measured as the quantity shipped.*

Deviation *means any instance where an affected source subject to this subpart, or an owner or operator of such a source:*

(1) Fails to meet any requirement or obligation established by this subpart, including but not limited to any emissions limitation or work practice standard;

(2) Fails to meet any term or condition that is adopted to implement an applicable requirement in this subpart and that is included in the operating permit for any affected source required to obtain such a permit; or

(3) Exceeds any operating limit established under this subpart.

Electrowinning *means a process that uses induced voltage on anode and cathode plates to remove metals from the continuous flow of solution, where the gold in solution is plated onto the cathode. Steel wool is typically used as the plating surface.*

Electrowinning Cells *means a tank in which the electrowinning takes place.*

Gold mine ore processing and production facility *means any industrial facility engaged in the processing of gold mine ore that uses any of the following processes: Roasting operations, autoclaves, carbon kilns, preg tanks, electrowinning, mercury retorts, or melt furnaces. Laboratories (see CAA section 112(c)(7)), individual prospectors, and very small pilot scale mining operations that processes or produces less than 100 pounds of concentrate per year are not a gold mine ore processing and production facility. A facility that produces primarily metals other than gold, such as copper, lead, zinc, or nickel (where these metals other than gold comprise 95 percent or more of the total metal production) that may also recover some gold as a byproduct is not a gold mine ore processing and production facility. Those facilities whereby 95 percent or more of total mass of metals produced are metals other than gold, whether final metal production is onsite or offsite, are not part of the gold mine ore processing and production source category.*

Melt furnace *means a furnace (typically a crucible furnace) that is used for smelting the gold-bearing material recovered from mercury retorting, or the gold-bearing material from electrowinning, the Merrill-Crowe process, or other processes for facilities without mercury retorts.*

Mercury retort *means a vessel that is operated under a partial vacuum at approximately 1,100° to 1,300 °F to remove mercury and moisture from the gold bearing sludge material that is recovered from electrowinning, the Merrill-Crowe process, or other processes. Mercury retorts are usually equipped with condensers that recover liquid mercury during the processing.*

Merrill-Crowe process *means a precipitation technique using zinc oxide for removing gold from a cyanide solution. Zinc dust is added to the solution, and gold is precipitated to produce a concentrate.*

Non-carbon concentrate processes *means the affected source that includes mercury retorts and melt furnaces at gold mine ore processing and production facilities that use the Merrill-Crowe process or other processes and do not use carbon (or resins that substitute for carbon) to recover (adsorb) gold from the pregnant cyanide solution.*

Ore dry grinding *means a process in which the gold ore is ground and heated (dried) prior to additional preheating or prior to entering the roaster.*

Ore preheating *means a process in which ground gold ore is preheated prior to entering the roaster.*

Ore pretreatment processes *means the affected source that includes roasting operations and autoclaves that are used to pre-treat gold mine ore at gold mine ore processing and production facilities prior to the cyanide leaching process.*

Pregnant solution tank (or preg tank) *means a storage tank for pregnant solution, which is the cyanide solution that contains gold-cyanide complexes that is generated from leaching gold ore with cyanide solution.*

Pregnant cyanide solution *means the cyanide solution that contains gold-cyanide complexes that are generated from leaching gold ore with a dilute cyanide solution.*

Quenching *means a process in which the hot calcined ore is cooled and quenched with water after it leaves the roaster.*

Roasting operation *means a process that uses an industrial furnace in which milled ore is combusted across a fluidized bed to oxidize and remove organic carbon and sulfide mineral grains in refractory gold ore. The emissions points of the roasting operation subject to this subpart include ore dry grinding, ore preheating, the roaster stack, and quenching.*

Because the permittee will own or operate a gold mine ore processing and production facility at an area source of HAP, requirements in Subpart EEEEEEE are applicable. The collection of ore pretreatment processes and the carbon process with mercury retort are affected sources. Ore pretreatment processes include the autoclave (AC). Carbon processes with mercury retort include the electrowinning cells and pregnant solution tank (EW), the mercury retort (MR), induction melting furnace (MF), and the carbon regeneration kiln (CKD).

Any source subject to 40 CFR 63, Subpart EEEEEEE is a Tier I source as defined in IDAPA 58.01.01.006.122.c. In accordance with IDAPA 58.01.01.313.01.b., 40 CFR 70.3(c)(2), and 40 CFR 63.11640(d), the permittee must submit a complete application to DEQ for an initial Tier I operating permit within 12 months of becoming a Tier I source.

This subpart includes mercury emissions limits for the collection of new ore pretreatment processes and for the new carbon processes with mercury retort. This subpart also requires weight measurement devices for measuring ore throughput for the autoclave (AC) and ~~ore concentrate~~mineral-bearing solution throughput for the electrowinning cells and pregnant solution tank (EW). Requires monitoring of mercury emissions, and monitoring of either inlet gas temperature for each process unit with a carbon filter (EW, MR, MF, CKD) or both water flow and pressure drop for each process unit with a wet scrubber not followed by a carbon filter (AC).

40 CFR 63, Subpart EEEEEEE is incorporated by reference into Permit Condition 2.23, and specific applicable requirements will be incorporated into the Tier I operating permit.

Permit Conditions Review

This section describes the permit conditions for this initial permit.

Permit Conditions 1.1–1.2

These permit conditions describe the purpose of this permitting action and the emission sources and the control equipment regulated by this permit. This reflects information presented in the application and relied upon in the development of emissions inventories, and in the evaluation of ambient air impacts in the modeling analyses. Refer to the Emissions Inventories and the Ambient Air Quality Impact Analyses sections for additional information concerning these analyses.

Because specific vendor and manufacturer information was unavailable at the time of permitting, documentation and testing requirements were included (Permit Condition 2.19) to verify consistency with the information specified in the application. Production values ~~limits~~ were based on process flow diagrams and engineering design information provided.

Permit Conditions 2.1–2.7

These permit conditions incorporate fugitive dust emission control requirements ~~limits~~ (Permit Condition 2.1) in accordance with IDAPA 58.01.01.650-651. Compliance is ensured by implementing reasonable control precautions and corrective actions when appropriate, excluding public access to operations, and complying with inspection, monitoring, recordkeeping, and notification requirements. Specific precautions are identified and required in the fugitive dust control plan (FDCP), and specific measures to control public access within the operations boundary are identified in and required by the Access Control Plan (ACP) (Permit Conditions 2.5 and 2.6, respectively).

Reduction of PM emissions from each of the identified conveyors by 80% was supported by assuming location of these material transfers at below grade (OC9, OC10) or enclosure on all sides (OC11), as specified. Reduction of PM emissions from haul roads by a combined 93.3% was supported by assuming appropriate application ~~liberal use~~ of water and magnesium chloride dust suppression; DEQ is cognizant that to consistently achieve this level of control requires conscientious efforts, vigilant inspection and monitoring, and a comprehensive FDCP. Maximum monthly haul mileage was based on the maximum operating scenario mileage (W3 = 16,415 mi/day ≈ 490,000 mi/mo). Because continuous operation was proposed, suppression measures will need to account for and accommodate all weather conditions including diurnal and seasonal variability, and all traffic loads including mining and public traffic along publicly accessible roads. Conditions outside of what may normally be anticipated may require additional measures such as a reduction in vehicle speeds or selection of a more effective chemical dust suppressant. Although the FDCP specifies a minimum of efforts required, additional operational limits and monitoring are to be considered moving forward and evaluated for incorporation into the FDCP comply with IDAPA 50.01.01.650-651 ~~to achieve this level of control~~ under all conditions and all operating scenarios. Certification of employees for visible emission inspections, training and orientation of relevant employees, and evaluation of FDCP requirements on at least a semi-annual basis are also required.

Comment [A11]: Please update this frequency per comments provided on the draft PTC.

Access control measures are described in the Ambient Air Boundary section of the application (Section 5.6), and address primary access points, secondary access points, and surveillance.

Permit Conditions 2.8–2.11

These permit conditions incorporate visible emission control requirements ~~limits~~ (Permit Condition 2.8) in accordance with IDAPA 58.01.01.625. Compliance is ensured by implementing corrective actions when appropriate and complying with inspection, monitoring, and recordkeeping requirements. Certification of employees for visible emission inspections, is also required.

Permit Condition 2.12

This permit condition incorporates PM emission limits for process equipment as defined in IDAPA 58.01.01.006, in accordance with IDAPA 58.01.01.700-703, which includes ~~all mining,~~ ore processing, ore concentration and refining, lime production, aggregate production, and concrete production equipment (Table 1). Compliance with operational and material throughput limits (Permit Conditions 3.3–3.8, 4.4–4.10, and 5.4–5.8) and control equipment requirements (Permit Conditions 2.5, 3.9–3.11, 4.11–4.16, and 5.9–5.16) and associated monitoring were considered adequate to ensure compliance with process weight-based PM emission limitations.

Comment [A12]: "all mining" is not mentioned in the draft PTC

Permit Conditions 2.13–2.14 incorporate odorous emission limits in accordance with IDAPA 58.01.01.776.01. Compliance is ensured by complying with monitoring and recordkeeping requirements, including corrective action when appropriate.

Permit Conditions 2.15–2.16 incorporate sulfur content limits for distillate fuel oil, in accordance with IDAPA 58.01.01.725. Compliance is ensured by complying with monitoring and recordkeeping requirements.

Permit Conditions 2.17–2.18 limit facility-wide gasoline fuel throughput. Limiting gasoline throughput limits PTE, ensures avoidance of Subpart CCCCCC requirements applicable to GDF exceeding 100,000 gal/mo, and requires recordkeeping in accordance with 40 CFR 63.11111(e). Compliance is ensured by complying with monitoring and recordkeeping requirements.

Permit Conditions 2.19–2.20 require developing and complying with the requirements of an O&M manual to ensure compliance with control equipment maintenance and operation general provisions (Permit Condition 7.2). Documentation of as-built process equipment specifications and control equipment performance guarantees and establishing control equipment operating parameters and procedures were required, since these were relied upon in the development of emissions inventories, and in the evaluation of ambient air impacts in the modeling analyses. Compliance is ensured by complying with monitoring and recordkeeping requirements.

Permit Conditions 2.21–2.23 incorporate applicable general compliance, notification, recordkeeping, reporting, applicable general provisions, and other federal requirements by reference in accordance with IDAPA 58.01.01.107.03 and 590-591. Compliance is ensured by complying with applicable federal testing, monitoring, recordkeeping, and reporting requirements.

These permit conditions specify that with regard to permit conditions referenced in accordance with federal requirements (i.e., NSPS and NESHAP requirements), should there be a conflict between the language of the permit condition and the language of the requirement, the language of the requirement shall govern. The permittee is also required to obtain a Tier I operation permit within 12 months of commencement of operation of any ore concentration and refining equipment (i.e., NESHAP 7E affected sources). Refer to NSPS Applicability (40 CFR 60) and MACT/GACT Applicability (40 CFR 63) sections for additional information concerning applicable requirements.

Permit Condition 2.24 specifies recommended test methods to be used when performance testing is required, unless otherwise specified in the permit, in accordance with IDAPA 58.01.01.157. The permittee is required to comply with notification and reporting requirements and is encouraged to submit performance test protocol to DEQ for approval prior to any performance testing in accordance with the performance testing general provisions (Permit Condition 7.7–7.9).

Permit Condition 2.25 provides DEQ agency contact information.

Permit Conditions 3.1–3.2

These permit conditions describe mining and ore processing equipment and controls. This reflects information presented in the application and relied upon in the development of emissions inventories, and in the evaluation of ambient air impacts in the modeling analyses.

Permit Conditions 3.3–3.8 and 3.12–3.17 establish limits on material throughput and production. These limits were relied upon in the development of emissions inventories and in the evaluation of ambient air impacts in the modeling analyses. Overall mine throughput is limited by hauling and excavating limits (Permit Condition 3.5). Compliance is ensured by complying with monitoring and recordkeeping requirements (Permit Conditions 3.12–3.17).

Permit Conditions 3.9–3.11 require measures to include in the facility's FDCP~~control fugitive emissions~~. Use of ~~building enclosures and~~ reasonable controls were relied upon in the development of emissions inventories and in the evaluation of ambient air impacts in the modeling analyses. Compliance is ensured by complying with fugitive dust monitoring and recordkeeping requirements (Permit Conditions 2.1–2.7).

Comment [A13]: Building enclosures were not relied upon in the emissions inventories for the crushers.

Permit Conditions 4.1–4.2

These permit conditions describe ore concentration and refining equipment and controls. This reflects information presented in the application and relied upon in the development of emissions inventories, and in the evaluation of ambient air impacts in the modeling analyses.

Permit Condition 4.3 and 4.30–4.31 establish emissions limits for ore concentration and refining equipment, consistent with estimates relied upon in the development of emissions inventories and in the evaluation of ambient air impacts in the modeling analyses for these sources. A sulfuric acid emission limit consistent with the modeled TAP emission rate from the autoclave was established in accordance with IDAPA 58.01.01.210.08. Compliance is ensured by complying with equipment operating and testing requirements (Permit Conditions 4.4–4.16, and 4.30–4.31).

Permit Conditions 4.4–4.10 and 4.17–4.23 limit operations of ore concentration and refining process equipment, consistent with the hours of operation and material throughput assumptions relied upon in the development of emissions inventories and in the evaluation of ambient air impacts in the modeling analyses for these sources. Compliance is ensured by complying with monitoring and recordkeeping requirements (Permit Conditions 4.16–4.23).

Permit Conditions 4.11–4.16 and 4.24–4.29 require control equipment for ore concentration and refining processes, consistent with controls relied upon in the development of emissions inventories and in the evaluation of ambient air impacts in the modeling analyses. Compliance is ensured by complying with monitoring and recordkeeping requirements (Permit Conditions 4.24–4.29).

Permit Condition requires testing of ore concentration and refining emission sources to demonstrate compliance with emissions limits (Permit Condition 4.3).

Permit Conditions 5.1–5.2

These permit conditions describe lime, aggregate, and concrete production equipment and controls. This reflects information presented in the application and relied upon in the development of emissions inventories, and in the evaluation of ambient air impacts in the modeling analyses.

Permit Condition 5.3 establishes emissions limits for lime, aggregate, and concrete production equipment, consistent with estimates relied upon in the development of emissions inventories and in the evaluation of ambient air impacts in the modeling analyses for these sources. Compliance is ensured by complying with equipment operating requirements (Permit Conditions 5.4–5.16).

Permit Conditions 5.4–5.8 and 5.17–5.21 limit operations of each lime, aggregate, and concrete production process equipment, consistent with material throughput assumptions relied upon in the development of emissions inventories and in the evaluation of ambient air impacts in the modeling analyses for these sources. Compliance is ensured by complying with monitoring and recordkeeping requirements (Permit Conditions 5.16–5.21).

Permit Conditions 5.9–5.11 require measures to ~~control fugitive emissions~~include in the facility's FDCP. Use of water sprays, building enclosures, and reasonable controls were relied upon in the development of emissions inventories and in the evaluation of ambient air impacts in the modeling analyses. Compliance is ensured by complying with fugitive dust monitoring and recordkeeping requirements (Permit Conditions 2.1–2.7).

Permit Conditions 5.12–5.16 and 5.22–5.25 require control equipment for lime, aggregate, and concrete production processes, consistent with controls relied upon in the development of emissions inventories and in the evaluation of ambient air impacts in the modeling analyses. Compliance is ensured by complying with monitoring and recordkeeping requirements (Permit Conditions 5.22–5.25).

Permit Condition 6.1

This permit condition describes the emergency power generation equipment. This reflects information presented in the application and relied upon in the development of emissions inventories, and in the evaluation of ambient air impacts in the modeling analyses.

Permit Conditions 6.2 and 6.3–6.4 limit operations of each emergency power generation engine, consistent with the purpose and hours of operation assumptions relied upon in the development of emissions inventories, in the determination of federal regulatory applicability, and in the evaluation of ambient air impacts in the modeling analyses for these sources. Compliance is ensured by complying with monitoring, recordkeeping, and notification requirements (Permit Conditions 6.3–6.4).

Permit Condition 7.1

The duty to comply general compliance provision requires that the permittee comply with all of the permit terms and conditions pursuant to Idaho Code §39-101.

Permit Condition 7.2

The maintenance and operation general compliance provision requires that the permittee maintain and operate all treatment and control facilities at the facility in accordance with IDAPA 58.01.01.211.

Permit Condition 7.3

The obligation to comply general compliance provision specifies that no permit condition is intended to relieve or exempt the permittee from compliance with applicable state and federal requirements, in accordance with IDAPA 58.01.01.212.01.

Permit Condition 7.4

The inspection and entry provision requires that the permittee allow DEQ inspection and entry pursuant to Idaho Code §39-108.

Permit Condition 7.5

The permit expiration construction and operation provision specifies that the permit expires if construction has not begun within two years of permit issuance or if construction has been suspended for a year in accordance with IDAPA 58.01.01.211.02.

Permit Condition 7.6

The notification of construction and operation provision requires that the permittee notify DEQ of the dates of construction and operation, in accordance with IDAPA 58.01.01.211.01 and 211.03.

Permit Condition 7.7

The performance testing notification of intent provision requires that the permittee notify DEQ at least 15 days prior to any performance test to provide DEQ the option to have an observer present, in accordance with IDAPA 58.01.01.157.03.

Permit Condition 7.8

The performance test protocol provision requires that any performance testing be conducted in accordance with the procedures of IDAPA 58.01.01.157 and encourages the permittee to submit a protocol to DEQ for approval prior to testing.

Permit Condition 7.9

The performance test report provision requires that the permittee report any performance test results to DEQ within 60 days of completion, in accordance with IDAPA 58.01.01.157.04-05.

Permit Condition 7.10

The monitoring and recordkeeping provision requires that the permittee maintain sufficient records to ensure compliance with permit conditions, in accordance with IDAPA 58.01.01.211.

Permit Condition 7.11

The excess emissions provision requires that the permittee follow the procedures required for excess emissions events, in accordance with IDAPA 58.01.01.130-136.

Permit Condition 7.12

The certification provision requires that a responsible official certify all documents submitted to DEQ, in accordance with IDAPA 58.01.01.123.

Permit Condition 7.13

The false statement provision requires that no person make false statements, representations, or certifications, in accordance with IDAPA 58.01.01.125.

Permit Condition 7.14

The tampering provision requires that no person render inaccurate any required monitoring device or method, in accordance with IDAPA 58.01.01.126.

Permit Condition 7.15

The transferability provision specifies that this permit to construct is transferable, in accordance with the procedures of IDAPA 58.01.01.209.06.

Permit Condition 7.16

The severability provision specifies that permit conditions are severable, in accordance with IDAPA 58.01.01.211.

PUBLIC REVIEW

Public Comment

An opportunity for public comment period on the application was provided in accordance with IDAPA 58.01.01.209.01.c. During this time, there was a request for a public comment period on DEQ's proposed action.

A public comment period was made available to the public in accordance with IDAPA 58.01.01.209.01.c.

Refer to the Application Chronology section for public comment opportunity and public comment period dates.

PET 458

1.0 Summary

Midas Gold Idaho, Inc. (Midas Gold) submitted a Permit to Construct (PTC) application to construct and operate the Stibnite Gold Project (SGP) in Valley County, Idaho. The SGP will consist of conventional open-pit mining operations and onsite ore preparation and gold extraction processes. The potential air emissions from the SGP are less than the applicable major source thresholds for both criteria and hazardous air pollutants (HAP), and therefore, the facility is designated as a minor source for Title V and New Source Review (NSR) requirements, and an area source for National Emission Standards for Hazardous Air Pollutants (NESHAP) applicability. Project-specific air quality analyses involving atmospheric dispersion modeling of estimated emissions associated with the facility were submitted to DEQ to demonstrate that applicable emissions do not result in violation of a National Ambient Air Quality Standard (NAAQS) or Toxic Air Pollutant (TAP) increment as required by the Idaho Administrative Procedures Act 58.01.01.203.02 and 203.03 (Idaho Air Rules Section 203.02 and 203.03). This memorandum provides a summary of the applicability assessment for analyses and air impact analyses used to demonstrate compliance with applicable NAAQS and TAP increments, as required by Idaho Air Rules Section 203.02 and 203.03.

Air Sciences, Inc. (Air Sciences), on behalf of Midas Gold, prepared the PTC application and performed ambient air impact analyses for this project. DEQ review of submitted data and DEQ analyses summarized by this memorandum addressed only the rules, policies, methods, and data pertaining to the air impact analyses used to demonstrate that estimated emissions associated with operation of the facility will not cause or significantly contribute to a violation of any applicable air quality standard. This review did not address/evaluate compliance with other rules or analyses not pertaining to the air impact analyses. Evaluation of emission estimates was the responsibility of the DEQ permit writer and is addressed in the main body of the DEQ Statement of Basis, and emission calculation methods were not evaluated in this modeling review memorandum.

Table 1 presents key assumptions and results to be considered in the development of the permit. Idaho Air Rules require air impact analyses be conducted in accordance with methods outlined in 40 CFR 51, Appendix W *Guideline on Air Quality Models* (Appendix W). Appendix W requires that air quality impacts be assessed using atmospheric dispersion models with emissions and operations representative of design capacity or as limited by a federally enforceable permit condition.

The submitted information and analyses: 1) utilized appropriate methods and models; 2) was conducted using reasonably accurate or conservative model parameters and input data (review of emission estimates was addressed by the DEQ permit writer); 3) adhered to established DEQ guidelines for new source review dispersion modeling; 4) showed either a) that estimated potential/allowable emissions are at a level defined as below regulatory concern (BRC) and do not require a NAAQS compliance demonstration; b) that predicted pollutant concentrations from emissions associated with the project as modeled were below Significant Impact Levels (SILs) or other applicable regulatory thresholds; or c) that predicted pollutant concentrations from emissions associated with the project, when appropriately combined with co-contributing sources and background concentrations, were below applicable NAAQS at ambient air locations where and when the project has a significant impact; 5) showed that TAP emission increases associated with the project will not result in increased ambient air impacts exceeding allowable TAP increments. This conclusion assumes that conditions in Table 1 are representative of facility design capacity or operations as limited by a federally enforceable permit condition. The DEQ permit writer should use Table 1 and other information presented in this memorandum to generate appropriate permit provisions/restrictions to assure emissions do not exceed applicable regulatory thresholds requiring further analyses and to assure the requirements of Appendix W are met regarding emissions representative of design capacity or permit allowable rates.

DRAFT

Table 1. KEY ASSUMPTIONS USED IN MODELING ANALYSES.	
Criteria/Assumption/Result	**Explanation/Consideration**
General Emission Rates. Emission rates used in the air impact analyses must represent maximum potential emissions as given by design capacity, inherently limited by the nature of the process or configuration of the facility, or as limited by the issued permit for the specific pollutant and averaging period.	Compliance has not been demonstrated for emission rates greater than those used in the air impact analyses.
Air Impact Analyses for Criteria Pollutant Emissions. SGP facility-wide maximum potential to emit are greater than the respective Level I thresholds for all criteria pollutants and averaging periods except for Lead. Therefore, modeling is triggered for applicable averaging periods for $PM_{2.5}$[a], PM_{10}[b], CO[c], NOx[d], and SO_2[e]. Modeling was not required for Lead.	Project-specific air impact analyses demonstrating compliance with NAAQS, as required by Idaho Air Rules Section 203.02, are required for pollutant increases above BRC thresholds, or for pollutants having an emissions increase that is greater than Level I modeling applicability thresholds (where the BRC exclusion cannot be used).
Air Impact Analyses for TAP Emissions. SGP facility-wide potential TAP emissions exceed the respective screening emission levels (ELs) for antimony, arsenic, cadmium, formaldehyde, nickel, and sulfuric acid. Therefore, air dispersion modeling was required for these six TAPs.	A TAP increment compliance demonstration would be required for any TAPs with emissions above ELs.
Significant Impact Level Analysis Not Conducted. A Significant Impact Level (SIL) analysis was not conducted for the SGP facility.	Based on the magnitude of the facility-wide emissions and preliminary modeling analyses, it was determined that the impacts from the SGP emissions exceeded the SIL for most criteria pollutants. Therefore, SIL analyses were considered redundant and not performed for the project.
Multiple Modeling Scenarios. To evaluate the worst-case air impacts from the SGP facility, a total of 14 scenarios were modeled. These scenarios represent the hauling of material, which can be either ore or development rock (DR), from four possible origins (three pits and a tailings facility) to five possible destinations (ore will be hauled to the crushing area while DR will be hauled to one of four development rock storage facilities [DRSF]). Modeled design values listed in this modeling memo represent the worst-case modeling scenario for every modeled pollutant and averaging period.	Conventional open-pit methods will be used to extract ore and DR from four possible origins (Yellow Pine Pit [YPP], Hangar Flats Pit [HFP], West End Pit [WEP], and Bradley Tailings [BT]). Ore and DR will be hauled to five possible destinations (Stockpile [STKP], Yellow Pine DRSF [YPDRSF], Hangar Flats DRSF [HFDRSF], West End DRSF [WEDRSF], and Fiddle DRSF [FDRSF]). Only 14 of the 20 possible scenarios were modeled. Six scenarios were not feasible because the timing of the activity within the sequence of mine operations makes the scenarios logistically impossible. Modeled results listed in this memo represent worst-case modeling scenarios.
Modeling of Material Origin and Destination. Each material origin location (YPP, HFP, WEP, and BT) was modeled as an AREA source. Ore destination (STKP) was modeled as a VOLUME source. Each DR destination (YPDRSF, HFDRSF, WEDRSF, and FDRSF) was modeled as a VOLUME source.	Each material origin location comprised appropriate emissions from drilling, material loading, dozing, and surface exploration. Ore destination comprised ore unloading emissions. Each DR destination comprised appropriate emissions from DR unloading, dozing, and wind erosion. For the four AREA and five VOLUME sources, the dimensions were developed by reasonably fitting an equal-area rectangle within the actual footprint of each fugitive source. For the pit and DRSF fugitive activity locations, the release height was based on the haul truck height. The applicable initial lateral dispersion for each VOLUME source was calculated from the respective shorter dimension and EPA-specified methods. The applicable initial vertical dispersion for each AREA and VOLUME source was calculated from the respective vertical dimension and EPA-specified methods.
Modeling of Haul Roads. A representative haul road network for hauling material from inside the pit to various destinations was developed for each of the 14 modeling scenarios.	The haul road network was divided into 22 sections. Each section was further divided into multiple segments with a length equal to twice the adjusted haul road width. Each of the segments was characterized as an individual VOLUME source in the model. Material hauling emissions associated with each origin-destination route were assigned to each

REC 0826

PET 460

Table 1. KEY ASSUMPTIONS USED IN MODELING ANALYSES.	
Criteria/Assumption/Result	**Explanation/Consideration**
	segment along the route based on estimated total emissions along the route and traffic distribution along each section.
Modeling of Blasting Emissions. Blasting emissions were represented by a VOLUME source inside a pit (YPPBL, HFPBL, and WEPBL). Blasting is not expected to occur in BT but was modeled (BTBL) in order to streamline the permitting process.	The blasting physical parameters were developed from dimensions based on blast area used in the emission calculation. The blasting release height was the midpoint of the blasting height. The initial lateral and vertical dispersion dimensions for blasting were calculated per methods specified in the AERMOD User's Guide.
Modeling of Burntlog Route Access Road. The access road portion within the operations boundary was characterized by a series of LINE sources laid along the actual route.	Emissions associated with the portion of the Burntlog Route mine access road that is within project boundary (from the south gate to the process area) are included in the SGP analyses. These include dust emissions generated from travel of maintenance equipment, light-duty pickup trucks and buses used for employee, visitor, and contractor transportation, and heavy-duty trucks used for cargo (including fuel, consumables, machine parts, ore processing supplies, ore concentrate, etc.) and services (including food supplies, trash, recyclables, etc.) transportation. Release parameters for the LINE sources were based on an estimated average vehicle height. The access road emissions were evenly distributed along the road by dividing the total access road emissions by its total area.
Control of Fugitive Dust from Roadways. Fugitive particulate emissions from roadways were assumed to be controlled above 93%, which is an aggressive level of control.	The high level of emission control was needed to demonstrate compliance with NAAQS. Compliance is not demonstrated for emissions greater than those associated with above 93% control.
NOx Chemistry and NO_2/NOx In-Stack Ratios. Ozone Limiting Method (OLM), a Tier 3 NO_2 screening method, was used to estimate the 1-hour and annual NO_2 impacts. The following NO_2/NOx In-Stack Ratios (ISR) were used in the modeling analyses: Blasting: 0.036 Diesel engines: 0.11 Propane heaters: 0.10	The OLM method requires an input of NO_2/NOx ISRs for each modeled source. The NO_2/NOx ratio for blasting was based on blasting plume measurements provided in published literature. The NO_2/NOx ratio for stationary diesel combustion sources was based on heavy-duty diesel trucks in the California Air Pollution Control Officers Association (CAPCOA) Guidance Document. This NO_2/NOx ratio (11 percent) is conservatively higher than the diesel combustion NO_2/NOx ratio provided in the EPA ISR database: 6 percent average, 9.8 percent maximum. The CAPCOA document and the EPA ISR database do not provide an NO_2/NOx ratio for propane boilers. The CAPCOA-recommended NO_2/NOx ratio for natural gas boilers was selected for the propane boilers. The natural gas boilers NO_2/NOx ratio is considered appropriate for the propane boilers because both are gaseous fuels with relatively similar combustion characteristics and are expected to have similar NO_2/NOx ratios. DEQ performed a sensitivity analysis using Tier 2 (Ambient Ratio Method 2), a more conservative NO_2 screening method, and found that the facility is safely below the 1-hour and annual NO_2 NAAQS.
Alternate Meteorological Data Processed Using Cloud Cover. An alternative meteorological dataset was processed without using the Bulk Richardson (BULKRN) method. This alternate processing (NON-BULKRN) used upper air data from Boise airport, supplemented with the cloud-cover data collected at the National Weather Service station in McCall, Idaho.	Meteorological data processing with and without BULKRN are considered acceptable regulatory options by EPA. The NON-BULKRN meteorological data yielded lower modeled design values than the meteorological data processed using the BULKRN method.
Ambient Air Boundary. Midas Gold will legally control the SGP, an active industrial site where mining activities will occur,	Ambient air is defined in Section 006 of the Idaho Air Rules as "that portion of the atmosphere, external to buildings, to

DRAFT

Table 1. KEY ASSUMPTIONS USED IN MODELING ANALYSES.	
Criteria/Assumption/Result	**Explanation/Consideration**
such as heavy equipment operation. Most areas of the mine will require strict safety protocols and controlled access. Midas Gold has established an operations boundary to identify the area where public access will be excluded. Public access inside the operations boundary will be restricted for the life of the mine by physical barriers at points of potential access, including the current Stibnite Road point of entry and proposed site access via the Burntlog Route, as well as natural features of the landscape that prevent access.	which the general public has access." Receptors must be placed at any portion of the atmosphere that is considered ambient air.
Onsite Background $PM_{2.5}$ and PM_{10} Concentrations. The following background $PM_{2.5}$ and PM_{10} concentrations were measured at SGP in 2014 and used in the cumulative NAAQS impact analysis: Annual $PM_{2.5}$: 3.5 µg/m^3 (weighted average of quarterly means) 24-hour $PM_{2.5}$: 15 µg/m^3 (98th percentile/8th high) 24-hour PM_{10}: 37 µg/m^3 (highest 2nd high)	Midas Gold developed an onsite monitoring program to collect site-specific meteorological parameters and determine ambient particulate matter ($PM_{2.5}$ and PM_{10}) concentrations at its Stibnite monitoring station. $PM_{2.5}$ and PM_{10} background concentrations were based on calendar year 2014 instead of the complete dataset (November 2013 through June 2015).
NW AIRQUEST Background CO, NO_2, and SO_2 Concentrations. The following background concentrations for CO, NO_2, and SO_2 were used in the cumulative NAAQS impact analysis: 1-hour CO: 1,740 µg/m^3 8-hour CO: 1,110 µg/m^3 1-hour NO_2: 4.3 µg/m^3 Annual NO_2: 0.9 µg/m^3 1-hour SO_2: 12.3 µg/m^3 3-hour SO_2: 16.8 µg/m^3	Gaseous pollutant background concentrations were determined using the Northwest International Air Quality Environmental Science and Technology Consortium (NW AIRQUEST) online tool. The NW AIRQUEST tool uses regional scale modeling of pollutants in Washington, Oregon, and Idaho, with model results adjusted according to available monitoring data.
Medium-Traffic Background Concentrations. To provide additional information regarding the relative contribution of traffic emissions, background concentrations were obtained from NW AIRQUEST for the road section between mile markers 143 and 144 on Highway 55 passing through the town of McCall.	The McCall location is approximately 38 miles west of the SGP. The annual average daily traffic count for this road section is over 10,000 vehicles per day. Although the background concentrations at McCall are not representative of the rural SGP area, they provide additional information regarding the relative contribution of traffic emissions.
Weight-of-Evidence Analyses for 24-hour PM_{10}. PM_{10} modeling with meteorological dataset processed using the site-specific BULKRN method shows up to five hotspot receptors for Scenario W5 (the highest PM_{10} modeling scenario) that exceed NAAQS. All modeled violations occur during winter when the average snow depth and average precipitation at the project site are 21-68 inches and 6.0 inches, respectively. Therefore, fugitive road dust emissions during high-modeled impact hours could be overestimated. PM_{10} modeling simulation was based on a mining production rate of 180,000 ton/day of development rock (6~~2~~5,700,000 ton/year, which is more conservative than the expected peak production rate of 42,692,000 ton/year). To investigate the effect of a lower modeled mining production rate on design value concentrations, DEQ performed a modeling simulation where mining production rate was assumed to be 120,000 ton/day instead of 180,000 ton/day, but everything else was held constant. Maximum modeled concentration, when summed with the background concentration, is lower than the 24-hour PM_{10} NAAQS thereby demonstrating NAAQS compliance. DEQ's weight-of-evidence analyses conclude that, considering all the collective conservative layers of the modeling analyses, including the use of meteorological data processed by two different methods, there is a satisfactory level of confidence that operation of the project as described in the application will not cause or contribute to a violation of NAAQS.	Meteorological data processing with and without BULKRN are considered acceptable by EPA, with the BULKRN method utilizing more of the onsite collected meteorological parameters. However, the BULKRN-processed meteorological data yielded higher modeled design value impacts for the SGP facility than the meteorological data processed without the BULKRN method. DEQ's supplemental analyses suggest that when emissions are more-closely representative of typical daily mining production rates for a high-production period (everything else held constant), the SGP facility is able to demonstrate compliance with 24-hour PM_{10} NAAQS at those few receptors showing a potential violation when using meteorological data processed with the BULKRN method.

DRAFT

Table 1. KEY ASSUMPTIONS USED IN MODELING ANALYSES.	
Criteria/Assumption/Result	**Explanation/Consideration**

[a.] Particulate matter with an aerodynamic diameter less than or equal to a nominal 2.5 micrometers.
[b.] Particulate matter with an aerodynamic diameter less than or equal to a nominal 10 micrometers.
[c.] Carbon monoxide.
[d.] Nitrogen oxides.
[e.] Sulfur dioxide.

Summary of Submittals and Actions

May 30, 2019	Modeling protocol was submitted to DEQ by Brown and Caldwell on behalf of the applicant.
June 27, 2019	Conditional modeling protocol approval was provided to Brown and Caldwell by DEQ.
August 21, 2019	Regulatory start date. PTC application and modeling report were prepared by Air Sciences on behalf of the applicant.
September 19, 2019	Application deemed incomplete by DEQ.
October 4, 2019	DEQ received a preliminary response and supplemental information from the applicant.
October 15, 2019	DEQ met with the applicant to review and discuss the preliminary response.
October 22, 2019	DEQ determined that the application remained incomplete while the applicant prepared a response to remaining items previously identified, and included a summary of recommendations provided at the meeting.
November 8, 2019	DEQ requested additional information from the applicant via e-mail, relating to items previously identified.
November 21, 2019	Applicant requested extension until November 27, 2019 to respond to incompleteness.
November 27, 2019	DEQ received supplemental information from the applicant, including a revised application with updated emission inventories and modeling analyses.
December 24, 2019	DEQ determined that the application was incomplete.
January 8, 2020	Applicant requested extension until February 7, 2020 to respond to incompleteness.
February 5, 2020	DEQ received supplemental information from the applicant, including a revised application with updated emission inventories and modeling analyses.
March 6, 2020	DEQ determined that the application was incomplete.
April 2, 2020	Applicant requested extension until April 15, 2020 to respond to incompleteness.

DRAFT

April 15, 2020	DEQ received supplemental information from the applicant, including updated modeling analyses.
May 15, 2020	DEQ determined that the application was complete.
June 24, 2020	DEQ received the final updated application.

2.0 Background Information

This section provides background information applicable to the project and the site proposed for the facility. It also provides a brief description of the applicable air impact analyses requirements for the project.

2.1 Project Description

The SGP will require the construction of significant infrastructure, including a power transmission line, a primary mine site access road, onsite haul roads, an ore processing facility, onsite workspaces, employee housing and recreation, water storage and distribution facilities, and sewage disposal facilities.

The SGP will include three years of pre-mining development and construction activities, followed by an operating mine life of approximately 12 years. Mining will occur in three open pits: Yellow Pine Pit (YPP), Hangar Flats Pit (HFP), and West End Pit (WEP). The general sequence of mining will be the YPP deposit, followed by the HFP and WEP deposits. Legacy tailings from the Meadow Creek valley (Bradley Tailings [BT]) also will be reclaimed and reprocessed during the initial project schedule. Surface exploration drilling will continue within the pits and the Scout Prospect decline (underground exploration) throughout the mine operation period. Restoration and reclamation of other legacy mining features will occur prior to mining, throughout the life of the mine, and as part of the mine closure.

Conventional open-pit methods including drilling, blasting, excavating, and hauling will be used to extract ore and waste rock, termed development rock (DR). Hydraulic shovels and front-end loaders will be used to load ore and DR into haul trucks. DR will be used for construction, restoration, and backfilling, or hauled to the dedicated development rock storage facilities (DRSF). Approximately 340 million tons of DR will be handled over the life of the mine. Ore will be hauled to the primary crusher area, where it will be fed directly into the crusher dump pocket or stockpiled. The ore crushing plant will be designed to operate at a maximum rate of 25,000 tons per day (ton/day). Approximately 100 million tons of ore will be mined from the three pits over the life of the project.

The metal-recovery process from ore will include conventional crushing and grinding, followed by froth-flotation circuits that will generate separate gold-silver and antimony-silver concentrates. The antimony-silver concentrate will be shipped offsite for refining, whereas additional onsite processing of the gold-silver concentrate will include pressure oxidation, carbon-in-leach circuits, and refining processes to recover gold and minor amounts of silver. The finely ground leftover ore material from the mineral-recovery process, termed tailings, will be neutralized, thickened, and transported via a pipeline to the tailings storage facility (TSF).

Lime used in the ore processing will either be purchased or manufactured onsite from limestone available at the site. In addition, certain construction and maintenance activities during operations may require sized aggregate. To allow for the operational flexibility to produce construction aggregate onsite, the application included two portable crushing and screening plants.

DRAFT

The following air pollutants are expected from operations at the SGP facility:

- Criteria air pollutants: carbon monoxide (CO), oxides of nitrogen (NOx), particulate matter less than 2.5 microns (µm) and 10 µm ($PM_{2.5}$ and PM_{10}), sulfur dioxide (SO_2), lead (Pb), and ozone (O_3) precursor volatile organic compounds (VOC)
- Hazardous air pollutants (HAP), including mercury (Hg)
- Other non-HAP toxic air pollutants (TAP)
- Greenhouse gases

The potential emissions from the SGP are less than the applicable major source thresholds for both criteria (100 ton/yr per pollutant) and hazardous air pollutants (HAP) (25 ton/yr aggregate and 10 ton/yr per single HAP); therefore, it is expected to be designated a minor source for Title V and New Source Review (NSR) (applicable threshold is 250 ton/yr per criteria pollutant) requirements and an area source for National Emission Standards for Hazardous Air Pollutants (NESHAP) applicability.

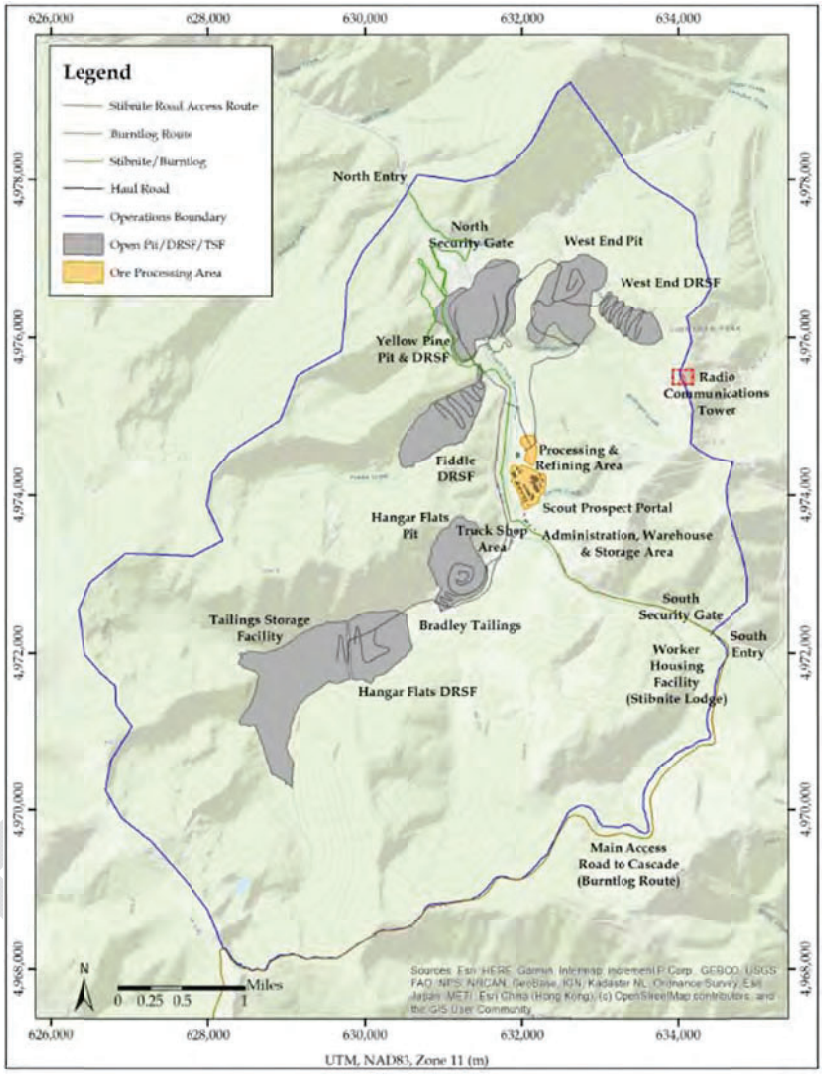
The PTC addresses all air pollutant-emitting activities associated with the facility.

2.2 Facility Location and Area Classification

The SGP is located in the Stibnite-Yellow Pine Mining District in Valley County, central Idaho (Northing: 4,973,751 meters [m]; Easting: 632,038 m; UTM Zone 11), approximately 100 miles northeast of Boise, 38 miles east of McCall, and approximately 10 miles east of Yellow Pine. A facility location map for the SGP is presented in Figure 1. This figure also shows the proposed Burntlog Route (access road) that will provide a year-round safe access to the site. The SGP site layout is presented in Figure 2.

The Stibnite-Yellow Pine Mining District is characterized by historic mining activities and unpatented (federal land) and patented (private land) mining claims that include deposits of gold, silver, tungsten, and antimony. The district lies in both Boise National Forest (BNF) and Payette National Forest (PNF), but is administered by the PNF's Krassel Ranger District (Midas Gold 2017a). The project area terrain is characterized by narrow valleys 6,000 to 6,600 feet above mean sea level (amsl), surrounded by steep mountains ranging over 8,500 feet amsl. The main drainage basin in the project area is the East Fork of the South Fork of the Salmon River (EFSFSR).

The EFSFSR joins Johnson Creek 16 miles downstream, near the village of Yellow Pine. The project area is encompassed by the watersheds of EFSFSR tributaries, including Sugar Creek, Meadow Creek, Johnson Creek, Riordan Creek, Burntlog Creek, Midnight Creek, and Trout Creek. Primary commercial activity in the area comprises mineral exploration, mining, logging, and dispersed recreation.



This area is designated as an attainment or unclassifiable area for SO_2, NO_2, CO, Lead, O_3, PM_{10}, and $PM_{2.5}$. The area is not classified as non-attainment for any criteria pollutants.

DRAFT

Figure 1. SGP FACILITY LOCATION MAP.

Figure 2. SGP SITE LAYOUT AND STIBNITE ROAD ACCESS ROUTE.

2.3 Air Impact Analyses Required for All Permits to Construct

Idaho Air Rules Sections 203.02 and 203.03:

> *No permit to construct shall be granted for a new or modified stationary source unless the applicant shows to the satisfaction of the Department all of the following:*

***02. NAAQS**. The stationary source or modification would not cause or significantly contribute to a violation of any ambient air quality standard.*

***03. Toxic Air Pollutants.** Using the methods provided in Section 210, the emissions of toxic air pollutants from the stationary source or modification would not injure or unreasonably affect human or animal life or vegetation as required by Section 161. Compliance with all applicable toxic air pollutant carcinogenic increments and toxic air pollutant non-carcinogenic increments will also demonstrate preconstruction compliance with Section 161 with regards to the pollutants listed in Sections 585 and 586.*

Atmospheric dispersion modeling, using computerized simulations, is used to demonstrate compliance with both NAAQS and TAPs. Idaho Air Rules Section 202.02 states:

***02. Estimates of Ambient Concentrations**. All estimates of ambient concentrations shall be based on the applicable air quality models, data bases, and other requirements specified in 40 CFR 51 Appendix W (Guideline on Air Quality Models).*

2.4 Significant Impact Level and Cumulative NAAQS Impact Analyses

If specific criteria pollutant emission increases associated with the proposed permitting project cannot qualify for a BRC exemption as per Idaho Air Rules Section 221, then the permit cannot be issued unless the application demonstrates that applicable emission increases will not cause or significantly contribute to a violation of NAAQS, as required by Idaho Air Rules Section 203.02.

The first phase of a NAAQS compliance demonstration is to evaluate whether the proposed facility/project could have a significant impact to ambient air. Section 3.1.1 of this memorandum describes the applicability evaluation of Idaho Air Rules Section 203.02. The Significant Impact Level (SIL) analysis for a new facility or proposed modification to a facility involves modeling estimated criteria air pollutant emissions from the facility or modification to determine the potential impacts to ambient air. Air impact analyses are required by Idaho Air Rules to be conducted in accordance with methods outlined in Appendix W. Appendix W requires that facilities be modeled using emissions and operations representative of design capacity or as limited by a federally enforceable permit condition.

A facility or modification is considered to have a significant impact on air quality if maximum modeled impacts to ambient air exceed the established SIL listed in Idaho Air Rules Section 006 (referred to as a "significant contribution" in Idaho Air Rules) or as incorporated by reference as per Idaho Air Rules Section 107.03.b. Table 2 lists the applicable SILs.

Table 2. APPLICABLE REGULATORY LIMITS.

Pollutant	Averaging Period	Significant Impact Levels[a] ($\mu g/m^3$)[b]	Regulatory Limit[c] ($\mu g/m^3$)	Modeled Design Value Used[d]
PM_{10}[e]	24-hour	5.0	150[f]	Maximum 6th highest[g]
$PM_{2.5}$[h]	24-hour	1.2	35[i]	Mean of maximum 8th highest[j]
	Annual	0.2	12[k]	Mean of maximum 1st highest[l]
Carbon monoxide (CO)	1-hour	2,000	40,000[m]	Maximum 2nd highest[n]
	8-hour	500	10,000[m]	Maximum 2nd highest[n]
Sulfur Dioxide (SO_2)	1-hour	3 ppb[o] (7.8 $\mu g/m^3$)	75 ppb[p] (196 $\mu g/m^3$)	Mean of maximum 4th highest[q]
	3-hour	25	1,300[m]	Maximum 2nd highest[n]
Nitrogen Dioxide (NO_2)	1-hour	4 ppb (7.5 $\mu g/m^3$)	100 ppb[s] (188 $\mu g/m^3$)	Mean of maximum 8th highest[t]
	Annual	1.0	100[r]	Maximum 1st highest[n]
Lead (Pb)	3-month[u]	NA	0.15[r]	Maximum 1st highest[n]

DRAFT

	Quarterly	NA	1.5[r]	Maximum 1st highest[n]
Ozone (O_3)	8-hour	40 TPY VOC[v]	70 ppb[w]	Not typically modeled

a. Idaho Air Rules Section 006 (definition for significant contribution) or as incorporated by reference as per Idaho Air Rules Section 107.03.b.
b. Micrograms per cubic meter.
c. Incorporated into Idaho Air Rules by reference, as per Idaho Air Rules Section 107.
d. The maximum 1st highest modeled value is always used for the significant impact analysis unless indicated otherwise. Modeled design values are calculated for each ambient air receptor.
e. Particulate matter with an aerodynamic diameter less than or equal to a nominal 10 micrometers.
f. Not to be exceeded more than once per year on average over 3 years.
g. Concentration at any modeled receptor when using five years of meteorological data.
h. Particulate matter with an aerodynamic diameter less than or equal to a nominal 2.5 micrometers.
i. 3-year mean of the upper 98th percentile of the annual distribution of 24-hour concentrations.
j. 5-year mean of the 8th highest modeled 24-hour concentrations at the modeled receptor for each year of meteorological data modeled. For the SIL analysis, the 5-year mean of the 1st highest modeled 24-hour impacts at the modeled receptor for each year.
k. 3-year mean of annual concentration.
l. 5-year mean of annual averages at the modeled receptor.
m. Not to be exceeded more than once per year.
n. Concentration at any modeled receptor.
o. Interim SIL established by EPA policy memorandum.
p. 3-year mean of the upper 99th percentile of the annual distribution of maximum daily 1-hour concentrations.
q. 5-year mean of the 4th highest daily 1-hour maximum modeled concentrations for each year of meteorological data modeled. For the significant impact analysis, the 5-year mean of 1st highest modeled 1-hour impacts for each year is used.
r. Not to be exceeded in any calendar year.
s. 3-year mean of the upper 98th percentile of the annual distribution of maximum daily 1-hour concentrations.
t. 5-year mean of the 8th highest daily 1-hour maximum modeled concentrations for each year of meteorological data modeled. For the significant impact analysis, the 5-year mean of maximum modeled 1-hour impacts for each year is used.
u. 3-month rolling average.
v. An annual emissions rate of 40 ton/year of VOCs is considered significant for O_3.
w. Annual 4th highest daily maximum 8-hour concentration averaged over three years.

If modeled maximum pollutant impacts to ambient air from the emission sources associated with a new facility or modification exceed the SILs, then a cumulative NAAQS impact analysis is necessary to demonstrate compliance with NAAQS and Idaho Air Rules Section 203.02.

A cumulative NAAQS impact analysis for attainment area pollutants involves assessing ambient impacts (typically the design values consistent with the form of the standard) from potential/allowable emissions resulting from the project and emissions from any nearby co-contributing sources (including existing emissions from the facility that are unrelated to the project), and then adding a DEQ-approved background concentration value to the modeled result that is appropriate for the criteria pollutant/averaging-period at the facility location and the area of significant impact. The resulting pollutant concentrations in ambient air are then compared to the NAAQS listed in Table 2. Table 2 also specifies the modeled design value that must be used for comparison to the NAAQS. NAAQS compliance is evaluated on a receptor-by-receptor basis for the modeling domain.

If the cumulative NAAQS impact analysis indicates an exceedance of NAAQS, a culpability analysis can determine if this exceedance is due to emissions from the proposed project. The permit may not be issued if the proposed project has a significant contribution (exceeding the SIL) to the modeled violation. If project-specific impacts are below the SIL, then the project does not have a significant contribution to the specific violations.

Compliance with Idaho Air Rules Section 203.02 is generally demonstrated if: a) applicable specific criteria pollutant emission increases are at a level defined as BRC, using the criteria established by DEQ regulatory interpretation (DEQ 2014); or b) all modeled impacts of the SIL analysis are below the

DRAFT

applicable SIL or other level determined to be inconsequential to NAAQS compliance; or c) modeled design values of the cumulative NAAQS impact analysis (modeling all emissions from the facility and co-contributing sources, and adding a background concentration) are less than applicable NAAQS at receptors where impacts from the proposed facility/modification exceeded the SIL or other identified level of consequence; or d) if the cumulative NAAQS analysis showed NAAQS violations, the impact of proposed facility/modification to any modeled violation was inconsequential (typically assumed to be less than the established SIL) for that specific receptor and for the specific modeled time when the violation occurred.

2.5 Toxic Air Pollutant Analyses

Emissions of toxic substances are generally addressed by Idaho Air Rules Section 161:

> *Any contaminant which is by its nature toxic to human or animal life or vegetation shall not be emitted in such quantities or concentrations as to alone, or in combination with other contaminants, injure or unreasonably affect human or animal life or vegetation.*

Permitting requirements for toxic air pollutants (TAPs) from new or modified sources are specifically addressed by Idaho Air Rules Section 203.03 and require the applicant to demonstrate to the satisfaction of DEQ the following:

> *Using the methods provided in Section 210, the emissions of toxic air pollutants from the stationary source or modification would not injure or unreasonably affect human or animal life or vegetation as required by Section 161. Compliance with all applicable toxic air pollutant carcinogenic increments and toxic air pollutant non-carcinogenic increments will also demonstrate preconstruction compliance with Section 161 with regards to the pollutants listed in Sections 585 and 586.*

Per Section 210, if the total project-wide emission increase of any TAP associated with a new source or modification exceeds screening emission levels (ELs) of Idaho Air Rules Section 585 or 586, then the ambient impact of the emission increase must be estimated. If ambient impacts are less than applicable Acceptable Ambient Concentrations (AACs) for non-carcinogens of Idaho Air Rules Section 585 and Acceptable Ambient Concentrations for Carcinogens (AACCs) of Idaho Air Rules Section 586, then compliance with TAP requirements has been demonstrated.

Idaho Air Rules Section 210.20 states that if TAP emissions from a specific source are regulated by the Department or EPA under 40 CFR 60, 61, or 63, then a TAP impact analysis under Section 210 is not required for that TAP. The DEQ permit writer evaluates the applicability of specific TAPs to the Section 210.20 exclusion.

3.0 Analytical Methods and Data

This section describes the methods and data used in the analyses to demonstrate compliance with applicable air quality impact requirements. The DEQ Statement of Basis provides a discussion of the methods and data used to estimate criteria and TAP emission rates.

3.1 Emission Source Data

Emissions of criteria pollutants and TAPs resulting from operation of the SGP facility were estimated by

DRAFT

Air Sciences for various applicable averaging periods. The calculation of potential emissions is the responsibility of the DEQ permit writer, and the representativeness and accuracy of emission estimates is not addressed in this modeling memorandum. DEQ air impact analysts are responsible for assuring that potential emission rates provided in the emission inventory are properly used in the model. The rates listed must represent the maximum allowable rate as averaged over the specified period.

Emission rates used in the impact modeling applicability analyses and any modeling analyses, as listed in this memorandum, should be reviewed by the DEQ permit writer and compared with those in the final emission inventory. All modeled criteria air pollutant and TAP emission rates must be equal to or greater than the facility's potential emissions calculated in the PTC emission inventory or proposed permit allowable emission rates.

Emissions from unpaved roads were calculated based on a control efficiency of 90% from chemical application and 33% from watering (combined control efficiency above 93%). Emission controls and emission calculations are not reviewed in this modeling memorandum. However, it is critical for NAAQS compliance that this high level of control be achieved.

Activity-specific (e.g., drilling, blasting, material crushing and conveying, refining, and other ancillary sources) emissions were estimated based on maximum activity rates, coupled with applicable emission estimation techniques. Maximum emissions were calculated on a short-term (hourly and daily) and long-term (annual) basis for ore processing and mining operations, as discussed below.

The ore-processing rate will range from 20,000 ton/day to 25,000 ton/day at full production. Therefore, maximum potential daily ore processing emissions were based on the maximum design rate of 25,000 ton/day. Maximum potential annual emissions were based on potential daily emissions multiplied by 365 days per year.

Emissions from mining operations (drilling, blasting, material extraction and movement, mobile mine machinery use, and other ancillary sources) vary for each year of the life of the mine (LOM). However, for the modeling analyses, the mining operation potential emissions were estimated using conservatively high maximum activity rates provided in Table 3.

Table 3. MINING ACTIVITY RATES FOR POTENTIAL EMISSION CALCULATIONS.

Activity	Maximum Rate		Comments
Drilling	600	holes per blast	--
Blasting	2	blasts per day	--
	1	blast per hour	--
Material extraction and hauling	180,000	tons per day	Ore or DR
Onsite dozing	144	hours per day	6 dozers operating continuously
Onsite grading	72	hours per day	3 graders operating continuously
Onsite water trucking	48	hours per day	2 trucks operating continuously

The potential hourly emission rates for ore processing and mining operation activities were calculated by dividing the daily rate by the 24 hour-per-day operation schedule, and annual rates were calculated by multiplying maximum daily emissions with 365 days per year. This is conservative because the mine is expected to operate for only 355 days per year.

The maximum mine production rate is approximately 42.7 million (MM) tons per year (ton/yr); however, a maximum daily production rate of 180,000 ton/day used for potential emission calculations results in a

DRAFT

conservatively higher production rate of approximately 65.7 MMton/yr, approximately 50 percent higher than the projected production rate.

Midas Gold will employ newer model year mining and maintenance machines (excavators, shovels, haul trucks, dozers, graders, portable light plants, etc.) that are expected to meet or exceed applicable regulatory emission standards. Non-road mobile equipment engines are exempt from permitting requirements; therefore, the tailpipe emissions resulting from fuel combustion in the non-road mobile equipment are not quantified for the SGP facility. Background concentrations from McCall, 38 miles west of the SGP, were used in the cumulative NAAQS impact analyses (Section 4.1.2) to conservatively account for the impact contribution of traffic emissions.

The approximately 38-mile long Burntlog Route mine access road will be outside the project ambient air boundary and open to the public. Traffic emissions on public roads generally are considered to be part of background concentrations. Therefore, emissions on the Burntlog Route mine access road that are outside of the project boundary are not included in the SGP analyses. However, the emissions associated with the portion of the Burntlog Route mine access road that is within project boundary (from the south gate to the process area) are included in the SGP analyses. These include dust emissions generated from travel of maintenance equipment, light-duty pickup trucks and buses used for employee, visitor, and contractor transportation, and heavy-duty trucks used for cargo (including fuel, consumables, machine parts, ore processing supplies, ore concentrate, etc.) and services (including food supplies, trash, recyclables, etc.) transportation.

3.1.1 Criteria Pollutant Modeling Applicability and Modeled Emission Rates

If project-specific emission increases for criteria pollutants would qualify for a BRC permit exemption as per Idaho Air Rules Section 221 if it were not for potential emissions of one or more pollutants exceeding the BRC threshold of 10 percent of emissions defined by Idaho Air Rules as significant, then a NAAQS compliance demonstration may not be required for those pollutants with emissions below BRC levels. DEQ's regulatory interpretation policy of exemption provisions of Idaho Air Rules is that: "*A DEQ NAAQS compliance assertion will not be made by the DEQ modeling group for specific criteria pollutants having a project emissions increase below BRC levels, provided the proposed project would have qualified for a Category I Exemption for BRC emissions quantities except for the emissions of another criteria pollutant*" (DEQ 2014). The interpretation policy also states that the exemption criteria of uncontrolled potential to emit (PTE) not to exceed 100 ton/year (Idaho Air Rules Section 220.01.a.i) is not applicable when evaluating whether a NAAQS impact analyses is required. A permit will be issued limiting PTE below 100 ton/year, thereby negating the need to maintain calculated uncontrolled PTE under 100 ton/year. The BRC exemption cannot be used to exempt a project from a pollutant-specific NAAQS compliance demonstration in most cases where a PTC is required for the action regardless of emission quantities, such as the modification of an existing emission or throughput limit.

A NAAQS compliance demonstration must be performed for pollutant increases that would not qualify for the BRC exemption from the requirement to demonstrate compliance with NAAQS.

Site-specific air impact modeling analyses may not be necessary for some pollutants, even where such emissions do not qualify for the BRC exemption. DEQ has developed modeling applicability thresholds, below which a site-specific modeling analysis is not required. DEQ generic air impact modeling analyses that were used to develop the modeling thresholds provide a conservative SIL analysis for projects with emissions below identified threshold levels. Project-specific modeling applicability thresholds are provided in the *Idaho Air Modeling Guideline* (DEQ 2013). These thresholds were based on assuring an ambient impact of less than the established SIL for specific pollutants and averaging periods.

DRAFT

If total project-specific emission rate increases of a pollutant are below Level I Modeling Applicability Thresholds, then project-specific air impact analyses are not necessary for permitting. Use of Level II Modeling Applicability Thresholds is conditional, requiring DEQ approval. DEQ approval is based on dispersion-affecting characteristics of the emission sources such as stack height, stack gas exit velocity, stack gas temperature, distance from sources to ambient air, presence of elevated terrain, and potential exposure to sensitive public receptors.

For the SGP analyses, several modeling scenarios were considered to evaluate the worst-case air impacts from the SGP facility. The different modeling scenarios are discussed in Section 3.1.3. Table 4 provides a comparison between facility-wide maximum PTE and modeling applicability thresholds. The short-term and long-term PTE emissions are equal to the sum of process and ancillary emissions and mining fugitive emissions. It is important to note that the process and ancillary source emissions remain the same for each modeling scenario discussed in Section 3.1.3.

Table 4. SITE-SPECIFIC CRITERIA POLLUTANT MODELING APPLICABILITY.

Source Category	Carbon Monoxide (CO)	Nitrogen Oxides (NOx)		$PM_{2.5}$[a]		PM_{10}[b]	Sulfur Dioxide (SO_2)		Lead (Pb)
	lb/hr[c]	ton/yr[d]	lb/hr	ton/yr	lb/hr	lb/hr	ton/yr	lb/hr	lb/month[e]
Process and ancillary	33.5	37.9	55.4	36.4	13.4	21.7	6.5	1.88	0.0437
Mining fugitive	1,742.0	17.1	46.8	98.9	22.5	224.7	0.03	0.09	--
Total	1,775.5	55.0	102.2	135.3	35.9	246.4	6.5	1.97	0.0437
Level I threshold	15.0	1.2	0.2	0.35	0.054	0.22	1.2	0.21	14.0
Modeling required	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	No

a. Particulate matter with an aerodynamic diameter less than or equal to a nominal 2.5 micrometers.
b. Particulate matter with an aerodynamic diameter less than or equal to a nominal 10 micrometer.
c. Pounds per hour.
d. Tons per year.
e. Pounds per month.

As indicated in Table 4, the SGP facility-wide maximum PTE are greater than the respective Level I thresholds for all criteria pollutants and averaging periods except for Pb. Therefore, modeling is triggered for applicable averaging periods for CO, NOx, $PM_{2.5}$, PM_{10}, and SO_2. Modeling is not required for Pb. The use of Level II modeling thresholds was not approved by DEQ for this project.

Tables 5-7 list criteria pollutant emission rates used in the cumulative NAAQS impact analyses for the worst-case modeling scenarios. Significant Impact Level (SIL) analyses were not performed. Based on the magnitude of the facility-wide emissions and preliminary modeling analyses, it was determined that the impacts from the SGP emissions exceeded the SIL for most criteria pollutants. Therefore, SIL analyses were considered redundant and not performed for this report. Table 5 lists the source-specific modeled emission rates for 24-hour and annual $PM_{2.5}$ and 24-hour PM_{10} (worst-case modeling scenario: W5). Table 6 lists the source-specific modeled emission rates for 1-hour and 8-hour CO and annual NO_2 (worst-case modeling scenario: W1). Table 7 lists the source-specific modeled emission rates for 1-hour NO_2 and 1-hour and 3-hour SO_2 (worst-case modeling scenario: B1). Modeling scenarios are discussed in Section 3.1.3. For 1-, 3-, and 8-hour averaging times, hourly emission rates provided in pounds per hour were used. For 24-hour averaging time, daily emission rates provided in pounds per day were used. For the annual averaging time, annual emission rates provided in tons per year were used. All modeled

DRAFT

emission rates in Tables 5-7 are listed in units of pounds per hour (lb/hr). The total modeled input emission rates (highest emission scenario) are listed in Table 8.

Table 8. CRITERIA POLLUTANT TOTAL MODELED EMISSION RATES.

Pollutant	Averaging Time	Emissions[a]

DRAFT

CO	8 hours	1,775.50	lb/hr
	1 hour	1,775.50	lb/hr
NO_2	1 year	54.93	ton/yr
	1 hour	58.07	lb/hr
$PM_{2.5}$	1 year	135.23	ton/yr
	24 hours	781.69	lb/day
PM_{10}	24 hours	5,768.93	lb/day
SO_2	3 hours	1.97	lb/hr
	1 hour	1.97	lb/hr

[a.] Combined process, ancillary, and fugitive emissions modeled. Fugitive emissions vary by pit scenario. Maximum pit scenario emissions are shown.

Ozone (O_3) differs from other criteria pollutants in that it is not typically emitted directly into the atmosphere. O_3 is formed in the atmosphere through reactions of VOCs, NOx, and sunlight. Atmospheric dispersion models used in stationary source air permitting analyses cannot be used to estimate O_3 impacts resulting from VOC and NOx emissions from an industrial facility. O_3 concentrations resulting from area-wide emissions are predicted by using more complex airshed models such as the Community Multi-Scale Air Quality (CMAQ) modeling system. Use of the CMAQ model is very resource-intensive and DEQ asserts that performing a CMAQ analysis for a particular permit application is not typically a reasonable or necessary requirement for air quality permitting.

Addressing secondary formation of O_3 within the context of permitting a new stationary source has been somewhat addressed in EPA regulation and policy. As stated in a letter from Gina McCarthy of EPA to Robert Ukeiley, acting on behalf of the Sierra Club (letter from Gina McCarthy, Assistant Administrator, United States Environmental Protection Agency, to Robert Ukeiley, January 4, 2012):

> *. . . footnote 1 to sections 51.166(I)(5)(I) of the EPA's regulations says the following: "No de minimis air quality level is provided for ozone. However, any net emission increase of 100 tons per year or more of volatile organic compounds or nitrogen oxides subject to PSD would be required to perform an ambient impact analysis, including the gathering of air quality data."*
>
> *"The EPA believes it unlikely a source emitting below these levels would contribute to such a violation of the 8-hour ozone NAAQS, but consultation with an EPA Regional Office should still be conducted in accordance with section 5.2.1.c. of Appendix W when reviewing an application for sources with emissions of these ozone precursors below 100 TPY."*

DEQ determined it was not appropriate or necessary to require a quantitative source-specific O_3 impact analysis because allowable emission estimates of VOCs and NOx are below the 100 tons/year threshold.

3.1.2 TAPs Modeling Applicability and Modeled Emission Rates

A comparison of the applicable non-carcinogenic and carcinogenic screening emission levels (EL) for the TAP from Idaho Administrative Procedures Act (IDAPA) 58.01.01, Sections 585 and 586, respectively, with applicable facility-wide maximum potential TAP emissions is provided in Table 9.

Table 9. TAP MODELING APPLICABILITY DETERMINATION.

HAP/TAP	Emissions (lb/hr)				EL (lb/hr)		Determination
	(a)	(b)	(c)	Total	(d)	(e)	
1,3-Butadiene	--	--	--	--	--	2.4E-5	EL not exceeded

[a] HAP/TAP emissions from propane combustion.
[b] HAP/TAP emissions from diesel combustion. Diesel engine HAP emissions are regulated by Code of Federal Regulations, Title 40, Part 63 (40 CFR 63), Subpart ZZZZ and therefore exempt from TAP analysis per IDAPA 58.01.01 Section 210.20.
[c] HAP/TAP emissions from material processing.
[d] Non-carcinogenic EL from IDAPA 58.01.01 Section 585.
[e] Carcinogenic EL from IDAPA 58.01.01 Section 586.

Table 9 shows that the SGP facility-wide potential TAP emissions exceed the respective EL for antimony, arsenic, cadmium, formaldehyde, nickel, and sulfuric acid. Therefore, modeling was required for these six TAPs.

3.1.3 Modeling Scenarios

As discussed in Section 2.1, conventional open-pit methods will be used to extract ore and DR from three pits: YPP, HFP, and WEP, and legacy tailings from BT. Ore will be hauled to the crushing area, and the DR will be moved to four DRSF: Yellow Pine (YPDRSF), Hangar Flats (HFDRSF), West End (WEDRSF), and Fiddle (FDRSF). The SGP site layout provided later in Figure 4 shows these locations.

Midas Gold plans for an up to three-year construction schedule to build mine site facilities and infrastructure, as well as the power transmission line, followed by 12 years of mining operations (i.e., LOM Years 1 through 12). Depending on the mine design and operating schedule, mining activity rates will vary temporally and spatially during the 12 years of mine production and operation. For example, ore production varies from approximately 6.8 MMton in LOM Year 1 (67% in YPP, 26% in WEP, and 7% in

DRAFT

BT) to 9 MMton in LOM 3 (78% in YPP, 10% in BT, 7% in WEP, and 5% in HFP). Similarly, DR production varies from approximately 4.8 MMton in LOM Year 12 (100% in WEP) to 34 MMton in each of LOM Years 4 through 9, with varying distribution among the four DRSF for each LOM Year. The total material (ore and DR) production varies from approximately 12.5 MMton in LOM Year 12 to 42.7 MMton in LOM Year 4.

Similar to the material production, the distribution and hauling of DR to the four destinations (YPDRSF, HFDRSF, WEDRSF, FDRSF) also will vary for each LOM year. Depending on the material origin (pits and BT) and destination (crushing area and DRSF), material hauling distances also will vary for each LOM year.

Therefore, depending on material production rates and origin, DR destination, and hauling distances, mining emissions will vary spatially and temporally throughout the mine life. For permitting purposes, Midas Gold used a maximum production rate of 180,000 tons of material (ore and/or DR) per day, for an annual production rate of 65.7 MMton/yr. This annual production rate is more than 50% higher than the estimated maximum total material production rate of 42.7 MMton/yr.

In order to allow Midas Gold with operation flexibility and to capture variability in material origin and destination in the air quality analyses, several pit scenarios were developed for the SGP air quality analyses. Each pit scenario uses the maximum production rate of 180,000 ton/day in a single pit and uses a single material destination. Each pit has a dedicated ore scenario that assumes all material produced is ore and is hauled to the crusher area; and depending on mine design multiple DR destination scenarios each assuming all material produced is DR and is transported to a single DRSF. For example, most of the DR from HFP will be moved to HFDRSF and during LOM Years 2 through 10, but a fraction of this rock will be moved to FDRSF during LOM Years 3 and 8, and a fraction to YPDRSF during LOM Year 9. Therefore, in order to evaluate all hauling scenarios originating from HFP, the following four (one for ore hauling, three for DR hauling) HFP scenarios were modeled:

1. HFP Scenario 1 – 180,000 ton/day of ore produced and hauled to the crusher area
2. HFP Scenario 2 – 180,000 ton/day of DR produced and hauled to the FDRSF
3. HFP Scenario 3 – 180,000 ton/day of DR produced and hauled to the HFDRSF
4. HFP Scenario 4 – 180,000 ton/day of DR produced and hauled to the YPDRSF

Overall, 14 scenarios were modeled for $PM_{2.5}$ and PM_{10} analyses to cover all possible origin and destination combinations. Each modeling scenario included processing and ancillary source potential emissions. The multiple scenarios modeled for $PM_{2.5}$ and PM_{10} analyses are presented in Table 10. This table also shows the six origin/destination options that are not applicable to the SGP Project as denoted by "0 ton/day." These six scenarios are not feasible because the timing of the activity within the sequence of mine operations makes the scenarios logistically impossible.

Table 10. MODELING SCENARIOS FOR $PM_{2.5}$ AND PM_{10} ANALYSES.

Pit Scenario	Pit/Origin (ton/day)				Ore Destination (ton/day)	DR Destination (ton/day)

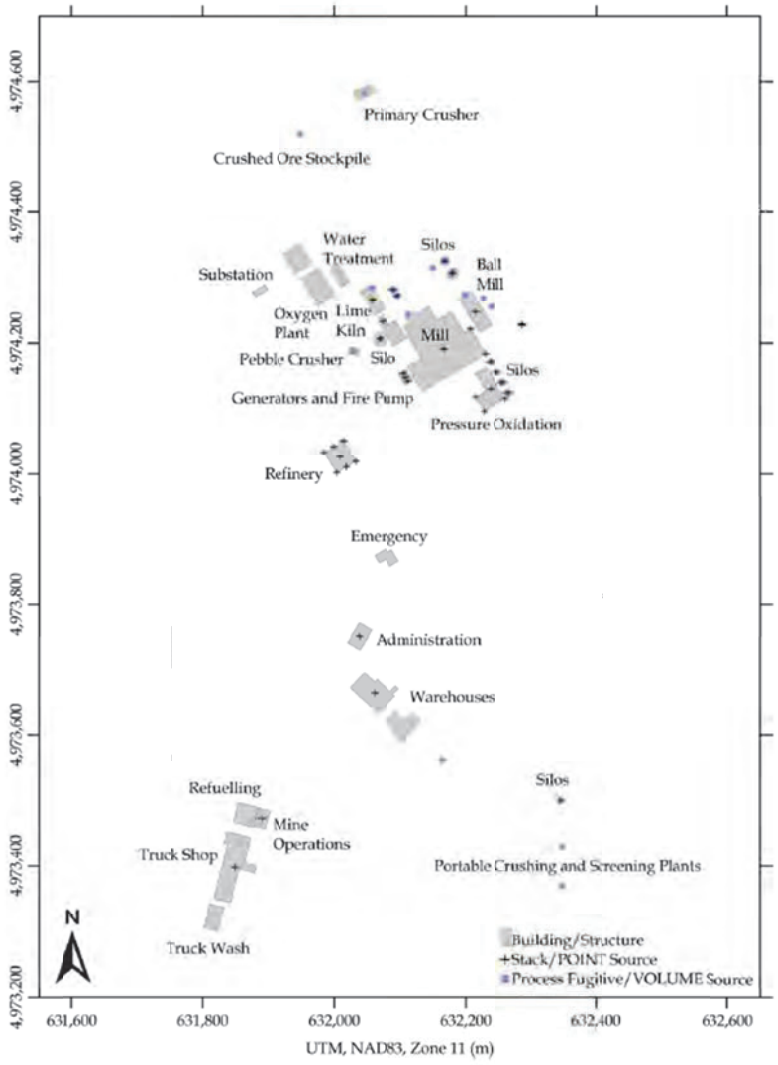
B2	--	--	--	180,000	--	--	180,000	--	--
B3	--	--	--	0	--	0	--	--	--
B4	--	--	--	0	--	--	--	0	--
B5	--	--	--	0	--	--	--	--	0

Scenario Y4 is not applicable because the YPDRSF and the YPP are in the same area; therefore, the pit cannot be backfilled with development rock until after mining of the pit is completed. Scenarios Y5 and H5 are not applicable because the WEDRSF will only be utilized by the WEP because of its proximity; it is only accessible from the WEP. Scenarios B3, B4 and B5 are not applicable because the development rock from the BT will only be hauled to the HFDRSF because of its proximity. All other development rock storage facilities are significantly farther away from BT.

The fugitive CO, NO_2, and SO_2 emissions are limited to pits only, and they do not vary by ore and/or DR hauling and destinations. Therefore, for these pollutants, one scenario for each pit, including processing and ancillary source potential emissions, was modeled, i.e., scenarios Y1, H1, W1, and B1.



The TAP emissions are limited to processing and ancillary sources, so a single scenario was modeled for each applicable TAP analysis.

3.1.4 Processing, Refining, and Ancillary Sources

The processing, refining, and ancillary sources with exhaust stacks, such as baghouse-equipped sources, generators, process and building heaters, autoclave, retort, smelting furnace, carbon kiln, lime kiln, etc., were modeled as POINT sources. The process sources without exhaust stacks, such as material transfers, ore screening and crushing, etc., were modeled as VOLUME sources. A plot plan showing the processing and refining area buildings and sources is provided in Figure 3. Process and ancillary source model input parameters are provided later in Tables 14 and 15.

DRAFT

Figure 3. PROCESSING AND REFINING AREA BUILDING AND SOURCE LAYOUT.

3.1.5 Fugitive Sources: Blasting, Material Origin and Destination, and Underground Exploration Emissions

Blasting emissions were represented by a VOLUME source located inside a pit. Each material origin location (YPP, HFP, WEP, BT) was modeled as an AREA source and comprised appropriate emissions from drilling, material loading, dozing, and surface exploration. Ore destination (crusher area) was modeled as a VOLUME source and comprised ore unloading emissions. Each DR destination (FDRSF,

HFDRSF, YPDRSF, WEDRSF) was modeled as a VOLUME source comprising appropriate emissions from DR unloading, dozing, and wind erosion. Emissions from underground core sampling drilling (UGEXP) in the Scout prospect decline were represented by an AREA source characterized by the portal opening dimensions.

Model input physical characteristics for blasting and possible material origin and destination locations, and Scout portal are presented in Table 11. This table also shows the source type and associated dimensions for each of the modeled fugitive source/location. The VOLUME source dimensions for blasting provided in Table 11 were based on an estimated blast area. For the remaining AREA and VOLUME sources listed in Table 11, the dimensions were developed by reasonably fitting an equal-area rectangle within the actual footprint of each fugitive source. Blasting is not expected to occur in BT. However, blasting emissions were modeled in BT (BTBL) in order to streamline the permitting process.

Table 11. MODELED FUGITIVE ACTIVITY LOCATIONS.

Model ID	Activity Location	Type	Lateral Dimensions (m)	Emission Sources
YPP	Yellow Pine Pit	AREA	882 × 882	Drilling, loading, dozing, surface exploration
HFP	Hangar Flats Pit	AREA	491 × 491	Drilling, loading, dozing, surface exploration
WEP	West End Pit	AREA	376 × 376	Drilling, loading, dozing, surface exploration
BT	Bradley Tailings	AREA	820 × 420	Loading, dozing, wind erosion
YPPBL	Yellow Pine Pit (Blasting)	VOLUME	87 × 87	Blasting
HFPBL	Hangar Flats Pit (Blasting)	VOLUME	87 × 87	Blasting
WEPBL	West End Pit (Blasting)	VOLUME	87 × 87	Blasting
BTBL	Bradley Tailings (Blasting)	VOLUME	87 × 87	Blasting
STKP	PC Stockpile	VOLUME	229 × 229	Unloading, dozing, wind erosion
FDRSF	Fiddle DRSF	VOLUME	775 × 775	Unloading, dozing, wind erosion
HFDRSF	Hangar Flats DRSF	VOLUME	752 × 752	Unloading, dozing, wind erosion
YPDRSF	Yellow Pine DRSF	VOLUME	784 × 784	Unloading, dozing, wind erosion
WEDRSF	West End DRSF	VOLUME	533 × 533	Unloading, dozing, wind erosion
UGEXP	Scout Portal	AREA	4.9 × 4.9	Sample core drilling

The model input physical parameters for blasting, material origin and destination locations, and Scout portal are provided in Table 12.

Table 12. MODEL INPUT PARAMETERS FOR FUGITIVE ACTIVITY LOCATIONS.

Model ID	Base Elevation (m)	Release Height (m)	Initial Lateral Dispersion (m)	Initial Vertical Dispersion (m)
YPP	1,832.4	4.7	N/A	4.4
HFP	1,993.3	4.7	N/A	4.4

HFPBL	1,890.6	15.0	20.2	7.0
WEPBL	1,994.0	15.0	20.2	7.0

DRAFT

BTBL	2,011.7	15.0	20.2	7.0
STKP	1,979.8	4.7	53.3	4.4
FDRSF	2,115.2	4.7	180.2	4.4
HFDRSF	2,079.8	4.7	174.8	4.4
YPDRSF	1,904.1	4.7	182.2	4.4
WEDRSF	2,376.5	4.7	124.1	4.4
UGEXP	2,018.0	0	N/A	0

The blasting physical parameters were developed from dimensions (provided in Table 11) based on blast area used in the emission calculation. The blasting release height is the midpoint of the blasting height (30 m).

The initial lateral and vertical dispersion dimensions for blasting were calculated per methods specified in (EPA 2018c) for a volume source not on or adjacent to a building, as:

$$Initial\ Lateral\ Dispesion = \frac{Width\ (87\ m)}{4.3}$$

$$Initial\ Vertical\ Dispesion = \frac{Height\ (30\ m)}{4.3}$$

For the pit and DRSF fugitive activity locations listed in Table 11, i.e., YPP, HFP, WEP, BT, FDRSF, HFDRSF, and WEDRSF, the release height was based on the haul truck height (weighted based on model-specific usage) and calculated using the recommendations provided in the Haul Road Workgroup Report (EPA 2012), as:

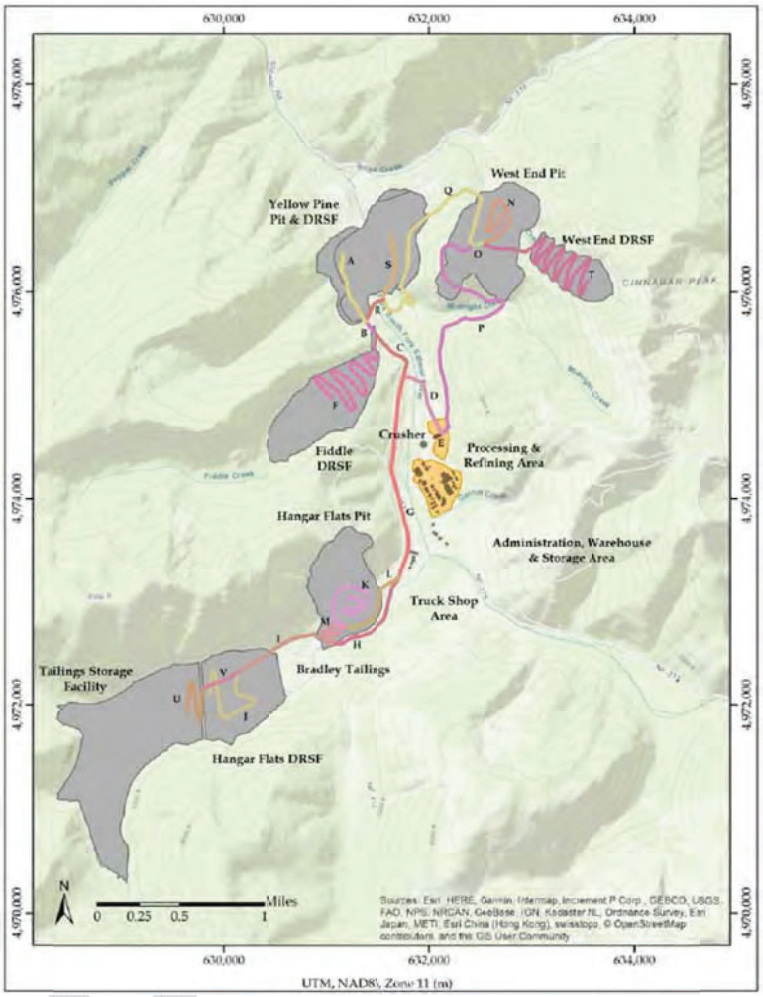
$$Release\ Height = \frac{Plume\ Top\ (Weighted\ Truck\ Height \times 1.7)}{2}$$

The applicable initial lateral dispersion for each VOLUME source was calculated from the respective shorter dimension and EPA-specified methods (EPA 2018c) (EPA 2016) as follows:

$$Initial\ Lateral\ Dispesion = \frac{Short\ Lateral\ Dimension}{2.15}$$

The applicable initial vertical dispersion for each AREA and VOLUME source was calculated from the respective vertical dimension and EPA-specified methods (EPA 2018c) (EPA 2016) as follows:

$$Initial\ Vertical\ Dispersion = \frac{Plume\ Top\ (Weighted\ Truck\ Height \times 1.7)}{2.15}$$



Scout portal was modeled as a surface-based AREA source with zero release height.

3.1.6 Fugitive Sources: Haul Roads

A representative haul road network for hauling material from inside the pit (or origin) to various destinations was developed for each pit scenario provided in Table 10. The haul road network is presented in Figure 4.

DRAFT

Figure 4. HAUL ROAD NETWORK AND SECTIONS.

As shown in Figure 4, the haul road network was divided into 22 sections, A through V. Each section was further divided into multiple segments with a length equal to twice the adjusted haul road width of 32.5 m (26 m road width plus 6 m (EPA 2012)). Each of the segments was characterized as an individual VOLUME source in the model, with a release height of 4.75 m (weighted-average truck height times 1.7, divided by 2 (EPA 2012)), an initial lateral dispersion of 15.1 m (adjusted road width divided by 2.15 (EPA 2012)), and an initial vertical dispersion of 4.42 m (weighted-average top-of-plume height divided by 2.15 (EPA 2012)). Material hauling emissions associated with each origin-destination route were assigned to each segment along the route based on estimated total emissions along the route and traffic distribution along each section, as provided in Table 13 for the four HFP scenarios.

Table 13. HAUL ROAD EMISSION DISTRIBUTION GRID FOR HFP SCENARIOS.					
Pit Scenario		**H1**	**H2**	**H3**	**H4**

S	13	--	--	--	1
T	72	--	--	--	--
U	19	--	--	--	--
V	7	--	--	--	--

The top row in Table 13 shows the pit scenarios, and the next two rows show hauling route and the associated segment emission denominator (SED) used to distribute segment emissions along each route. The remainder of Table 13 presents the number of segments for each road section (shown in Figure 4) and the associated traffic distribution factor for each route. The emission distribution for each applicable segment is illustrated in the following example.

For route: HFP–STKP (Hangar Flats pit to crusher stockpile), Figure 4 shows that material from HFP will be hauled to the crusher area following the route along Sections K, L, G, and D. All (100%) of the ore from HFP will travel on each of these sections; therefore, each of these sections has a traffic distribution factor of 1.0 for this route.

The SED for each route is the sum-product of the number of segments and traffic distribution for the applicable sections. The SED for the HFP–STKP route is calculated as:

$$SED_{(HFP-STKP)} = (28 \times 1) + (16 \times 1) + (38 \times 1) + (14 \times 1) = 96$$

Emissions for each section-segment were estimated by dividing the total emissions along the route by its SED and multiplying by the section distribution factor. For example, the emission rate for each of the 28 segments along Section K was calculated as:

$$Emission\ Rate - Section\ K_{(Segments\ 1-28)} = \frac{Total\ Emissions_{(HFP-STKP)}}{96} \times 1$$

DRAFT

3.1.7 Fugitive Sources: Burntlog Route Access Road

The access road portion within the operations boundary was characterized by a series of LINE sources laid along the actual route. Emissions associated along this access road include dust emissions generated from travel of maintenance equipment, light-duty pickup trucks and buses used for employee, visitor, and contractor transportation, and heavy-duty trucks used for cargo and services transportation. These sources were assigned a release height of 3 m and an initial vertical dispersion of 2.8 m. These release parameters were based on an estimated average vehicle height of 3.5 m, which is representative of an overall approximation of anticipated vehicle heights (grader – 3.7 m, heavy-duty truck – 3.6 m, and pickup truck – 3.2 m) and the AREA source parameterization recommendations provided in the Haul Road Workgroup Report (EPA 2012). The AERMOD emission input units for AREA source are grams per meter square. The access road emissions were evenly distributed along the road by dividing the total access road emissions by its total area, i.e., the Burntlog Route section within the operations boundary (2,950 m) multiplied by the road width (6.1 m).

3.1.8 Emission Release Parameters

Table 14 lists the emission release parameters, including stack height, exhaust temperature, exhaust velocity, and stack diameter for SGP's process and ancillary point sources in metric units (English units are in parentheses). Table 15 lists the emission release parameters for SGP's process and ancillary volume sources in metric units (English units are in parentheses). Emission release parameters were based on information provided in the application. Justification for emission release parameters is summarized in the next section.

Table 14. PROCESS AND ANCILLARY POINT SOURCE EMISSION RELEASE PARAMETERS IN METRIC UNITS (ENGLISH UNITS IN PARENTHESES).

3.1.9 Emission Release Parameter Justification

Modeled Process and Ancillary Point Sources

The pneumatic transfer silo loadings and bin transfers (LS1L, MillS2L, ACS1L, ACS2L, ACS3L, ACS4L, PSL, CS1L, CS2L, LS6, LSBM, LS9, LSL) were modeled as POINT sources with a 3-foot bin vent above standard silo height as release height. Exit velocity was estimated using the standard stack diameter and flow rates for similar sources (NDEP 2019) or 0.001 meter per second for horizontal exhaust. These sources were modeled with ambient exhaust temperature.

For propane-fired process (Sb1, ACB, CKB, PV, HS) and building heaters (H1M, H2M, HM, HAC, HR, HA, HMO, HTS, HW), exhaust flow rates were calculated using EPA Method 9 with 3% oxygen content and 15% moisture content. Standard stack diameters were selected based on the heater rating. The process heaters were modeled with a 10-foot stack above the building, whereas the building heaters were modeled with a release height of 1 foot above the respective buildings.

Similar source exhaust temperature, flow, and diameter from (NDEP 2017) were used for refinery sources, including the carbon regeneration kiln (CKD), electrowinning cells (EW), mercury retort (MR), and induction furnace (MF). Each of these sources was modeled with a 10- foot stack above the refinery building.

For emergency generators (EDG1, EDG2, EDG3) and the fire pump (EDFP), the exhaust flow rates were calculated using EPA Method 9 with 9% oxygen content and 8% moisture content. Standard stack diameters were selected based on engine rating. Each engine was modeled with a 7-foot-high stack.

Antimony bagging (Sb2), autoclave (AC), lime kiln (LK) (common stack with kiln burner (LKC)), and lime crushing (LCR) were characterized with similar source parameters from (NDEP 2015b), (APT 2013), and (NDEP 2010). Each of these sources was modeled with a 10-foot stack above its respective building.

Release parameters for the process and ancillary point sources were appropriately documented and justified. DEQ's source-group analysis (Table 28 in Section 4.1.4) suggests that the process and ancillary point sources contribute a small amount to the modeled design concentrations.

Modeled Process and Ancillary Volume Sources

For the following VOLUME source characterization discussion, release height was estimated as half of the vertical length (for example, building height), initial vertical dispersion was calculated by dividing the vertical length by the applicable EPA-recommended constant (EPA 2018c) for a single VOLUME source (4.3), and initial lateral dispersion was determined using the lesser lateral dimension (for example, building width) divided by the applicable EPA-recommended constant (EPA 2018c) for the surface source or elevated source with a building (2.15).

DRAFT

The sources associated with the primary crusher building, including loader transfer (OC1), grizzly feeder (OC2), apron feeders (OC3, OC4), ore transfers (OC5, OC6), and primary crusher (OC7), were characterized by the primary crusher building dimensions: 128’ high and 52.9’ wide.

The stockpile height (71.6’) and the conveyor width (3’) were used to determine the VOLUME source parameters for the stockpile feed conveyor (OC8).

Tunnel exit dimensions (8’ high and 8’ wide) were used to estimate the VOLUME release parameters for the stockpile transfer points (OC9, OC10). The SAG mill feed conveyor transfer (OC11) was characterized by a building opening (4’ high and 4’ wide) at the mid-height (70’) of the mill building.

Pebble crusher building dimensions (20’ high and 32.7’ wide) were used to characterize the pebble crusher-associated sources (OC12, OC13).

Silo/bin unloading sources (LS1U, Mill2SU, ACS1U, ACS2U, ACS3U, ACS42U, PSU) were characterized by a typical screw discharge feeder characteristic, i.e., 5’ above the ground with a 1’ diameter.

Aggregate transfer and handling sources (CS1U, CS2U, CAL, CAU, CM) were characterized by the aggregate stockpile dimensions: 20’ high and 72.2’ wide.

Each portable crushing and screening plant was characterized by typical portable crushing and screening plant dimensions: 14’ high and 185’ wide.

Sources associated with limestone crushing (LS1, LS2, LS3, LS4, LS5) were characterized by the associated crusher building dimensions: 22.6’ high and 22.6’ wide.

The crushed limestone/pebble lime transfers (LS7, LS10, LSU) were characterized by a typical screw discharge to a conveyor characteristic, i.e., 5’ above the ground, 3’ drop, and a 1’ diameter.

The limestone ball mill feed discharge (LS8) was characterized by a building opening (4’ high and 4’ wide) at the mid-height (30’) of the ball mill building.
The limestone fines screening (LS11) was characterized by screen dimensions: 5’ drop and 8’ wide.

The limestone kiln feed (LS12) was characterized by a building opening (4’ high and 4’ wide) at the mid-height (70’) of the kiln building.

Model input source characterization for fugitive emissions is described in Sections 3.1.5 and 3.1.6. Fugitive activity locations and their respective dimensions are provided in Table 11 and associated release parameters are listed in Table 12.

Release parameters for the process and ancillary volume sources were appropriately documented and justified. DEQ’s source-group analysis (Table 28 in Section 4.1.4) suggests that the process and ancillary volume sources contribute a small amount to the modeled design concentrations.

3.2 Background Concentrations

Background concentrations are used if a cumulative NAAQS impact analysis is needed to demonstrate compliance with applicable NAAQS.

DRAFT

3.2.1 *Onsite Particulate Monitoring*

To establish background ambient air conditions for the SGP area, Midas Gold developed an onsite monitoring program to collect site-specific meteorological parameters and determine ambient particulate matter ($PM_{2.5}$ and PM_{10}) concentrations at its Stibnite monitoring station.

In September 2015, Midas Gold submitted the data collected at the Stibnite monitoring station for the period of November 2013 through June 2015 to DEQ. After reviewing the data and associated quality control procedures, DEQ concluded that the $PM_{2.5}$ and PM_{10} data collected at the Stibnite monitoring station satisfied the applicable regulatory requirements and approved the data to be used for background concentrations in the SGP air quality analyses. In its conclusions, DEQ recommended that the $PM_{2.5}$ and PM_{10} background concentrations should be based on calendar year 2014 instead of the complete dataset (November 2013 through June 2015).

DEQ-approved $PM_{2.5}$ and PM_{10} background concentrations, in units of micrograms per cubic meter ($\mu g/m^3$), are provided in Table 16.

Table 16. DEQ-APPROVED $PM_{2.5}$ AND PM_{10} BACKGROUND CONCENTRATIONS FOR SGP.

Pollutant	Averaging Time	Background Concentration ($\mu g/m^3$)	Design Value Rank
$PM_{2.5}$	1 year	3.5	Weighted average of quarterly means
	24 hours	15	98th percentile/8th high
PM_{10}	24 hours	37	Highest 2nd high

3.2.2 *Gaseous Pollutant Background Concentrations*

With a few exceptions of very large facilities or facilities located in nonattainment areas, regulatory agencies do not require the collection of gaseous criteria pollutants, including CO, NOx (and/or nitrogen dioxide [NO_2]), O_3, and SO_2. For these gaseous pollutants, data collected at government-regulated monitoring stations located in settings similar to the project area in terms of terrain, land use, and proximity of emission sources are typically used to establish background concentrations.

To determine representative background concentrations of CO, NOx, O_3, and SO_2 for the SGP site, which is located in a remote rural area, the DEQ-maintained ambient monitoring network was reviewed by Air Sciences. This review revealed that DEQ only conducts limited trace monitoring for CO, NOx, O_3, and SO_2 in the Boise metropolitan area along the Interstate 84 corridor. Thus, the data collected at these monitors are exposed to high emissions from industrial, urban, and transportation sources (DEQ 2015a) (DEQ 2018). For this reason, the gaseous pollutant concentrations recorded at these urban monitoring locations were not considered to be representative of a rural area, like the SGP site.

The EPA-maintained monitoring stations (EPA 2018a) in Idaho and surrounding states also were reviewed by Air Sciences to determine representative gaseous pollutant background concentrations for the SGP site. This review also did not identify any representative monitoring station to establish background gaseous pollutant concentrations for the SGP site.

The DEQ-recommended (DEQ 2019) CO, NOx, O_3, and SO_2 background concentrations for the SGP air quality analyses in units of parts per billion (ppb) and $\mu g/m^3$, are provided in Table 17. These background concentrations were obtained from the Northwest International Air Quality Environmental Science and

DRAFT

Technology Consortium (NW AIRQUEST; https://arcg.is/1jXmHH) online tool using the project site coordinates. These background air pollutant levels are based on regional-scale air pollution modeling of pollutants in Washington, Oregon, and Idaho, with modeling results adjusted according to available monitoring data.
