3.2.3 Medium-Traffic Pollutant Background Concentrations

For additional information, background concentrations were obtained from NW AIRQUEST for the road section between mile markers 143 and 144 on Highway 55 passing through the town of McCall. This site (latitude 44.906° N, longitude 116.098° W) is approximately 38 miles west of the SGP. The annual average daily traffic count for this road section is over 10,000 vehicles per day. Table 18 provides the background concentrations for this medium traffic site. Although these concentrations are not representative of the rural SGP area, they do provide additional information regarding the relative contribution of traffic emissions.

Table 18. MEDIUM-TRAFFIC BACKGROUND CONCENTRATIONS.

3.3 Impact Modeling Methodology

This section describes the modeling methods used by the applicant/consultant to demonstrate preconstruction compliance with applicable air quality standards.

3.3.1 General Overview of Impact Analyses

Air Sciences performed the project-specific air pollutant emission inventory and air impact analyses that were submitted with the application. The submitted information/analyses, in combination with results from DEQ's air impact analyses, demonstrate compliance with applicable air quality standards to DEQ's

DRAFT

satisfaction, provided the facility is operated as described in the submitted application and in this memorandum.

Table 19 provides a brief description of parameters used in the modeling analyses.

Table 19. MODELING PARAMETERS.

Parameter	Description/Values	Documentation/Addition Description
General Facility Location	Stibnite, Idaho	The area is an attainment or unclassified area for all criteria pollutants.
Model	AERMOD	AERMOD with the PRIME downwash algorithm, version 19191.
Meteorological Data	Onsite and McCall, Idaho surface data; Boise upper air data	See Section 3.3.5 of this memorandum for additional details of the meteorological data.
Terrain	Considered	1/3 arc second National Elevation Dataset (NED) was acquired from the USGS for the surrounding area. AERMAP version 18081 was used to process terrain elevation data for all buildings and receptors. See Section 3.3.6 for more details.
Building Downwash	Considered	Plume downwash was considered for the structures associated with the facility. BPIP-PRIME was used to evaluate building dimensions for consideration of downwash effects in AERMOD. See Section 3.3.7.
NOx Chemistry	Ozone Limiting Method	See Section 3.3.8.
Receptor Grid	**SIL Analysis** A SIL analysis was not performed.	
	Cumulative NAAQS Impact Analysis The selection of receptors for use in the cumulative NAAQS impact analysis is as follows (see Section 3.3.1~~1~~2):	
	Boundary	25-meter (m) spacing
	Grid 1	50-m spacing, 0.25 kilometers (km) out
	Grid 2	100-m spacing, 0.25 km to 1.25 km out
	Grid 3	500-m spacing, 1.25 km to 5 km out
	Grid 4	1,000-m spacing, 5 km to 10 km out
	Hotspot	25-m spacing, 200-m × 200-m around highest model impacts
	TAPs Analysis The receptor network used in the cumulative NAAQS impact analysis was also used in the TAPs analysis.	

3.3.2 Modeling Protocol

A modeling protocol for the SGP analyses was submitted to DEQ prior to the application, on May 30, 2019. The protocol was submitted by Brown and Caldwell on behalf of Midas Gold. Conditional DEQ protocol approval was provided to Brown and Caldwell on June 27, 2019.

3.3.3 Modeling Methodology

Project-specific modeling and other required impact analyses were generally conducted using data and methods described in the *Idaho Air Quality Modeling Guideline* (DEQ 2013).

3.3.4 Model Selection

Idaho Air Rules Section 202.02 requires that estimates of ambient concentrations be based on air quality models specified in Appendix W. The refined, steady-state, multiple-source, Gaussian dispersion model AERMOD was promulgated as the replacement model for ISCST3 in December 2005. AERMOD retains the single straight-line trajectory of ISCST3, but it includes more advanced algorithms to assess turbulent mixing processes in the planetary boundary layer for both convective and stable stratified layers.

DRAFT

AERMOD version 19191 was used by Air Sciences for the modeling analyses to evaluate impacts of the facility. This version was the current version at the time the application was received by DEQ.

3.3.5 Meteorological Data

AERMOD requires an input of hourly meteorological data to estimate pollutant concentrations in ambient air resulting from modeled source emissions. These data are commonly obtained from National Weather Service (NWS) stations at airports throughout the state. Applicants select data from an airport site that is determined to be reasonably representative of the permitted site location. Collection of meteorological data from the permitted site is not typically required by DEQ for minor source permit applications. The collection of one year of onsite data is required for permitting projects subject to the Prevention of Significant Deterioration (PSD) program, which is triggered by larger non-fugitive emission quantities.

Site-specific hourly surface meteorological data were collected and used in air impact analyses for this project, as described in the submitted modeling report. These data were collected from January 1, 2014 through December 31, 2014 at the Stibnite monitoring station. They were collected for analyses supporting an Environmental Impact Statement (EIS) and the Idaho DEQ minor source permit.

The site-specific surface data were supplemented with the twice-daily upper-air data (all levels) collected at the National Weather Service (NWS) station in Boise, Idaho (WBAN 24131).

These meteorological datasets were processed with the most recent version (19191) of the AERMOD meteorological pre-processor, AERMET, to produce AERMOD-input-ready hourly surface and profile meteorological files. The default option of adjusted surface friction velocity (ADJ_U*) and the Bulk Richardson (BULKRN) method for boundary layer parameter calculations was used for this meteorological data processing.

Additionally, an alternative meteorological dataset was processed without using the BULKRN method (NON-BULKRN). This alternate processing used the onsite and upper air datasets discussed above, supplemented with the cloud-cover data collected at the NWS station in McCall, Idaho (WBAN 94182).

Both processing methods (BULKRN and NON-BULKRN) are considered default for regulatory modeling analyses. EPA Region X Regional Modeling Contact, Jay McAlpine, PhD, was consulted for guidance on which data processing procedure to require for the analyses supporting the Idaho PTC. The BULKRN method was used for air impact analyses supporting the EIS after consultation with EPA, DEQ, and the US Forest Service. EPA recommended (June 18, 2019, email from Jay McAlpine, EPA, to Kevin Schilling, DEQ) using the BULKRN method since "use of the onsite data best fulfills the Guidance, and ensures consistency with the EIS, but this should be looked upon as technical advice only and not a requirement of the EPA."

Compliance with all NAAQS was easily demonstrated using meteorological data processed by the NON-BULKRN method; however, a small number of receptors showed 24-hour PM_{10} violations when the meteorological data processed with BULKRN method was used. DEQ performed a weight of evidence analyses (see Section 4.1.4 of this memorandum) to further evaluate the confidence of NAAQS compliance, using sensitivity analyses of various model input variables and the meteorological data processed using the BULKRN method.

AERMET requires the input of three surface boundary layer parameters: midday Bowen ratio (B_o), midday albedo (r), and surface roughness length (z_o). These parameters are dependent on the land use and

DRAFT

vegetative cover of the area being evaluated. The EPA-recommended model, AERSURFACE, was used to estimate these surface parameters for the Stibnite meteorological data processing. AERSURFACE uses 1992 National Land Cover Data to determine these surface characteristics.

The determination of B_o is dependent on ambient moisture conditions (i.e., wet, average, or dry). For this purpose, historic 30-year (1985–2014) precipitation data from the Taylor Ranch station in Idaho (the closest station from which this type of data is available) were used.

The 70th and 30th percentile values estimated from the 30-year precipitation data were used to assign a moisture class to each calendar month per the following scheme: monthly precipitation greater than the 70th percentile was considered "wet"; between the 70th and 30th percentiles was considered "average"; and less than the 30th percentile was considered "dry." The monthly season and moisture classifications and estimated r and B_o for 2014 Stibnite meteorological data processing are presented in Table 20.

Table 20. 2014 MONTHLY SEASON AND MOISTURE CLASSIFICATION, AND CALCULATED r AND B_O.

Month	Season	r	30-Year Precipitation Percentile (in)		2014 Precipitation (in)	Moisture Classification	*Bo*
			30th	70th			
January	Winter	0.38	0.64	1.29	0.74	Average	0.50
February	Winter	0.38	0.40	0.81	0.99	Wet	0.50
March	Spring	0.13	0.83	1.23	2.33	Wet	0.34
April	Spring	0.13	1.11	1.57	0.99	Dry	1.57
May	Spring	0.13	1.43	2.23	0.74	Dry	1.57
June	Summer	0.13	1.17	1.80	1.32	Average	0.37
July	Summer	0.13	0.46	1.45	0.40	Dry	0.76
August	Summer	0.13	0.42	1.11	2.03	Wet	0.25
September	Fall	0.13	0.27	1.23	0.43	Average	0.87
October	Fall	0.13	0.59	1.69	1.75	Wet	0.35
November	Fall	0.13	0.72	1.44	3.73	Wet	0.35
December	Winter	0.38	0.64	1.16	0.83	Average	0.50

The seasonal z_o values in m for each 30-degree sector of the 1-km radius for the Stibnite monitoring station are provided in Table 21 (i.e., Sector 1 is 0° to 30° clockwise from the north, Sector 2 is 30° to 60° clockwise from the north, etc.).

Table 21. CALCULATED SEASONAL z_O VALUES (m).

Sector	Winter	Spring	Summer	Fall
1	0.410	0.564	0.610	0.607
2	0.212	0.347	0.392	0.387
3	0.517	0.640	0.671	0.669
4	0.769	0.865	0.894	0.894
5	0.989	1.044	1.055	1.055
6	0.741	0.874	0.918	0.915
7	0.400	0.563	0.617	0.614

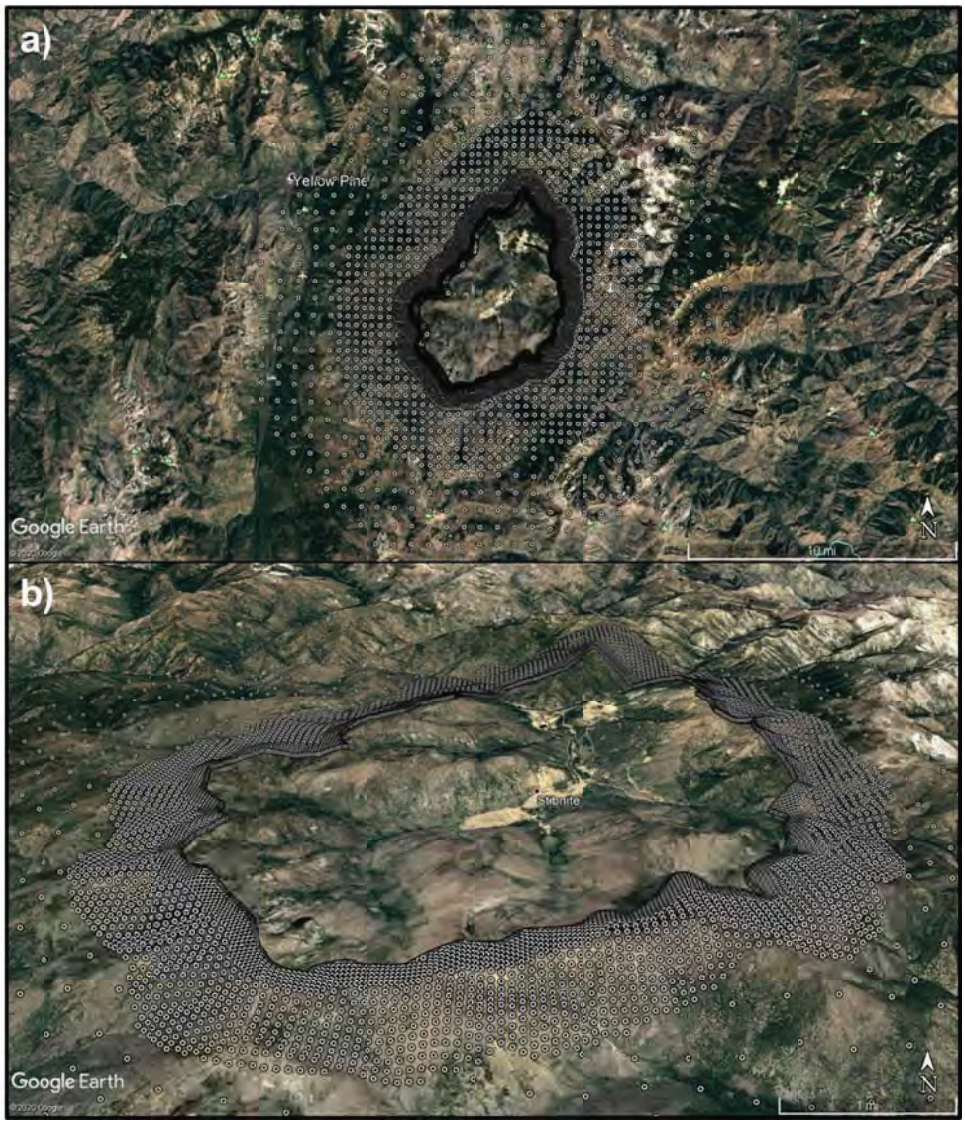
Figure 6. METEOROLOGICAL STATION LOCATIONS FOR SGP MODELING.



3.3.6 Effects of Terrain on Modeled Impacts

Submitted ambient air impact analyses used terrain data extracted from United States Geological Survey (USGS) National Elevation Dataset (NED) files.

The terrain preprocessor AERMAP version 18081 was used by Air Sciences to extract the elevations from the NED files and assign them to receptors in the modeling domain in a format usable by AERMOD. AERMAP also determined the hill-height scale for each receptor. The hill-height scale is an

elevation value based on the surrounding terrain which has the greatest effect on that individual receptor. AERMOD uses those heights to evaluate whether the emission plume has sufficient energy to travel up and over the terrain or if the plume will travel around the terrain. Figure 7a depicts the full receptor grid used in the modeling analyses and Figure 7b illustrates a close-up of Figure 7a, overlaid on a terrain image from Google Earth.

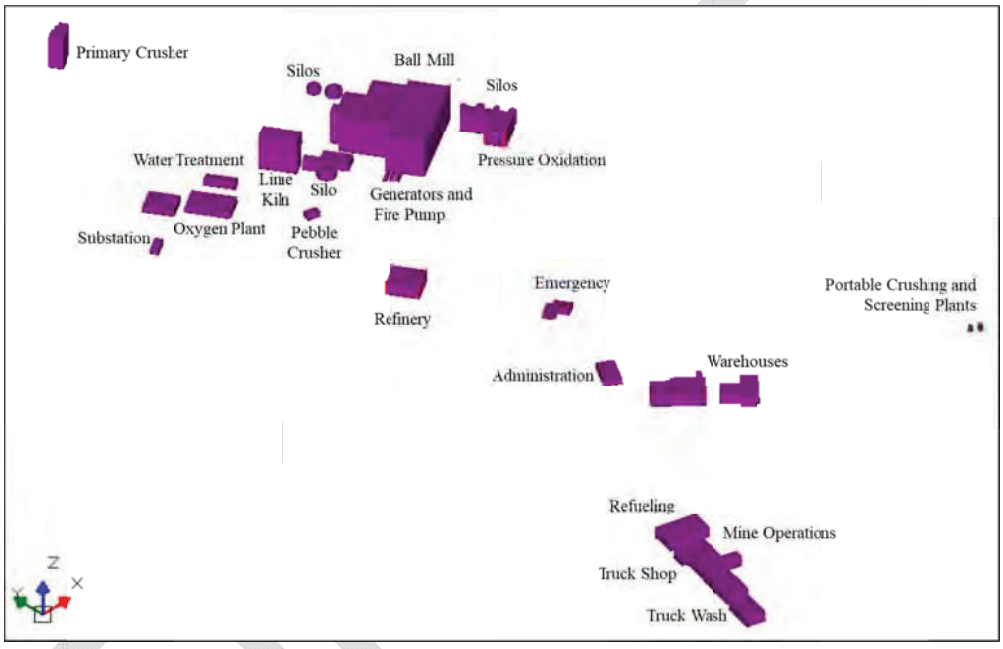


Figure 7. RECEPTOR GRID CENTERED AT THE SGP FACILITY.

3.3.7 Facility Layout and Downwash

Figure 3 shows the processing and refining area buildings and sources at the SGP facility. Figure 8 below depicts a three-dimensional view of Figure 3, as viewed from the southwest.

Figure 8. THREE-DIMENSIONAL VIEW OF PROCESSING AND REFINING AREA BUILDINGS AND SOURCES AT THE SGP FACILITY AS VIEWED FROM THE SOUTHWEST.

DEQ verified proper identification of the site location and the ambient air boundary by comparing a graphical representation of the modeling input file to aerial photographs on Google Earth (available at https://www.google.com/earth).

Potential downwash effects on emission plumes were accounted for in the model by using building dimensions and locations (locations of building corners, base elevation, and building heights). Dimensions and orientation of proposed buildings were used as input to the Building Profile Input Program for the Plume Rise Model Enhancements downwash algorithm (BPIP-PRIME version 04274) to calculate direction-specific dimensions and Good Engineering Practice (GEP) stack height information for input to AERMOD.

3.3.8 NOx Chemistry

The atmospheric chemistry of NO, NO_2, and O_3 complicates accurate prediction of NO_2 impacts resulting from NOx emissions. The conversion of NO to NO_2 can be conservatively addressed through the use of

REC 0867

PET 501

several methods as outlined in a *2014 EPA NO_2 Modeling Clarification Memorandum* (EPA 2014). The guidance outlines a three-tiered approach:

- Tier 1 – assume full conversion of NO to NO_2 where total NOx emissions are modeled and modeled impacts are assumed to be 100 percent NO_2.
- Tier 2 – use an ambient ratio to adjust impacts from the Tier 1 analysis.
- Tier 3 – use a detailed screening method to account for $NO/NO_2/O_3$ chemistry such as the Ozone Limiting Method (OLM) or the Plume Volume Molar Ratio Method (PVMRM).

The default option of the Ozone Limiting Method (OLM), a third-tier method from 40 CFR 51, Appendix W, was used by Air Sciences to estimate the NO_2 1-hour and annual impacts for these analyses. The OLM method requires an input of in-stack NO_2/NOx ratio for each modeled source.

An in-depth literature review was conducted by Air Sciences to identify reasonable NO_2/NOx ratios for different combustion source categories. Based on this research, the NO_2/NOx ratio recommended for the heavy-duty diesel trucks in the California Air Pollution Control Officers Association (CAPCOA) Guidance Document (CAPCOA 2011) was selected for stationary diesel combustion sources. This NO_2/NOx ratio (11 percent) is conservatively higher than the diesel combustion NO_2/NOx ratio provided in the EPA ISR (In-Stack Ratio) database: 6 percent average, 9.8 percent maximum. The CAPCOA document and the EPA ISR database do not provide an NO_2/NOx ratio for propane boilers. The CAPCOA-recommended NO_2/NOx ratio for natural gas boilers was selected for the propane boilers. The natural gas boilers NO_2/NOx ratio is considered appropriate for the propane boilers because both are gaseous fuels with relatively similar combustion characteristics and are expected to have similar NO_2/NOx ratios. The NO_2/NOx ratio for blasting is based on blasting plume measurements provided in an Australian study (CSIRO 2008). The NO_2/NOx ratios used for the SGP NO_2 analyses are presented in Table 22.

Table 22. NO_2/NOx RATIOS.

Source Type	NO_2/NO_X Ratio	Reference
Blasting	0.036	Commonwealth Scientific and Industrial Research Organisation (CSIRO 2008)
Diesel Engines	0.11	CAPCOA Guidance Document, heavy-duty diesel trucks (CAPCOA 2011)
Propane Heaters	0.10	CAPCOA Guidance Document, natural gas boilers (CAPCOA 2011)

DEQ performed a sensitivity analysis using a Tier 2 screening method (ARM2), which is more conservative than OLM, and found that the SGP facility is safely below the 1-hour and annual NO_2 NAAQS. Results are summarized in Section 4.1.3.

3.3.9 Particulate Deposition

For $PM_{2.5}$ and PM_{10} analyses, default particulate modeling methods, including deposition (Method 1, to account for depletion due to particulate settling), were used. To account for particulate settling, AERMOD requires the following source-specific variables:

1. Mass-mean aerodynamic particle diameter (PARTDIAM) for each particle size bin
2. Mass fraction (MASSFRAX) for each particle size bin
3. Particle density (PARTDENS) for each particle size bin

DRAFT

A list of references that were used to develop the broad source category particle size bins and associated mass fractions was provided in the application. Midas Gold (Midas Gold 2017b) provided the ore and DR material densities. The diesel and propane combustion particulate densities were adopted from technical literature (UMN 2002) and (Khalizov et al. 2012), respectively. Densities for the remaining materials were obtained from the Engineering Toolbox (https://www.engineeringtoolbox.com/density-materials-d_1652.html). An average density was used when a material-specific density range was available.

For sources that were aggregated and modeled as activity locations, deposition parameters were selected for the dominant source within the activity location. For open-pits (YPP, HFP, WEP), approximately 90% of emissions were associated with drilling; therefore, drilling deposition parameters were assigned to these sources. Similarly, emissions from dozing accounted for over 70% of emissions in the DRSF (FDRSF, HFDRSF, WEDRSF) and BT; therefore, these sources were assigned deposition parameters based on a dozing particulate profile.

The deposition parameters including mass fractions, mass mean diameters, and densities for the different source categories/groups are provided in Table 23.

Table 23. DEPOSITION PARAMETERS BY SOURCE CATEGORY.

Source Category	Parameter	PM_{10}				$PM_{2.5}$	
		Bin 1	Bin 2	Bin 3	Bin 4	Bin 1	Bin 2

	Mass Fraction	0.06	0.94	--	--	1.00	--
	Mass Mean Diameter (µm)	2.50	10.00	--	--	2.50	--
	Density (g/cm^3) (Ore or DR)	Pit-specific, see Table 24.					
Dozing	Bin Upper Diameter (µm)	2.50	10.00	--	--	2.50	--
	Mass Fraction	0.55	0.45	--	--	1.00	--
	Mass Mean Diameter (µm)	2.50	10.00	--	--	2.50	--
	Density (g/cm^3) (DR)	Pit-specific, see Table 24.					

In order to account for variability in ore and DR densities for different pits, pit-specific densities were used for the ore and DR for each modeling scenario, with the following exception – for haul roads, access roads, and portable crushers, the average DR density from YPP, HFP, and WEP was used. Note that the BT density was excluded from those sources because the BT material will not be used for roads or construction. The pit-specific ore and DR densities are provided in Table 24.

Table 24. PIT-SPECIFIC ORE AND DEVELOPMENT ROCK (DR) DENSITIES FOR DEPOSITION.

Pit	Material	Density (g/cm^3)
YPP	Ore	2.59
BT	Ore	2.00
HFP	Ore	2.59
WEP	Ore	2.68
YPP	DR	2.48
BT	DR	2.00
HFP	DR	2.34
WEP	DR	2.57
Average (YPP,HFP, WEP)	DR	2.46

3.3.10 Ambient Air Boundary

Ambient air is defined in Section 006 of the Idaho Air Rules as "that portion of the atmosphere, external to buildings, to which the general public has access."

DRAFT

Midas Gold will legally control the SGP, an active industrial site where mining activities will occur, such as heavy equipment operation. Most areas of the mine will require strict safety protocols and controlled access. Midas Gold has established an operations boundary to identify the area where public access will be excluded. Public access inside the operations boundary will be restricted for the life of the mine by physical barriers at points of potential access, including the current Stibnite Road point of entry and proposed site access via the Burntlog Route, as well as natural features of the landscape that prevent access. Consistent with the guidance provided in the EPA's draft revised policy on ambient air (EPA 2018b), public access control will include the following measures:

- Primary Access Points: The Stibnite Road (north) and Burntlog Route (south) access points will include locked gates. Guard shacks will be located at each gate to monitor all vehicle ingress/egress. Each gate also will include appropriate adjacent barriers (i.e., fencing, bollards, boulders, or other barriers) to prevent any vehicle from circumventing the gate and gaining site access. These primary access points are also controlled by adjacent natural features, such as streams and creeks, steep topography, and areas of thick vegetation and undergrowth that serve as natural barriers or impediments to access.

- Secondary Access Points: Other potential access points, such as secondary roadways and trails, will include posted signs warning the public against entry into the site. At these locations, boulders will be placed across the trail and at an appropriate width adjacent to the trail to prevent any vehicle from circumventing the barrier. These secondary access points also incorporate adjacent natural features, such as streams and creeks, steep topography, and areas of thick vegetation and undergrowth that serve as natural barriers or impediments to access. Some mine features, such as the TSF and process plant areas, will include perimeter fencing.

- Surveillance: Midas Gold security personnel will routinely patrol mine facilities and roadways for unauthorized individuals. In addition, all onsite personnel will be trained on the necessity of restricting public access to areas within the operations boundary. Any suspected trespassing by unauthorized individuals will be reported immediately to security, and trespassers will be escorted off the site.

In response to comments from local community citizens, Midas Gold will manage an access route to provide the general public with limited access through the SGP site between Stibnite Road at Sugar Creek and Thunder Mountain Road at Meadow Creek (shown in Figure 2). This route will be managed in accordance with the Stibnite Road Access Management Plan which is summarized as follows:

The proposed Stibnite Road access route through the SGP site is meant to provide controlled through-site access that is safe, provides travel-time comparable to current conditions and is consistent with the United States Forest Service travel management plan. The Stibnite Road access route extends from the north entry point southward to the Administration, Warehouse and Storage Area. Continuing southward, the Stibnite Road access route incorporates the Burntlog access road segment that occurs within the operations area and extends to the south entry point as shown on Figure 2. Midas Gold has the legal authority to control access to the Stibnite Road access route and would provide seasonal (non-winter conditions) access only. At the discretion of Midas Gold, additional access controls may occur during various phases of construction, during mine operations that present potential safely hazards such as blasting, due to inclement weather, or under any other circumstances that may present a threat to the protection of public or employee health and safety. Midas Gold has the legal and practical ability to enforce its control over roadway access and to monitor traffic passing through the SGP site. Signage will be placed at the North Security Gate (near the bridge over Sugar Creek) and the South Security Gate (near the Stibnite Lodge) to provide information to travelers, and guard shacks will be located at each gate to

DRAFT

monitor all vehicle ingress/egress. Persons wishing to traverse the SGP site on the Stibnite Road access route will be required to check in at the security gate to receive a safety briefing and to alert mine staff of their presence. Travelers will be required to check out upon exiting the site to ensure passage through the site in a safe and timely manner. Travelers will not be allowed to stop or loiter while traveling though the operations area. Along its full length, the Stibnite Road access route would have appropriate signage to direct travelers and would be separated from mine haul roads and areas of mine operations by fencing, berms, or gates to prevent travelers from straying from the route. When possible and to the degree practicable, anticipated public access restrictions will be communicated to the public in a timely manner so that they may plan appropriately. Receptors on the Stibnite Road access route were not included in the SGP air quality analyses as this road is not considered ambient air.

The worker housing facility will be located within the project operations boundary, near the south access security gate. This housing facility will be used strictly for accommodating employees, contractors, and official visitors, and it will not be accessible to the general public. Therefore, the atmosphere over the land occupied by the worker housing facility is not considered ambient air, and receptors were not placed at this location for the air quality analyses.

The operations boundary, shown in Figure 2 above and Figure 9 below, was used to define the ambient air boundary for air dispersion modeling purposes.

3.3.11 Nearby Co-Contributing Sources

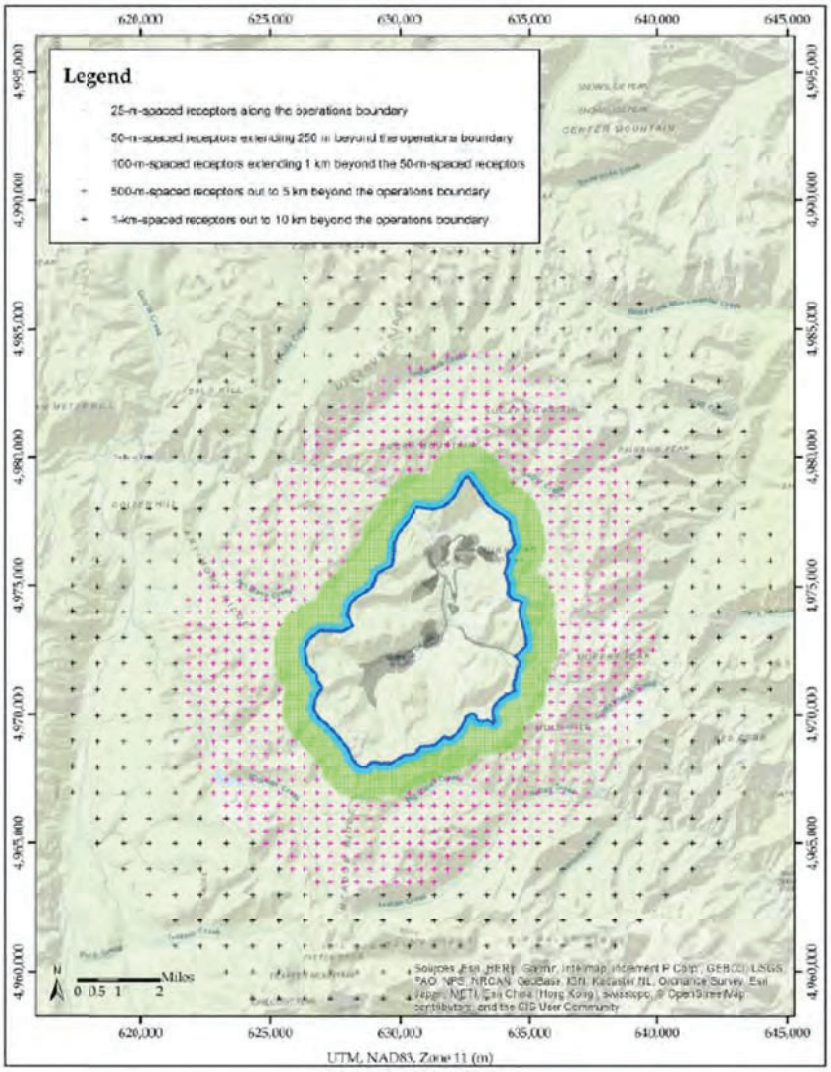
If impacts of neighboring emission sources on receptors showing a significant impact from the sources subject to the permitting action are not adequately accounted for by the background concentration used, then emissions from those sources must be modeled. The nearest significant permitted facility to SGP is Tamarack Mill, located more than 75 kilometers (km) west. This facility is located too far away to cause a significant concentration gradient along the periphery of the SGP and was therefore not included in the cumulative impact analyses for SGP.

3.3.12 Receptor Network

DEQ determined that the receptor grid used in the submitted modeling analyses was adequate to resolve maximum modeled impacts.

The SGP air quality analyses were performed using the following receptor spacing and extents (Table 19):

- 25-m-spaced receptors placed along the ambient air boundary;
- 50-m-spaced receptors extending 250 m beyond the ambient air boundary;
- 100-m-spaced receptors extending 1 km beyond the 50-m-spaced receptors;
- 500-m-spaced receptors extending 5 km beyond the ambient air boundary; and
- 1-km-spaced receptors extending 10 km beyond the ambient air boundary.



In addition, each highest modeled impact was evaluated further by performing a hot-spot analysis using a finer 25-m-spacing receptor grid. The modeling receptor grid is shown below in Figure 9. The full grid, along with the fenceline receptors, includes a total of 9,631 receptors. A SIL analysis was not conducted. The full receptor grid was used in the cumulative NAAQS impact and TAPs impact analyses.

The receptor grid used in the submitted modeling analyses met the minimum recommendations specified in the *Idaho Air Quality Modeling Guideline* (DEQ 2013), and DEQ determined that the receptor network

DRAFT

was effective in reasonably assuring compliance with applicable air quality standards at all ambient air locations.

Figure 9. SGP AMBIENT AIR BOUNDARY AND MODELING RECEPTOR GRID.

3.3.13 Good Engineering Practice Stack Height

An allowable good engineering practice (GEP) stack height may be established using the following equation in accordance with Idaho Air Rules Section 512.03.b:

H = S + 1.5L, where:

H = good engineering practice stack height measured from the ground-level elevation at the base of the stack.

S = height of the nearby structure(s) measured from the ground-level elevation at the base of the stack.

L = lesser dimension, height or projected width, of the nearby structure.

Sources from the SGP facility are below GEP stack height. Therefore, consideration of downwash caused by nearby buildings was required.

4.0 NAAQS and TAPs Impact Modeling Results

4.1 Results for NAAQS Analyses

4.1.1 Significant Impact Level Analyses

A SIL analysis was not performed for the SGP project.

4.1.2 Cumulative NAAQS Impact Analyses

Table 25 provides results (highest of 14 scenarios) for the cumulative NAAQS impact analysis. It provides the model-predicted maximum design concentration (including the hot-spot analyses) and the associated modeling scenario, the background concentration, and the estimated total concentration (SGP impact plus background) for each pollutant-averaging time combination. A comparison of the estimated total concentrations with the applicable NAAQS is also provided in this table. For each pollutant and averaging period, two modeled design concentrations are listed, each corresponding to the meteorological data processed with (BULKRN) and without (NON-BULKRN, grey shading) the Bulk Richardson method.

Table 25. RESULTS FOR CUMULATIVE NAAQS IMPACT ANALYSIS.

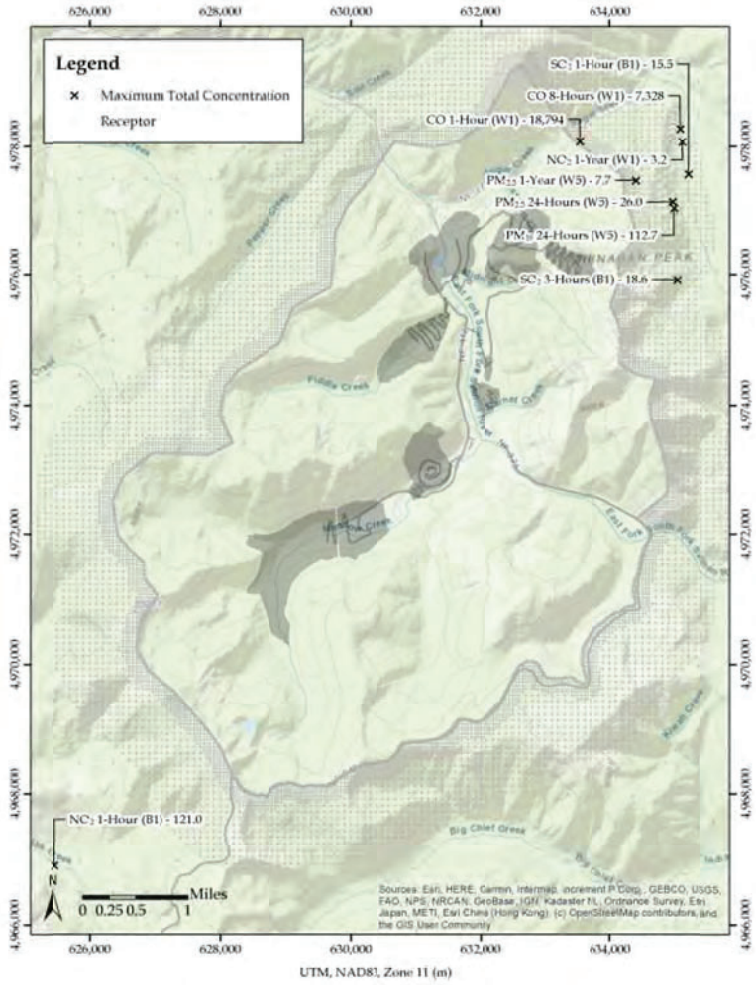
g. Particulate matter with an aerodynamic diameter less than or equal to a nominal 2.5 micrometers.
h. Particulate matter with an aerodynamic diameter less than or equal to a nominal 10 micrometers.
i. Results for 24-hour PM_{10} with meteorological data processed using BULKRN show up to five hotspot receptors that exceed NAAQS. Refer to Section 4.1.4 of this modeling memo for a weight-of-evidence analysis demonstrating NAAQS compliance.

Table 25 shows that modeled concentrations derived using the BULKRN meteorological data are higher than the NON-BULKRN dataset. It also shows that the total (modeled + background) concentrations from the SGP cumulative impact analyses do not exceed the applicable NAAQS, except for when the BULKRN meteorological data are used in modeling 24-hour PM_{10} (total concentration is 105.7% of the 24-hour PM_{10} NAAQS).



PM_{10} modeling with the meteorological dataset processed with the BULKRN method shows up to five hotspot receptors for three modeling scenarios (W1, W3, and W5) with slight exceedance of NAAQS. Scenario W5 is the worst-case scenario, with a maximum total concentration of 158.5 µg/m^3 which exceeds the NAAQS of 150 µg/m^3. A weight-of-evidence analysis demonstrating PM_{10} NAAQS compliance is presented in Section 4.1.4 of this modeling memo.

The locations of the maximum impacts for each pollutant and averaging time are illustrated in Figure 10. The results presented in this figure include the hot-spot analyses conducted for each applicable pollutant-averaging time combination. For $PM_{2.5}$ and PM_{10}, the alternate meteorological data (NON-BULKRN) were used.

Modeling for ozone and secondary $PM_{2.5}$ were not performed for this minor stationary source. These analyses are typically associated with applications for major stationary sources. Nonetheless, taking the ratio of the VOC, NOx, and SO_2 emissions from the SGP facility by the emissions and resulting concentrations of O_3 and secondary $PM_{2.5}$ from EPA's modeled emission rates for precursors (MERPs) guidance yields estimated O_3 and secondary $PM_{2.5}$ concentrations of less than 1 ppb of O_3 and less than 0.1 µg/m^3 of $PM_{2.5}$ (24-hour and annual) for the SGP. These estimated concentrations have a negligible effect on compliance demonstration with the NAAQS.

DRAFT

Figure 10. SGP CUMULATIVE IMPACTS (µg/m^3) AND LOCATIONS.

Higher background concentrations from McCall that include medium-traffic emissions provided in Section 3.2.3 were then combined with the SGP model-predicted maximum design concentrations to provide an additional level of conservatism in demonstrating compliance. These results are shown in Table 26. For $PM_{2.5}$ and PM_{10}, the alternate meteorological data (NON-BULKRN) were used. For the rest of the criteria pollutants, the BULKRN meteorological data were used.

4.1.3 DEQ's Sensitivity Analyses for 1-hour and annual NO_2

DEQ performed a sensitivity analysis for 1-hour and annual NO_2 using a Tier 2 (ARM2) screening method. Minimum and maximum NO_2/NOx ratios of 0.5 and 0.9, respectively, were used. Results from DEQ's cumulative NAAQS impact analyses, summarized below in Table 27, indicate that the SGP facility is safely below the 1-hour and annual NO_2 NAAQS even when using a more conservative NO_2 screening method.

Table 27. RESULTS FOR DEQ'S NO_2 SENSITIVITY ANALYSES USING TIER 2 (AMBIENT RATIO METHOD 2) SCREENING METHOD.

4.1.4 DEQ's Weight-of-Evidence Analyses for 24-hour PM_{10}

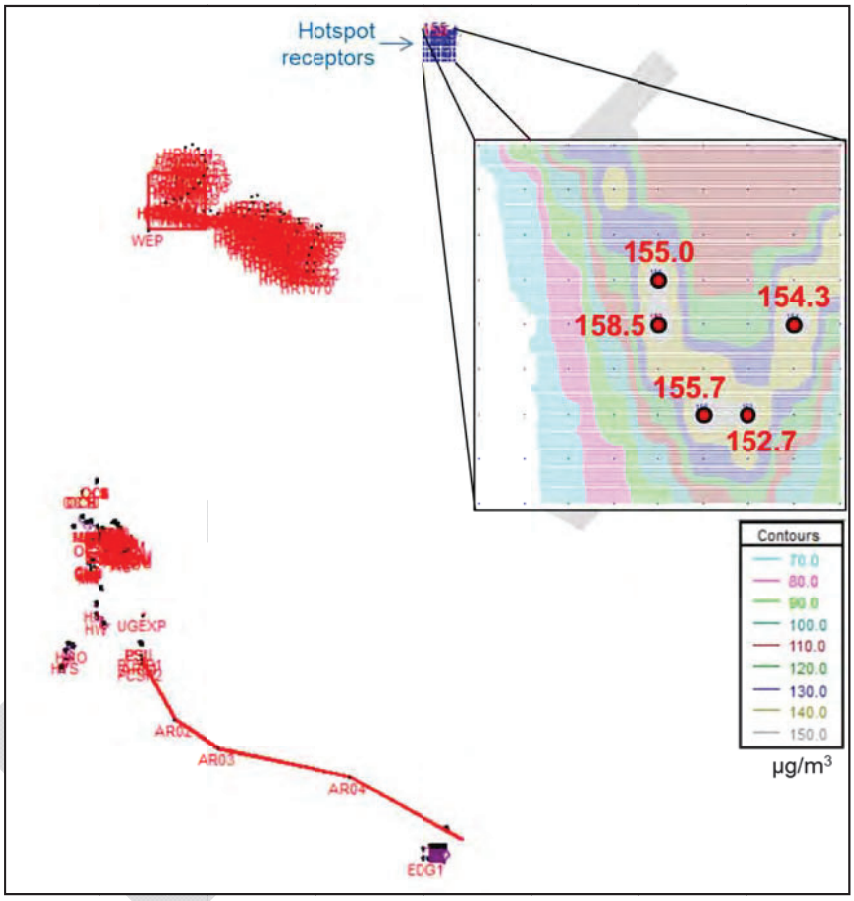
This section describes a weight-of-evidence analysis that provides additional analytical information to evaluate the degree of NAAQS compliance confidence for 24-hour PM_{10}. NAAQS compliance was demonstrated in the submitted application using meteorological data processed with an EPA-approved method using regional cloud cover to calculate stability parameters rather than site-specific monitored solar radiation and measured temperature differences with height.

As described in Section 4.1.2, PM_{10} modeling with meteorological dataset processed using the site-specific BULKRN method shows up to five hotspot receptors for Scenario W5 (the highest PM_{10} modeling scenario) that exceed NAAQS (150 µg/m^3). The hotspot receptors have a 25-meter grid

DRAFT

spacing. Hotspot receptors that exceed 24-hour PM_{10} NAAQS have total (modeled + background) concentrations of 152.7, 154.3, 155.0, 155.7, and 158.5 µg/m^3. Locations of these receptors are illustrated in Figure 11. Figure 12 shows these receptors overlaid on Google Earth.

Figure 11. HOTSPOT RECEPTORS THAT EXCEED 24-HOUR PM_{10} NAAQS (SCENARIO W5, BULKRN METEOROLOGICAL DATA).



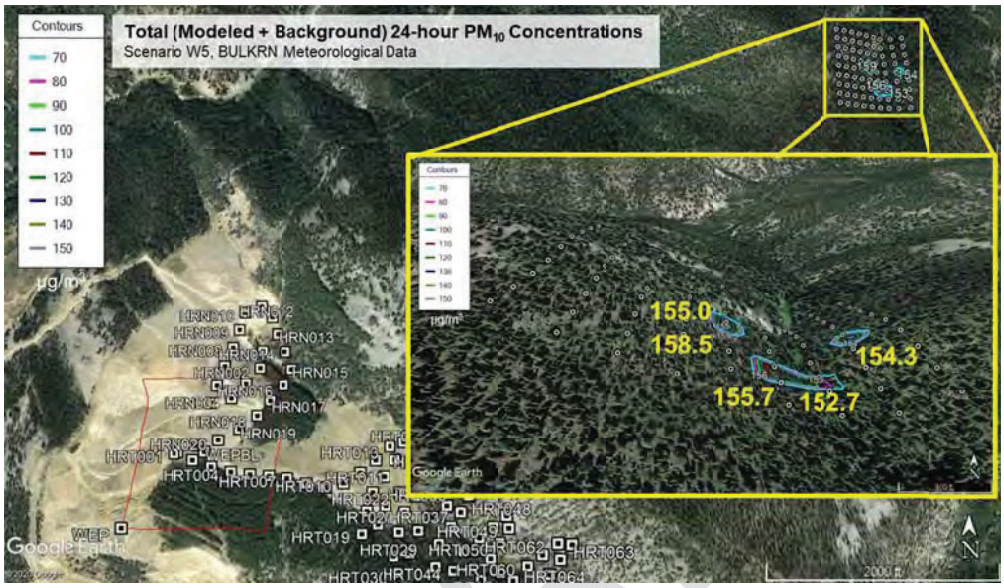


Figure 12. HOTSPOT RECEPTORS THAT EXCEED 24-HOUR PM_{10} NAAQS, OVERLAID ON GOOGLE EARTH IMAGE (SCENARIO W5, BULKRN METEOROLOGICAL DATA).

Figures 11 and 12 show that the modeled PM_{10} NAAQS exceedances are located northeast of the SGP facility. These receptors are located 2 km away from the center of the West End Pit (WEP). The AERMOD output files indicate that all modeled violations occur during winter (all modeled violations occur on December 23, 2014). Data provided in the SGP baseline study (Midas Gold 2017a) specify an average snow depth of 21-68 inches and an average precipitation of 6.0 inches at the project site during this period. Therefore, fugitive road dust emissions during high-modeled impact hours could be overestimated.

DEQ performed a source-group analysis (Table 28) which indicates that emissions from the WEP and the Haul Road (HR) are the largest contributors to the maximum modeled PM_{10} design concentrations. For comparison, source-group analyses using the NON-BULKRN meteorological data are also listed in Table 28.

Table 28. SOURCE-GROUP ANALYSIS FOR 24-HOUR PM_{10} (SCENARIO W5).

Emission Source Group	Modeled Design Concentration ($\mu g/m^3$)[a]

[a.] Micrograms per cubic meter.

The six source groups listed in Table 28 that are related to mining activity and emissions (WEP, WEPBL, WEDRSF, HR, ACCRD, UGEXP) were examined further. Table 29 lists the daily modeled PM_{10} emissions (in pounds per day [lb/day]), grouped according to mining activity. Key assumptions for calculating the daily emissions are also listed in this table. Total modeled PM_{10} emission from mining activity for Scenario W5 is 3,336.76 lb/day. The contribution from each source group is listed in the second column of Table 29, and a pie chart is illustrated in Figure 13.

Table 29. KEY ASSUMPTIONS FOR CALCULATING DAILY MINING ACTIVITY EMISSIONS FOR 24-HOUR PM_{10} (SCENARIO W5).

Mining Activity	Emissions (lb/day)[a]
WEP (West End Pit)	**885.54**
Open Pit Drilling	
• Blasting 180,000 tons of material (DR) per day • Drilling 1,200 holes per day	811.20

[a] Pounds per day.

Figure 13. PIE CHART FOR DAILY MODELED PM_{10} EMISSIONS FROM MINING ACTIVITY (SCENARIO W5).

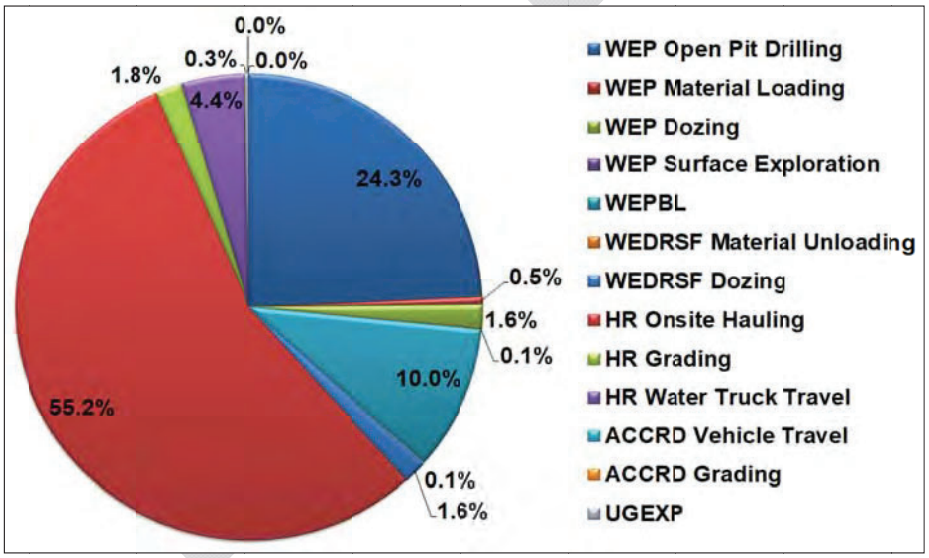

Figure 13 shows that onsite hauling on haul roads ("HR Onsite Hauling") accounts for 55.2% of the total daily PM_{10} emissions. Open pit drilling at the WEP ("WEP Open Pit Drilling") and blasting ("WEPBL") account for 24.3% and 10.0% of the daily PM_{10} emissions, respectively. Therefore, it is not surprising that HR, WEP, and WEPBL are the largest contributors to the modeled design concentrations in Table 28.

As listed in Table 29, PM_{10} modeling simulation for Scenario W5 was based on a mining production rate of 180,000 ton/day of development rock. This corresponds to 6~~2~~5,700,000 ton/year, which is more conservative than the expected peak production rate of 42,692,000 ton/year (116,964 ton/day). To

REC 0881

PET 515

investigate the effect of a lower modeled mining production rate on design value concentrations, DEQ performed a modeling simulation ("DEQ Run 1") where mining production rate was assumed to be 120,000 ton/day instead of 180,000 ton/day, but all other model variables were held constant. This adjustment lowered the modeled daily emission rates for WEP, WEDRSF, and HR, which are summarized in Table 30. Because the modeled emission rates were lower, the modeled design concentrations were also lower. Results for DEQ's sensitivity analyses are summarized in Table 31.

Table 30. DAILY MINING ACTIVITY EMISSIONS USED IN DEQ'S SENSITIVITY ANALYSES FOR 24-HOUR PM_{10} (SCENARIO W5).

a. Max. Conc. = maximum modeled design concentration.
b. Micrograms per cubic meter.
c. Back. Conc. = background concentration.
d. Total Conc. = total (modeled + background) concentration.
e. Particulate matter with an aerodynamic diameter less than or equal to a nominal 10 micrometers.
f. DEQ Run 1: mining production rate was modeled at 120,000 ton/day instead of 180,000 ton/day. Everything else was held constant.

Maximum modeled concentration for "DEQ Run 1", when summed with the background concentration, is lower than NAAQS thereby demonstrating NAAQS compliance. Total (modeled + background) concentrations for all hotspot receptors are depicted in Figure 14; maximum total impact is depicted by

DRAFT

the red circle. The SGP facility complies with the 24-hour PM_{10} NAAQS when daily mining production rates closer to a more typical daily rate for a high-production period are used in the model, instead of a very conservative mining production rate, even when using site-specific BULKRN meteorological data.

Figure 14. RESULTS FOR DEQ'S SENSITIVITY ANALYSES SHOWING TOTAL (MODELED + BACKGROUND) 24-HOUR PM_{10} CONCENTRATIONS AT HOTSPOT RECEPTORS (SCENARIO W5, BULKRN METEOROLOGICAL DATA).

Meteorological data processing with and without BULKRN are considered acceptable by EPA. However, the BULKRN meteorological data yielded higher modeled design values for the SGP facility than the meteorological data processed without the BULKRN method. DEQ's analyses suggest that when daily mining production rates closer to a more typical daily rate for a high-production period are used (everything else held constant), the SGP facility is able to demonstrate compliance with 24-hour PM_{10} NAAQS at those few receptors showing a potential violation when using meteorological data processed with the BULKRN method.

Maximum modeled design value 24-hour PM_{10} impacts, even with the use of more reasonably expected daily production rates, are still just under the 150 $\mu g/m^3$ NAAQS. As noted earlier in this section, these high values were observed during the winter season. During this period, not only are fugitive emissions minimized because of the higher moisture content of material handled or driven over, but background concentrations in such remote areas are generally much lower because of the absence of wildfires and dust-generating sources.

DEQ's weight-of-evidence analyses show that, considering all the collective conservative layers of the modeling analyses, modeling efforts using both site-specific and alternative meteorological datasets show acceptable impacts.

4.1.5 DEQ's Sensitivity Analyses for a Lower Fugitive Road Dust Control Efficiency

Fugitive particulate emissions from roadways were estimated by the applicant to be controlled above 93%, which is an aggressive level of control. The high level of emission control was needed to demonstrate compliance with NAAQS. To investigate the effect of lower unpaved road emission control efficiency, DEQ performed a modeling simulation ("DEQ Run 2") where the control efficiency was set to 90%. The daily mining production rate was assumed to be 120,000 ton/day instead of 180,000 ton/day, but everything else was held constant. These adjustments lowered the daily modeled emission rates for WEP and WEDRSF, but increased the daily modeled emission rate for HR and the Access Road (ACCRD) (Table 32). Five receptors exceed the 24-hour PM_{10} NAAQS. Figure 15 shows the locations of these receptors.

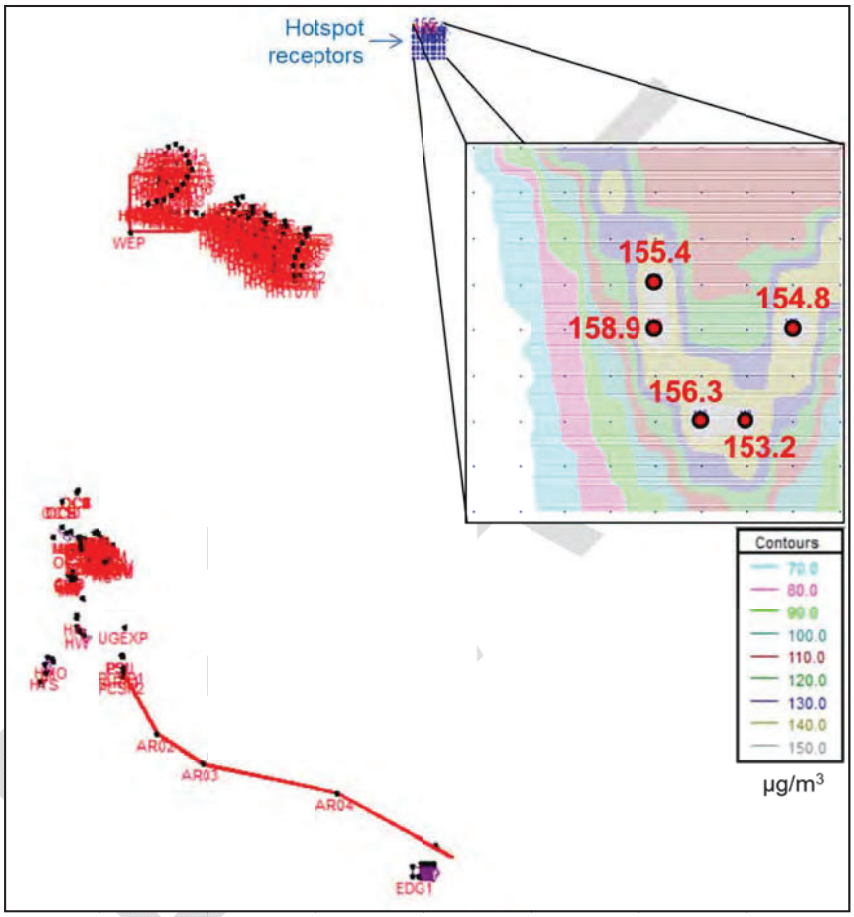

Table 32. DAILY MINING ACTIVITY EMISSIONS USED IN DEQ'S SENSITIVITY ANALYSES FOR 24-HOUR PM_{10} (SCENARIO W5).

DRAFT

Figure 15. RESULTS FOR DEQ'S SENSITIVITY ANALYSES SHOWING HOTSPOT RECEPTORS THAT EXCEED 24-HOUR PM_{10} NAAQS, ASSUMING MINING PRODUCTION RATE OF 120,000 TONS PER DAY AND FUGITIVE ROAD DUST CONTROL EFFICIENCY OF 90% (SCENARIO W5, BULKRN METEOROLOGICAL DATA).

DEQ's sensitivity analyses suggest that a few hotspot receptors exceed the 24-hour PM_{10} NAAQS when the unpaved road control efficiency falls below 93% and the meteorological data processed with the BULKRN method is used. However, all the hotspot receptors demonstrate compliance with NAAQS at a 90% control efficiency when using the meteorological data processed without the BULKRN method, and at both examined production levels:

- maximum impact at 120,000 ton per day – 73.9 µg/m^3 + 37.0 µg/m^3 = 110.9 µg/m^3.
- maximum impact 180,000 ton per day – 84.6 µg/m^3 + 37.0 µg/m^3 = 121.6 µg/m^3.

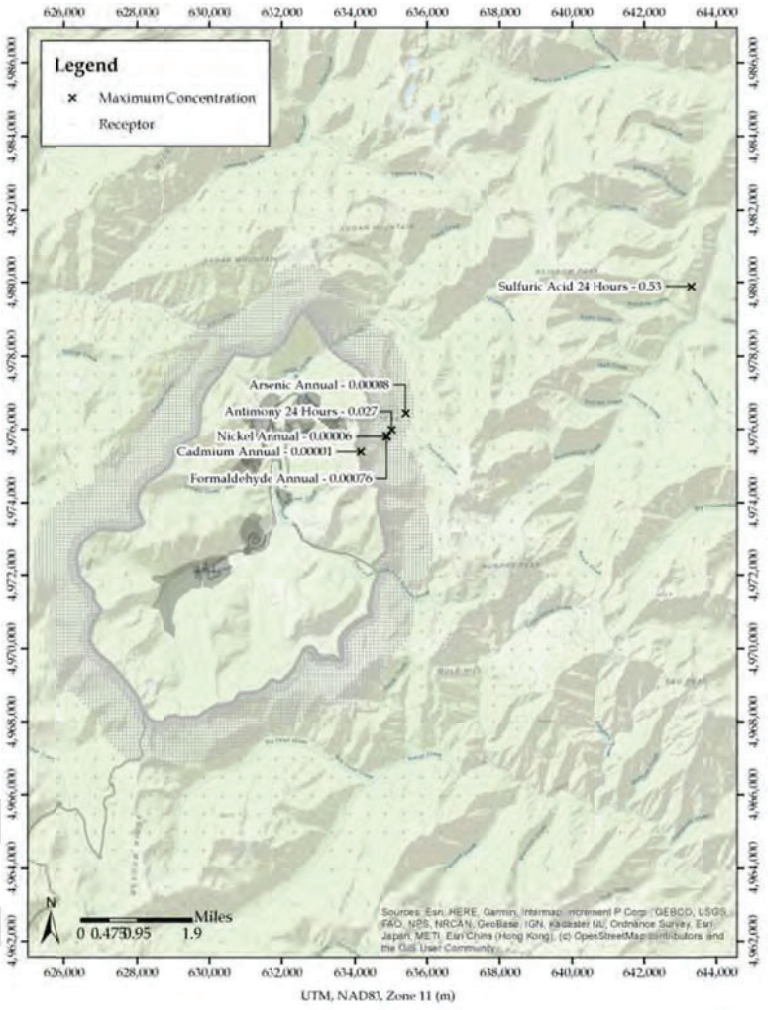
As previously stated, meteorological data processing with and without BULKRN are both considered

acceptable regulatory options by EPA. Therefore, this demonstrates that emissions resulting from a lower unpaved road control efficiency (even potentially less than 90%) do not cause or contribute to a NAAQS violation. Nonetheless, the permit requires ~~This highlights the need for~~ an aggressive implementation of measures to ~~achieve above 93%~~ control ~~efficiency for~~ fugitive particulate emissions from roadways.

4.2 Results for TAPs Impact Analyses

The SGP TAP modeling results and their comparison with the applicable AACs/AACCs are provided in Table 33.

Table 33. RESULTS FOR TAPS IMPACT ANALYSIS.



Pollutant	Averaging Time	Maximum Modeled Concentration ($\mu g/m^3$)[a]	Model Scenario	AAC[b] ($\mu g/m^3$)	AACC[c] ($\mu g/m^3$)	Percent of AAC/AACC
Antimony	24 hours	2.7E-02	B1	25	--	0.1%
Arsenic	Annual	8.0E-05	All	--	0.00023	34.8%
Cadmium	Annual	1.0E-05	All	--	0.00056	1.8%
Formaldehyde	Annual	7.6E-04	All	--	0.077	1.0%
Nickel	Annual	6.0E-05	All	--	0.0042	1.4%
Sulfuric Acid	24 hours	5.3E-01	All	50	--	1.1%

a. Micrograms per cubic meter.
b. Acceptable Ambient Concentration of a non-carcinogenic TAP.
c. Acceptable Ambient Concentration of a Carcinogenic TAP.

Table 33 shows that the modeled TAP impacts from the SGP sources do not exceed the applicable AACs/AACCs. The locations of the maximum impacts for each TAP are presented in Figure 16.

DRAFT

Figure 16. SGP TAP IMPACTS (µg/m^3) AND LOCATIONS.

5.0 Conclusions

The information submitted with the PTC application, combined with DEQ's air impact analyses, demonstrated to DEQ's satisfaction that emissions from the Stibnite Gold Project in Valley County, Idaho will not cause or significantly contribute to a violation of any applicable ambient air quality standard or TAP increment.

Midas Gold Idaho, Inc. - Stibnite Gold Project
Stibnite Road Access Management Plan – Version 1

April 15, 2020

1 Purpose and Objectives

This Stibnite Road Access Management Plan (Plan) describes the methods whereby Midas Gold Idaho, Inc. (Midas Gold), an Idaho corporation, would manage access on designated roads that traverse the proposed Stibnite Gold Project (SGP) mine site. The SGP is described in Midas Gold's Plan of Restoration and Operations (PRO).

The SGP is a proposed open pit mine that will be located at Stibnite, in central Idaho (see inset, Figure 1). The United States Forest Service (USFS) Forest System Road (FR) that passes through Stibnite (Stibnite Road; FR 50412) extends from the village of Yellow Pine eastward along the East Fork of the South Fork of the Salmon River for approximately 14 miles. Stibnite Road then continues south through the historic Stibnite mine site and connects with Thunder Mountain Road (FR 50375) on the southeastern portion of the proposed SGP. This route also allows for access to Meadow Creek Lookout Road (FR 51290; see Figure 1). As initially proposed, construction and operations at the SGP would prohibit access through the mine site for the life of the mine (approximately 20 to 25 years). During this period, alternative access to Thunder Mountain Road and Meadow Creek Lookout Road would be provided via the newly constructed Burntlog Route; a proposed mine access route that would connect the existing Burnt Log Road to Thunder Mountain Road with a new section of roadway and an upgraded section of Meadow Creek Lookout Road. Additionally, as proposed in the PRO, an off-highway vehicle (OHV) Trail would be upgraded to connect Horse Heaven/Powerline Road to Meadow Creek Lookout Road. Public access routes proposed in the PRO are illustrated in Figure 1. As part of reclamation of the SGP and closure of the mine site, Stibnite Road would be re-established in an alignment similar to its current location and would become the primary access route to Thunder Mountain Road. The Burntlog Route would be reclaimed to its previous condition and would no longer be connected to Thunder Mountain Road.

Following the presentation of the proposed public access routes described above in Midas Gold's PRO, an alternative public access route has been proposed by Midas Gold and would pass through the SGP mine site (Stibnite Road access route). This alternative route is under evaluation as part of the USFS's obligation to review the SGP in accordance with the National Environmental Policy Act (NEPA). One of the alternatives currently being evaluated in the Draft environmental impact statement (EIS), Alternative 2, would provide continued access through the SGP site on a realigned Stibnite Road during mine operations. The implementation of this Plan is contingent upon the selection of the applicable alternative by the USFS as the preferred alternative for the SGP and inclusion of the proposed Stibnite Road access route as a component of the approved SGP.

The health and safety of the public and the employees of the SGP is Midas Gold's priority. The procedures included in this Plan would be implemented by Midas Gold over the course of the life of the mine to ensure that the use of the Stibnite Road access route is conducted safely and responsibly.

2 Project Information

2.1 Introduction

Midas Gold has proposed to redevelop portions of the Stibnite Mining District (District) as described in the SGP PRO, submitted to the United States Forest Service (USFS) in September 2016. The SGP will be located at Stibnite in Valley County, approximately 92 miles by air and 144 miles by road northeast of Boise, Idaho; 44 air miles northeast of Cascade, Idaho; and 10 air miles east of Yellow Pine, Idaho. Current access to the site is from State Highway 55 to the SGP area via Warm Lake, Johnson Creek, and Stibnite Roads as shown in Figure 1. The proposed layout of the SGP mine features is illustrated in Figure 2.

Mining operations in the District first began in the 1920s and continued episodically through 1996. Proposed SGP mine operations described in Section 9 of the PRO would include open-pit mining in the three previously mined areas:

- The Yellow Pine open pit will encompass the area of the former Yellow Pine pit, Homestake pit, and portions of the Bradley Mining Company rock dumps.
- The West End open pit will encompass the former Stibnite Mines, Inc., open pits.
- The Hangar Flats open pit will encompass the former underground Meadow Creek Mine area, Hecla heap, and adjacent former mill and smelter area.

Other features and facilities that would be part of SGP mine operations include development rock storage facilities (DRSF), a tailings storage facility (TSF) and tailings pipeline, surface water management features (diversions, collection ditches, stormwater collection ponds), an ore processing facility, a water treatment facility, equipment maintenance and storage buildings, a worker housing facility, and all associated haul roads and access roads. The north and south points of entry to the SGP would have security gates and guard shacks that would be occupied on a continual basis. Features related to SGP mine but located off-site are illustrated in Figure 1 and include the Landmark Road Maintenance Facility, Stibnite Gold Logistics Facility, and features associated with powerline upgrades and extension.

The general timeline for constructing, operating, restoring, and mitigating the SGP is approximately 20 to 25 years, including 3 years of site preparation, construction, and early restoration activities; 12 to 15 years of operations; and 5 to 7 years of final closure and reclamation work. The SGP will produce gold, silver, and antimony over the 12- to 15-year mining period.

2.2 The SGP and NEPA

The proposed SGP occurs on patented mining claims (private land) and land administered by the United States Forest Service (USFS) within both the Boise National Forest (BNF) and Payette National Forest (PNF). The Big Creek/Stibnite Management Area 13, which includes the District, is administered by the Krassel Ranger District of the PNF. Proposed actions that occur on Federally managed lands require environmental review and analysis in compliance with NEPA. The NEPA analysis for the SGP was initiated

in mid-2017 with the USFS as the lead agency. The USFS is preparing an EIS to evaluate the environmental effects of the proposed SGP as well as a range of alternatives to the proposed action.

Public comments received for the SGP indicated that the change in access through the SGP for 20 to 25 years was of significant concern, particularly for those in the Johnson Creek and Yellow Pine area who use Stibnite Road to access Thunder Mountain Road and points beyond. At the direction of the USFS, Midas Gold evaluated numerous additional access options for the SGP that provided access similar to existing conditions and travel times. Midas Gold identified a suitable access route through the SGP site that would provide through-site access during operations. The road was designed to be separated from mine operations and to provide access similar to that provided by the existing Stibnite Road. The alternative access route through the SGP was included for consideration in the Draft EIS document as a component of Alternative 2.

2.3 Proposed Stibnite Road Access Route Through the SGP

The proposed SGP Stibnite Road access route that is currently under evaluation in the SGP Draft EIS is illustrated in Figure 2 and would include one of the two optional routes described below. During mine site construction, a new 12-foot-wide gravel road would be constructed to provide public access from Stibnite Road on the northern end of the SGP to Thunder Mountain Road on the southeastern end of the site. Along its full length, the Stibnite Road access route would have appropriate signage to direct travelers and would be separated from mine haul roads and areas of mine operations by fencing, berms, or gates to prevent travelers from straying from the route.

Two optional routes were identified and include variations in alignment in the vicinity of the Yellow Pine pit:

- **Stibnite Road Access Route: Option 1** – The access road would begin at the North Security Gate and would be constructed along a widened bench of the western portion of Yellow Pine pit during an early operational phase of the mine. South of the Yellow Pine pit this road would pass beneath the mine haul leading to the Fiddle Creek DRSF and would then parallel a mine haul road along a partially revegetated portion of the former Bradley mine haul road. In the central portion of the SGP site near the Mine Administration Building, the road would connect with the Burntlog Route and continue southeast toward the Worker Housing Facility and the South (Main) Security Gate. From the north end (North Security Gate) of the SGP to the south end (South Security Gate), this road would be approximately 3 miles in length.

- **Stibnite Road Access Route: Option 2** – The access road would begin at the North Security Gate and would be constructed west of the Yellow Pine pit. South of the Yellow Pine pit this road would pass beneath the mine haul leading to the Fiddle Creek DRSF and would then parallel a mine haul road along a partially revegetated portion of the former Bradley mine haul road. In the central portion of the SGP site near the Mine Administration Building, the road would connect with the Burntlog Route and continue southeast toward the Worker Housing Facility and the South (Main) Security Gate. From the north end (North Security Gate) of the SGP to the south end (South Security Gate), this road would be approximately 4 miles in length.

Based on assessment of impacts and public and agency feedback, one of these two options would be selected if Alternative 2 is identified as the Preferred Alternative for the Midas Gold SGP.

2.4 Access Controls

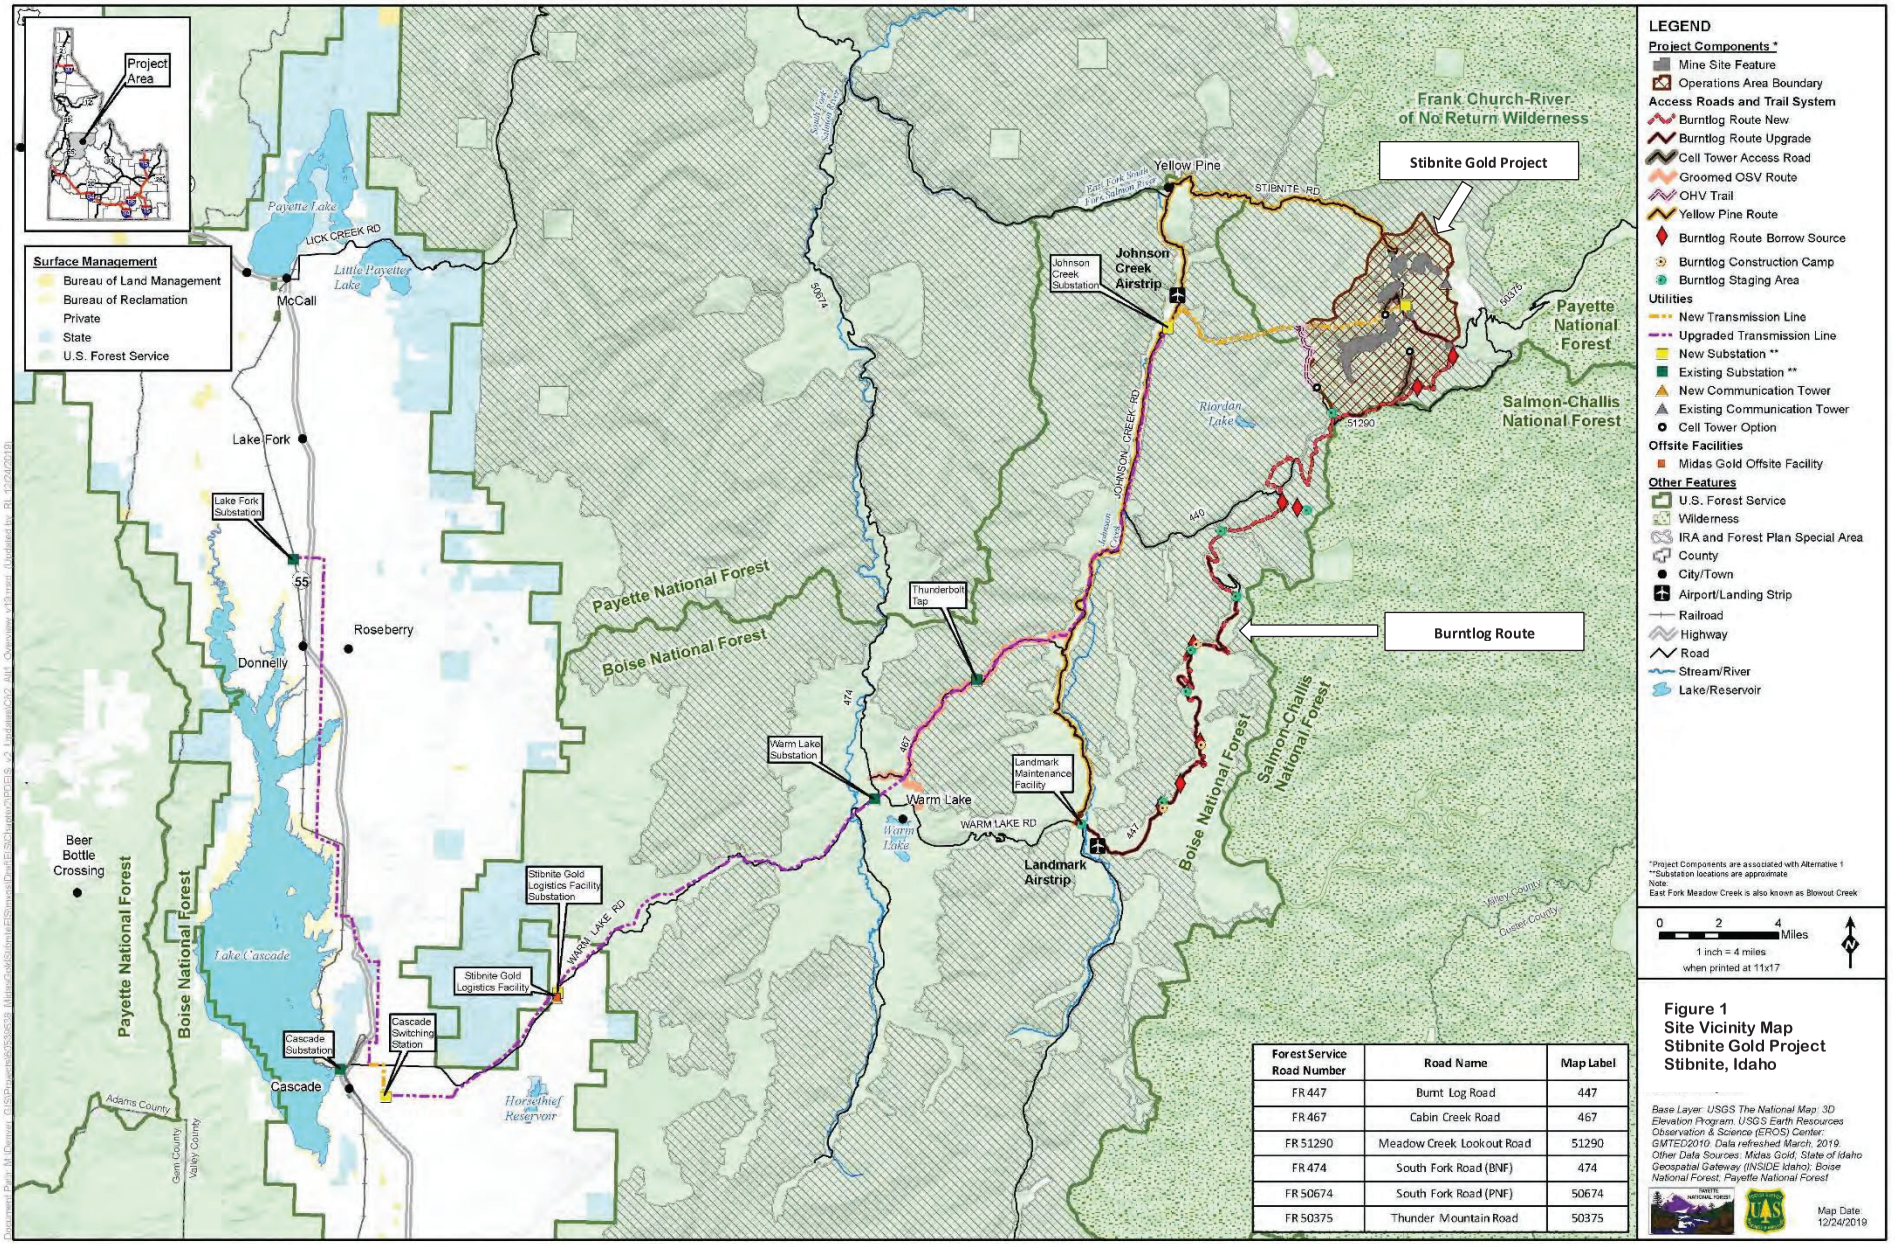
The proposed Stibnite Road access route through the SGP site is meant to provide controlled, through-site access that is safe, and provides travel-time comparable to current conditions. Additionally, the Stibnite Road access route would provide access that is consistent with the USFS travel management plan. Whereas Stibnite Road between Yellow Pine and Stibnite is not plowed in winter, Midas Gold would operate the Stibnite Road access route on a seasonal basis, i.e. access would not be provided in winter. Public access to the road would begin when Stibnite Road becomes passable in the Spring.

For either of the two route options described above, the northern extent of the Stibnite Road access route would begin at the North Security Gate, would continue southward traversing the SGP mine site, would connect with the Burntlog Route and would continue southeastward out of the mine operations area. The access route would exit South Security Gate near the employee housing facility.

Midas Gold has the legal authority to control access to the Stibnite Road access route and would provide seasonal (non-winter conditions) access only. At the discretion of Midas Gold, additional access controls may occur during various phases of construction, during mine operations that present potential safety hazards such as blasting or pit expansion, due to inclement weather, or under any other circumstances that may present a threat to the protection of public health and safety. Midas Gold has the legal and practical ability to enforce its control over roadway access and to monitor traffic passing through the SGP site. Signage would be placed at the North Security Gate (near the bridge over Sugar Creek) and the Main (South) Security Gate (near the Stibnite Lodge) entry points to provide information to travelers, and guard shacks would be located at each SGP Site entry gate to monitor all vehicle ingress/egress. To ensure passage through the site in a safe and timely manner, persons wishing to traverse the SGP site on the Stibnite Road access route would be required to check in at the security gate upon entry to receive a safety briefing and to alert mine staff as to their presence. After passing through the SGP site, travelers would also be required to stop at the guard shack upon exiting to check out. Travelers would not be allowed to stop or loiter while traveling though the operations area. Along its full length, the Stibnite Road access route would have appropriate signage to direct travelers and would be separated from mine haul roads and areas of mine operations by fencing, berms, or gates to prevent travelers from straying from the route.

Midas Gold would have the ability to temporarily restrict travel along the Stibnite Road access route for the protection of public health and safety. When possible and to the degree practicable, anticipated public access restrictions would be communicated to the public in a timely manner so that they may plan appropriately.

3 Conclusion



Midas Gold's SGP is under evaluation by the USFS and is proceeding through environmental analysis under NEPA. Midas Gold's proposed action and several alternatives to the proposed action will be included in the forthcoming Draft EIS. Alternative 2 in the Draft EIS includes an access alternative that would route a roadway, the Stibnite Road access route, through the mine site.

Maintaining and protecting SGP mine employee and public health and safety is Midas Gold's priority. This Stibnite Road Access Management Plan has been prepared to demonstrate that appropriate best practices, roadway construction features, and Midas Gold SGP site security measures would be in place over the life of the SGP mine and would effectively control access to the Stibnite Road access route.

This Plan will be updated and revised as appropriate.

Re: Facility ID No. 085-00011, Midas Gold Idaho, Inc., Stibnite Gold Project, Draft Permit to Construct No. P-2019.0047, Project 62288, Issued for Applicant Review

Dear Mr. Simon and Mr. Lewis:

Midas Gold Idaho, Inc. (Midas Gold) greatly appreciates the opportunity to provide these comments on the Idaho Department of Environmental Quality's (IDEQ) Stibnite Gold Project (SGP) Draft Permit to Construct (PTC) No. P-2019.0047, Project 62288 (Draft Permit), dated July 14, 2020. Midas Gold has also received the updated Appendix B to the Statement of Basis from IDEQ on July 31, 2020, starting the 10-day review. Additional comments on the Statement of Basis, if any, will be presented to IDEQ before the close of the 10-day review period. During our review, Midas Gold examined examples of PTCs for similar surface mining operations authorized by IDEQ to evaluate consistency within this industry. Our proposed changes and edits are shown in a redlined version of the Draft Permit enclosed with this letter.

A short description of each of the noneditorial proposed change is provided below:

1. Condition 1.2, Table 1.1, and Condition 3.2, Table 3.1 (Item 31): Please remove the control efficiency values listed for haul roads (93.3%) and enclosures (80%). It appears that these percentages are provided for descriptive purposes only. As such, this information would more appropriately be provided in the Statement of Basis only. In addition, it does not appear that Idaho mining PTCs typically contain control efficiency values for fugitive sources. Alternatively, the following language may be added to Condition 1.2, "Control equipment information and maximum process rate information is provided for information only unless also included in specific enforceable permit conditions."

2. Condition 1.2, Table 1.1, Hauling, and Condition 2.5, 2nd (Item 13) and 17th (Item 20) Bullets: Please remove the Maximum Process Rate of "490,000 mi/mo" and related monitoring obligation. The

   mining excavation rate is already limited to 180,000 T/day, which directly impacts vehicle miles traveled. At this limit, all hauling scenarios were modeled to capture the maximum-case hauling distances, which included a hauling mileage of 16,415 mi/day (492,465 mi/30 days or 508,880 mi/31 days). The maximum-case mileage far exceeds the peak production total actual annual hauling mileage of 1.4 million mi/yr (116,700 mi/mo). Therefore, a mileage limit is not necessary to limit emissions, and recording miles daily adds unnecessary and burdensome monitoring.

3. Condition 1.2, Table 1.1, Prill Silos, and Conditions 3.8 and 3.17 (Item 32): Please revise the Maximum Process Rate of "608/month" to "200 T/day." The daily rate was used for the 24-hour PM_{10} and 24-hour $PM_{2.5}$ modeling. See Appendix B, pages 11, 12, and 15 of the June 23, 2020, PTC Application (Application). No other criteria pollutants or toxic air pollutants (TAP) are emitted by these insignificant sources. The Application also requested a 7,300 T/yr limit. However, it has come to our attention that an annual limit of 9,000 T/yr is needed. This change has essentially no effect on the annual emission inventory for annual $PM_{2.5}$ modeling. The $PM_{2.5}$ emission change from increasing the annual throughput from 7,300 T/yr to 9,000 T/yr (an increase of 0.00005 g/s) is less than five-thousandth of a percent of the total $PM_{2.5}$ emissions.

4. Condition 1.2, Table 1.1, Autoclave (AC) and Electrowinning Cells: Please remove "and as limited by Subpart EEEEEEE" from the Maximum Process Rate. Subpart EEEEEEE does not contain any process rate limits. This subpart only provides emission limits, and control and monitoring requirements as noted in Condition 4.2, Table 4.1, and Conditions 4.18 and 4.19.

5. Condition 1.2, Table 1.1, POX Boiler, and Condition 4.4 (Item 36): Please replace the Maximum Process Rate of "1 hr/day and 30 hr/yr" with "operation is limited to AC start-up only." The boiler is used only for starting up the AC. Once the AC is running, the boiler is turned off; however, a start-up will be longer than 1 hour. AC start-ups are expected to require up to 10 hours of POX Boiler firing, and there may be as many as three start-ups per year. Limiting operation only to start-up provides flexibility and reflects the proposed operating scenario. Midas will continue to monitor boiler operating hours during AC start-up, per Condition 4.17.

6. Condition 1.2, Table 1.1, PFR Shaft Lime Kiln Combustion: Please replace "20.5" with "22.0 MMBtu/hr." See page 93 of the Application.

7. Condition 1.2, Table 1.1, SAG Mill and AC Lime Silos: The Maximum Process Rate of "169 T/day and 52,337 T/yr" only applies to LS-L/U, LK, and LCR. The SAG Mill and AC Lime Silos (6 storage silos) have a combined Maximum Process Rate of 70,000 T/yr of lime.

8. Condition 1.2, Table 1.1, Concrete Production, and Condition 5.8 (Item 41): Please replace the Maximum Process Rate of "80 T/day and 60,000 T/yr (cement + aggregate)" with "2,480 T/day and 560,000 T/yr of (cement + aggregate)." See page 47 of the Application. Also, the Central Mixer capacity is 120 T/hr (20 T/hr of cement plus 100 T/hr of aggregate).

9. Condition 1.2, Table 1.1, Concrete Production, Central Mixer Loading, and Conditions 5.1 and 5.2 (Item 39): Please revise the control description to match the control options listed in AP-42 and the Application (page 7 and Appendix B page 11).

10. Condition 2.4: Please replace the facility-wide inspection frequency with "monthly." A monthly inspection rate is typical for large mining operations and consistent with other Idaho mining PTCs.

11. Condition 2.5, 1st Paragraph: IDAPA 58.01.01.799 applies to nonmetallic mineral processing plants. Thus, clarifying language should be added: "IDAPA 58.01.01.799 applies to fugitive dust sources at the limestone crushing plant and aggregate production plant."

12. Condition 2.5, 1st Bullet: Please replace "to 20 miles per hour or lower if appropriate" with "in accordance with the FDCP." The Application did not propose a 20 miles per hour speed limit, and certain haul road sections may be driven at higher speeds while emissions are minimized.

13. Condition 2.5, 2nd Bullet: Please remove this bullet as discussed in Condition 1.2, Table 1.1, Hauling, above (Item 2).

14. Condition 2.5; 3rd, 4th, 5th, 7th, 13th, 15th Bullets: Each of these bullets require some action if fugitive PM emissions are observed to exceed 20% or leaving a roadway in the case of haul roads. However, the periods that trigger corrective action in these bullets are inconsistent with each other. IDAPA 58.01.01.650 does not impose a trigger for action, other than the requirement to take reasonable precautions. While the visible emissions rule IDAPA 58.01.01.625 does not suit fugitive emission observations, for comparison, that rule states, "for a period or periods aggregating more than ***three*** minutes in any 60-minute period." The Draft Permit states, "for a period or periods aggregating more than ***one*** minute in any 60-minute period." If IDEQ prefers to establish a threshold for dust mitigation action, then the following period would be acceptable to Midas Gold:

    - Whenever visible fugitive PM emissions exceed 20% for more than two consecutive minutes (4th, 5th, 7th bullets)

    - Whenever visible fugitive PM emissions are observed leaving a roadway for more than two consecutive minutes (3rd bullet). Note that this would also apply to the 13th and 15th bullets, but Midas Gold is proposing to remove these conditions.

15. Condition 2.5, 4th Bullet: Please add language to address upstream water sprays to provides downstream control via moisture carryover.

16. Condition 2.5, 6th Bullet: There are no plans to apply water or chemical to the "mine working face." Please revise to, "Apply appropriate dust control at the initial point of material handling to suppress dust throughout the material handling process, as necessary."

17. Condition 2.5, 13th Bullet: Please remove "Whenever visible fugitive PM emissions are observed leaving a roadway during inspection or valid complaint (Permit Condition 2.3), the adequacy of water and dust suppressant application rates should be evaluated." These requirements are already addressed elsewhere:

    - The Condition 2.5, 3rd bullet addresses the dust mitigation action whenever visible PM emissions are observed leaving a roadway.

    - The Condition 2.5, 20th bullet addresses the periodic evaluation of the FDCP, including dust suppressant application rates.

    - The Condition 2.3 addresses valid complaints.

18. Condition 2.5, 14th Bullet: Please remove this bullet. Chemical suppressant application will be based on the manufacturer's recommendations and periodic inspections of fugitive dust, not atmospheric conditions.

19. Condition 2.5, 15th Bullet: Please remove this bullet, as it is a repeat of the 2nd sentence of the 13th bullet.

20. Condition 2.5, 17th Bullet: Please remove this bullet as discussed in Condition 1.2, Table 1.1, Hauling, above (Item 2).

21. Condition 2.5, 18th Bullet: Please remove this bullet as the 10th bullet already requires that "Chemical dust suppressants shall be applied consistent with manufacturer's instructions and recommendations" and the 16th bullet already requires that "At least once per day during operation, monitor and record the frequency of application and application rates for water and suppressant controls."

22. Condition 2.5, 20th Bullet: Please add "and evaluate effectiveness of practices including dust suppressant application rates."

23. Condition 2.5, 20th Bullet: Please replace "every six-months" with "every year." Annual review is more typical for the mining industry. Also, it does not appear that Idaho mining PTCs typically require a six-month review of FDCPs.

24. Condition 2.9: Please replace "each shift" with "each month" and add "including any stack, vent, or functionally equivalent opening" after "potential sources of visible emissions" to clarify which sources are subject to this condition. It does not appear that Idaho mining PTCs typically contain a visible emission inspection frequency for each shift.

25. Condition 2.11: Please revise "and 22" to "and knowledgeable of procedures of Method 22" language to reflect that there is no certification for Method 22.

26. Condition 2.21, NSPS 40 CFR 60, Subpart LL: Please remove "OC8." Conveyor drops to stockpiles are not subject to Subpart LL.

27. Condition 2.23: Please add the citation "40 CFR 70.3(c)(2)" to specify that the Tier I operating permit is required only for the emission units that cause the source to be subject to the part 70 program.

28. Condition 2.24, Table 2.1, Pollutant: Please replace "PM" with "PM_{10}" as this is the pollutant that is required to be tested in the Draft Permit (Condition 4.3).

29. Condition 2.24, Table 2.1, Test Method: Please add Method 201A for PM_{10}.

30. Condition 2.24, Table 2.1, Additional Requirements: Please revise the PM Additional Requirements to: "Particulate matter (PM) including condensable PM as defined in IDAPA 58.01.01.006, with an aerodynamic diameter less than or equal to a nominal 10 micrometers for PM_{10}, and less than or equal to a nominal 2.5 micrometers for $PM_{2.5}$" to make it consistent with the rest of the Draft Permit.

31. Condition 3.2, Table 3.1: Please revise as discussed in Condition 1.2, Table 1.1, above (Item 1).

32. Condition 3.8 and 3.17: Please revise as discussed in Condition 1.2, Table 1.1, Prill Silos, above (Item 3).

33. Condition 3.11: Please remove this condition. The crushers will be controlled by water sprays. No emission control credit was taken for the buildings, which will likely have door and vent openings.

34. Condition 4.2, Table 4.1: Please revise as follows:

    - Carbon bed pressure drop is a <u>maximum</u> limit (O&M)
    - Carbon bed inlet gas temperature is a <u>maximum</u> limit (Subpart EEEEEEE)
    - Baghouse pressure is a <u>maximum</u> limit (O&M)

35. Condition 4.3, Table 4.2: Please remove footnote (c) from NO_X, CO, VOC, and SO_2 as there is no testing required for these pollutants.

36. Condition 4.4: Please revise as discussed in Condition 1.2, Table 1.1, POX Boiler, above (Item 5).

37. Condition 4.11 through 4.16: Please remove "and in accordance with IDAPA 58.01.01.210.21." The rule states, "Additional procedures and requirements to demonstrate and ensure actual and continuing compliance may be required by the Department in the permit to construct." Conditions 4.11 through 4.16 establish procedures or requirements regarding compliance, and therefore it is not necessary to cite this rule. Including the citation suggests that there are more requirements than stated in the PTC, but any additional requirements are to be in the PTC according to the rule text.

38. Condition 4.28: Please add carbon filter monitoring requirements.

39. Conditions 5.1 and 5.2: Please revise as discussed in Condition 1.2, Table 1.1, Concrete Production, Central Mixer Loading, above (Item 9):

40. Condition 5.3: Please remove footnote (c) as there are no testing requirements for these pollutants.

41. Condition 5.8: Please revise as discussed in Condition 1.2, Table 1.1, Concrete Production, above (Item 8).

42. Condition 5.11: Please remove this condition. The crushers will be controlled by water sprays. No emission control credit was taken for the building, which will likely have openings.

Thank you for your consideration of these comments. We note that the updated Appendix B to the Statement of Basis was received via email from Morrie Lewis on July 31, 2020. Any additional comments that we have to the Statement of Basis will be submitted to IDEQ within the 10-day review period. We will notify you via email prior to that date if we have no additional comments.

If you have any questions regarding this submittal, please contact me at 208-901-3053 or ahaslam@midasgoldinc.com.

Sincerely,
MIDAS GOLD IDAHO, INC.

Alan Haslam

Enclosure: Redlined Draft Permit

APPENDIX F – SUBSECTION 210.20 INTERPRETATION OF ADDRESSED

STATE OF IDAHO
DEPARTMENT OF
ENVIRONMENTAL QUALITY

1410 N Hilton Street, Boise, ID 83706
(208) 373-0502

Brad Little, Governor
Jess Byrne, Director

Examples of How DEQ Interprets the Word "Addressed" in Subsection 210.20

For example, 40 CFR 63 Subpart 6J - National Emission Standards for Hazardous Air Pollutants for Industrial, Commercial, and Institutional Boilers Area Sources regulates HAP emissions from coal, biomass, and oil-fired boilers. However, the subpart specifically exempts gas-fired (i.e. natural gas-fired) boilers because EPA determined that HAP emissions from these sources were too inconsequential to be regulated by the Subpart. DEQ interprets this to mean EPA did "address" natural gas boiler HAP emissions by choosing to exempt them. Thus, HAP emissions that are also TAP emissions from coal, biomass, oil-fired boilers, and natural gas-fired boilers are not required to demonstrate compliance with IDAPA 58.01.01.210 per section 210.20.

For example, 40 CFR 63 Subpart ZZZZ - National Emissions Standards for Hazardous Air Pollutants for Stationary Reciprocating Internal Combustion Engines regulates HAP emissions from IC engines by regulating CO emissions as a surrogate for HAP emissions. Therefore, HAP emissions from IC engines are not directly regulated by the Subpart. DEQ interprets this to mean EPA "addressed" HAP emissions by regulating CO emissions as a surrogate. Therefore HAP emissions that are also TAP emissions from IC engines are not required to demonstrate compliance with IDAPA 58.01.01.210 per section 210.20.

For example, HAP/TAP emissions from lumber drying kilns were evaluated in promulgating 40 CFR 63 Subpart DDDD - National Emission Standard for Hazardous Air Pollutants: Plywood and Composite Wood Products (PCWP). This Subpart regulates major sources of HAP emissions and includes lumber drying kilns at PCWP manufacturing facilities and "at any other kind of facility" as affected sources, even though this subpart does not include any substantive requirements to control or limit emissions from the kilns. In developing Subpart DDDD EPA stated "…we know of no other lumber kilns that are controlled for HAP, and we know of no cost effective HAP controls for lumber kilns…" (see Fed. Reg. /Vol 68, No. 6/Thursday, Jan 9, 2003/Proposed Rules page 1285). DEQ interprets this to mean EPA "addressed" HAPS that are also TAPS for both major and minor sources of HAP emissions; and therefore, lumber kilns are not required to demonstrate compliance with IDAPA 58.01.01.210, per section 210.20.

For example, when EPA regulated Phosphoric Acid Manufacturing for new sources, only the wet-process phosphoric acid line, superphosphoric acid process line, phosphate rock dryer, and the phosphate rock calciner have specific emissions limits in the rule. However, other emissions sources at facility were also looked at but they were determined by EPA to be insignificant and were not regulated in the rule. Therefore, when EPA looks at a source category to regulate, all emissions sources associated with the source category are "addressed" whether EPA establishes specific emissions limits for the emissions sources or not.
In sum, the term "addressed" is interpreted to mean EPA (1) specifically regulated, (2) specifically regulated by a surrogate, (3) reviewed, or (4) evaluated, the HAP emissions that are also TAPs.

Please note that in all cases it is presumed that EPA evaluated the 187 HAPs when developing the emission standards for new, modified or existing stationary sources regulated by 40 CFR Part 63 Subparts. Therefore, in all cases IDAPA Toxic Air Pollutants that are not one of the 187 Hazardous Air Pollutants will still need to be evaluated for compliance with IDAPA 58.01.01 Section 210.

APPENDIX G – T-RACT ANALYSIS

6.0 T-RACT ANALYSIS

Per IDAPA 58.01.01.210.14(a), this section documents the T-RACT control technologies.

6.1 Drilling Dust Control System

As discussed in Section 5.1, Perpetua Resources will install and operate drilling rigs mounted with dust collection systems. The following paragraphs evaluate this control as T-RACT:

Identification of all possible control technologies

Drilling operations create dust-related metal TAP emissions. The possible control technologies for these emissions are as follows:

- Applying best management practices
- Wet drilling with water injection
- Dry drilling with dust collectors

Best management practices include: (1) avoiding drilling operations during high dust conditions, and (2) shrouding drill areas to limit dust emissions.

Wet drilling includes injected water flows through the center of the drill and out though the drill bit to reduce dust emissions by 96% to 98%.[10]

Dry drilling includes rigs equipped with dust collection systems that shroud dust generated from the drilling area, capture, and remove dust through a dust collection system composed of an exhaust fan and filters that can achieve up to 99% control efficiency (CDC 2012).

Elimination of technologically infeasible or unreasonable technologies

Wet drilling at the SGP has the following disadvantages:

- It is subject to freezing at the low temperatures expected for the SGP location.
- It can result in drill bit plugging, drill rotation binding, and drill bit degradation.
- A wet drill hole can interfere with the blasting agent.

Based on the above disadvantages of wet drilling, it is considered an infeasible or unreasonable technology for the SGP.

[10] *Testing has demonstrated that dust control efficiencies of up to 98 percent can be obtained using the water separator sub while dust control efficiencies of wet drilling without the water separator sub were 96 percent* (CDC 2012).

Ranking the remaining technologies by control effectiveness

The ranking of the possible control technologies for drilling by control effectiveness is as follows (highest to lowest):

1. Dry drilling with dust collectors – up to 99% control efficiency
2. Best management practices

Evaluation of the most effective control technology and selection of T-RACT

Perpetua Resources selects the top (most effective) control technology of dry drilling with dust collectors as T-RACT. Selecting the top control negates the need for considering economic, energy, and environmental impacts regarding the other control technologies.

6.2 Haul Road Dust and Arsenic Control

Dust emissions from unpaved roads are caused by vehicle traffic on these roads. Particles are lifted and dropped from the rolling wheels, and the turbulent wake behind the vehicles causes these particulates to become air borne. Dust control options include surface improvement (paving) or surface treatment (chemical suppressant application or watering).

As discussed in the SOB from February 18, 2021, Perpetua Resources will control dust emissions from haul roads by treating the surface with frequent watering and the periodic application of a chemical suppressant. Reducing dust emissions reduces dust-related metal TAP emissions. In addition, Perpetua Resources will reduce arsenic emissions by capping the haul roads outside of the pits and DRSFs with clean (low arsenic) development rock, as discussed in Section 5.2. The following sections evaluate these control measures as T-RACT.

6.2.1 Dust Control Technologies

Identification of all possible control technologies

Vehicle traffic on unpaved haul roads creates dust-related metal TAP emissions. The possible control technologies for these emissions are as follows:

- Paving
- Application of a chemical dust suppressant
- Watering

Paving: *The control efficiencies achievable by paving can be estimated by comparing emission factors for unpaved and paved road conditions* (EPA 2006). The particulate emission factor for a paved road with a silt loading of 0.2 g/m^2 (based on the EPA default value for the SGP average daily traffic of 500–5,000 trips per day) (EPA 2011a) and the SGP average vehicle weight of 182.6 tons is

0.515 lb/VMT. The SGP unpaved road particulate emission factor is 14.43 lb/VMT (uncontrolled). Based on these emission factors, the estimated control efficiency of paving the haul roads is 96%.

Dust suppressant and watering: The SGP dust emissions from unpaved haul roads are calculated based on a surface treatment control efficiency of 90% (annual basis) for the application of a chemical dust suppressant supplemented with frequent watering. As discussed in the SGP Application, this control efficiency is supported by EPA's AP-42 13.2.2 referenced test reports, which show that a chemical dust suppressant alone can achieve 90% to 99% control efficiency and 98% for magnesium chloride in particular (Air Sciences 2020, Appendix A to Attachment A). A control efficiency of 90% is also supported by the control efficiency limits established under Reasonable Achievable Control Technology (RACT), Best Available Control Technology (BACT), and Lowest Achievable Emission Rate (LAER) determinations under EPA's New Source Review permitting program.

The EPA RACT/BACT/LAER Clearinghouse (RBLC) database contains case-specific information on the air pollution technologies required by major stationary sources seeking a permit under EPA's New Source Review (NSR) program. This database was queried for all listings of air pollution technologies for unpaved roads using chemical dust suppressants or a combination of chemical dust suppressants and watering. The results of the query identified 10 projects containing a control efficiency of 90% or greater for unpaved roads. These determinations are listed in Table 10.

Table 10. EPA RBLC Determinations for 90% or Greater Control Efficiency of Unpaved Roads

State	Facility Name	RBLC-ID	Dust Control	Dust Control Efficiency
AK	Donlin Gold Project	AK-0084	water/chem	90%
AR	Turk Power Plant	AR-0094	water/chem	90%
CO	Rio Grande Portland Cement Corp.	CO-0043	water/chem	90%
IN	Nucor Steel	IN-0034	chem	90%
LA	Nucor Steel Louisiana	LA-0239	water/chem	90%
MO	Lafarge Corp.	MO-0048	chem	90%
NV	Sloan Quarry	NV-0045	chem	98%
NV	Nellis Air Force Base	NV-0047	water/chem	90%
OH	Unlimited Concrete	OH-0126	water/chem	90%
OH	Unlimited Concrete	OH-0131	water/chem	90%

(EPA 2021)

Elimination of technologically infeasible or unreasonable technologies

Paving haul roads at the SGP has the following disadvantages:

- The paving of haul roads is not conventional practice at mining operations.
- Paved highway weight limits are only approximately 20,000 pounds (10 tons).
- Paving is costly.

The conventional practice for mining operations is to utilize unpaved haul roads with treated surfaces to control fugitive dust. Haul trucks are single axle vehicles with a gross loaded weight of 60 tons to 685 tons. The loaded weight range for the SGP haul trucks is 60 to 260 tons. These weights significantly exceed regulatory weight limits for paved highways of 10 tons. Furthermore, the SGP mining activity locations move as mining progresses. This requires haul roads to be rerouted as necessary. Due to the temporary nature of hauling routes and the heavy weight of haul trucks, paving is considered an infeasible or unreasonable technology for the SGP.

Ranking the remaining technologies by control effectiveness

The ranking of the possible control technologies for drilling by control effectiveness is as follows (highest to lowest):

1. Application of a chemical dust suppressant – 90% to 99% control efficiency

REC 0913

PET 547

2. Watering – 75% to 95% control efficiency (EPA 2006, Figure 13.2.2-2)

Evaluation of the most effective control technology and selection of T-RACT

After eliminating paving as a viable control option, Perpetua Resources selects the next most effective control technologies of the application of a chemical dust suppressant supplemented with frequent watering as T-RACT.

6.2.2 Arsenic Control Technologies

After applying T-RACT for dust control, as discussed in Section 6.2.1, dust-related arsenic emissions can only be further reduced by capping the haul roads with clean (low-arsenic) development rock. The median arsenic concentration of the SPG onsite material is 667 ppm (Midas Gold 2017c). However, there are quartzite rock deposits at the West End pit that have significantly lower mineralization and, thus, lower arsenic levels. The median arsenic concentration of this quartzite rock is 90 ppm (Perpetua 2021g), and there is approximately 3 million tons of this material available. Figure 6 shows the locations of the quartzite rock deposits.

Figure 6. Quartzite Rock Areas

Perpetua Resources proposes capping the haul roads that are outside of the pits and DRSFs with clean (low-arsenic) development rock as a T-RACT work practice, in addition to the T-RACT dust control measures discussed in Section 6.2.1. Haul roads within the pits and DRSFs cannot be capped with this material because of steep grades and periodic road rerouting as mining areas develop.

Air Quality Permitting
Response to Public Comments

June 17, 2022

Permit to Construct No. P-2019.0047

Project No. 62288

Perpetua Resources Idaho, Inc.
Stibnite, Idaho

Facility ID No. 085-00011

Prepared by:
Kelli Wetzel, Permit Writer
AIR QUALITY DIVISION

FINAL

Table of Contents

BACKGROUND 2

PUBLIC COMMENTS AND RESPONSES 2

BACKGROUND

1 The Idaho Department of Environmental Quality (DEQ) provided a third public comment period on the proposed permit to construct (PTC) for Perpetua Resources Idaho, Inc. (PRI) from January 13 – March 16, 2022, in accordance with IDAPA 58.01.01.209.01.c. During this period, comments were submitted in response to DEQ's proposed action.

2 DEQ appreciates all of the comments received concerning this project during the third comment period. Substantive comments were provided, particularly concerning the representativeness and uncertainty of emissions, the preconstruction demonstrations of compliance with toxic and mercury standards, and the PSD classification for the lime plant. These topics and DEQ's responses to each comment pertaining to air quality are provided in the sections that follow, and updates to the proposed permit and technical review have been made. As described in the responses that follow, the following conditions have been updated in Permit to Construct No. P-2019.0047 Project 62288:

- Permit Conditions 1.2 (Table 1.1), 2.4, 2.6, 2.7, 2.8, 2.13, 2.20, 2.21, 3.2 (Table 3.1), 3.9, 3.13, 4.4 – 4.6, 4.9, 4.10, 5.2 (Table 5.1), 5.5, 5.8, 5.9, 5.22, 6.2, 6.4, 6.5, and 6.6

The following sections of technical and regulatory analyses have been updated in the Statement of Basis:

- Application Scope, permit condition numbering in the Controlled Hazardous and Toxic Air Pollutant Emissions, Ambient Air Quality Impact Analyses, Mercury Emission Standard, and Particulate Matter – New Equipment Process Weight Limitations, and Permit Conditions Review sections

PUBLIC COMMENTS AND RESPONSES

Additional public comments regarding the technical and regulatory analyses and the air quality aspects of the proposed permit are summarized below. Questions, comments, and suggestions received during the comment period that did not relate to the air quality aspects of the permit application, the Department's technical analysis, or the proposed permit were not addressed. It is also noted that while a response to each comment is provided herein, many of the topics discussed were also previously addressed in the first and second Response to Public Comments, in the Statement of Basis, and/or in PRI's application materials. All original public comments submitted for this project can be requested via the public records request process as DEQ has included public comments that may not include in-text citations.

PET 550

REC 0916

REPRESENTATIVENESS AND UNCERTAINTY OF EMISSIONS

3 Several comments were received relating to the representativeness and uncertainty of parameters used in developing the emission factors used to estimate emissions. Although some degree of uncertainty is present in all emission factors used in estimating emissions, all emission factors were adequately supported and the approach of estimating potential to emit (PTE) at design capacity and maximum activity rates was considered a sufficiently conservative approach. Maximum hourly and daily activity rates were used to estimate the maximum 24hour and annual emission rates, and emissions were modeled based on these maximum shortterm activity rates occurring continuously every day.

It was recognized by DEQ and by commenters that emissions estimates and modeling of $PM/PM_{10}/PM_{2.5}$, HAP, and TAP are all sensitive to each of the specified controls and sitespecific parameters identified in the following paragraphs. Representativeness of these parameters was discussed with and reconfirmed by PRI at various points during review,[1,2,3,4,5,6] and the estimates of emissions and underlying assumptions were supported to the satisfaction of DEQ. Sufficient information was provided to demonstrate preconstruction compliance with applicable TAP and mercury standards and to support facility classifications.

4 Relevant DEQ guidance concerning the acceptability of emissions data can be found in DEQ's Guidance on Emissions Data Hierarchy:
https://www2.deq.idaho.gov/admin/LEIA/api/document/download/5521

Water and chemical dust suppressant control efficiencies

5 A combined control efficiency of 93.3% was included in the permit for haul roads because this was recognized as an aggressive level of control and because haul roads were identified as a key contributing source to ambient air quality impacts. PRI has committed to undertaking all measures necessary to achieve this level of control and has confirmed based on a review of test studies that this can be achieved using water and magnesium chloride dust suppressants (Appendix A to the application – Model Parameter/Assumption/Data Level of Conservatism).

6 DEQ recognizes that in practice chemical and water dust suppressants are used in combination for the control of dust from haul roads, and that achieving the target combined control efficiency of 93.3% is ultimately important to ensure compliance with applicable standards. It is for this reason that the combined control efficiency was listed in the permit in lieu of separate chemical (90% control) and water (33.3%) dust suppressant control efficiencies. DEQ agrees with commenters that compliance with fugitive dust requirements is also necessary to ensure compliance with applicable standards, including application of both water and chemical dust suppressant in proper amounts and at proper frequencies as local conditions dictate.

7 *Silt content*

8 The use of site-specific median values for silt content is commonly accepted by DEQ, and the values used in calculations were supported by PRI. Metal hazardous air pollutant (HAP) and toxic air pollutant (TAP) emissions from process materials were based on median measured metal concentration profiles from onsite core samples of ore and limestone materials, including 98 samples of PRI limestone and over 55,000 samples of PRI ore. PRI has confirmed that ore samples were taken primarily from the mineralized zones of the PRI pits and were representative for the purposes of estimating emissions. Although a median value of sampled silt percentages of roadway material was used in emission estimates presented in the application, DEQ recognizes the importance of the silt content parameter in the estimation of emissions. Since compliance with the 24-hour PM_{10} National Ambient Air Quality Standards (NAAQS) is the primary driver of NAAQS compliance, minimizing variability of the parameter is very important to ensure NAAQS compliance. To achieve this, the permit will limit *maximum silt content* to 4.0 %, as specified in Section 3.13 Haul Road Capping of the PTC as well as associated monitoring and recordkeeping.

Metal concentrations

9 The use of site-specific median values for metal concentrations is commonly accepted by DEQ, and the values used were supported by PRI. Metal hazardous air pollutant (HAP) and toxic air pollutant (TAP) emissions from process materials were based on median measured metal concentration profiles from onsite core samples of ore and limestone materials, including 98 samples of PRI limestone and over 55,000 samples of PRI ore. PRI has confirmed that ore samples were taken primarily from the mineralized zones of the PRI pits and were representative for the purposes of estimating emissions. While the use of an average or 90^{th} percentile value is a more conservative approach, the use of sitespecific median values combined with estimating and modeling PTE at design capacity and maximum activity rates was considered a sufficiently conservative approach and is commonly accepted by DEQ. Furthermore, use of a median value is appropriate for long-term standards (annual and above), since short-term spikes in emissions do not heavily influence a long-term average concentration. PRI has confirmed that use of a concentration average would be unduly influenced by a high values in a skewed distribution. PRI has confirmed that the use of mineralized metal profiles is conservative when compared to low-mineralization materials such as development rock (DR) and clean gravel. DEQ does not typically require applicants to include an analysis of potential HAP and TAP emissions from materials used in capping of unpaved roads.

Material balance

While a material balance is a useful approach to developing emission estimates, it is not a requirement, and the use of maximum activity rates and representative performance test data to estimate and model emissions is commonly accepted by DEQ. While the use of an average or maximum value is a more conservative approach, the use of sitespecific median values combined with estimating and modeling PTE at design capacity and maximum activity rates was considered a sufficiently conservative approach.

COMPLIANCE WITH TOXIC AND MERCURY STANDARDS

10 Several comments were received relating to the methods used to demonstrate compliance with toxic and mercury standards. As discussed in the Emissions Inventories section and reported in Table 6 of the Statement of Basis as "Adjusted TAP Emissions", HAP TAP and mercury emissions from *addressed* sources were excluded from emission totals used to demonstrate preconstruction compliance with toxic standards (TAP) and the mercury emission standard in accordance with the Rules and DEQ guidance. Detailed discussion is provided in the "Subsection 210.20", Table 9, and "Mercury Emission Standard" sections of the Statement of Basis, and DEQ guidance on the interpretation of "addressed" is included in Appendix F to the Statement of Basis.

11 Specifically in regard to the applicability to National Emission Standard for Hazardous Air Pollutants: Gold Mine Ore Processing and Production Area Source Category Subpart EEEEEEE (NESHAP Subpart 7E), PRI has proposed construction and operation of an affected source meeting the definition of "gold mine ore processing and production facility" as defined in 40 CFR 63.11651 and will construct autoclave, carbon kiln, preg tank, electrowinning, mercury retort, and melt furnace processes. The permit is issued on this basis, and applicable NESHAP Subpart 7E requirements are incorporated by reference (Permit Condition 2.22).

12 *Source categories* are classified using the North American Industry Classification System (NAICS), and the primary classification code for PRI is 212221 for "Gold Ore Mining," as identified in Table 9 of the Statement of Basis. The description for this code is "this U.S. industry comprises establishments primarily engaged in developing the mine site, mining, and/or beneficiating (i.e., preparing) ores valued chiefly for their gold content. Establishments primarily engaged in transformation of the gold into bullion or doré bar in combination with mining activities are included in this industry." Beyond identifying the *source category*, a variation of this descriptive language was similarly included in Table 9.

13 The methods for demonstrating preconstruction compliance with TAP and mercury emission standards and by extension compliance with Section 161 are defined in Section 210 of the Rules and DEQ guidance. As detailed in DEQ guidance regarding the interpretation of "addressed" in Appendix F to the Statement of Basis, when EPA looks at a source category to regulate, it is presumed that all emissions sources associated with a *source category* are "addressed" whether EPA establishes specific emissions limits for the emissions sources or not in the NESHAP. For carcinogens including arsenic and antimony, the TAP screening emission levels (EL) and the acceptable ambient concentrations for carcinogens (AACC) were established in Section 586 of the Rules based on the probability of developing excess cancers over a 70-year lifetime exposure. Beyond these considerations, a risk analysis is not required to obtain a PTC.

PSD CLASSIFICATION FOR THE LIME PLANT

A response to a request for additional information was submitted by PRI[3] in which the emissions units comprising the lime plant were identified. The project includes a lime manufacturing plant (LMP) that uses a Parallel Flow Regenerative Shaft Kiln to produce lime product from limestone by calcination, which is a designated facility as defined in 40 CFR 52.21(b)(1)(i)(*a*). As described in the "Facility Classification" and "PSD Classification" section of the Statement of Basis, the LMP is a designated facility "nested" inside a non-designated facility. As explained in the United States Environmental Protection Agency's (EPA) March 6, 2003, guidance,[67] an example is "A coal mine with an onsite coal cleaning plant with a thermal dryer. The primary activity of the source, in this example, is the mining of coal, and coal mines are not a listed source category. The coal cleaning plant, however, does fall within a listed source category. Fugitive emissions are only included from the coal cleaning plant to determine if the source is a major stationary source." Applying this guidance, these emissions are included in Table 10 of the Statement of Basis. For each regulated pollutant, LMP emissions did not exceed 100 T/yr, and facility-wide emissions did not exceed 250 T/yr applicability thresholds. To be conservative, DEQ has demonstrated that if the LMP was considered as the primary activity of the mine and the marble overburden mining associated with the LMP is included in the list of LMP sources, LMP emissions did not exceed 100 T/yr (see Table 11 of the Statement of Basis).

[67] "Clarification on fugitive emissions policy" letter to Janet McCabe, Assistant Commissioner, Office of Air Quality, Indiana Department of Environmental Management, March 6, 2003.

FUGITIVE DUST CONTROL EFFICIENCY

Comment 1 - Nez Perce Tribe (NPT): DEQ's reliance on a 93.3% fugitive dust control efficiency to ensure compliance with permit requirements and for the Project to be classified as a synthetic minor source is unsupported

Permit conditions must ensure compliance and enforceability, and DEQ has not demonstrated evidence that a 93.3% fugitive dust control efficiency is attainable or practically enforceable. DEQ has not provided any case studies that a 93.3% fugitive dust control efficiency can be met through a combination of chemical suppressant and added water. Not only is the 93.3% control efficiency requirement not backed up by supporting technically accurate documentation to be possible in the real world, permit conditions are not written so that it is possible to verify compliance and document violations when enforcement would be necessary. DEQ is, therefore, unable to ensure that permit conditions can be met.

DEQ also relies on the unproved 93.3% fugitive dust control efficiency for the Project to be considered a synthetic minor for facility-wide emissions of PM/PM10/PM2.5 to be below 250 tons/yr PSD applicability thresholds, Title V 100 tons/yr applicability thresholds, and to limit facility-wide emissions of single and total HAP to below HAP major source applicability thresholds of 10/25 tons/yr. As described above, because the 93.3% fugitive dust control efficiency is not practically achievable or enforceable, the Project does not meet the standard to avoid classification as a major source for PSD, Title V, and HAP**.**

DEQ Response:

14 For the Fugitive Dust Control Plan (FDCP), the minimum and substantive requirements were specified in the permit (Permit Conditions 2.1-2.6, 2.7-2.8, 2.20-2.21). DEQ contends that these and other relevant conditions are sufficient, reasonable, and appropriate to ensure compliance with applicable requirements including National Ambient Air Quality Standards (NAAQS). Relevant conditions include visible emissions limits (Permit Conditions 2.9-2.12), material throughput and operational limits (Permit Conditions 3.3-3.9, 4.5-4.12, 5.4-5.9, 6.3), emissions limits (Permit Conditions 4.3-4.4, 5.3), control device requirements (Permit Conditions 3.10-3.12, 4.13-4.17, 5.10-5.16), and testing (Permit Condition 4.33) requirements. To ensure enforceability of each of these requirements, supporting testing and monitoring, recordkeeping, and reporting (MRR) requirements were also included. In addition, DEQ will review and approve the FDCP which is incorporated by reference in the permit and is enforceable as part of the permit.

As described previously in the Representativeness and Uncertainty of Emissions section, although some degree of uncertainty is present in all emission factors used in estimating emissions, all emission factors were adequately supported and the approach of estimating potential to emit (PTE) at design capacity was considered a conservative approach. DEQ contends that the material throughput, operational limits, emissions limits, control device requirements, testing, and supporting MRR requirements in combination with reagent usage limits for cyanide and xanthate (Permit Conditions 4.4-4.6) are sufficient, reasonable, and appropriate to ensure HAP minor source classification and to verify that dust controls are being achieved.

Comment 2 – Environmental Protection Agency (EPA): Limiting PTE of the Mining Fugitive Dust Emissions for NAAQS and Title V HAP Purposes

The permit does not ensure that the fugitive dust emissions related to the mining of ore and limestone will not cause or significantly contribute to a violation of the NAAQS or exceedance of the Title V HAP major source permitting thresholds. The emission limits necessary to ensure compliance with the NAAQS and Title V HAP applicability limits do not appear to be enforceable as a practical matter. In particular (I) achieving 93.3% control efficiency for fugitive dust resulting from mining activities (excavation and haul roads) and 90% control efficiency for drilling activities are critical to ensuring no violation of the NAAQS and Title V HAP limits, (2) the permit does not contain the conditions necessary to ensure the permittee achieves those efficiencies at all times and (3) the permit record does not demonstrate that those efficiencies are achievable based on the

site-specific conditions at the Perpetua mine. EPA made similar comments in its March 19, 2021, comment letter to IDEQ regarding the previous Perpetua draft.

Examples of these specific issues include, but may not be limited to, the following:

Mining Fugitive Dust PTE Permit Limitations:

16. PTE limitations consistent with the 93.3% control efficiency applicable to haul road and access road do not appear to be specified in the permit conditions. These PTE limitations may include permit conditions requiring control measures such as how frequently chemical suppressant supplemented with watering must be applied, the atmospheric and operational conditions under which magnesium chloride supplemented with watering should be applied, the time of day that magnesium chloride supplemented with watering should be applied, and/or the amount that should be applied. [13] The permit requires that fugitive road dust PTE limitations such as those indicated above are to be developed by the permittee after the permit is issued. The permit also allows these types of PTE limitations to be changed without IDEQ review and approval. PTE limitations addressing the 93.3% control efficiency must be reviewed and approved by IDEQ, subject to review by the public during the public comment period and must be enforceable at all times upon the issuance of the initial permit. Also, any changes to the approved PTE limitations after the permit is issued that are less stringent must go through IDEQ public review and approval and must be enforceable at all times upon the issuance of the revised permit.

17. PTE limitations to achieve a 93.3% control efficiency for fugitive dust emissions associated with the mining excavation activities as specified in Table 1.1 and Table 3.1 do not appear to be specified in the permit conditions. Although permit condition 3.10 requires the "permittee shall control emissions from mining... emission sources (Table 3.1) in accordance with the Fugitive Dust Control Plan." it does not specify what those controls are and as such are unenforceable. These control measures must be specified as part of the permit consistent with the permitting record and subject to review during the public comment period. In addition, these control measures must be enforceable at all times upon issuance of the permit. Any changes that are less stringent than the approved control measures made after the initial permit is issued must be proposed for review using public notice procedures and must be enforceable at all times upon issuance of the revised permit.

18. To make the PTE limitations enforceable as a practical matter, the permit should include the parameters and assumptions used to develop the fugitive dust emission factors estimates for the haul roads and access roads (see AP-42 Section 13.2.2, Equation la).[14] Per AP-42 and the application, these parameters and assumptions include surface material silt content (%), mean vehicle weight (tons), speed limit (mph), and daily vehicle miles travelled.

Mining PTE Fugitive Dust Control Efficiencies and Emissions Factors:

19. IDEQ's permitting record does not appear to provide support for a 93.3% control efficiency applicable to fugitive dust emissions resulting from mining excavation operations and haul roads. IDEQ's permitting record cites three studies that address the control efficiencies associated with fugitive dust emissions associated with haul roads but not mining excavation activities. Based on these studies, IDEQ concludes that applying magnesium chloride will achieve a control efficiency of 90%. However, IDEQ's permitting record does not provide a reasoned analysis consistent with AP-42's control effectiveness factors (or equivalent) that this control efficiency and associated control measures identified by these studies would be representative of Perpetua's mining operation. In addition, IDEQ's permitting record does not identify the specific study details that support their conclusion and does not include copies of these studies for review during public comment period. (see Appendix A, Air Sciences 2020 application, page 339 of 421). IDEQ's permitting record indicates that a control efficiency of 90% is also supported by control efficiency limits established for 10 projects in the EPA RACT/BACT/LAER Clearinghouse (RBLC) database. However, IDEQ's permitting record does not provide a reasoned analysis consistent with AP-42's control effectiveness factors (or equivalent) that the control efficiencies and associated control measures identified by these permitting projects would be representative of Perpetua's mining operation. In addition, IDEQ's permitting record does not identify the specific details from the permitting projects and associated documentation that support their conclusions (IDEQ's 2021 TAP Addendum,

page 37 of226). Moreover, IDEQ's permitting record does not provide any technical studies showing that the supplementing magnesium chloride with watering will improve the control efficiency of magnesium chloride. Lastly, IDEQ's permitting record does not appear to provide support for a 10% opacity associated with a 93.3% control efficiency for haul roads as established in Permit Condition 2.5. To support the 93.3% claim of road dust control efficiency, a see-no see approach to opacity monitoring may be more appropriate.

DEQ Response:

Enforceable monitoring, recordkeeping, and reporting requirements were established in the permit. PM/PM_{10}/$PM_{2.5}$ emissions limits for point sources were established with supporting activity rate limits and MRR requirements. While emissions limits and emission factors are not commonly included in the permit for fugitive sources, activity rate limits and MRR requirements were established for those sources that were identified as process rate-limiting (as summarized in Table 1.1 of the permit). These activity rate limits serve as surrogate emissions limits for PM, PM_{10}, $PM_{2.5}$, HAP and TAP from fugitive sources. And while documented in the Statement of Basis and application materials, underlying parameters associated with calculating emissions such as vehicle speed limit, type, and miles traveled are not typically included in the permit but can be found in the application materials (Appendix A).

15 Based on public comment, Permit Condition 2.8 has been updated to include DEQ approval both initially (before startup) and after any subsequent changes and that the Fugitive Dust Control Plan (FDCP) shall be approved 30 days prior to startup. The approved FDCP is incorporated by reference in the permit and is enforceable as part of the permit. For the FDCP, the minimum and substantive requirements are specified in the permit and available for public review (Permit Conditions 2.1-2.6). DEQ contends that these and other relevant conditions are sufficient, reasonable, and appropriate to ensure compliance with applicable requirements including National Ambient Air Quality Standards (NAAQS).

DEQ recognizes that in practice chemical and water dust suppressants are used in combination for the control of dust from haul roads, and that achieving the target combined control efficiency of 93.3% is ultimately important to ensure compliance with applicable standards. It is for this reason that the combined control efficiency was listed in the permit in lieu of separate chemical (90% control) and water (33.3%) dust suppressant control efficiencies. An instantaneous 10% opacity limit for vehicle traffic on haul roads is considered a very conservative control trigger level to ensure that an appropriate control measure is taken to reasonably control emissions of fugitive dust (Permit condition 2.5). DEQ agrees with commenters that compliance with fugitive dust requirements is also necessary to ensure compliance with applicable standards, including application of both water and chemical dust suppressant in proper amounts and at proper frequencies as local conditions dictate.

Comment 3 – Idaho Conservation League (ICL)/ Save the South Fork Salmon (SSFS): Dust Control Efficiency

IDEQ states in this permit that the Applicant will have to achieve a dust control efficiency of at least 93.3% on the haul roads in order to achieve air quality compliance, yet the agency has not provided sufficient evidence that such a high target is attainable or practically enforceable. In Appendix G of the Statement of Basis, IDEQ discusses the T-RACT Analysis, including dust control efficiency. We have reviewed the references listed in Appendix G, Table 10 of other facilities with determinations of 90% or greater control efficiency for unpaved roads. Upon investigation of these references through the EPA's Clean Air Technology Center database,[2] we found that only 1 of the 10 facilities referenced actually has *verified* compliance of achieving at least 90% control efficiency. The other nine facilities listed in Table 10 had either unverified or unknown compliance with that permit condition. In addition, only one of these facilities is actually a gold mining operation and therefore most of these references should not be used as a point of comparison to the Stibnite project.

Listed Facilities in Appendix G, Table 10
AK Donlin Gold Project AK-0084 water/chem 90% (unverified/unknown compliance)
AR Turk Power Plant AR-0094 water/chem 90% (unverified/unknown compliance)

CO Rio Grande Portland Cement Corp. CO-0043 water/chem 90% (unverified/unknown compliance)
IN Nucor Steel IN-0034 chem 90% (unverified/unknown compliance)
LA Nucor Steel Louisiana LA-0239 water/chem 90% (unverified/unknown compliance)
MO Lafarge Corp. MO-0048 chem 90% (unverified/unknown compliance)
NV Sloan Quarry NV-0045 chem 98% (compliance verified)
NV Nellis Air Force Base NV-0047 water/chem 90% (unverified/unknown compliance)
OH Unlimited Concrete OH-0126 water/chem 90% (unverified/unknown compliance)
OH Unlimited Concrete OH-0131 water/chem 90% (unverified/unknown compliance)

According to the T-RACT analysis, the Applicant has eliminated paving as a control mechanism due to it being deemed too costly, instead selecting the application of a chemical dust suppressant supplemented by frequent watering. However, there is no assurance that other facilities of this size and nature have been able to achieve this high bar for dust control efficiency. IDEQ itself states on page 22 of the Statement of Basis that "it may prove challenging to consistently and continuously achieve the targeted level of fugitive dust control for emissions from traffic on unpaved roadways, with over 55 miles of haul truck routes within the mining operations boundary, a fleet of 32 haul trucks weighing between 37 and 357 tons, and a targeted dust control efficiency of 93.3% accomplished by application of both dust suppressant and water controls." Because the fugitive dust control efficiency is not practically attainable or enforceable, this facility should not be classified as a non-major source.

IDEQ should:

- Rigorously evaluate if the 93.3% dust control efficiency target is realistically attainable by the Applicant. If not, reclassify the facility as a major source.
- Include enforceable provisions in the permit to hold the Applicant to continuous achievement of that dust control efficiency level.
- Adjust emission calculations for ore handling and processing activities when temperatures are below freezing and proposed water controls would not be practical.

DEQ Response:

The Fugitive Dust Control Plan (FDCP) contains the minimum and substantive requirements and were specified in the permit and available for public review (Permit Conditions 2.1-2.6). DEQ contends that these and other relevant conditions are sufficient, reasonable, and appropriate to ensure compliance with applicable requirements including National Ambient Air Quality Standards (NAAQS). In addition, DEQ will review and approve the FDCP which is incorporated by reference in the permit and is enforceable as part of the permit. DEQ recognizes that in practice chemical and water dust suppressants are used in combination for the control of dust from haul roads, and that achieving the target combined control efficiency of 93.3% is ultimately important to ensure compliance with applicable standards. It is for this reason that the combined control efficiency was listed in the permit in lieu of separate chemical (90% control) and water (33.3%) dust suppressant control efficiencies. DEQ agrees with commenters that compliance with fugitive dust requirements is also necessary to ensure compliance with applicable standards, including application of both water and chemical dust suppressant in proper amounts and at proper frequencies as local conditions dictate. The references listed in Appendix G, Table 10 from the EPA RBLC database were provided as additional supporting information. The references illustrate that a control efficiency of 90% is achievable by treating unpaved roads with chemical suppressant in various states with similar operations.

Air impact sensitivity modeling analyses for the project, prior to refined adjustments for background pollutant levels, shows all modeled PM_{10} violations occur during the winter (Statement of Basis, Appendix B) where emissions and background levels are likely overestimated. Data provided in the SGP baseline study specify an average snow depth of 21-68 inches and an average precipitation of 6.0 inches at the project site during this period. Therefore, fugitive dust emissions during high-modeled impact hours could be overestimated and may be controlled by more than 93%. An impact modeling sensitivity analysis, using meteorological data processed with the Bulk Richardson (BULKRN) method, with exclusion of the high impacting operating scenario W5, and

with background concentrations adjusted for seasonality, showed compliance with the 24-hour PM_{10} NAAQS at all receptor locations.

Comment 4 – Ian von Lindern, TerraGraphics International Foundation (TIFO): Estimated Unpaved Roads Emissions

As pointed out by numerous public comments and critiques, calculations of unpaved roads are not based on conservative data as required by State regulations and USEPA guidance. This remains a major concern as use of conservative values could show that this facility would not comply with particulate and toxic air pollutant health standards. The Applicant has now admitted that these same particulate emissions, as calculated, cannot comply with carcinogenic risk ambient air standards; has requested a ten-fold relaxation in health-risk protectiveness; and alleges a 57% reduction in PTE is required reach compliance. The consequences of IDEQ's reliance on these uncertain Applicant assertions are immense, as it could determine whether the facility can be permitted under the current configuration, and whether public health and the environment can be protected. IDEQ continues to resist requiring meaningful and effective monitoring that could detect these exceedances should the Applicant's assertions prove untrue. Nor are there any provision for corrective actions should the health criteria be exceeded.

These potential dangers are exacerbated by the T-RACT proposal and additional critique is offered for the Agency's consideration in the following Section 8.0 T-RACT REVIEW.

DEQ Response:

The Fugitive Dust Control Plan (FDCP) contains the minimum and substantive requirements and were specified in the permit and available for public review (Permit Conditions 2.1-2.6). DEQ contends that these and other relevant conditions are sufficient, reasonable, and appropriate to ensure compliance with applicable requirements at a reasonable level of confidence, including National Ambient Air Quality Standards (NAAQS). In addition, DEQ will review and approve the FDCP which is incorporated by reference in the permit and is enforceable as part of the permit.

T-RACT is an emission standard based on the lowest emission of toxic air pollutants that a particular source is capable of meeting by the application of control technology that is **reasonably available**, as determined by DEQ, considering technological and economic feasibility. T-RACT is an allowable analysis to demonstrate preconstruction compliance for toxic air pollutants (IDAPA 58.01.01.210.12) that PRI has used to demonstrate compliance for arsenic.

DEQ asserts that ambient air monitoring is not warranted for the SGP. Although there are identified uncertainties in the analyses predicting air pollutant emissions and atmospheric dispersion of such emissions, DEQ is reasonably confident that impacts to ambient air will be below applicable standards. Furthermore, ambient monitoring would only be required where such monitoring would serve to protect a potentially exposed public residing in the area of impact. The areas where maximum potential impacts from the SGP are highest are remote, located far from areas where the general public live and reside. There are no public residences, public businesses, schools, hospitals, or other areas where members of the general public would be expected on a continual basis.

INSUFFICIENT MONITORING AND RECORDKEEPING

Comment 5 - NPT: The state of Idaho's internal controls and program resources are inadequate to guarantee permit conditions will be met

The PTC lacks sufficient monitoring for enforcement and compliance to ensure that permit conditions are met. In the Tribe's March 18, 2021 comment letter, the Tribe states that a once every two years inspection schedule and response by phone was woefully insufficient to ensure the Project is meeting the 93.3 percent fugitive dust control permit requirements that guarantee human life, animal life, and vegetation, and the Tribe's Treaty-reserved resources are not injured or unreasonably affected. DEQ now states that the inspection schedule will be even more insufficient – at a rate of once every five years.

Meteorological data used in the modeling came from on-site monitoring at one location. With the complex terrain of the site, the inputs to the modelling will not be representative of the actual weather throughout the entire mining site over the life of the mine. With that in mind, fenceline monitoring should be a requirement to ensure compliance with the PM10 NAAQS, if the permit is issued.

As described in our November 10, 2020 comments, additional monitoring (real-time continuous, federal reference PM2.5 and PM10 monitoring, web cameras, aerial drones, and collocation of meteorological monitoring) and weekly on-site inspections are necessary for DEQ to accomplish its responsibilities under the Clean Air Act to implement and enforce permit conditions and ensure the NAAQS are not violated.

DEQ Response:

The Fugitive Dust Control Plan (FDCP) contains the minimum and substantive requirements that were specified in the permit and available for public review (Permit Conditions 2.1-2.6). DEQ contends that these and other relevant conditions are sufficient, reasonable, and appropriate to ensure compliance with applicable requirements at a reasonable level of confidence, including National Ambient Air Quality Standards (NAAQS). In addition, DEQ will review and approve the FDCP which is incorporated by reference in the permit and is enforceable as part of the permit.

DEQ is requiring extensive fugitive dust control measures in the permit and has reviewed or conducted modeling analyses that demonstrates compliance with NAAQS at a satisfactory level of confidence for permit issuance. Therefore, DEQ is not requiring any ambient air monitoring in the permit.

DEQ disagrees that a PM/PM_{10} ambient air PM_{10} monitoring is necessary to ensure NAAQS compliance. The issued permit includes limits on operational levels and key parameters such as (but not limited to) ore excavation and hauling rates, silt content of roadway material, application of dust suppressant measures, etc. These limits represent values associated with maximum or upper-level emissions for the time interval consistent with the averaging period of the standard. The permit also includes monitoring and recordkeeping requirements to ensure compliance with permit limits and ultimately ensure compliance with NAAQS and TAP increments at a satisfactory level of confidence to support permit issuance.

The comment is correct in that use of one meteorological monitoring site for such a large area with complex terrain is not representative of conditions throughout the area. However, considering other conservative assumptions used in analyses and the permitting process, combined with DEQ's extensive fugitive dust control measures, DEQ has determined that operation of the SGP as described in the application will not likely cause a violation of a NAAQS or TAP increment. This constitutes a *satisfactory* demonstration, thereby justifying permit issuance as required by *Idaho Air Rules* Section 203.

Comment 6 - EPA: Mining Fugitive Dust Monitoring, Recordkeeping, and Reporting Requirements

22. No monitoring, recordkeeping and reporting (MRR) requirements appear to be specified for the excavation mining controls required by permit conditions 3.10 to ensure their enforceability.

23. No monitoring, recordkeeping, and reporting requirements appear to be specified for the 90% control efficiency applicable to the drilling activities required in permit condition 3.11.

24. The monitoring methods associated with the haul roads appear to be unenforceable as they do not specify how the monitoring and recordkeeping demonstrating compliance with the applicable PTE limitations will be achieved. For example, Permit Condition 3.16 specifies "the permittee shall monitor and record" using the "devices and methodologies ... identified in the O&M Manual" for the PTE limitation associated with the 180,000 tpd hauling PTE limitation in permit condition 3.5. The permit must include all monitoring, recordkeeping and reporting necessary to assure compliance with the permit emission limitations and applicable requirements.

25. Given the high level of uncertainty in the assumptions and requirements to ensure compliance with the PM10 24-hr NAAQS, the addition of post-construction ambient monitoring requirements is highly prudent. IDEQ may be able to require post-construction monitoring when determined to be necessary to determine the effect a stationary source may have on air quality in the vicinity of the source, especially when there is high uncertainty in project air quality impacts determined from modeling. The EPA recommends IDEQ add a permit requirement for the source to deploy a fenceline PM10 monitoring network, in a manner determined to be adequate by IDEQ, to demonstrate 24-hour and annual PM10 NAAQS compliance.

DEQ Response:

The emissions from mining and ore processing sources shall be controlled in accordance with the FDCP in Permit condition 2.6. The minimum and substantive requirements were specified in the permit under the FDCP. DEQ contends that these and other relevant conditions are sufficient, reasonable, and appropriate to ensure compliance with applicable requirements including National Ambient Air Quality Standards (NAAQS) at a reasonable level of confidence.

DEQ contends that, like other control equipment in the permit, the drilling rigs dust control system will be operated in accordance with the O&M manual which specifies a copy of the vendor-supplied performance guarantee shall be included along with minimum pressure drop, procedures for proper operation, and routine inspection and maintenance. The minimum requirements for the O&M manual are specified in the permit to demonstrate that the drilling rigs dust control system operates as designed. Likewise, the O&M manual (Permit Condition 2.20) specifies that each monitoring device and methodology used to measure weight rates of materials, installation, calibration, and maintenance shall be described to demonstrate compliance with each material throughput limit.

DEQ disagrees that ambient air PM_{10} monitoring is necessary to ensure NAAQS compliance. The issued permit includes limits on operational levels and key parameters such as (but not limited to) ore excavation and hauling rates, silt content of roadway material, application of dust suppressant measures, etc. These limits represent values associated with maximum or upper-level emissions for the time interval consistent with the averaging period of the standard. The permit also includes monitoring and recordkeeping requirements to ensure compliance with permit limits and ultimately ensure compliance with NAAQS and TAP increments at a satisfactory level of confidence to support permit issuance.

DEQ recognizes the uncertainty of predicted impacts (from the use of dispersion models) in complex terrain, the uncertainty in predicted impacts when using modeling techniques for fugitive emission sources, the uncertainty in emission factors and equations, the uncertainty and variability in input parameters to emission equations, and the variability in background pollutant concentrations. However, these uncertainties and variabilities are offset by other approaches in the permitting process and modeling methods that are

conservative (overstating impacts). Some of these include (for 24-hour PM_{10}, which is the driver in analyses): 1) not accounting for times when fugitive emissions will be greatly reduced because of precipitation or lingering periods of high moisture content of material handled or roadways driven over; 2) assuming emissions from short-term maximum allowable operational rates, and from the worst-case operational scenario for the receptor location in question, occur during each day of operation; 3) DEQ's high level of confidence that required emission control efficiencies will be the minimum level attained during operations, verified through the use of emission-affecting parameter monitoring and record-keeping; 4) ensuring that fugitive emissions are less than estimated values provided in the application through required frequent inspection of emission sources that drive highest modeled impacts; 5) assuming that maximum modeled design value impacts occur simultaneously with design value background concentrations.

Idaho Air Rules Section 203 requires that a permit may not be issued unless it is demonstrated to DEQ's satisfaction that the proposed project will not cause or contribute to a violation of a NAAQS or TAP increment. In conclusion, through DEQ's review of the application and DEQ's additional analyses, DEQ has determined that operation of the SGP as described in the permit application is unlikely to cause a violation of an applicable NAAQS or TAP increment. This represents a satisfactory demonstration to support permit issuance.

DEQ does not typically require ambient air pollutant monitoring for permit issuance, especially at facilities with emissions below major source thresholds. Ambient monitoring is not considered unless DEQ lacks a satisfactory confidence of NAAQS or TAP increment compliance (as specified by *Idaho Air Rules* Section 203.02 and 203.03) without such monitoring. All of the following conditions would normally be required to justify post-construction ambient air monitoring:

1. The application used questionable, non-conservative data or assumptions in the calculation of emissions or dispersion-affecting parameters.
2. There is an inability to verify emissions or dispersion-affecting parameters during operation of the facility. This would include monitoring parameters of emission equations or monitoring indicators of a condition of unacceptable control of emissions.
3. There are sensitive receptors (private residence, school, public business, hospital, or other area where members of the general public would be expected to be present) in areas where elevated ambient air impacts could occur.

The SGP does not meet the above criteria to justify the requirement of ambient air monitoring. It has been indicated that PRI did not use convincingly conservative data and assumptions for some emission calculations. Where the conservatism of such data was in question, DEQ required enhanced monitoring and record-keeping of such parameters. Such monitoring includes the monitoring of maximum road silt content, monitoring of production levels to verify estimated vehicle miles traveled (VMT) used in fugitive road dust emission calculations, and monitoring of the median arsenic content of road base material to help justify fugitive road dust arsenic emissions used in TAP analyses. Finally, there are no sensitive receptors identified near the ambient boundary of the facility, where elevated impacts of pollutants would be expected.

Comment 7 - EPA: Ore Processing Monitoring, Recordkeeping and Reporting Requirements/

6. The monitoring method does not appear to specify how and where the PTE limitations will be measured consistent with the application's emissions calculations. For example, Permit Condition 3.18 specifies "The devices and methodologies used to measure weights shall be identified in the O&M Manual" for determining compliance with the input to the primary crusher. Per the application, this monitoring should apply at OCI (Loader Transfer of ORE to Grizzly) and not OC7 (Primary Crusher) as specified in the permit condition. The permit also does not specify generally how the weight is measured such as by a truck scale or some other method but is to be developed in an O&M Manual after the permit is issued and is not enforceable to this permit condition (see permit conditions 2.20 and 2.21). The permit must include all monitoring, recordkeeping and reporting necessary to assure compliance with the permit emission

limitations and applicable requirements. This comment is also applicable to permit conditions 3.16 through 3.20, 4.18 through 4.32, 4.34, and 5.16 through 5.24.

7. IDEQ required monitoring of baghouse pressure drop to assure compliance in permit condition 4.31. Though pressure drop monitoring can be an indicator of the source's maintenance program, monitoring experts within EPA have concluded that pressure drop is not a reliable approach for monitoring baghouse compliance. Alternatives to pressure drop include opacity monitoring/readings and bag leak detectors. Bag leak detectors are a good alternative for baghouses that require a more rigorous level of scrutiny than periodic observations provide. These monitoring techniques can be combined with a good operation and maintenance program to assure compliance. This comment is also applicable to permit conditions 5.21, 5.22, and 5.23.

DEQ Response:

Permit condition 3.7 establishes a primary crusher limit. Compliance is ensured by complying with the monitoring and recordkeeping requirements specified in Permit Condition 3.18. The monitoring on the primary crushing circuit, per the application (see the process flow diagram), is via a weighometer on the Coarse Ore Stockpile Feed conveyor downstream of the primary crusher. This is standard practice for the mining industry. The O&M manual (Permit Condition 2.20) specifies that each monitoring device and methodology used to measure weight rates of materials, installation, calibration, and maintenance shall be described to demonstrate compliance with each material throughput limit. DEQ contends that the O&M manual specifies that each monitoring device and methodology used to measure weight rates of materials, installation, calibration, and maintenance shall be described to demonstrate compliance with each material throughput limit and is an enforceable permit condition.

Based on public comment, Permit Condition 2.20 has been updated to state that the O&M manual shall be developed 30 days prior to startup of any process equipment. In the case of the O&M Manual, certain operating parameters will not be determined or available until after control equipment has been installed. Permit Condition 2.21 was updated to include DEQ approval 30 days prior to startup and 30 days before any subsequent changes are made to the O&M Manual.

Although bag leak detectors are a reliable approach to ensure baghouse monitoring compliance, measuring pressure drop across the baghouse is commonly accepted by DEQ as an effective way of determining proper baghouse operation.

Comment 8 - EPA: Lime Plant Monitoring, Recordkeeping and Reporting Requirements

12. Consistent with comment #6 for ore processing, the lime plant MRR requirements appear to be unenforceable as Permit Condition 5.16 specifies "the permittee shall monitor and record" using the "devices and methodologies ... identified in the O&M Manual" for the PTE limitation associated with the limestone primary crusher. The permit must include all monitoring, recordkeeping and reporting necessary to assure compliance with the permit emission limitations and applicable requirements.

13. If the O&M Manual is used to provide the monitoring, recordkeeping, and reporting (MRR) requirements for the applicable PTE limitations then the O&M Manual would need to be reviewed and approved by IDEQ, available for review during the public comment period and must be enforceable at all times upon issuance of the permit. Also, any changes to the O&M Manual that that would make the approved MRR requirements less stringent would be subject to the same IDEQ and public review approval process and need to be enforceable at all times upon issuance of the revised permit.

DEQ Response:

The O&M manual (Permit Condition 2.20) specifies that each monitoring device and methodology used to measure weight rates of materials, installation, calibration, and maintenance shall be described to demonstrate compliance with each material throughput limit. DEQ contends that the O&M manual specifies

that each monitoring device and methodology used to measure weight rates of materials, installation, calibration, and maintenance shall be described to demonstrate compliance with each material throughput limit and is an enforceable permit condition.

Based on public comment, permit condition 2.20 has been updated so that the O&M manual shall be developed 30 days prior to startup of any process equipment. Enforceable testing and monitoring, recordkeeping, and reporting (MRR) requirements that were determined reasonable and appropriate were established and incorporated in the permit. The O&M manual establishes a regular schedule for operation, inspection, maintenance, and repair of the control equipment to ensure compliance.

Comment 9 - ICL/SSFS: PM/PM10 Monitoring

In order to make this air permit practically enforceable, IDEQ must require that the Applicant install a PM/PM10 monitoring system on site at the ambient air boundary to ensure that PM/PM10 NAAQS are not violated. This step is warranted because of the uncertainty surrounding dust control efficiency and emissions factors associated with this project. To our knowledge, it is neither technologically or financially infeasible for the Applicant to install this monitoring. Additionally, IDEQ should include penalties and corrective actions in the permit that would be triggered if this monitoring system shows NAAQS violations occurring at the ambient air boundary. These penalties should entail a mandatory reduction in mining and processing throughput.

IDEQ should:

- Add a permit condition that requires the Applicant to install a comprehensive continuous PM/PM10 monitoring system on site.
- Add enforceable penalties and corrective actions to the permit that are triggered if this monitoring system ever indicates that NAAQS are being exceeded.

DEQ Response:

DEQ disagrees that a PM/PM_{10} ambient monitoring network is necessary to make the PTC practically enforceable. As discussed previously in DEQ's response to Comment 6, the issued permit includes limits on operational levels and key parameters such as (but not limited to) ore excavation and hauling rates, silt content of roadway material, application of dust suppressant measures, etc. These limits represent values associated with maximum or upper-level emissions for the time interval consistent with the averaging period of the standard. The permit also includes monitoring and recordkeeping requirements to assure compliance with permit limits and ultimately assure compliance with NAAQS and TAP increments at a satisfactory level of confidence to support permit issuance.

Even though DEQ is not proposing a monitoring network, it should be noted that any violation of the permit would be processed in accordance with DEQ's enforcement procedures manual.

CONCERNS WITH THE FCDP, O&M MANUAL, AMP, AND HRCP

Comment 10 - NPT: Concerns with Fugitive Dust Control Plan (FDCP), Operations and Maintenance Manual (O&M), Access Management Plan (AMP), and Haul Road Cap Plan (HRCP) submission and review process

These plans are key to holding Project emissions at or below assumed emissions in the emissions inventory and modeling used to determine the source applicability of the Project. Any assumptions, including emission controls, need a practically enforceable permit requirement to keep the Project a synthetic minor for PSD, Title V, and HAP. As these plans are not yet written, and their associated permit conditions not included in the PTC, the PTC is not practically enforceable.

Our understanding is that the first opportunity for meaningful comment on the FDCP, O&M, AMP, and HRCP will be when a Tier I air operating permit is drafted. Strict adherence to these plans is critical to ensuring compliance, and only giving the public the opportunity to review and comment on these plans when the Tier I air operating permit is drafted, and every five years thereafter, is inadequate.

DEQ Response:

16 For the Fugitive Dust Control Plan (FDCP), Operations and Maintenance (O&M) Manual, AMP, and HRCP the minimum and substantive requirements were specified in the permit (Permit Conditions 2.1-2.6, 2.7-2.8, 2.20-2.21, 3.13). DEQ has added additional minimum requirements for the AMP and HRCP (Permit Conditions 2.7 and 3.13). DEQ contends that these and other relevant conditions are sufficient, reasonable, and appropriate to ensure compliance with applicable requirements including National Ambient Air Quality Standards (NAAQS). Relevant conditions include visible emissions limits (Permit Conditions 2.9-2.12), material throughput and operational limits (Permit Conditions 3.3-3.9, 4.5-4.12, 5.4-5.9, 6.2), emissions limits (Permit Conditions 4.3-4.4, 5.3), control device requirements (Permit Conditions 3.10-3.12, 4.13-4.17, 5.10-5.16), and testing (Permit Condition 4.33) requirements. To ensure enforceability of each of these requirements, supporting testing and monitoring, recordkeeping, and reporting (MRR) requirements were also included. In addition, DEQ will review and approve the FDCP, O&M's, AMP and HRCP. These approved plans and manuals are incorporated by reference in the permit and are enforceable as part of the permit.

All state and federally applicable requirements are incorporated into the Tier I permit as required by 40 CFR 63 Subpart EEEEEEE, including all applicable PTC, NESHAP and NSPS requirements. Copies of all permit-required compliance documents, including but not limited to the FDCP, O&M, AMP, and HRCP are required to be included in the permit application and thus included in the docket for review during each Tier I public comment period (Tier I Application Completeness Checklist). As such, any plan updates will be subject to public review during each Tier I permit renewal comment period once every five years. Additionally, DEQ plans to post the FDCP, O&M, AMP, and HRCP on DEQ's website with the final permit and statement of basis when completed. Once DEQ approves these plans they will also be available for public records request.

Comment 11 - NPT: Concerns with Permit Condition 2.20 O&M Manual

Permit condition 2.20 requires the permittee to develop and maintain an Operation and Maintenance (O&M) manual to ensure compliance with emission limits and the control equipment maintenance and operation general provision. The Tribe has the following concerns about section 2.20:

- Please explain why the O&M manual is termed a "manual" and not a "plan", and please justify why the O&M manual does not require approval by DEQ when DEQ approval is required for the FDCP, AMP and HRCP plans.
- Please explain the rationale for the O&M manual being due 60 days after startup of any process equipment, unlike the 60 days after permit issuance required for the FDCP, AMP, and HRCP plans.
- The O&M permit condition, 2.20, states a once per month visible emission (VE) inspection requirement for wet scrubber, carbon filter, baghouse, and bin vents, but permit condition 2.10 requires the following VE

inspection: "Each day during daylight hours and under normal operating conditions, the permittee shall conduct a facility-wide inspection of potential point sources of visible emissions including stacks, vents, and functionally equivalent openings." Since wet scrubber, carbon filter, baghouse, and bin vents have openings, the VE inspection requirement for this control equipment should be the same as permit condition 2.10.

DEQ Response:

Based on public comment, Permit Condition 2.20 has been updated to be consistent with the FDCP, AMP, and HRCP to state that the O&M manual shall be developed 30 days before startup of any process equipment. In the case of the O&M Manual, certain operating parameters will not be determined or available until after control equipment has been installed. Permit Condition 2.20 was also updated to describe the schedule and procedures for routine inspection as a see-no-see visible emissions inspection conducted at least once per day to eliminate the discrepancy with Permit Condition 2.10. Permit Condition 2.21 was updated to include DEQ approval 30 days prior to startup and 30 days before any subsequent changes are made to the O&M Manual.

Comment 12 - NPT: Concerns with Permit Condition 3.11 Drilling Rigs Dust Control System

We appreciate that DEQ has added controls for the drilling activities. However, the details in actually achieving the 90% control are to be included in an O&M manual which will be developed after the PTC permit is issued. If DEQ relied on vendor-stated control efficiencies, there should be testing requirements included in the PTC to validate the emissions controls.

DEQ Response:

DEQ contends that, like other control equipment in the permit, the drilling rigs dust control system will be operated in accordance with the O&M manual which specifies a copy of the vendor-supplied performance guarantee shall be included along with minimum pressure drop, procedures for proper operation, and routine inspection and maintenance. These minimum requirements for the O&M manual were specified in the permit.

Comment 13 - NPT: Concerns with Permit Condition 3.13 Haul Road Capping

The addition of permit condition 3.13 Haul Road Capping is appreciated. However, haul road surfaces will degrade over time. Because the arsenic concentration in the roadbed will come from both the road material itself and spilled ore, DEQ should require periodic testing of both silt and arsenic content of the road bed to validate assumptions underlying the estimated emissions and assure the representativeness of the emission factors used. Periodic measurement would increase confidence that the NAAQS are being protected (PM10 from haul road fugitives) and fugitive arsenic is being controlled. We suggest use of most conservative average arsenic concentration in the quartzite used. In the 55,000 ore samples presented, that would be the mean, not the median as proposed in 3.13. Please explain in better detail how DEQ justified the assumption that 50% of the vehicle miles traveled (VMT) will occur on low-arsenic capped haul roads and what level of detail will be required in the HRCP such that the emission limits are enforceable.

DEQ Response:

DEQ concurs that silt content is an important component in the HRCP. Permit condition 3.13 has been updated to include a silt content maximum percentage of 4.0% and a corresponding sampling plan including frequency and method of analysis for verification. As discussed previously in the Representativeness and Uncertainty of Emissions section, the use of site-specific median values for silt content is commonly accepted by DEQ, and the values used in calculations were supported by PRI. Although a median value of sampled silt percentages of roadway material was used in emission estimates presented in the application, DEQ recognizes the importance of the silt content parameter in the estimation of fugitive emissions. Since compliance with the 24-hour PM_{10} NAAQS is the primary driver of NAAQS compliance, minimizing variability of this parameter is very important to ensure NAAQS compliance.

The HRCP contains the minimum and substantive requirements in the permit to ensure compliance with the NAAQS. The assumption that 50% of the vehicle miles traveled (VMT) will occur on low-arsenic capped haul roads has been substantiated in a reference email from PRI on June 16, 2021 where the annual average percentage of haul road travel on capped roads is over 60%. A lower value of 50% was used in the analysis as a conservative assumption.

Comment 14 - NPT: Concerns about fugitive dust controls

The FDCP plan is key for the facility to reach the 93.3% fugitive dust control that allows DEQ to demonstrate the facility is a synthetic minor. We are concerned that the use of such non-specific permit requirement terms of "as necessary" and "periodic" is not practical enforceability.

We are very concerned about PRI's commitment to 93.3% control for fugitives on haul roads. In Facility Comment #10, PRI asked for a change from a twice daily to a monthly frequency for permit condition 2.4 fugitive emission inspection. A monthly inspection frequency is woefully inadequate. We appreciate that DEQ has retained the twice daily inspection frequency.

Retention of records should exceed five years. The records of FDCP are key to compliance checking and it is plausible that inspection frequency will exceed 5 years. The description of the facility information in the Statement of Basis states "the SGP will include three years of premining development and construction activities, followed by an operating mine life of approximately 12 years." And permit condition 2.24 states "In accordance with IDAPA 58.01.01.313.01.b., the permittee shall submit a complete application to DEQ at the address provided (Permit Condition 2.26) for an initial Tier I operating permit within 12 months of becoming a Tier I source or commencing operation." Therefore, it is very plausible the facility will operate for 4 years or more before an operating permit is issued. If compliance inspection is every 5 years, earthmoving activities at the mine may go for 9 years before any compliance check is made by DEQ.

Permit condition 2.5 includes a 10% opacity trigger: "Fugitive dust control measures shall be applied to haul roads on a frequency such that visible emissions from vehicle traffic on a haul road do not exceed 10% opacity". We are unaware of any study showing that a 10% opacity limit ensures a 93.3% fugitive dust control efficiency. A more protective trigger would be an instantaneous see/no-see. Any trigger, to be sufficiently evaluated, should specify a timeframe for measurement (example: instantaneous or 15 second), a location, and when to take the opacity reading (example: immediately after a loaded ore truck passes near surface of the road bed). Additionally, with over 55 miles of haul roads, there should be multiple locations being monitored during each inspection.

DEQ Response:

Enforceable testing and monitoring, recordkeeping, and reporting (MRR) requirements that were determined reasonable and appropriate were established and incorporated in the permit. DEQ contends that program resources are adequate for the purposes of monitoring compliance with permit conditions, for inspection, and for complaint response and that the inspection schedule is sufficient for a minor source of emissions.

DEQ recognizes that in practice chemical and water dust suppressants are used in combination for the control of dust from haul roads, and that achieving the target combined control efficiency of 93.3% is ultimately important to ensure compliance with applicable standards. It is for this reason that the combined control efficiency was listed in the permit in lieu of separate chemical (90% control) and water (33.3%) dust suppressant control efficiencies. A 10% opacity is considered a very conservative control trigger level to ensure that an appropriate control measure is taken to reasonably control emissions of fugitive dust (Permit condition 2.5). DEQ agrees with commenters that compliance with fugitive dust requirements is also necessary to ensure compliance with applicable standards, including application of both water and chemical dust suppressant in proper amounts and at proper frequencies as local conditions dictate.

Comment 15 - NPT: Regular testing requirements needed for process and control equipment

Permit Conditions 2.20-2.21 require developing and complying with the requirements of an O&M manual to ensure compliance with control equipment maintenance and operation general provisions (Permit Condition 7.2). Documentation of as-built Process equipment specifications and control equipment performance guarantees and establishing control equipment operating parameters and procedures were required, since these were relied upon in the development of emissions inventories, and in the evaluation of ambient air impacts in the modeling analyses. Compliance is ensured by complying with monitoring and recordkeeping requirements. There should be regular testing required to confirm process and control equipment are operating/performing to the specifications, guarantees, and parameters identified in the PTC application.

DEQ Response:

Based on public comment, Permit Condition 2.20 has been updated so that the O&M manual shall be developed 30 days prior to startup of any process equipment. Enforceable testing and monitoring, recordkeeping, and reporting (MRR) requirements that were determined reasonable and appropriate were established and incorporated in the permit. The O&M manual establishes a regular schedule for operation, inspection, maintenance, and repair of the control equipment to ensure compliance.

Comment 16 - EPA: Mining Access Management Plan (AMP) for NAAQS Purposes

26. Permit Condition 2.7 requires the development of an Access Management Plan (AMP) to address whether the NAAQS apply to the mine's access road through the Perpetua Mining site given the extent of public access allowed. Permit Condition 2.8 allows the AMP to be developed after the permit is issued and does not require the AMP to be enforceable. For the AMP to preclude the applicability of the NAAQS along the access road, the AMP must be reviewed and approved by IDEQ, subject to review by the public during the public comment period and must be enforceable at all times upon issuance of the initial permit. Any changes to the AMP that are less stringent than the approved AMP must be reviewed and approved by IDEQ, subject to review by the public, and enforceable at all times upon issuance of the revised permit.

27. Given the unique situation with a public access road traversing the mine site, the key assumptions, parameters, and methodologies used to preclude public access from the mine site must be fully disclosed in the permit record and the necessary requirements be included in the permit and available for public review and comment. The State assumes measures taken to preclude public access will be appropriate and adequately comply with EPA's Revised Policy on Exclusions from Ambient Air (as specified in the December 2, 2019, memo from Andrew Wheeler to the EPA Regional Administrators). Section 2.7 of the permit provides requirements for the source to develop a plan to preclude public access, but these requirements offer a range of measures the source may choose to implement and are therefore ambiguous. Without full disclosure in the record of the exact measures and permit requirements to ensure compliance with national ambient air policy, it is not clear if the public access road can be excluded from ambient air protections. The state needs to provide sufficient justification to demonstrate the measures and requirements to preclude public access and ensure members of the public traversing the road can be classified as "guests of the mine" sufficiently complies with national ambient air policy. Given the uniqueness and ambiguity of the situation, a petition to the EPA national ambient air policy team for review and concurrence with the State's findings could be warranted.

DEQ Response:

Ambient air is defined in *Idaho Air Rules* Section 005.09 as, “That portion of the atmosphere, external to buildings, to which the general public has access.” To exclude areas from consideration as ambient air in air pollutant impact analyses, the following must be met:

1. The permittee must have the legal authority to exclude the *general public* from the area.
2. The boundary to ambient air must be clearly discernable to the *general public*.
3. The *general public* must be effectively precluded from accessing the facility.

4. The *general public* is not considered: employees of the facility; those having official business with the facility; guests of facility, including participants in facility tours and those seeking access for a specific purpose.

PRI has asserted they have complete and sole authority to control access to or through the facility, granting or excluding access at their discretion to anyone wishing to visit the site or pass through the site. Section 2.7 of the PTC establishes requirements to effectively preclude public access to the facility by: 1) adequately informing anyone approaching an access point that travel beyond the established gate involves entering an active mine site as a guest of PRI; 2) providing verbal or written requirements that must be followed while on the SGP site to all wishing to access the site. Since those requesting access to the site are guest of PRI and no longer members of the public, health and safety of such guests and managing how guests are monitored or escorted while on the site is the responsibility of PRI and outside of the scope of the PTC. It is not DEQ's responsibility or concern as to the reasons PRI may invite people to access the facility as a guest; it is primarily DEQ's concern that those accessing the facility understand the are no longer on public property and are entering an active mine site and agree to accept all such risks associated with the site and requirements imposed by the facility.

PRI may allow controlled use of a facility roadway to access offsite areas that would otherwise require a longer travel time around the mine. This roadway was excluded from consideration as ambient air and those using the road are considered guests of PRI rather than members of the general public. Since PRI has legal authority control all access through the facility, this meets the first criteria for exclusion from ambient air. To achieve the second and third criterion, PRI will post signs indicating the entry to the mine site and will establish manned access gates at points prior to the ambient air boundary. All persons seeking access will be required to register at the access gate and will be instructed on procedures and any potential hazards of areas they may encounter while on the SGP mine site (see Permit Condition 2.7).

Based on public comment, Permit Condition 2.7 has been updated with the following: "Only registered guests of the facility will be allowed access to or through the facility. Those seeking to be a guest for the sole purpose of passing through the facility to another destination shall be provided a registration sheet that explains PRI's requirements for accessing the site and identifies potential hazards of the site."

DEQ is confident in its interpretation of ambient air for the PRI minor source PTC, and DEQ asserts the methods used to excluded areas from ambient air is solid and unambiguous. Therefore, consultation with EPA's ambient air policy team is not warranted.

Comment 17 - EPA: Mining Dust Haul Road Capping Plan (HRCP) for NAAQS and Title V HAP Purposes

28. Permit Condition 3.13 requires the development of a Haul Road Capping Plan (HRCP) to address fugitive dust emissions from the haul roads and development rock storage facilities after the permit is issued.

29. To the extent that this plan is being relied upon to limit fugitive dust emissions for Title V HAP applicability and NAAQS compliance purposes, the HRCP would need to be reviewed and approved by IDEQ prior to the public comment period, subject to review during the public comment period, and enforceable upon the issuance of the initial permit. Also, any changes to the HRCP after the permit is issued and that are less stringent than the approved HRCP would need IDEQ approval and public review and be enforceable at all times after the revised permit is issued. There does not appear to be a reason that the HRCP can't be developed and incorporated into the permit now.

DEQ Response:

The HRCP is a T-RACT control for arsenic. DEQ has added additional minimum requirements for the HRCP (Permit Condition 3.13) and has updated Permit Condition 2.21 to include DEQ approval both initially (before startup) and after any subsequent changes.

17 All state- and federally- applicable requirements are incorporated into the Tier I permit as required by 40 CFR 63 Subpart EEEEEEE, including all PTC requirements and all NESHAP and NSPS requirements. Copies of all permit-required compliance documents, including but not limited to the FDCP, O&M, AMP, and HRCP are required to be included in the permit application and thus included in the docket for review during each Tier I public comment period (Tier I Application Completeness Checklist). As such, any plan updates will be subject to public review during each Tier I permit renewal comment period once every five years. Additionally, DEQ plans to post the FDCP, O&M, AMP, and HRCP on DEQ's website with the final permit and statement of basis when completed. Once DEQ approves these plans they will also be available for public records request. In addition, all approved plans and manuals are incorporated by reference in the permit and are enforceable as part of the permit.

Comment 18 - ICL/SSFS: Fugitive Dust Control Plan

The Fugitive Dust Control Plan (FDCP) continues to be an area of significant concern for us. IDEQ has required the applicant to complete this plan as a condition of this permit. However, despite the FDCP clearly being a crux of the applicant's air quality compliance, the public will not have the opportunity to review and comment on this plan. We once again formally request the opportunity to do so. Furthermore, the permit specifies that the FDCP shall be submitted within 60 days of permit issuance. In this case, the permit would be approved without IDEQ or the public knowing specifically how the applicant will attain this aggressive standard of dust control. For instance, we have no indication of how the applicant will suppress fugitive emissions sources other than roads.

Given that the specifics of the FDCP are crucial to ascertaining exactly how the applicant will achieve the lofty 93.3% dust control efficiency required to achieve compliance, and how enforceable the limits are, this permit should not be approved until a FDCP is submitted to IDEQ, reviewed by both IDEQ, EPA, and the public, and approved or denied pending modifications. A review of the FDCP prior to permit issuance is necessary to ensure compliance with air quality standards. If approved, the salient points of FDCP should be incorporated in the permit as clearly enforceable limits. This permit cannot be issued without enforceable provisions and limits to ensure that the high bar of fugitive dust control will actually be attained at the Stibnite Gold Project.

IDEQ should:

- Allow for public review and comment on the Fugitive Dust Control Plan *before* it is finalized.
- Incorporate clear, enforceable limits for fugitive dust control into this permit *before* any potential approval.

DEQ Response:

18 Based on public comment, Permit Condition 2.8 has been updated to include DEQ approval both initially (before startup) and after any subsequent changes and that the plan shall be submitted 30 days prior to startup. For the Fugitive Dust Control Plan (FDCP), the minimum and substantive requirements were specified in the permit and available for public review (Permit Conditions 2.1-2.6). DEQ contends that these and other relevant conditions are sufficient, reasonable, and appropriate to ensure compliance with applicable requirements including National Ambient Air Quality Standards (NAAQS).

All state- and federally- applicable requirements are incorporated into the Tier I permit as required by 40 CFR 63 Subpart EEEEEEE, including all PTC requirements and all NESHAP and NSPS requirements. Copies of all permit-required compliance documents, including but not limited to the FDCP, O&M, AMP, and HRCP are required to be included in the permit application and thus included in the docket for review during each Tier I public comment period (Tier I Application Completeness Checklist). As such, any plan updates will be subject to public review during each Tier I permit renewal comment period once every five years. Additionally, DEQ plans to post the FDCP, O&M, AMP, and HRCP on DEQ's website with the final permit and statement of basis when completed. Once DEQ approves these plans they will also be available for public records request.

POTENTIAL TO EMIT AND EMISSION FACTORS

Comment 19 - NPT: Representativeness of the emission factors

The applicability determination depends on the emissions inventory (EI). The EI depends on the proposed processes and the EFs used to characterized these activities. There are instances where we are concerned that inappropriate EFs have been used. The EFs for the ore processing come from AP 42 chapter 11.19 Crushed Stone Processing and Pulverized Mineral Processing. The AP-42 chapter 11.24 Metallic Minerals Processing might be a better representation for the OC1- OC13. In all cases, the most conservative EFs should be used.

When an EF has a control efficiency built into it, the permit should specify conditions to assure equipment will employ the same controls to assure the representativeness of the EF. Permit conditions do not clearly specify this.

DEQ Response:

As discussed previously in the Representativeness and Uncertainty of Emissions section, although some degree of uncertainty is present in all emission factors used in estimating emissions, all emission factors were adequately supported and the approach of estimating potential to emit (PTE) at design capacity was considered a conservative approach. Emission factors with control efficiencies built into them were adequately supported by that corresponding control device listed in the permit. The facility's emission inventory includes crushers, screens, and conveyors controlled by water sprays. EPA's AP-42 11.19.2 (08/2004) provides representative emission factors for these specific processes and controls.

Comment 20 - NPT: Emissions estimate values are not sufficiently conservative

DEQ should use conservative values for all emission estimates. For any emission factor (EF) requiring an average value, the most conservative average value should be used to protect human health. Examples include the silt content for used in EF for Haul Road fugitives and the metal concentrations in the ore for HAP/TAP. The median is only a statistical number. The arithmetic mean is most commonly considered the average.

In the Statement of Basis it states, "It is noted that PRI projected actual annual production at approximately 42.7 million T/yr, or 65% of the permitted annual production limit of 65.7 million T/yr (Permit Condition 3.5), and that as a result actual emissions are expected to be lower than presented." The 65.7 MT/y value comes from 180,000 T/day for 365 days, however, permit condition 3.5 also has a 135,000 T/day limit based on a 5-year rolling average. Thus the actual permit limit is 49.3 MT/y (135,000 T/day x 365 day/y). Therefore, the projected actual annual production is closer to 87% (42.7/49.3) of the permitted annual production limit. The permit is less protective than DEQ has presented.

DEQ Response:

As described previously in the Representativeness and Uncertainty of Emissions section, the use of site-specific median values for silt content is commonly accepted by DEQ, and the values used in calculations were supported by PRI. Although a median value of sampled silt percentages of roadway material was used in emission estimates presented in the application, DEQ recognizes the importance of the silt content parameter in the estimation of emissions. Since compliance with the 24-hour PM_{10} NAAQS is the primary driver of NAAQS compliance, minimizing variability of the parameter is very important to ensure NAAQS compliance. To achieve this, the permit will limit *maximum silt content* to 4.0 %, as specified in Permit Condition 3.13 Haul Road Capping of the PTC as well as associated monitoring and recordkeeping.

The hauling and excavating limit of 135,000 T/day of ore and DR (Permit Condition 3.5) on a 5-year rolling average was added as a T-RACT level of control. This is not a daily limit but a 5-year limit expressed as a daily average rate. This limit actually lowers the production limit of the facility on a 5 year rolling basis and is potentially a more restrictive limit than 180,000 T/day for long-term impacts.

Comment 21 - EPA: Limiting PTE for PSD, Title V (including HAP) and NAAQS Purposes

Many of the emission limits in the permit are derived from emissions factors. Similarly, the permit assumes control efficiencies for certain emission sources. However, the permit lacks conditions incorporating the numerous assumptions and parameters associated with the emissions factors and control efficiencies. Emission factors include numerous operating assumptions and variables regarding the source. Accordingly, the permit should contain conditions to ensure the operating assumptions and variables underlying the emission factor accurately reflect site-specific conditions and are enforceable.[4] Similarly, when permits require add-on controls operated at a specified efficiency level, permit writers should include, so that the operating efficiency condition is enforceable as a practical matter, those operating parameters and assumptions which the permitting agency depended upon to determine that the control equipment would have a given efficiency.[5]

The permit record does not demonstrate that the emission factors used to estimate the source's PTE and derive the emission limits are technically accurate. Emission factors used to derive a PTE limitation must be technically accurate.[6] In general, AP-42 emissions factors are based on averages and are not intended for establishing source-specific limits.[7] When using AP-42 emissions factors to establish limits on PTE, EPA recommends using these emissions factors only when source specific emissions factors are not available and selecting conservatively higher emissions factors.[8]

EPA states in AP-42, "Before simply applying AP-42 emission factors to predict emissions from new or proposed sources, or to make other source-specific emission assessments, the user should review the latest literature and technology to be aware of circumstances that might cause such sources to exhibit emission characteristics different from those of other, typical existing sources. Care should be taken to assure that the subject source type and design, controls, and raw material input are those of the source(s) analyzed to produce the emission factor. This fact should be considered, as well as the age of the information and the user's knowledge of technology advances."[9]

When permits contain emissions, production or operational PTE limitations, they should also have monitoring, recordkeeping, and reporting requirements that allow a permitting agency to verify a source's compliance with its limits.[10] The permit should provide for the collecting, maintaining, and reporting of information necessary to determine emissions of each pollutant as well as compliance with operating parameters. [11] The permit must include conditions that clearly specify the monitoring requirements and how the permittee must demonstrate compliance via the monitoring requirements. [12]

DEQ Response:

19 As discussed previously in the Representativeness and Uncertainty of Emissions section, maximum hourly and daily activity rates were used to estimate the maximum 24hour and annual emission rates, and fugitive dust control requirements, emission rate limits, material activity rate limits, and supporting testing and monitoring, recordkeeping, and reporting (MRR) requirements were established as synthetic minor limits for the purposes of limiting facility-wide emissions of $PM/PM_{10}/PM_{2.5}$ to below 250 T/yr PSD applicability thresholds and Title V 100 T/yr applicability thresholds. These limits were also established for the purposes of limiting facility-wide emissions of single and total HAP to below HAP major source applicability thresholds (10/25 T/yr), and to ensure compliance with all NAAQS. Limits were established consistent with current DEQ guidance and the estimates of emissions and underlying assumptions were supported to the satisfaction of DEQ.
20

Enforceable monitoring, recordkeeping, and reporting requirements were established in the permit. $PM/PM_{10}/PM_{2.5}$ emissions limits for point sources were established with supporting activity rate limits and MRR requirements. While emissions limits and emission factors are not commonly included in the permit for fugitive sources, activity rate limits and MRR requirements were established for those sources that were identified as process rate-limiting (as summarized in Table 1.1 of the permit). These activity rate limits serve as surrogate emissions limits for PM, PM_{10}, $PM_{2.5}$, HAP and TAP from fugitive sources. And while documented in the Statement of Basis and application materials, underlying parameters associated with calculating emissions such as vehicle speed limit, type, and miles traveled are not typically included in the permit.

Comment 22 - EPA: Limiting PTE of the Mining Fugitive Dust Emissions for NAAQS and Title V HAP Purposes

21. As noted in Comment #15 and #16, the mining excavation PTE limitation of 180,000 tpd may not be technically accurate because it is not based on emission factors that are representative of mining emission sources. For example, AP-42 Section 11.9 Western Surface Coal Mining Section includes emission factors applicable to mining excavation operations. However, the application appears to use AP-42 emissions factors from Section 11.19.2 Crushed Stone Processing for truck loading and unloading of crushed stone.

DEQ Response:

As described previously in the Representativeness and Uncertainty of Emissions section, although some degree of uncertainty is present in all emission factors used in estimating emissions, all emission factors were adequately supported and the approach of estimating potential to emit (PTE) at design capacity was considered a conservative approach. Emission factors with control efficiencies built into them were adequately supported by that corresponding control device listed in the permit. The facility's emission inventory includes crushers, screens, and conveyors controlled by water sprays. EPA's AP-42 11.19.2 (08/2004) provides representative emission factors for these specific processes and controls.

Comment 23 - EPA: Limiting PTE for the Ore Processing and Lime Plant Operations for PSD, Title V (including HAP), and NAAQS Purposes

The Permit does not appear to specify technically accurate emission limitations and the portions of the source subject to the limitation because: (i) the permit may not adequately require compliance with all PTE emission limits for each emission source or include PTE emissions limits representing all emissions sources, (ii) the permit record may not adequately demonstrate that the emission limits are based on accurate emissions factors, and (iii) the permit may not contain monitoring, recordkeeping, and reporting conditions sufficient to ensure compliance with all emission limits and associated controls.

Examples of these specific issues with respect to the Ore Processing and Lime Plant Operations include, but may not be limited to, the following:

Ore Processing PTE Limitations:

1. A PTE limitation appears to be needed to restrict the amount of ore material storage piles consistent with the emission estimates in the permit application.

2. Per Table 1.1, the 80% control efficiency applicable to the associated ore storage piles, and source ID. No. OC9, OC10 and OC11 is not included.

3. Per the application Ore Processing Diagram (Figure 1), the 108 ton per day (tpd) process rate associated with the Sb Drying and Bagging, the 7.5 tpd process rate associated with the Carbon Regeneration, and the 6,980 tpd rate associated with the Autoclave are not included.

PET 574

REC 0940

4. Per the application Ore Processing Diagram (Figure 1), emission sources Sb1 and Sb2 are not included in Table 1.1 or specified in the permit conditions.

Ore Processing PTE Emission Factors:

5. Some of the PTE limitations may not be technically accurate because they are not based on emission factors that are representative of the emission sources. For example, AP-42 Section 11.24 Metallic Minerals Processing emission factors applies to the processing of hard ores including gold. However, the application uses AP-42 emissions factors from Section 11.19.2 Crushed Stone Processing that is applicable to non-metallic mineral processing. The permitting record does not provide a reasoned explanation as to why emission factors from Section 11.24 were selected over those from Section 11.19.2.

DEQ Response:

The ore materials are limited by the primary crusher limit and pebble crusher limit (Permit Conditions 3.7 and 3.8) for storage pile feed.

Source ID. Nos. OC9, OC10, and OC11 list control equipment in Table 1.1 as reasonable control and FDCP. An 80% control efficiency is achieved through implementation of the FDCP (Permit Condition 2.6), below-grade of storage piles, and enclosure of the conveyor (Permit Condition 3.2).

Tables 1.1 and 4.1 were updated in the permit to remove the antimony process dryer and bagging operation (sources Sb1 and Sb2) as requested by PRI, and consistent with proposed mercury control devices for the autoclave.

21 As discussed previously in the Representativeness and Uncertainty of Emissions section above, the estimates of emissions and underlying assumptions were supported to the satisfaction of DEQ, and sufficient information was provided to demonstrate preconstruction compliance with applicable TAP and mercury standards and to support facility classifications. The facility's emission inventory includes crushers, screens, and conveyors controlled by water sprays. EPA's AP-42 11.19.2 (08/2004) provides representative emission factors for these specific processes and controls.

22

Comment 24 - EPA: Lime Plant PTE Limitations

8. The following PTE limitations specified in Table 1.1 and the application do not appear to be included in the permit including: 267 tpd applicable to LK, LCR, and LS-L/U; 250 tpd applicable to LS1-L/U and MillS2-L/U; 1,000 tpd applicable to ACS1, ACS2, and ACS3; 500 tpd applicable to ACS4; and 70,000 tons per year applicable to LSI-L/U, MillS2-L/U, ACS1-L/U, ACS2-L/U, AC3-L/U and ACS4-L/U.

9. The PTE limitation of 1,130 tpd of limestone in permit condition 5.4 may not be technically accurate as it does not appear to account for all of the emissions sources comprising the lime plant subject to PSD and Title V permitting limits of a 100 tons per year. For example, the limestone mining activities (e.g., drilling, blasting, excavating, hauling, and storage piles) and all of the lime plant processing emission units and activities shown in the application's Figure 2 do not appear to be included in the emissions estimates. These emission units presented in Figure 2 include the dump truck unloading, stationary grizzly, rock breaker, primary crusher feed hopper, vibrating grizzly feeder, and the emission units and activities following the limestone ball mill and lime slaker (e.g., Milk of Lime Distribution Tank). Emissions from those aspects of the limestone handling and processing that would not happen if the lime plant did not exist must be accounted for as support activities to the lime plant. Furthermore, if the mining of limestone (including overburden removal) would not be done if the lime plant did not exist, emissions from those activities must also be included with the lime plant emission inventory. For example, IDEQ's SOB and Perpetua's letter dated September 23, 2021, indicates that the limestone is overburden excavated from the Middle Marble Geologic Unit (MMGU) located in the northwest portion of the West End Pit and that the overburden must be removed to access the gold ore. However, Midas Gold documents from 2016 and 2020 indicate, contrary to this information, that the MMGU is located in the northeast portion of the West End Pit, is located

beneath a 30 ft- to 250 ft-thick quartzite unit and requires the addition of a haul road to transport limestone to the lime plant processing facility. Because the limestone deposits are buried 30 to 250 feet below the surface, as noted above, it appears more than 1,130 tpd of material would need to be excavated to access the limestone deposit.

10. IDEQ's PSD applicability analysis in the Statement of Basis (SOB) does not appear to include all of these emission sources or provide the necessary information to support their Lime Plant PSD emission estimates.

DEQ Response:

Lime production limits for LK, LCR, and LS-L/U are limited by the Parallel Flow Regenerative Kiln output limit in Permit Condition 5.5. As can been seen in the Lime Production Flow Diagram in the application, 267 tpd is the maximum capacity and input to the Kiln. DEQ chose to limit the output of the Kiln as seen in Permit Condition 5.5 (169 T/day). The mill and autoclave lime silos (LS1, MillS2, and ACS1-4) are limited by the control requirements in Permit Condition 5.16 and the lime usage, which is inherently limited by the gold ore processing limits in Permit Conditions 3.7 and 3.8 for the mill and Permit Condition 4.8 for the autoclave. All above equipment has emission limits specified in Permit Condition 5.3 (Table 5.2). As a result of the comments received, although the lime silos (LS1-L/U, MillS2-L/U, ACS1 – ACS4) are permitted at maximum capacity, DEQ has added a permit condition to limit the lime silos to 4,000 T/day and 70,000 T/yr combined (new Permit Condition 5.9) with corresponding monitoring and recordkeeping (new Permit Condition 5.22).

23 A response to a request for additional information was submitted by PRI[3] in which the emissions units comprising the lime plant were identified. The project includes a lime manufacturing plant (LMP) that uses a Parallel Flow Regenerative Shaft Kiln to produce lime product from limestone by calcination, which is a designated facility as defined in 40 CFR 52.21(b)(1)(i)(*a*). As described in the "Facility Classification" and "PSD Classification" section of the Statement of Basis, permitted facilitywide emissions (PTE) were less than 100 tons per year (T/yr) for regulated pollutants. For each regulated pollutant, LMP emissions did not exceed 100 T/yr, and facility-wide emissions did not exceed 250 T/yr applicability thresholds. For the purposes of classification, the LMP was true minor for all NSR pollutants. Per EPA's March 6, 2003, guidance, both fugitive and non-fugitive emissions from the LMP must be counted toward a determination of a major stationary source. Total emissions are below 100 tons per year for each pollutant (Table 10 in the Statement of Basis). However, even if fugitive emissions from the upstream stone crushing and milling equipment and marble overburden mining were included, emissions would still not exceed 100 tons per year (Table 11 in the Statement of Basis).
24
Restrictions on PTE from fugitive and non-fugitive sources and supporting monitoring, recordkeeping, and reporting were established in the permit, including control of fugitive dust (Permit Conditions 2.1–2.6), emissions limits (Permit Condition 5.3), a PFR Kiln output limit (Permit Conditions 5.5 and 5.17), and control device requirements (Permit Conditions 5.11-5.12, 5.14-5.15, and 5.21-5.22). Emissions are not permitted to exceed these limits during startup, shutdown, and malfunction. Any emissions that exceed emissions limits are required to be reported in accordance with excess emissions requirements (Permit Condition 7.11). While emissions limits and emission factors are not commonly included in the permit for fugitive sources, activity rate limits and MRR requirements were established for those sources that were identified as process rate-limiting (as summarized in Table 1.1 of the permit). These activity rate limits serve as surrogate emissions limits for PM, PM_{10}, $PM_{2.5}$, HAP and TAP from LMP fugitive sources.

Comment 25 - EPA: Lime Plant PTE Emission Factors

11. IDEQ's SOB Table 10 PSD emission estimates may not be technically accurate because they do not appear to be based on emission factors that are representative of the emission sources. For example, AP-42 Section 11.17 Lime Manufacturing emission factors applies to the processing of lime derived from marble. However, the application uses AP-42 emissions factors from Section 11.19.2 Crushed Stone Processing. In addition, the limestone excavating emission estimates (Material Load & Unload) appear to use emission factors from Section

11.19.2 Crushed Stone Processing instead of Section 11.9 Western Surface Coal Mining emission factors that are representative and specific to mining excavation activities. The permitting record does not explain why emission factors from 11.19.2 were selected over those from 11.17 and 11.9. If IDEQ does not have a good technical reason for their selection of emission factors, consistent with comment #5, the most conservative emission factor should be used for emission units that make verification difficult. Comment 19 would also apply to fugitive dust emissions resulting from limestone mining sources including limestone drilling, blasting, excavating, and haul road activities.

DEQ Response:

As described previously in the Representativeness and Uncertainty of Emissions section, although some degree of uncertainty is present in all emission factors used in estimating emissions, all emission factors were adequately supported and the approach of estimating potential to emit (PTE) at design capacity was considered a conservative approach. Emission factors with control efficiencies built into them were adequately supported by that corresponding control device listed in the permit. Representative emission factors from EPA's AP-42 Section 11.17, 11.19.2 and 11.9 were used to estimate emissions from the lime plant, lime plant support equipment, and marble overburden mining, respectively. The facility's emission inventory includes crushers, screens, and conveyors controlled by water sprays. EPA's AP-42 11.19.2 (08/2004) provides representative emission factors for these specific processes and controls.

Comment 26 - EPA: Other PTE Limitations

14. Central Mixer Loading (Source ID No. CM) controls are unspecified in Table 1.1 and the permit consistent with the emission estimates in the permitting record.

15. Engine PTE limitations specifying the capacity of 1,000 bkW for the three emergency generators (EDG1, EDG2, and EDG3) should be specified in the permit. Also, the monitoring and recordkeeping requirement specified in permit condition 6.3 should include all hours of operation, not just non-emergency operating hours, and specify the devices and methodologies by which the monitoring and recordkeeping will be achieved.

DEQ Response:

Central Mixer Loading (CM) controls are specified in Tables 1.1 and 5.1 as reasonable control and the FDCP. Controls can include water sprays, enclosures, hoods, curtains, shrouds, movable and telescoping chutes, and central dust collection systems. Permit Condition 5.3 lists the emission limits for CM and Permit Condition 5.10 states that emissions must be controlled in accordance with the FDCP.

The capacity of the three emergency generators (EDG1, EDG2, and EDG3) are specified in Table 1.1. The emergency generators are subject to NSPS 40 CFR 60, Subpart IIII and those requirements are incorporated by reference (Permit Condition 2.22) and specific applicable requirements have been added to the permit including monitoring and recordkeeping to include all hours of operation (Permit Conditions 6.2, 6.4, and 6.5).

Comment 27 - ICL/SSFS: Conservatism

We have continued concern with IDEQ's position on conservative analyses and uncertainty in emissions calculations. IDEQ's response to previous critiques of emission calculations states:

> "… (the) approach of estimating potential emissions (PTE) at design capacity and maximum activity rates was considered a sufficiently conservative approach. Maximum hourly and daily activity rates were used to estimate the maximum 24-hour and annual emission rates, and emissions were modeled based on these maximum short-term activity rates occurring continuously every day."

IDEQ is conflating the "conservative" strategy long inherent in the PTC process with the conservative analyses required in estimating the potential to emit (PTE). Even if IDEQ uses a "conservative" strategy, the agency is still using non-conservative model input parameters for the emissions calculations. PTCs have been based on design PTE calculated using "maximum 24-hour and annual emission rates, and emissions modeled based on these maximum short-term activity rates occurring continuously every day" since the inception of the Clean Air Act (CAA). Comparing these required conservative rates to the Applicant's "good intentions" to operate below design capacity is not a conservative approach. The CAA has long recognized that any facility may change management, exploit additional resources, accept feedstock from adjacent properties, or numerous other production scenarios that could utilize design capacity.

IDEQ's *Guidelines for Performing Ambient Impact Analyses* states:

> "To demonstrate compliance, potential emissions must be used in the modeling analyses rather than future projected actual emissions. The maximum emission rate for each averaging period must be identified. For example, PM2.5 has both a 24 hour and annual standard. If a source will only operate 7000 hours per year, but can operate for 24 hours in a single 24 hour period, then different emission rates would be modeled for the 24 hour and annual standard" (Section 6.4.1).

The analyses for impacts for pollutants with averaging periods less than annual are not using maximum potential emissions over those short-term averaging periods. Annual emission impact analyses were also based upon an estimate of the five-year average of projected actual emissions. In assuring the appropriate level of health protectiveness, the permit process is, and has always been, designed to assure compliance at design capacity.

With respect to the use of AP-42 Emission Factors in calculating the PTE, IDEQ regulations require that "screening engineering analyses use unrefined conservative data." (6-30-95). Moreover, IDEQ guidance ranks the use of AP-42 as a last choice, with the least reliable data, and the greatest potential to underestimate emissions.[1] Accordingly, it is incumbent on IDEQ to require use of conservative emission factors. Accepting promises that intended operations will not exploit the full design capacity of the facility is not a substitute for utilizing conservative emissions factors in calculating PTE emissions.

DEQ Response:

25 As discussed previously in the Representativeness and Uncertainty of Emissions section, maximum hourly and daily activity rates were used to estimate the maximum 24hour and annual emission rates, and fugitive dust control requirements, emission rate limits, material activity rate limits, and supporting testing and monitoring, recordkeeping, and reporting (MRR) requirements were established as synthetic minor limits for the purposes of limiting facility-wide emissions of PM/PM_{10}/$PM_{2.5}$ to below 250 T/yr PSD applicability thresholds and Title V 100 T/yr applicability thresholds. These limits were also established for the purposes of limiting facility-wide emissions of single and total HAP to below HAP major source applicability thresholds (10/25 T/yr), and to ensure compliance with all NAAQS. Limits were established consistent with current DEQ guidance and the estimates of emissions and underlying assumptions were supported to the satisfaction of DEQ.

26 Enforceable monitoring, recordkeeping, and reporting requirements were established in the permit. PM/PM_{10}/$PM_{2.5}$ emissions limits for point sources were established with supporting activity rate limits and MRR requirements. While emissions limits and emission factors are not commonly included in the permit for fugitive sources, activity rate limits and MRR requirements were established for those sources that were identified as process rate-limiting (as summarized in Table 1.1 of the permit). These activity rate limits serve as surrogate emissions limits for PM, PM_{10}, $PM_{2.5}$, HAP and TAP from fugitive sources. And while documented in the Statement of Basis and application materials, underlying parameters associated with calculating emissions such as vehicle speed limit, type, and miles traveled are not typically included in the permit.

The regulatory bar for permit issuance is that the applicant, through analyses submitted in the application, demonstrate to the satisfaction of the Department that the proposed facility or modification not cause or

significantly contribute to a violation of a NAAQS or TAP increment (as per *Idaho Air Rules* Section 203). Air pollutant impact analyses performed for mining operations typically involve considerable uncertainty and variability in emission-affecting parameters and in dispersion-affecting parameters to estimate potential impacts to ambient air for specific averaging periods.

Uncertainty can be reduced by obtaining more application-specific information on the operation or parameter in question. Use of site-specific or project-specific information/data to better estimate emissions and dispersion-affecting parameters represents refining the analyses rather than use of non-conservative methods. A non-conservative approach would involve using the lower-emitting value of a listed range without justification. Variability cannot be reduced by more refined approaches. Variability can be accounted for by either: 1) using a worst-case approach of assuming the upper values (resulting in highest emissions) of the parameter persist at all times; 2) use of a more probabilistic approach to consider the variability either in a quantitative statistical approach or in a more qualitative "weight of evidence" approach. A weight of evidence approach is implemented where the use of clearly conservative values for all methods and data would result in an unrealistically high impact, thereby misrepresenting potential impacts and potentially triggering inappropriate monitoring and record-keeping requirements.

The comment also states that a 5-year average allowable emission rate was used for demonstrating compliance with the arsenic carcinogenic AACC, which is expressed as an annual average value. However, the definition of *Toxic Air Pollutant Carcinogenic Increments* in *Idaho Air Rules* Section 005.125, states, "Those ambient air quality increments based on the probability of developing excess cancers over a seventy (70) year lifetime exposure to one (1) microgram per cubic meter (1 $\mu g/m^3$) of a given carcinogen and expressed in terms of a screening emission level or an acceptable ambient concentration for a carcinogenic toxic air pollutant." Since the AACCs are based on a 70-year exposure, use of a 5-year averaging period is appropriate.

Comment 28 - ICL/SSFS: Facility Classification

In the Statement of Basis (SOB), IDEQ classified this facility as a synthetic minor source (SM) for PM, PM10, and PM2.5 and Class B for Hazardous Air Pollutants (HAPs). A number of comments by ICL, SSFS, and other reviewers address instances where we believe that HAP emissions continue to be underestimated. Once IDEQ completes the appropriate analyses and calculations to verify the PM and HAP emissions, the agency should assess whether the source still meets the requirements of a synthetic minor.

The Applicant and IDEQ calculations show that this facility will also emit >30,000 tons per year (TPY) of uncontrolled PM (removing the 90% control on hauling fugitive emissions + the emissions total for uncontrolled point sources) and 3,655 TPY of permitted PM point source + fugitive emissions (Table 3, SOB). However, IDEQ contends the Major Source classification of 100 TPY is not met despite the apparent 36-fold exceedance. IDEQ continues to ignore 3,569 TPY of permitted PTE PM fugitive emissions from mining operations (97.6% of total controlled PM by the Applicant's calculation) and 986 TPY of associated PM10 fugitive emissions. This clear exclusion of significant emissions from regulatory constraints is a major concern for us. Furthermore, this determination avoids the federal oversight that this permit would be afforded if classified properly as a Major Source.

To avoid including the fugitive emissions sources, IDEQ apparently relies on IDAPA 58.01.01.220.01:

> *For purposes of Sections 220 through 223, fugitive emissions shall not be considered in determining whether a source meets the applicable exemption criteria unless required by federal law.*

Accepting the Applicant's and IDEQ assertions, the current classification determination for this facility as a synthetic minor source is based on merely 2.4% of the total PM emissions. If only 13.6 TPY (0.4%) of the excluded PM fugitive emissions were included in the source classification determination, the facility would be a Class A Major Source, subject to federal review.

In the interest of health and environmental responsibility, it is imperative that the IDEQ consider all emissions including mining fugitive impacts and classify this a Major Category A Source. The only comparable facilities operating in the U.S. at this time, in Nevada, are Class 1 Major Sources according to the same criteria as Idaho's designation, even though most of the Nevada facilities do not include onsite gold ore processing. Idahoans should be afforded the same level of air quality protection as Nevadans.

Even by IDEQ exclusion criteria, some of the ignored sources asserted to be "mining fugitives" should be considered as mineral processing activity emissions controlled with and attendant to specific point sources included in the source classification determination. Significant percentages of mine ores are trucked to stockpiles and placed in storage to be processed months or years later. Alleged mine fugitive emissions also include significant on-site hauling associated with the Portable Crusher and Screening Plant. Some of this hauling is related to the lime plant and gold ore refinery operations, which are specifically listed by federal rules as requiring inclusion of fugitive emission in determining source classification.

Subchapter C Part 70.3(d). Fugitive emissions from a part 70 source shall be included in the permit application and the part 70 permit in the same manner as stack emissions, regardless of whether the source category in question is included in the list of sources contained in the definition of major source.

This rule should be interpreted that if any portion of the emissions is due to a listed source, then all emissions from that source should be included in the source classification determination.

These alleged "excluded mine fugitive" sources alone (not including On-site Hauling) exceed 270 TPY PM. If only 5% of these activities were considered attendant to listed sources or mineral processing and stockpile point source operations (as opposed to mining) then the Major A Source Category threshold would be met. Unfortunately, it is not possible for us or other reviewers to quantify these sources from the available emission inventories. Fugitive emissions were reportedly estimated for a dozen different operational scenarios. However, Table 7 of the SOB and the example calculations provided use scenario W-3, because it is the maximum total PM emissions. This scenario is heavily weighted toward exploitation of the West End Pits, and provides little information to assess the potential emissions associated with those sources that might not be exempt on closer examination.

Examination of the W3 scenario also shows that the 2,901 TPY of PM estimated for On-Site Hauling is 100% attributed to hauling emissions from the West End Pit to the Hangar Flat DRSF. This is the main process stream for limestone feeding the lime plant, gold oxidation circuit, neutralization of waste streams, etc. This scenario also attributes zero hauling emissions from stockpiles to crushers. It is not possible to ascertain from these data how much of the fugitive emissions are attendant to these listed sources or are attendant to mineral processing point sources. However, the W3 scenario does not encompass other haul routes that will be used as part of the mining operation; therefore, the total PM emissions attributed to hauling would be expected to be greater than 2,901 TPY.

These observations suggest that IDEQ's reliance on operational scenarios designed to support modeling analyses to assess fugitive exclusion from Source Classification has allowed listed and point source attendant emissions to be misclassified as excluded mining fugitives. Misclassification of only a tiny percentage of the massive excluded emissions prevents Major Source determination and federal review of key portions of this PTC. The ambient impact analysis must consider the potential impacts of any operational scenario allowable under the federal approval process and the IDEQ permit.

Lastly, the classification of the facility as a synthetic minor source for criteria pollutants and HAPs is hugely dependent upon the facility consistently attaining the target 93.3% fugitive dust control effectiveness. A facility that does not have legally enforceable conditions to ensure those fugitive dust controls, which IDEQ states will be challenging to show continual compliance with, should be considered a major source. Enforceability is extremely important because without enforceable limits, the source otherwise has the potential to emit criteria pollutants in amounts that are at or above the threshold for a major source.

IDEQ should:

- Carefully review these fugitive emission claims with regard to the exclusion criteria, and publicly disclose the review.
- Update the source classification determination for this facility based on these comments.
- Ensure total consistency between project processes and activities approved in the air permit with those that would be approved in the federal approval process.

DEQ Response:

In accordance with IDAPA 58.01.01.006. a stationary source is defined as any building, structure, facility, emissions unit, or installation which emits or may emit any air pollutant. The fugitive emissions shall not be considered in determining whether a permit is required unless required by federal law. For New Sources Review permitting purposes, the fugitive emissions shall not be considered in determining whether the facility is major unless the facility is a designated facility per IDAPA 58.01.01.008.10.c.i. A gold mine is not a listed designated facility under IDAPA 58.01.01.006.30 and therefore fugitive emissions are not considered. Fugitive emissions of criteria pollutants are counted toward PSD classification from designated facilities such as the lime plant. Lime plant fugitive emissions are quantified under the PSD Classification section of the Statement of Basis.

For Title V permitting purposes arsenic is a HAP and arsenic fugitive emissions from haul roads do count towards the major source determination of 10 tons per year of any HAP and 25 tons per year for any combination of HAP. Accounting for water and chemical dust suppressant control efficiencies and use of the equations cited from AP-42 Section 13.2.2 (11/2006) for unpaved roads and site-specific silt values supports an arsenic HAP PTE from the haul roads of 30.3 tons per year (T/yr) for uncontrolled emissions (above 20 T/yr as described in the Statement of Basis) and 2.03 T/yr for controlled emissions. Despite the noted limitations of using AP-42, these equations remain commonly used and accepted by DEQ.

As discussed previously in the Representativeness and Uncertainty of Emissions section above, the estimates of emissions and underlying assumptions were supported to the satisfaction of DEQ, and sufficient information was provided to demonstrate preconstruction compliance with applicable TAP and mercury standards and to support facility classifications. Key assumptions identified in this section and by the commenter (including 93.3% control efficiency for haul roads) were confirmed by PRI and accepted by DEQ and were the basis of the facility classifications.

Comment 29 - ICL/SSFS: TAPs Mass Balance

We recommend that IDEQ develop a material balance for TAPs to inform and assist the agency in assessing the quality and uncertainty inherent in the data underlying the Applicant's assertions. Many other states specifically require a material balance for criteria pollutants, HAPs, and TAPs. IDEQ's response reiterates the same "conservative" claim:

"While a material balance is a useful approach to developing emission estimates, it is not a requirement, and the use of maximum activity rates and representative performance test data to estimate and model emissions is commonly accepted by DEQ. While the use of an average or maximum value is a more conservative approach, the use of site-specific median values combined with estimating and modeling PTE at design capacity and maximum activity rates was considered a sufficiently conservative approach."

IDEQ's own TAPs guidance, however, specifies the use of AP-42 and mass balance techniques:

"Determine if a new (constructed after June 30, 1995) emission unit has the potential to emit a TAP listed in IDAPA 58.01.01.585 (Rules Section 585) or IDAPA 58.0101.586 (Rules Section 586). Potential toxic air pollutants can be determined by reviewing commonly available emission factors, such as EPA's AP-42, or calculating emissions using a mass balance."

Mass balance analyses would be invaluable in enhancing regulators' and the public's ability to follow and review emission calculations, and designing appropriate operational limitations and controls for this PTC.

IDEQ should:

- Require a facility-wide mass balance for TAPs in subsequent submittals for this PTC.

DEQ Response:

As described previously in the Representativeness and Uncertainty of Emissions section, while a material balance is a useful approach to developing emission estimates, it is not a requirement, and the use of maximum activity rates and representative performance test data to estimate and model emissions is commonly accepted by DEQ. While the use of an average or maximum value is a more conservative approach, the use of sitespecific median values combined with estimating and modeling PTE at design capacity and maximum activity rates was considered a sufficiently conservative approach.

Comment 30 - ICL/SSFS: Arsenic Emissions

The proposed Stibnite Gold Project clearly presents hazardous concerns associated with toxic metal releases. Arsenic and mercury are of particular concern due to their high toxicity and importance in the metallurgical processes. This facility will potentially emit 170 to 360 TPY of arsenic. About 85-90% of the uncontrolled arsenic emissions are proposed to be contained or captured by proposed controls and approximately 13 to 38 TPY will be released to the atmosphere as fine particulate (controlled PTE). The PTC Application underestimates these emissions by a factor of 5.6 to 12 times by our calculations (see previous public comments on version 2 of this PTC), and asserts arsenic emissions of about 30 TPY PTE uncontrolled and 2.4 TPY controlled PTE. Most of this mischaracterization is associated with road dust suspended from the massive volume of heavy trucks moving thousands of loads of arsenical contaminated materials across the site. The Applicant apparently achieves this low estimate by using minimal emission factors and particulate arsenic content, and claiming an unprecedented capability to control 93.3% of the road dust through chemical suppressants and watering.

An in-depth review of the Emissions Inventory reveals there are several factors that have not been given appropriate treatment in developing the arsenic emissions totals. We incorporate our detailed prior comments on this matter by reference into this latest round of comments and continue to have significant concerns that the arsenic emissions from this facility are being grossly underestimated.

The underestimation of fugitive dust emissions from haul roads resulting from the use of non-conservative modeling parameters is exacerbated when one considers that there appear to be three largely unaccounted for processes that will increase the arsenic content of haul road related fugitive dust emissions over time: 1) haul truck spillage of ore or waste rock containing higher arsenic content than the surface aggregate, 2) an increase in silt-sized particles in the haul road surface layer due to traffic wear, and 3) the application of dust abatement water sourced from the East Fork South Fork of the Salmon River containing elevated levels of arsenic.

DEQ Response:

As discussed previously in the Representativeness and Uncertainty of Emissions section above, the estimates of emissions and underlying assumptions were supported to the satisfaction of DEQ, and sufficient information was provided to demonstrate preconstruction compliance with applicable TAP and mercury standards and to support facility classifications. Key assumptions identified in this section and by the commenter (including 93.3% control efficiency for haul roads) were confirmed by PRI and accepted by DEQ, and were the basis of the facility classifications. As discussed previously, enforceable testing and monitoring, recordkeeping, and reporting (MRR) requirements were also established and incorporated in the permit.

Comment 31 - NPT: Antimony hauling not sufficiently characterized

The mineral products from the proposed Stibnite Gold Project are gold and antimony, accounting for 1 and 99% by mass, respectively. In earlier versions of the PTC, the antimony concentrated was going to be dried and bagged, and then was proposed to be dewatered and packaged wet.

Page six of the Statement of Basis states, "The metal-recovery process from ore will include conventional crushing and grinding, followed by froth-flotation circuits that will generate separate gold-silver and antimony-silver concentrates. The antimony-silver concentrate will be shipped offsite for refining... ". In Footnote c) of Table 3 in the Statement of Basis; it states that "In the response to a request for additional information, PRI confirmed that antimony process dryer and bagging operation emission sources (Sbl and Sb2) initially proposed would be replaced by a dewatering/packaging circuit. As a result, these emission sources have been removed from the permit and post-project PTE." Please include documentation confirming there are no air emissions associated with removing the antimony-silver concentrate from the site and how hauling the antimony concentrate from the processing area to the property boundary is accurately accounted for in the emissions inventory for the permit. If no market for the antimony is found and the concentrate is either stockpiled, stored on-site, or hauled to the tailings storage facility, emissions from this concentrate should be reevaluated.

DEQ Response:

PRI has confirmed and as stated in the Statement of Basis, the antimony process dryer and bagging operation emission sources (Sb1 and Sb2) has been removed from the permit and project potential to emit. The hauling of antimony is accounted for in the emission inventory in ore concentrate haulage under the mining tab of the emission inventory spreadsheet (Appendix A in the Statement of Basis).

Comment 32 - TIFO: IDEQ response to previous comments

TIFO has reviewed all three revisions of the Draft Permit to Construct and associated documents and submitted comments on three previous occasions. The current version of IDEQs draft Response to Comments indicates that several of alternative data and calculations provided in earlier reviews were not demonstrated to be more accurate or appropriate than data provided by the Applicant, and accepted by IDEQ.

TIFO requests that the past comments be incorporated as supporting the additional critiques offered in this review, and be reconsidered by IDEQ with supplemental data and analyses presented below. Specifically, there is continued concern with IDEQs position on conservative analyses and uncertainty in emissions calculations.

IDEQ response to previous critiques of emission calculations states:

> … (the) approach of estimating potential emissions (PTE) at design capacity and maximum activity rates was considered a sufficiently conservative approach. Maximum hourly and daily activity rates were used to estimate the maximum 24-hour and annual emission rates, and emissions were modeled based on these maximum short-term activity rates occurring continuously every day.

IDEQ is conflating the “conservative” strategy long inherent in the PTC and Operating Permit process, with the conservative analyses required in the estimating PTE. Since the inception of the Clean Air Act (CAA), PTCs and Operational Permits have been based on design PTE calculated using “maximum 24-hour and annual emission rates, and emissions modeled based on these maximum short-term activity rates occurring continuously every day”.,. Comparing these required conservative rates to *good intentions to operate below design capacity alleged by the Applicant* is not a conservative approach. The CAA has long recognized that any facility may change management, exploit additional resources, accept feedstock from adjacent properties, or create numerous other production scenarios that could subsequently utilize design capacity. In assuring the appropriate level of health protectiveness, the Permit process is, and has always been, designed to assure compliance at design capacity.

With respect, specifically, to the use of AP-42 Emission Factors in calculating the PTE, IDEQ regulations, <u>specifically</u>, requires:

> “Screening engineering analyses use <u>unrefined conservative data</u>. (6-30-95).

With respect to uncertainty and reliability, IDEQ guidance ranks the use of AP-42 as a last choice, with the least reliable data, and the greatest potential to underestimate emissions. (https://www2.deq.idaho.gov/admin/LEIA/api/document/download/5521

As a result, it is incumbent on IDEQ to require use of conservative Emission Factors. Accepting promises that intended operations will not exploit the full design capacity of the facility is not a substitute for utilizing conservative EFs in calculating PTE emissions.

On a similar note, TIFO has advised IDEQ that development of a material balance for toxic air pollutants is good engineering practice and could inform and assist the Agency in assessing the quality and uncertainty inherent in the data underlying the Applicant's assertions; and that many State's specifically require a material balance for criteria pollutants, HAPs, and TAPs. IDEQ's response reiterates the same "conservative" claim:

> While a material balance is a useful approach to developing emission estimates, it is not a requirement, and the use of maximum activity rates and representative performance test data to estimate and model emissions is commonly accepted by DEQ. While the use of an average or maximum value is a more conservative approach, the use of site-specific median values combined with estimating and modeling PTE at design capacity and maximum activity rates was considered a sufficiently conservative approach.

IDEQs own TAPS guidance, however, specifies the use of AP-42 and mass balance techniques:

> Determine if a new (constructed after June 30, 1995) emission unit has the potential to emit a TAP listed in IDAPA 58.01.01.585 (Rules Section 585) or IDAPA 58.0101.586 (Rules Section 586). Potential toxic air pollutants can be determined by reviewing commonly available emission factors, such as EPA's AP-42, or calculating emissions using a mass balance.

Mass balance analyses would be invaluable in designing appropriate operational limitations and controls in a T-RACT application. IDEQ should require a facility-wide mass balance for TAPs in revised or new submittals for this PTC.

DEQ Response:

As described previously in the Representativeness and Uncertainty of Emissions section, while a material balance is a useful approach to developing emission estimates, it is not a requirement, and the use of maximum activity rates and representative performance test data to estimate and model emissions is commonly accepted by DEQ. Use of a mass balance is one method that can be used to assess emissions. Perpetua elected to use other methods based on emission factors. DEQ has reviewed those methods and has found them to be reasonably accurate or conservative. A potential problem with some mass balance approaches can be observed in the accuracy of calculating a very small value by examining the difference between two large values. Because the uncertainty in the beginning inputs is greater than the final value, confidence in the final value is very low.

Similarly, use of maximum values of emission-affecting parameters is recommended for permitting analyses, especially when considering compliance with short-term standards (24-hour PM_{10} and 24-hour $PM_{2.5}$). Where compliance cannot be demonstrated when using upper limit values of parameters, DEQ may allow values representative of an average or median value. This is contingent on other aspects of the air impact analyses (emission-affecting parameters and pollutant dispersion-affecting parameters) providing an overall weight of evidence that NAAQS compliance confidence is high enough to support permit issuance, as required by *Idaho Air Rules* section 203. Although a median value of sampled silt percentages of roadway material was used in emission estimates presented in the application, DEQ recognizes the importance of the silt content parameter in the estimation of emissions. Since compliance with the 24-hour PM_{10} NAAQS is the primary driver of NAAQS compliance, minimizing variability of the parameter is very important to

ensure NAAQS compliance. To achieve this, the permit will limit *maximum silt content* to 4.0 %, as specified in Section 3.13 Haul Road Capping of the PTC.

Also, despite the noted limitations of AP-42, these emission factors remain commonly used and accepted by DEQ in the absence of site-specific data, manufacturer emissions guarantee, or continuous emissions monitoring data.

Comment 33 - TIFO: General comments and discussion

The following analyses are the fourth round of public comments offered on three revisions of the proposed PTC and Draft Permit for the SGP. Some progress has been achieved in securing health and environmental protectiveness through this repetitive review process. However, despite the Agency's persistent attempts to obtain objective and transparent submittals from the Applicant, this patchwork approach to upgrade an inherently deficient application is eroding public trust in the process to provide for health and environmental protectiveness.

The proposed Midas Gold / Perpetua Resources Idaho (PRI) mining operations clearly offer hazardous concerns associated with toxic metal releases. Arsenic and mercury are of particular concern due to the high toxicity and importance in the metallurgical processes. The principal refractory gold ores proposed for exploitation are auro-arsenical deposits yielding an estimated 230 to >1000 pounds of waste arsenic for each ounce of gold captured. Approximately 493,000 (mean) to 2,190,000 tons (95^{th} %-tile) of arsenic will be excavated according to prospective mining reports issued by the Applicant. Nearly all of the arsenic will be disposed of on-site, or released by air and water to adjacent public lands and water. Much of this arsenic is handled repeatedly during operations and is present as, converted to, and released to the environment as, the more toxic chemical species.

With regard to arsenic air pollution, this facility will potentially emit 170 to 360 tons per year (TPY) (or about 1%) of the total arsenic waste. About 85-90% of the uncontrolled emission will be contained or captured by proposed controls and approximately 13 to 38 TPY will be released to the atmosphere as fine particulate (controlled Potential Total Emissions PTE). The PTC Application underestimates these emissions by a factor of 5.6 to 12 times, (See previous public comments – Draft 2 PTC), and asserts about 30 TPY PTE uncontrolled and 2.4 TPY controlled PTE. Most of this mischaracterization is associated with road dust suspended from the massive volume of heavy trucks moving thousands of loads of arsenical contaminated materials across the site. The Applicant achieves this low estimate by using minimal emission factors (EFs) and particulate arsenic content, and claiming an unprecedented capability to control 93.3% of the road dust through chemical suppressants and watering. A detailed critique of these emissions was provided in the comments to Draft 2 PTC, and are amplified below in these comments.

The public should be aware that IDEQ is extending unusual latitude to the Applicant in reviewing the PTC, accepting minimal technical parameters, and accepting unrealistic control assumptions. These overly optimistic particulate and arsenic emission claims are necessary to obtain the PTC. The proposed facility would not be able to comply with health standards if conservative EFs, arsenic content and more realistic control levels were used in the calculations, as required by the regulations.

The public should also be aware that (3569/(3569+86,6)) 97.6 % of controlled particulate emissions admitted to in the PTC are classified as "mining fugitive" emissions. Mining fugitive emissions are exempt from consideration in Major Source Classification in Idaho. As a result, this source, which will be one of the largest in the State, is classified as Synthetic Minor and is precluded from federal review. Many of these alleged mining fugitive sources are arguably not exempt and could be classified as attendant to listed or point sources. If only 0.4 % of these "mining fugitive" emissions (13.4 TPY) were reclassified, the facility would be a Major A Source and the Idaho public could apply to the federal government for relief.

The public should also be aware that application for a PTC, prior to receiving approval from the federal government on a project requiring an Environmental Impact Statement EIS), is also unusual. The Applicant is attempting to secure both State and federal Agencies approvals simultaneously. Generally, the federal

approval dictates the type of facility that is acceptable, followed by State implementation of the required controls. The Applicant is submitting confusing, and apparently inconsistent, air pollution emission estimates to the different regulators, hampering the transparency required for the public to understand and comment in both forums. Both the proposed PTC and Draft EIS largely ignored potential airborne toxic arsenic impacts in the initial submittals. These comments are being forwarded to the US Forest Service and Environmental Protection Agency for their consideration.

DEQ Response:

In accordance with IDAPA 58.01.01.006. a stationary source is defined as any building, structure, facility, emissions unit, or installation which emits or may emit any air pollutant. The fugitive emissions shall not be considered in determining whether a permit is required unless required by federal law. For New Sources Review permitting purposes, the fugitive emissions shall not be considered in determining whether the facility is major unless the facility is a designated facility per IDAPA 58.01.01.008.10.c.i. A gold mine is not a listed designated facility under IDAPA 58.01.01.006.30 and therefore fugitive emissions are not considered. Fugitive emissions of criteria pollutants are counted toward PSD classification from designated facilities such as the lime plant. Lime plant fugitive emissions are quantified under the PSD Classification section of the Statement of Basis.

For Title V permitting purposes arsenic is a HAP and arsenic fugitive emissions from haul roads do count towards the major source determination of 10 tons per year of any HAP and 25 tons per year for any combination of HAP. Accounting for water and chemical dust suppressant control efficiencies and use of the equations cited from AP-42 Section 13.2.2 (11/2006) for unpaved roads and site-specific silt values supports an arsenic HAP PTE from the haul roads of 30.3 tons per year (T/yr) for uncontrolled emissions (above 20 T/yr as described in the Statement of Basis) and 2.03 T/yr for controlled emissions. Despite the noted limitations of using AP-42, these equations remain commonly used and accepted by DEQ.

As discussed previously in the Representativeness and Uncertainty of Emissions section above, the estimates of emissions and underlying assumptions were supported to the satisfaction of DEQ, and sufficient information was provided to demonstrate preconstruction compliance with applicable TAP and mercury standards and to support facility classifications. Key assumptions identified in this section were confirmed by PRI and accepted by DEQ and were the basis of the facility classifications.

Comment 34 - TIFO: Facility Source Classification

IDEQ's initially classified this facility as a synthetic minor source (SM) for PM, PM10 and PM25 and Class B for HAP. The initial PTC application erroneously characterized this facility as a minor source with negligible environmental, and no health, significance. Unraveling the complex and confusing calculations that supported these conclusions required public information hearings, access to IDEQ Staff, weeks of reverse engineering, and in-depth review by public commenters.

The PM classification determination is apparently based on "mineral processing" point source PM emissions totaling 560 TPY uncontrolled and 86.6 TPY permitted controlled PTE emissions, indicating an overall 85% control of these sources. In Table 2 of the current Statement of Basis (SOB), IDEQ compares the 86.6 TPY PTE to the 100 TPY threshold for major source classification, indicating SM80 classification (>80 but <100 TPY). It is unclear why IDEQ classifies the source as SM despite this finding. The HAP classification has been modified from B to SM based on the IDEQ inclusion of previously excluded arsenic emissions.

The Applicant and IDEQ calculations show that this facility will also emit >30,000 TPY of uncontrolled PM and 3655 TPY of permitted PM emissions (Table 3, SOB). However, the Agency contends the Major Source classification of 100 TPY is not met (despite the 36-fold exceedance). This illogical conclusion is a continuing example of IDEQs exclusions of massive emissions from regulatory constraints, and a major source of concern for the Public. More disconcerting, this determination avoids federal oversight and severely impedes the Public's ability to secure protection from federal authorities.

IDEQ continues to ignore 3569 TPY of permitted PTE PM fugitive emissions from mining operations (97.8% and of total controlled PM by the Applicant's calculation) and 986 TPY of associated PM10 emissions (all of which are likely underestimated by 1.6 to 3.5 times).

In avoiding consideration of these thousands of tons of annual particulate emissions, IDEQ apparently relies on:

> **220.GENERAL EXEMPTION CRITERIA FOR PERMIT TO CONSTRUCT EXEMPTIONS.**
> 01. **General Exemption Criteria**.
> … For purposes of Sections 220 through 223, fugitive emissions shall not be considered in determining whether a source meets the applicable exemption criteria unless required by federal law.

Accepting the Applicant's and IDEQ assertions, this classification determination is based on 2.4% of the total PM emissions. If only 13.6 TPY (0.4%) of the massive excluded PM emissions were included in the Source Classification determination, the facility would be a Major A Source, subject to federal review.

In the interest of health and environmental responsibility, it seems logical, if not imperative, that the Agency consider all emissions including mining fugitive impacts and classify this a Major Category A Source. Comparable facilities operating in the US at this time, in the State of Nevada, are Class 1 Major sources according to the same 100 TPY criteria as Idaho's A designation. Idahoans should be accorded the same level of protection as Nevadans. In addition, these facilities are not co-located mining, mineral processing, waste disposal, reclamation, and remediation activities; ongoing simultaneously in mountainous complex terrain, on the headwaters of a wild-scenic river, as is proposed at Stibnite.

The proposed facility is a sophisticated combined integrated mining and mineral processing and refining operation, located in a challenging environmental setting. The current PTC classifies practically all fugitive emissions as "mining fugitives". Even by IDEQ exclusion criteria, some of the ignored sources asserted to be "mining fugitives" should be considered as mineral processing activity emissions controlled with, and attendant to, specific point sources included in the Classification determination. These "fugitive emissions" should be included in the Source Classification totals. Significant percentages of mine ores are trucked to stockpiles and placed in storage to be processed months or years later. Alleged mine fugitive emissions also include significant on-site hauling associated with Portable Crusher and Screening Plants. Some of this hauling is related to the lime plant and gold ore refinery operations, that are specifically listed by federal rules as requiring inclusion of fugitive emission in determining source classification. For example,

> Subchapter C Part 70.3d) Fugitive emissions from a part 70 source shall be included in the permit application and the part 70 permit in the same manner as stack emissions, regardless of whether the source category in question is included in the list of sources contained in the definition of major source.

This rule should be interpreted that if the any portion of the emissions is due to a listed source, then all emissions from that source should be included in the Source Classification determination. A portion of the maintenance grading, dozing and load/unload activities and all watering truck, placement of "clean gravel" and dust suppressant emissions are applied continually, independent of the mine production rate, specifically for PM control. These sources should also be assessed as attendant to T-RACT "*environmental impacts caused by the control technology that cannot be mitigated"*, in part, for listed sources and considered for inclusion in Source Categorization.

These alleged "excluded mine fugitive" sources alone (not including On-site Hauling) exceed 270 TPY. If only 5% of these activities were considered attendant to listed sources or mineral processing and stockpile point source operations (as opposed to mining) then the Major A Source Category threshold would be met. Unfortunately, it is not possible for public reviewers to assess the magnitude of or quantify these sources from the available emission inventories. Fugitive emissions were reportedly estimated for a dozen different operational scenarios. However, Table 7 of the SOB and the example calculations provided use scenario W-3, because it is the maximum total PM emissions. This scenario is heavily weighted toward exploitation

of the West End Pits, and provides little information to assess the potential emissions associated with those sources that might not be exempt on closer examination.

Examination of the W3 scenario also shows that the 2901 TPY of PM estimated for On-site Hauling is 100% attributed to hauling from the West End Pit to the Hangar Flat DRSF. This is the main process stream for limestone feeding the lime plant, gold oxidation circuit, neutralization of waste streams, etc. This scenario also attributes zero hauling from stockpiles to crushers. It is not possible to ascertain from these data how much of the fugitive emissions are attendant to these listed sources or to mineral processing point sources.

These observations suggest that IDEQ's reliance on operational scenarios, designed to support modeling analyses to assess fugitive exclusion from Source Classification, has allowed listed and point source attendant emissions to be misclassified as excluded mining fugitives. Misclassification of only a tiny percentage of the massive excluded emissions prevents Major source determination and federal review of key portions of this defective PTC.

IDEQ should carefully review these fugitive emission claims with regard to the exclusion criteria and publicly disclose the review.

DEQ Response:

As noted in the previous response, in accordance with IDAPA 58.01.01.006. a stationary source is defined as any building, structure, facility, emissions unit, or installation which emits or may emit any air pollutant. The fugitive emissions shall not be considered in determining whether a permit is required unless required by federal law. For New Sources Review permitting purposes, the fugitive emissions shall not be considered in determining whether the facility is major unless the facility is a designated facility per IDAPA 58.01.01.008.10.c.i. A gold mine is not a listed designated facility under IDAPA 58.01.01.006.30 and therefore fugitive emissions are not considered. Fugitive emissions of criteria pollutants are counted toward PSD classification from designated facilities such as the lime plant. Lime plant fugitive emissions are quantified under the PSD Classification section of the Statement of Basis.

For Title V permitting purposes arsenic is a HAP and arsenic fugitive emissions from haul roads do count towards the major source determination of 10 tons per year of any HAP and 25 tons per year for any combination of HAP. Accounting for water and chemical dust suppressant control efficiencies and use of the equations cited from AP-42 Section 13.2.2 (11/2006) for unpaved roads and site-specific silt values supports an arsenic HAP PTE from the haul roads of 30.3 tons per year (T/yr) for uncontrolled emissions (above 20 T/yr as described in the Statement of Basis) and 2.03 T/yr for controlled emissions. Despite the noted limitations of using AP-42, these equations remain commonly used and accepted by DEQ.

As discussed previously in the Representativeness and Uncertainty of Emissions section above, the estimates of emissions and underlying assumptions were supported to the satisfaction of DEQ, and sufficient information was provided to demonstrate preconstruction compliance with applicable TAP and mercury standards and to support facility classifications. Key assumptions identified in this section were confirmed by PRI and accepted by DEQ, and were the basis of the facility classifications.

AMBIENT AIR – PUBLIC ACCESS ROAD

Comment 35 - NPT: DEQ has erred in its interpretation of EPA's Revised Policy on Exclusions from "Ambient Air"[4] for the public access road through the mine site

The public access road between Stibnite Road at Sugar Creek and Thunder Mountain Road at Meadow Creek should not be excluded from the regulatory definition of ambient air. This road is intended to allow public access, not preclude it. EPA's revised Ambient Air Policy describes conditions by which the public is to be excluded from an area controlled by a source and which would then justify excluding an area for purposes of analyzing the source's impact on ambient air. Controlling public access on the public access road between Stibnite Road at Sugar Creek and Thunder Mountain Road at Meadow Creek, as is described Section 3.3.10 of the Statement of Basis, Appendix B Ambient Air Quality Impact Analyses Review Memorandum, consists of providing "controlled through-site access that is safe, provides travel-time comparable to current conditions and is consistent with the United States Forest Service travel management plan."[5] Controlling public access through a site is not excluding public access to a site, thus the EPA revised Ambient Air Policy does not apply, and, therefore, the public access road should be considered ambient air.

As the public access road is ambient air, all emissions, modeling, and controls must be characterized and considered, and subject to the NAAQS.

DEQ Response:

DEQ does not agree with the comment that the access road between Stibnite Road at Sugar Creek and Thunder Mountain Road at Meadow Creek was inappropriately excluded from consideration as ambient air. The roadway is not public, as PRI has sole control of access through the site. As explained in DEQ's response to Comment 16, those seeking to use the roadway will be guests of PRI, subject to those conditions specified by PRI. The issued permit requires PRI to clearly identify the roadway as "not public" and managed by PRI.

Comment 36 - ICL/SSFS: Ambient Air Boundary Determination

We are concerned that the exclusion of the public access road between Stibnite Road at Sugar Creek and Thunder Mountain Road at Meadow Creek from the regulatory definition of ambient air is inconsistent with Clean Air Act's definition of ambient air,[3] EPA's long-standing policy that allows excluding certain areas of a source's property from ambient air,[4] and EPA's most recent revised policy for ambient air.[5] Allowing the public to access this road, even under the conditions of the Stibnite Road Access Management Plan, may result in acute exposure of the public to hazardous air conditions.

EPA's long-standing policy has been to exempt "the atmosphere over land owned or controlled by the source and to which public access is precluded by a fence or other physical barriers" from ambient air requirements.[6] In 2019, recognizing advances in surveillance and monitoring capabilities, EPA revised the "fence or other physical barriers element of this ambient air policy while maintaining public health protection" to allow stationary sources to use "other types of measures "to support exclusion of an area from ambient air."[7] Key to this policy revision was the fact that "legal" access – whether the public has the right or permission to enter a specific property – did not change the definition of ambient air. In other words, "if 'ambient air' is defined as that to which the general public has access, then that to which the general public does not have access is not ambient air."[8]

Under this permit, the general public would have access to the road through the project area and not be entirely precluded from using it throughout the life of the mine. Based on EPA's policy, since the general public would have access, albeit restricted, the road is ambient air. The Response to Comments justifies this exclusion because "[t]he roadway is completely within the boundary of the mine," "[u]se of the roadway by [the public] is completely at the discretion of PRI and will be tightly controlled," and the public "will be considered [business invitees] of PRI."[9] This rationale cannot be reconciled with EPA's policy.

The EPA Revised Policy explains:

> "The EPA's view is that the general public has legal access to areas that are owned and controlled by parties other than the owner or operator of a stationary source. The EPA continues to view the "general public" to include any person(s) other than those who are permitted access to the property as employees or business invitees of a specific stationary source (including trespassers)."[10]

In other words, people that are traveling on the road through the mine site to access public (Forest Service) property are members of the general public. The Applicant's attempt to label the public as "guests of PRI"[11] is disingenuous and "would expand the exclusion beyond reason and deny the protection of the NAAQS to large numbers of people."[12] The fact that these "guests" would "abide by access and safety procedures established by PRI" is meaningless in terms of protecting the public from exposure to hazardous air conditions. There are no air quality monitors on the road because it has been excluded from ambient air.[13] Thus, it will not be known to those traveling on the road what type of acute exposure to air pollutants will result.

Moreover, IDEQ's own definition of "ambient air" is "[t]hat portion of the atmosphere, external to buildings, to which the general public has access."[14] The public access road through the project area fits that definition exactly. In addition, IDEQ's Modeling Guidelines[15] for determining the ambient air boundary demonstrate that this public road should <u>not</u> be excluded from the ambient air boundary:

- "It shall be assumed that the air within the facility boundaries is ambient air unless the facility can demonstrate that public access is precluded." Here, although public access might be controlled, it will not be precluded. Filing for required federal permits acknowledges that the Applicant does not have the right to preclude public access across the project site. Thus the road should not be excluded from an ambient air analysis.
- "For the purpose of defining ambient air, the 'general public' is considered anyone not directly associated with the facility. In general, if someone present at the site would not be subject to OSHA or other worker exposure regulations, then they are considered as the general public." People passing through the facility to access public land on the other side of the project area are not "directly associated with the facility" and would not be "subject to OSHA or other worker exposure regulations" and therefore are the general public
- "If the facility is not controlled by a physical barrier AND/OR general public access is not discouraged by the type of area, size of the facility, or the remoteness of the facility location, then the ambient air boundary is determined to be inside the property boundary." The Applicant does not propose a physical barrier. General public access is not discouraged by the items listed above. Access to these public lands is long-standing, an important part of Valley County's recreational experience, and acknowledged in fillings for federal permits.
- "Is the general public allowed on site as a part of a right-of-way easement or a common service road? If "yes," then the right-of-way is determined to be ambient air." The public is allowed access through the site because it is a public road. The Applicant cannot completely preclude public access.

IDEQ precedent, reaffirmed as recently as 2021, makes it clear that a public right-of-way access through a project area is considered – not excluded from – ambient air, and regulatory analyses of the potential impacts along that road must show compliance with all ambient impact limits for averaging periods under one year. This determination has been applied by IDEQ for public roads, non-navigable rivers, and railroad tracks. Here, the general public would be allowed access through the mine site on a public road that the Applicant does not have the right to completely deny access. There is no indication that this public road should be treated any differently from past projects. Nothing in the ambient air impact assessments supporting this permit includes any analysis of the impacts on the road through the project area.

IDEQ should:

- Reassess the ambient air boundary determination and model ambient air concentrations along public access routes.

DEQ Response:

DEQ does not agree with the comment that the road between Stibnite Road at Sugar Creek and Thunder Mountain Road at Meadow Creek should be considered as ambient, as previously explained in DEQ's response to Comment 16. PRI is not obligated to allow access to those seeking passage through the site, and PRI is able to state the conditions of allowed access. In this regard, those passing are guests of PRI in the same manner as those touring the facility as part of a classroom fieldtrip as the road is not a "right-of-way easement."

SILT CONTENT

Comment 37 - EPA: Limiting PTE of the Mining Fugitive Dust Emissions for NAAQS and Title V HAP Purposes

20. IDEQ estimated fugitive dust emissions from haul roads based on a 4.0% surface material silt content.[15] However, the arithmetic average silt content for haul roads based on Perpetua's site-specific data is 4.3%. The silt content value can have a significant impact on the representativeness and conservativeness of the emissions factor and, thus, emissions estimate.[16] Use of the 4.3% average value results in about 7% more fugitive dust emissions from the haul roads than estimated using the median value. IDEQ's modeling sensitivity study showed values just below the NAAQS, such that an 7% increase in fugitive dust from haul roads would have resulted in 24-hour PMl0 NAAQS violations. AP-42 values for similar operations show a wide range of silt fractions, with average values around 8% silt fraction for mine haul roads. The permit record does not include an adequate justification for using the 4.0% silt content figure to derive the fugitive dust haul roads emissions factor and whether a 4.3% is representative for the haul roads including inside the open pits.

DEQ Response:

The use of site-specific median values for silt content is commonly accepted by DEQ, and the values used in calculations were supported by PRI. Metal hazardous air pollutant (HAP) and toxic air pollutant (TAP) emissions from process materials were based on median measured metal concentration profiles from onsite core samples of ore and limestone materials, including 98 samples of PRI limestone and over 55,000 samples of PRI ore. PRI has confirmed that ore samples were taken primarily from the mineralized zones of the PRI pits and were representative for the purposes of estimating emissions. Although a median value of sampled silt percentages of roadway material was used in emission estimates presented in the application, DEQ recognizes the importance of the silt content parameter in the estimation of emissions. Since compliance with the 24-hour PM_{10} NAAQS is the primary driver of NAAQS compliance, minimizing variability of the parameter is very important to ensure NAAQS compliance. To achieve this, the permit will limit *maximum silt content* to 4.0 %, as specified in Section 3.13 Haul Road Capping of the PTC as well as associated monitoring and recordkeeping.

Comment 38 - ICL/SSFS: Silt Content

As IDEQ has acknowledged in their response to comments, there are three key data-based variables used in estimating controlled, unpaved road arsenic emissions: silt content, arsenic content of the silt, and control efficiency. We remain concerned that using a 4% silt content for surface aggregate material for haul roads is too low according to scientific literature. Using a lower than reasonable silt content results in an underestimation of fugitive dust emissions. In its response to comments, IDEQ failed to provide a rationale for why the Applicant’s assumption that a 4% silt content was appropriate in this case when EPA’s publication AP-42 (that IDEQ relies on for other purposes) provides a mean silt content range for industrial unpaved haul roads of 5.8 to 24%.

Table 13.2.2-1. TYPICAL SILT CONTENT VALUES OF SURFACE MATERIAL ON INDUSTRIAL UNPAVED ROADS			
AP-42		All Gravel Road	Haul Roads
	Industry Types	18	4
	No. Sites	53	10
	No. Samples	272	58
	Minimum	4.3%	5.8%
	Maximum	24.0%	24.0%
	Average	10.1%	11.6%
	Median	8.4%	8.4%
	Geomean	8.8%	9.9%

The mean silt content range reported in AP-42 is consistent with other scientific literature. Tannant and Regensberg's *Guidelines for Haul Road Design* (2001), for example, provides guidelines for haul road surface material properties (Section 5.1.1, pg. 58) and recommend a range of 5-10% fines (material passing a #200 sieve). They cite two separate studies stating 5-15% and 5-10% respectively to support this guideline. We have not been able to find any evidence for *functional* haul road surface material having less than 5% silt content. The following table summarizes plausible values for three variables at this site. These values are rated as minimal, typical, and conservative emissions factors.

Comparison of Characteristic Values for Key Variables Used in Calculating Particulate and Arsenic Emissions from Gravel Haul Roads				
Characteristic Values	Silt Content All Gravel Roads	Silt Content Haul Roads	As Content ppm	Control Efficiency % Emitted
AP-42 Minimal	4.3%	5.8%	909	10%
AP-42 Typical	8.8%	9.9%	1231	15%
AP-42 Conservative	10.1%	11.6%	1812	20%
Midas PRI	4%	4%	667	6.7%

In each case, the Applicant has used less than minimal values. Our concern is that reliance on an unrealistically low silt characteristic value combined with the need for extremely aggressive fugitive dust control efficiencies raises the significant likelihood that this permit may exceed National Ambient Air Quality Standards for particulate matter. IDEQ's response to comments simply states that the assumption for a 4% silt content was "confirmed by

no stated rationale
is particular haul

IDEQ should:

- Reassess emissions calculations and fugitive dust control efficiencies using a more realistic silt content for haul roads.

DEQ Response:

The use of site-specific median values for silt content is commonly accepted by DEQ, and the values used in calculations were supported by PRI. Metal hazardous air pollutant (HAP) and toxic air pollutant (TAP) emissions from process materials were based on median measured metal concentration profiles from onsite core samples of ore and limestone materials, including 98 samples of PRI limestone and over 55,000 samples of PRI ore. PRI has confirmed that ore samples were taken primarily from the mineralized zones of the PRI pits and were representative for the purposes of estimating emissions. Although a median value of sampled silt percentages of roadway material was used in emission estimates presented in the application, DEQ recognizes the importance of the silt content parameter in the estimation of emissions. Since compliance with the 24-hour

PM_{10} NAAQS is the primary driver of NAAQS compliance, minimizing variability of the parameter is very important to ensure NAAQS compliance. To achieve this, the permit will limit *maximum silt content* to 4.0 %, as specified in Section 3.13 Haul Road Capping of the PTC as well as associated monitoring and recordkeeping.

PET 595

REC 0961

T-RACT

Comment 39 - ICL/SSFS: T-RACT

In this latest iteration of the permit, the T-RACT control measures were applied to meet human health criteria for airborne toxics. A T-RACT application is an admission that compliance with environmental health criteria is not feasible with reasonably available control technology (RACT). This is in contrast to prior IDEQ assertions that all standards would be met with available technology. The previous submittals also assured the public there were no environmental or health concerns associated with Toxic Air Pollutants (TAPs) compliance. This proposal requests exemptions from those standards. It is both confusing and concerning that IDEQ has modified its position from no significant impact to requiring T-RACT without disclosing the analyses that support these conclusions.

Before granting T-RACT, IDEQ should require the Applicant to address the feasibility of achieving compliance through more aggressive application of the current RACT proposed for particulate control, and require the necessary supporting calculations regarding environmental, cost, and energy impacts. These analyses should be based on appropriate RACT emissions and should identify the levels of control necessary for compliance with the AACC.

For detailed technical comments on T-RACT, we refer IDEQ to Section 8.0 of the comments submitted by Ian von Lindern, P.E. PhD, from the TerraGraphics International Foundation. To summarize his technical comments, IDEQ should disapprove this T-RACT submittal in accordance with IDAPA 58.01.01.14 based on the following considerations:

- The emissions used to support modeling are based on inappropriate multi-year averages and do not reflect the PTE or T-RACT.
- The proposed operational limits on mine production will have no practical constraint on facility operations, emissions, or ambient impacts.
- The lifetime averaging of exposure is inappropriate. Just because this facility proposes to have “only” a 16-year life of mine, the Applicant is not therefore entitled to expend a receptor’s equivalent 70 years of allowable exposure with regards to cancer risk.
- If the direct comparison of predicted maximum annual average ambient arsenic concentrations to the AACC is correctly applied, it shows a 30-factor exceedance, or 3 times the T-RACT AACC.
- Considerably higher levels of operational constraints will be required to support T-RACT. These limits are likely to require reductions in the proposed MODPRO2 levels of operations.
- The T-RACT controls are largely unenforceable, do not require any effective monitoring, or provisions for corrective actions, should the Applicant’s assurances prove unachievable.
- The T-RACT analysis does not address the requirements in IDAPA 58.01.01.210.14.c.ii to access “the environmental impacts caused by the control technology that can not be mitigated, including, but not limited to, water pollution” despite the massive amounts of magnesium chloride and associated products that would be required to achieve the unprecedented dust control effectiveness proposed.

This relaxation of health protections deserves intensive review, public involvement, and consideration by other regulators. We are concerned that the repetitive nature of this PTC review undermines public awareness regarding the significance of this major change in strategy regarding emissions control from this facility as well as the health implications of relaxing health standards.

DEQ Response:

DEQ does not agree with the comment that, “A T-RACT application is an admission that compliance with environmental health criteria is not feasible with reasonably available control technology (RACT).” The established criteria for carcinogenic TAPs is 10 times the listed AACC, and emission controls that are deemed

T-RACT must be used when impacts are greater than the AACC. This is provided by *Idaho Air Rules* Section 210.12.

Initial technical analyses for the SGP attempted to demonstrate compliance with carcinogenic TAP increments without justification that T-RACT will be used for emissions. When it was determined that additional sources had to be included in the arsenic TAP impact modeling analyses, a more refined approach was needed to demonstrate compliance, including demonstrating T-RACT is used to allow the criteria of 10 times the AACC to be used.

DEQ has no regulatory authority to require facilities to utilize other measures before using the T-RACT adjustment. The T-RACT adjustment is provided by *Idaho Air Rules* and can be used at the discretion of permit applicants.

Regarding the bullet list of comments, DEQ has the following responses (in the same order as the comments):

- Carcinogenic AACCs are expressed as annual averages, but as stated in DEQ's response to Comment 27, the definition of *Toxic Air Pollutant Carcinogenic Increments* in *Idaho Air Rules* Section 005.125, states, "Those ambient air quality increments based on the probability of developing excess cancers over a seventy (70) year lifetime exposure to one (1) microgram per cubic meter (1 $\mu g/m^3$) of a given carcinogen and expressed in terms of a screening emission level or an acceptable ambient concentration for a carcinogenic toxic air pollutant." Since the AACCs are based on a 70-year exposure, use of a 5-year averaging period is appropriate.
- DEQ has incorporated requirements to monitor and record operational parameters that are limited by the permit, thereby making them practically enforceable.
- DEQ disagrees with the comment that allowing a lifetime allowable risk to occur over a 16-year mine life is inappropriate. The acceptability criteria is that a facility not pose a cancer risk greater than 1-in-1,000,000 or 1-in-100,000 if T-RACT is used. The annual value of the AACC is provided under the assumption that a facility will emit at such a level on a permanent basis. Since the criteria of Idaho's TAP rules is the risk associated with the project, the time over which that risk is spread is immaterial. If an individual's lifetime total cancer risk were the focus of Idaho's TAP rules, then the rules would have required a cumulative risk assessment, accounting for existing risks at the location of actual receptors.
- The comparison offered, comparing maximum annual impacts to the T-RACT adjusted AACC, is irrelevant. Compliance with TAPs rules was demonstrated through a refined analysis, so there is no utility in focusing on results from a more conservative, less refined analysis.
- How meeting the requirements of the DEQ issued PTC affects proposed MODPRO2 levels of operation is outside the scope of DEQ's permitting process.
- T-RACT controls are included in the PTC as a daily hauling limit based on a 5-year rolling average (Permit Condition 3.5), a life of mine hauling and excavating limit (Permit Condition 3.6), a drilling rigs dust control system (Permit Condition 3.11), and a Haul Road Capping Plan (Permit Condition 3.13). All listed permit conditions have enforceable monitoring and recordkeeping associated with them.
- T-RACT did not address magnesium chloride application on the roads because it was not a proposed control. Magnesium chloride application is addressed in the Fugitive Dust Control Plan in Permit Condition 2.6.

Comment 40 - TIFO: PTC Public review

The initial PTC submittal and IDEQ's position were particularly disappointing. The draft PTC excluded 99.3% of carcinogenic arsenic from regulation and 97.6% of PM emissions from Source Classification. Aside from the disregard for public health and the environment, issuing the initial proposed permit would have had the likely effect of:

-exceedance of criteria pollutant standards,
-arsenic concentrations in the 10^{-3} cancer risk range,
-providing for no monitoring or measurement of critical emissions or ambient impact,
-requiring no corrective actions during operations, and
-precluding federal oversight.

Questioning of IDEQ Staff during public information meetings revealed that these mining friendly determinations depended on:

-unreasonable interpretations of 7E NESHAPS definitions,
-non-conservative estimates of PM emissions and potential control efficiencies,
-minimal estimates of toxic concentrations in PM, and
-exclusions of major sources from permit classification determinations.

The original PTC was an irresponsible proposal and a cause for concern that the Applicant and the environmental/ health agency put it forward. It should not be the responsibility of public reviewers to identify these threats and suggest remedies for these situations. Public entities do not have the resources to repeatedly rebut insufficient industry submittals. The Public depends on IDEQ to ensure health and environmental protection.

Review of the T-RACT (Toxic - Reasonable Available Control Technology) analysis in this third submittal continues the same uncomfortable pattern of minimal, insufficient, and vague calculations; ineffective monitoring; and lack of provisions for enforcement and corrective actions. In the broadest overview, the refined air quality modeling underlying the T-RACT analysis suggests that massive disturbance of toxic arsenic contemplated in the proposed multiple open-pit operation cannot meet air quality criteria in the complex terrain and environmental setting of Stibnite.

The T-RACT Review below also reveals enhanced concerns with respect to insufficiencies pointed out in the previous drafts of the PTC Application. Considerable concern remains with respect to IDEQ's acceptance of the Applicant's assertion regarding three areas of the PTC:

-Estimated Unpaved Road Emissions.
-Facility Source Classification
-T-RACT Review

As a result, these specific concerns are re-iterated and additional comments are found in the following Sections.

DEQ Response:

In accordance with IDAPA 58.01.01.006. a stationary source is defined as any building, structure, facility, emissions unit, or installation which emits or may emit any air pollutant. The fugitive emissions shall not be considered in determining whether a permit is required unless required by federal law. For New Sources Review permitting purposes, the fugitive emissions shall not be considered in determining whether the facility is major unless the facility is a designated facility per IDAPA 58.01.01.008.10.c.i. A gold mine is not a listed designated facility under IDAPA 58.01.01.006.30 and therefore fugitive emissions are not considered. Fugitive emissions of criteria pollutants are counted toward PSD classification from designated

facilities such as the lime plant. Lime plant fugitive emissions are quantified under the PSD Classification section of the Statement of Basis.

For Title V permitting purposes arsenic is a HAP and arsenic fugitive emissions from haul roads do count towards the major source determination of 10 tons per year of any HAP and 25 tons per year for any combination of HAP. Accounting for water and chemical dust suppressant control efficiencies and use of the equations cited from AP-42 Section 13.2.2 (11/2006) for unpaved roads and site-specific silt values supports an arsenic HAP PTE from the haul roads of 30.3 tons per year (T/yr) for uncontrolled emissions (above 20 T/yr as described in the Statement of Basis) and 2.03 T/yr for controlled emissions. Despite the noted limitations of using AP-42, these equations remain commonly used and accepted by DEQ.

As discussed in the Representativeness and Uncertainty of Emissions section above, the estimates of emissions and underlying assumptions were supported to the satisfaction of DEQ, and sufficient information was provided to demonstrate preconstruction compliance with applicable TAP and mercury standards and to support facility classifications. Key assumptions identified in this section and by the commenter (including 93.3% control efficiency for haul roads) were confirmed by PRI and accepted by DEQ and were the basis of the facility classifications.

T-RACT is an emission standard based on the lowest emission of toxic air pollutants that a particular source is capable of meeting by the application of control technology that is reasonably available, as determined by DEQ, considering technological and economic feasibility. T-RACT is an allowable analysis to demonstrate preconstruction compliance for toxic air pollutants (IDAPA 58.01.01.210.12) that PRI has used to demonstrate compliance for arsenic.

How DEQ reviews impacts associated with the proposed SGP is governed by *Idaho Air Rules* pertaining to permit applicability and permit issuance. While commenters may not agree with approaches directed by *Idaho Air Rules*, DEQ does not have latitude to deviate from what is established by rule. Comments suggesting the inappropriateness of approaches mandated by rules are outside the scope of this project and responses will not be provided.

Comment 41 - TIFO: T-RACT Review

T-RACT is an unusual exemption to meeting health criteria undertaken because the facility is unable to comply with health criteria using reasonably available control technology, and the Applicant requests a permit that allows a ten-fold increase in cancer risk. This relaxation of health protections deserves intensive review, public involvement, and consideration by other regulators. There is concern that the repetitive nature of this PTC review undermines public awareness regarding the significance of this major change in strategy regarding emissions control from this facility, and the health implications of relaxing health standards. In that regard, the public should be informed if IDEQ has considered the following questions:

> Is there precedent in Idaho for this relaxation of health standards for a facility of this size?
>
> Have any similar facilities received comparable relief in other jurisdictions?
>
> Has there been any public notice specifically referencing this unusual request and relaxation of health standards?
>
> Have the cancer risk calculations been reviewed by qualified risk assessment personnel?
>
> Has the Agency requested advice or guidance from other environmental or health agencies in the application of the T-RACT?

With regard to the T-RACT analysis and the request for relief, IDEQ regulations define T-RACT as:

> 12. Toxic Air Pollutant Reasonably Available Control Technology (T-RACT). An emission standard based on the lowest emission of toxic air pollutants that a particular source is capable of meeting by the application of control technology that is reasonably available, as determined by the Department, considering technological and economic feasibility. If control technology is not feasible, the emission standard may be based on the application of a design, equipment, work practice or operational requirement, or combination thereof. (5-1-94)

Compliance Feasibility: A T-RACT application is an admission that compliance with environmental health criteria is not feasible with reasonably available control technology (RACT). This is in contrast to earlier Agency assertions that all standards would be met with available technology. The previous submittals also assured the public there were no environmental or health concerns associated with (Toxic Air Pollutant) TAPs compliance. This proposal requests exemptions from those standards. It is confusing that IDEQ has modified its position from no significant impact to T-RACT without disclosing the analyses that support these conclusions.

With regard to *"...if control technology is not feasible ..."*, IDEQ has not demonstrated that it is infeasible to comply with the required ambient air quality standard with the application of RACT. Despite numerous public requests, the Agency has not publicly disclosed the estimated ambient arsenic concentrations associated and with this facility's design capacity PTE arsenic emissions using RACT, nor has IDEQ compared this ambient concentration to AACC carcinogenic risk criteria. This comparison should be presented to document the lack of feasibility, the magnitude of the exceedance at maximum design operations, and to demonstrate the methodology. In this way the public can understand and meaningfully assess the degree of relief the IDEQ is proposing to yield to the Applicant. The correct comparison is the maximum 1-year average ambient concentration calculated through refined modelling, using the maximum 1-year annual RACT PTE, compared to the Section 586 AACC annual standard.

The Statement of Basis should be amended to present the derivation of the RACT facility design PTE, model inputs, and the appropriate ambient concentrations comparison to the AACC.

Determining RACT: The first requirement of a T-RACT analysis is calculation of "… *the lowest emission of toxic air pollutants that a particular source is capable of meeting by the application of control technology that is*

reasonably available…". With regard to determining the *control technology that is reasonably available* for the largest arsenic source, IDEQ accepts the Applicant's contention that RACT is 90% control of road dust through application of chemical suppressants and water; and now contends this level of control is insufficient to meet the TAPs criteria (with no supporting calculation, as noted above). It is curious that the Applicant asserts 90% control for RACT; while simultaneously claiming that 93.3% control is readily achievable, and has committed to that level as reasonable and available to meet PM10 standards without a RACT determination. The Applicant is simultaneously claiming one level of control is readily achievable for compliance with the PM-10 standard, but that same level is not achievable for the arsenic in the same particulate matter.

In justifying the 93.3% control assumption, the Applicant provides support information that this technology can allegedly achieve higher control levels up to 98%. Review of the pertinent research regarding these controls, indicates achieving these levels requires extensive maintenance and massive continuous application of suppressants. If these levels of control are, indeed, achievable, then IDEQ should deny the T-RACT exemption relaxing the cancer risk criteria.

The T-RACT analyses should explore the efficacy, environmental, energy and cost feasibility of more aggressive application of the current technology. The analyses also indicate higher levels of control could be achieved with paved or hard surfaced roads. The Applicant maintains that paving is cost prohibitive and a typical highway design would not support the heavy traffic. The application provides no supporting information for these claims. Neither the RACT nor TRACT feasibility analyses discuss or present the supporting material required by State regulations regarding "*environmental impacts caused by the control technology that cannot be mitigated, energy requirements of the control technology"; or "costs of necessary mitigation measures, capital costs, cost effectiveness, annualized cost of the control technology divided by the amount of emission reduction, difference in costs between the particular source and other similar sources".* All of these supporting analyses are specifically cited in:

> Department of Environmental Quality - Air Quality Division, Toxic Air Pollutant (TAP) Preconstruction Compliance Application Completeness Checklist

IDEQ has noted that this an aggressive control level not previously demonstrated in Idaho. Several commenters have expressed concerns both that this level of control cannot be maintained, and that even higher levels of control will be required if PM emissions are under- estimated. The Section below summarizes concerns related to the insufficiencies in calculating emissions.

There seem to be contradictory IDEQ positions regarding the effectiveness of controls for particulates and arsenic from the same source. Values ranging from 85% to 98% are cited throughout the PTC and support material. The analyses seem to select the most convenient control level depending on the need to demonstrate compliance for the contaminant under review, even for the same physical particle. Does IDEQ have an explicit opinion of the levels of control that are achievable, feasible, and reasonably available for these dust sources? If so, IDEQ should publicly disclose the conservative, average, RACT, minimal, and maximal level of control for these particulate and arsenic sources.

Before granting T-RACT, IDEQ should require the Applicant to address the feasibility of achieving compliance through more aggressive application the current RACT proposed for particulate control, and require the necessary support calculations regarding environmental, cost and energy impacts of these and hard surfaced road options. These analyses should be based on appropriate RACT emissions and should identify the levels of control necessary for compliance with the AACC, as noted above.

Determining RACT Emissions: T-RACT requires calculation of "… *the lowest emission of toxic air pollutants that a particular source is capable of meeting by the application of control technology that is reasonably available…".* Assuming the Applicant's current submittal represents RACT, IDEQ identifies this baseline RACT PTE arsenic emission rate as 0.544 lbs/hr in Table 7 of the TAPS Addendum. Review of the calculations reveals that 0.464 lbs/hr is attributable to Haul Roads. As another example of the confusion regarding control levels, IDEQ states in the SOB that this rate is calculated at 93.3% control, while the supporting spreadsheets

seems to indicate 90% control. As noted in previous comments, this emission rate is not based on conservative data, and has yet to be appropriately estimated. This failure to appropriately calculate RACT emissions exacerbates the insufficiencies of calculating T-RACT limit.

For this reason, additional critiques of this determination are important to highlight. State regulations require PTE to be calculated as follows:

> **02. Quantification of Emission Rates**.
>
> **a.** The applicant may use standard scientific and engineering principles and practices to estimate the emission rate of any toxic air pollutant at the point(s) of emission. (6-30-95)
>
> i. Screening engineering analyses use unrefined conservative data. (6-30-95)
>
> ii. Refined engineering analyses utilize refined and less conservative data including, but not limited to, emission factors requiring detailed input and actual emissions testing at a comparable emissions unit using EPA or Department approved methods. (6-30-95)

For estimating unpaved road fugitive emissions, no option ii) (refined engineering analyses) techniques exist. Emissions are calculated using option i) Screening analyses and unrefined conservative data. In this case, procedures outlined in Section 13.2 of EPA AP-42 unpaved road techniques were applied. IDEQ has acknowledged that the Agency routinely accepts these AP- 42 techniques.

IDEQ's Guidance on Emissions Data Hierarchy: correctly notes that AP-42 calculations are the last choice and "worst data" acceptable for emissions calculations and offer the following warning:

> *AP-42 emissions factors represent the average emissions for a given group of stationary sources or activities. Being averages, AP-42 emission factors must be used with caution because emissions from half of the group of stationary sources or activities may be higher than the emission factor while emissions from the other half of the group may be lower.AP-42 emissions factors are rated A through E; A is considered the most reliable and E the least reliable. The rating of the AP-42 factor must be considered in determining how accurately the AP-42 emissions factor represents actual emissions from the subject source. If industry derived emissions factors are used, they must be accompanied with documentation describing how the emission factor was derived.*
> https://www2.deq.idaho.gov/admin/LEIA/api/document/download/5521

IDEQ acknowledges that AP-42 parameters are averages and 50% of emissions calculated using this technique likely have higher values than those calculated using average EFs. This PTC application uses minimal EFs, indicating >>50% likelihood that emissions are under- estimated. This amplifies the requirement to use conservative data in the interest of health protectiveness, and particularly with respect to carcinogenic air pollutants.

As IDEQ has acknowledged in previous response to comments, there are three key (data- based) variables used in estimating controlled, unpaved road arsenic emissions: silt content, arsenic content of the silt, and control efficiency. The silt content values recommended from AP- 42 are summarized in the following Table:

Table 13.2.2-1. TYPICAL SILT CONTENT VALUES OF SURFACE MATERIAL ON INDUSTRIAL UNPAVED ROADS		
AP-42	All Gravel Road	Haul Roads
Industry Types	18	4
No. Sites	53	10
No. Samples	272	58
Minimum	4.3%	5.8%
Maximum	24.0%	24.0%
Average	10.1%	11.6%
Median	8.4%	8.4%
Geomean	8.8%	9.9%

The silt content observations represent 272 gravel road samples from 53 sites at 18 different industries. Ten (10) sites and 58 samples were obtained specifically from Haul Roads. The minimal mean silt content from any one site was 4.3% and for all gravel roads and 5.8% from Haul Roads. Midas – PRI uses 4.0%. The following Table summarizes plausible values for the three key variables at this site as noted in previous comments. These values are rated as minimal, typical, and conservative EFs.

Comparison of Characteristic Values for Key Variables Used in Calculating Particulate and Arsenic Emissions from Gravel Haul Roads				
Characteristic	Silt Content	Silt Content	As Content	Control
Values	All Gravel Roads	Haul Roads	ppm	%- Emitted
AP-42 Minimal	4.3%	5.8%	909	10%
AP-42 Typical	8.8%	9.9%	1231	15%
AP-42 Conservative	10.1%	11.6%	1812	20%
Midas PRI	4%	4%	667	6.7%

In each case, the Applicant has used less than minimal values. Moreover, these equations are non-linear and variables are multiplicative, exacerbating the degree of under-estimation. IDEQ has in each case accepted the minimal plausible value, despite the requirement that conservative values be used, and IDEQs own guidance includes warnings regarding the uncertainties. The result is that it is likely that emissions are underestimated by several times. It is important to note that, if even a modest increase in PTE for haul roads is acknowledged, this facility will not be able to meet particulate and carcinogenic arsenic standards. Use of any combination of typical or conservative values would likely result in exceedance of particulate and arsenic health criteria.

The potential health related consequences associated with under-estimation of haul road related emissions continues to haunt the PTC and is amplified in the T-RACT analysis.

Calculating the T-RACT Emission Limit: State regulations require that:

> **d.** The T-RACT emissions rate of a toxic air pollutant from a source or modification is calculated using the maximum capacity of the source or modification under its physical and operational design with the effect of: (6-30-95)
>
> i. Any physical or operational limitation other than control equipment that has been specifically described in a written and certified submission to the Department; and (6-30-95)

The T-RACT emission rate should be calculated in the same manner as the original PTE estimates, but allowing for enforceable operational limitations noted in i) above. These operational limitations have the practical effect of reducing the design capacity, and enforcing an artificial ceiling on the facility's ability to pollute. The

T-RACT calculation should then parallel the original PTE analyses, substituting this artificial design capacity. Subsequent Operating Permit conditions should then reflect rigid controls to that ensure the facility will not operate beyond the T-RACT PTE ceiling.

With regard to Haul Road emissions the Applicant offers two operational limitations:

- Limiting long-term mining production to 135,000 T/day (5-year rolling total)
- Capping the haul roads that are outside of the pits and development rock storage facilities (DRSFs) with clean development rock (T-RACT)

The proposed T-RACT emission used by IDEQ is not an operationally constrained equivalent of the PTE determined for the 180,000 TPD design limit used in the original PTC. The current PTC T-RACT analysis uses an inappropriate levels of averaging to modify the calculation. Emissions are calculated based on an apparently arbitrary rolling five-year average mine production rate limit of 135,000 TPD. Although IDEQ accepts this artificial manipulation to support a 25% reduction in modeled emissions and estimated ambient impacts; this limitation has no practical constraint on facility operations, emissions or ambient impacts; and does not reflect PTE under T-RACT. This alleged T-RACT emission limit is not based on a maximum annual rate, or a maximum hourly rate scaled to a maximum annual rate, as required to subsequently compare to an AACC. It is an apparent arbitrary average of 1825 consecutive days of alleged intended operations.

The correct T-RACT emission limit should be the maximum single-year annual PTE rate consistent with enforceable design-equivalent operational constraints, not a rolling average based on good intentions. Because the AACC for carcinogens is an annual incremental standard, there is no specific provision for averaging emissions or ambient concentrations for carcinogenic toxic air pollutants over periods greater than one year. There are provisions for adjusting the AACC for short-term exposures less than the standard basis (<5 year exposures).

> **15. Short Term Source Factor**. For short term sources, the applicant may utilize a short term adjustment factor of ten (10). For a carcinogen, multiply either the applicable acceptable ambient concentration (AACC) or the screening emission rate, but not both, by ten (10), to demonstrate preconstruction compliance. This method may be used for TAPs listed in Section 586 only and may be utilized in conjunction with standard methods for quantification of emission rates (Subsections 210.05 through 210.08).

It should be noted that this calculation specifically excludes simultaneous adjustments to both the emission rates and ambient criteria, as undertaken in the current T-RACT analyses.

Table 7 TAPS Addendum shows the overall decrease in the T-RACT emission limit used by IDEQ in modelling (0.544 vs. 0.232 lbs/hr) reflects a 57% (not a 25%) reduction from the original alleged controlled emission rate. Presumably this reduction reflects both the 25% reduction due to the alleged production limitation, with the remainder due to the low arsenic gravel cover.

These calculations are referenced to an Appendix in the TAPS Addendum, but are not possible to reproduce from the information provided. As such, the efficacy of the additional operational constraints associated with gravel cover is difficult to evaluate. However, it also appears to be based on minimal, rather than conservative, emission factors (i.e., median concentration of contaminants, optimistic control levels, minimal silt content, and no enrichment factor accounting for spillage of high arsenic content ores and development rock fines spilled on the roads).

With respect to the alleged production curtailment, the 135,000TPY mining capacity is not an appropriate operational control for haul road source limits for T-RACT. The MODPRO2 operational scheme uses extensive stockpiling of ores and development rock to effect a near- constant rate of mineral processing activities as shown in Figures 1.2, 1.3 and 1.4 in the STIBNITE GOLD PROJECT, FEASIBILITY STUDY TECHNICAL REPORT, M3-PN170045, Effective Date 12/22/2020 and Figures 3-9 and 3-10 of the STIBNITE GOLD PROJECT: REFINED PROPOSED ACTION – MODPRO2, Perpetua Resources Idaho Inc. October 15, 2021. In contrast, the proposed mine plan initiates and concludes with low rates of ore production and varying rates of

material mined production over the 16 years of alleged life of mine, making a five-year rolling average meaningless in terms of limiting production throughout the complex.

Alleged mine fugitive emissions also include significant on-site hauling associated with Portable Crusher and Screening Plant, lime plant and limestone amendment activities that are months or years removed from mine production; and maintenance, load/unload, watering truck, lime plant, limestone amendments to the gold-refinery, etc. emissions that are applied continually, independent of mine production. These Haul Road and other fugitive emissions are dependent on mineral processing schedules, not mine production. As a result, these should be separately addressed in T-RACT as enforceable operational process rate limitations imposed on milling, refining, and disposal operations, as well as mine production. These sources should also be considered in Source Categorization determinations, as noted above.

Calculating T-RACT Ambient Concentrations: State regulations specify that TAPs increments be calculated as follows:

> **03. Quantification of Ambient Concentrations**. (6-30-95)
>
> **a.** The applicant may use the modeling methods provided in Subsection 202.02 to estimate the ambient concentrations at specified receptor sites for any toxic air pollutant emitted from the point(s) of emission. (6-30-95)
>
> i. For screening modeling, the models use arbitrary meteorological data and predict maximum one (1) hour concentrations for all specified receptor sites. For toxic air pollutants listed in Section 586, multiply the maximum hourly concentration output from the model by a persistence factor of one hundred twenty five one-thousandths (0.125) to convert the hourly average to an annual average. For toxic air pollutants listed in Section 585, multiply the maximum hourly concentration output from the model by a persistence factor of four tenths (0.4) to convert the hourly concentration to a twenty-four (24) hour average. (6-30- 95)
>
> ii. For refined modeling, the models use site specific information. If actual meteorological data is used and the model predicts annual averages for toxic air pollutants listed in Section 586 and twenty-four (24) hour averages for toxic air pollutants listed in Section 585, persistence factors need not be used. (6-30-95)

In order to secure a permit under T-RACT, the Applicant needs to identify enforceable operational limitations that reduce PTE to levels that, when applied through refined modelling, comply with the appropriate AACC. The appropriate comparison under T-RACT is the maximum one-year annual average concentration compared to 10 times the listed AACC. This process is equivalent to PTE modeling of PM pollutants compared to ambient air quality standards. There is no provision for altering or averaging emissions or ambient concentration for intended operations schemes. Similarly, there should be no provision to modify either emissions or the AACC for alleged long-term cancer exposure considerations. The cancer risk calculation is an incremental screening method that looks at the immediate potential impact of the source in the absence of background, past, or future exposures from other sources. As such, both procedures have inherent large margins of safety (i.e., emissions calculated at maximum rates and compared to stringent standards annual maximum concentrations. The 78% life-of-mine (LOM) to receptor lifetime reduction (16 yr LOM/70 yr lifetime) is inappropriate, as this facility is not entitled to consume the remaining 54 years of the receptor's lifetime acceptable exposure during the Applicant's alleged 16 years of operation.

> b. The point of compliance is the receptor site that is estimated to have the highest ambient concentration of the toxic air pollutant of all the receptor sites that are located either at or beyond the facility property boundary or at a point of public access; provided that, if the toxic air pollutant is listed in Section 586, the receptor site is not considered to be at a point of public access if the receptor site is located on or within a road, highway or other transportation corridor transecting the facility.

The ambient concentrations used for the point of compliance are incorrect. Three levels of inappropriate dilution of ambient values are accomplished by IDEQ in alleging compliance with T-RACT. In addition to the inappropriate dilution of emissions noted above, IDEQ inappropriately dilutes ambient concentrations by averaging the results of two scenarios, decreasing the maximum annual average by 41%. This technique is justified on the basis that no one scenario will apply during the life of the mine. A third averaging technique further dilutes the ambient calculation by adjusting the by the ratio of the life of the mine to the assumed lifetime of the receptor. All three manipulations are incorrect.

Once again, IDEQ conflates conservativeness built into the evaluation criteria, with claims of conservatism associated with alleged intended operations. Additionally, the analysis then confuses screening level concentrations with exposure. The correct compliance comparison is the maximum annual ambient concentration to the annual AACC, or T_RACT AACC. There are no provisions for adjusting this concentration to alleged exposures average over multiple years. Any relaxation of health standards on the basis of exposure requires comprehensive risk assessment analyses considering external factors not addressed in the derivation of incremental standards.

The T-RACT analysis accepted by IDEQ seems to be a one-step hybrid of the traditional three step process of risk-adjusted compliance with carcinogenic exposures. The State of Washington, for example, requires a three-tiered analysis formalizing this procedure (Guidance Document First, Second, and Third Tier Review of Toxic Air Pollution Sources (Chapter 173-460 WAC.)

Generally, the first Step requires a relatively simple incremental calculation of ambient concentrations, compared to a conservative risk-based standard or acceptable concentration. These calculations are reviewed and compliance is confirmed if these conservative criteria are met. In this step, the calculation/comparison is the maximum annual concentration compared to the annual AACC and the averaging period is one year. IDEQ never performed, or disclosed, this comparison, which should be accomplished with RACT PTE. As frequently practiced throughout this PTC Application, the required conservative values were modified to reflect lower emission and the AACC was modified to reflect lower concentrations.

These analyses used a non-conservative emission rate, averaged over five years (not one year). It is not possible from the available data to determine how this five-year average compared to the maximum one-year emission rate that should have been used. The overall, reduction appears to be 43% of RACT PTE. The ambient concentration predicted is then additionally reduced by 41% by averaging two different five-year scenarios. Finally, the AACC is reduced by adjusting the result downward by 78% to account for the life of the mine (LOM). This inappropriate triple dilution comparison then alleges compliance.

Direct comparison of the once-diluted emissions predicted annual concentration to the one-year incremental AACC fails by 30-fold (or is 3-fold times the T-RACT AACC). These exceedances are dependent on the once-diluted five-year, non-conservative emission calculations discussed extensively in these comments. Use of required one-year maximum conservative emission calculations, would likely result in orders of magnitude exceedances of the associated one-year maximum concentration T-RACT AACC.

IDEQ should present this calculation.

In a typical carcinogenic risk analyses, the second Step in evaluating the TAPs exemption would apply risk assessment techniques, requiring consideration of receptor and environmental setting characteristics; site history; other sources, including background and potential future increments; susceptible populations, and alternate exposure frequencies and duration, data quality, and uncertainties. This step would transparently address many of the factors allegedly considered in the dilution of the AACC in this PTC analysis.

Revision of the incremental AACC through post-modeling to collectively reflect select factors inherent in the risk assessment/management is neither correct nor transparent, and neglects numerous factors that should be considered in the public interest.

The third Step introduces risk management considerations that would limit emissions sufficiently to effect ambient concentrations consistent with allowable exposures determined in the risk assessment phase (i.e. the T-RACT emission level). This step would consider effective operational limits and controls, establish a *de facto* design capacity, and establish rigid permit limits that would guarantee compliance with the T-RACT AACC.

Even considering these diluted non-conservative emissions used in these analyses, the prospect for complying with carcinogenic risk criteria is doubtful. The modeled results, based on the .232 lbs/hr alleged T-RACT emission rate, indicate that the maximum one-year average ambient air arsenic concentration at the point of compliance is .00698 ug/m^3 under the W-3 scenario. This value exceeds the 10^{-6} AACC for Arsenic of 0.00023 ug/m^3 by 30 times. Applying the allowable T-RACT relief factor of 10 increase in cancer risk indicates a 3-fold exceedance of the appropriate .0023 ug/m^3 maximum annual increment limit. This translates to a required T-RACT emission limit of .232 / (.00698/.0023) = .076 lbs/hr to achieve compliance.

This is an (1-(076/.544)) = 86% required reduction in the under-estimated PTE. In reality, the currently accepted PTE for this facility must be reduced by 86% to achieve compliance through enforceable operational constraints to comply with T-RACT. Even accepting the underestimated PTE as accurate, and assuming that (43-24%) = 19% can be obtained through application of low arsenic road gravel, a 67% reduction is required to be achieved through enforceable production limitations to comply under T-RACT.

This calculation uses the five-year rolling average mining production limitation, offered as an operational control. This proposed operational control both dilutes the emission calculation, and is practically meaningless in limiting emissions and largely unenforceable. The most effective and enforceable limitations would likely be restrictions on annual site-wide VMT limits, rigorously applied to both mineral process-related and mine hauling activities. A 67% annual VMT reduction will require substantial decreases in both mine and process related milling, refining, and disposal operations hauling.

Additionally, IDEQ has argued that the T-RACT controls proposed in the current PTC are conservative citing various levels of mine operation schemes offered by the Applicant. (i.e., 180,000 TPD design rate, alleged135,000 TPD T-RACT rate, 402,859,000 ton LOM alleged MODPRO2 rate), However, the required >67% reduction required to meet T-RACT likely requires limits well below MODPRO2 mine production rates. Developing such a plan would likely require substantial re-evaluation of MODPRP2 strategy.

9.0 ENFORCEABILITY

With regard to air pollution impacts, there are major concerns associated with potential mining and mineral processing fugitive emissions of particulates and arsenic. Unprecedented fugitive emissions control levels will be required to meet NAAQS criteria especially with regard to PM10 compliance. The Applicant is also requesting T-RACT relief from TAPs carcinogenic risk health standards. T-RACT, by definition, asserts that the required PM10 control levels are insufficient to meet carcinogenic risk levels in the ambient air.

There is considerable, if not unprecedented, levels of uncertainty in the magnitude and toxicity of the PTE and T-RACT emission estimates. Should the optimistic emission rates and control levels proposed by the Applicant prove untrue, the facility emissions and subsequent ambient air concentrations will exceed health standards at the facility boundary and result in hazardous exposures to workers, resident worker families, and on-site visitors within the facility.

The proposed Permit Conditions are ineffective in exercising requisite control over these emissions and rely largely on a Fugitive Dust Control Plan, to be developed and implemented later, after issuance of the Permit.

Because this is a proposed T-RACT Site, the Fugitive Dust Control Plan is the primary enforcement mechanism for both NAAQS and TAPs. The control and enforcement strategies for the sources are inextricably linked, as these are the same physical particles. Curiously, NAAQS compliance is achieved by Applicant asserted extra-ordinary (93.3%) controls levels, which is 33% less emissions than the alleged RACT (90.0%), TAPs compliance requires (RACT) and adds operational controls limiting production capacity to achieve emissions

well below design PTE. Whether this is supposedly accomplished at 93.3% or at 90% is unclear, and not trivial as it represents a 33% increase in emissions.

The T-RACT operational controls must be effective in reducing T-RACT emissions to levels that result in meeting the AACC. To effectively reduce these emissions, the operational controls should be aimed at reducing traffic-related fugitive releases. This should be accomplished by the Operator demonstrating the capacity to maintain required Emission Factors (EF)s that will result in NAAQS and T-RACT AACC compliance; and monitoring the ambient environment to assure the necessary control level has been achieved.

As a result, to provide health and environmental protectiveness and ensure enforceability and the effectiveness of the Fugitive Dust Control Plan:

- The facility should be Classified as Major A to ensure federal oversight of the simultaneous NAAQS and TAPs controls, and associated federal review and approval of the Fugitive Dust Control Plan should be required.

- The specific technical specifications, monitoring plan, and corrective action requirements of the Fugitive Dust Control Plan should be explicitly stated as Permit Conditions prior to issuance of the PTC, included in the Operating Permit, and be a condition for State and federal approval.

- The Permit Conditions should include explicit monitoring requirements for ambient air and the key emission factors (EF)s used in estimating PTE and T-RACT emissions. These are roadbed silt content, silt arsenic content, ambient air total PM and PM arsenic content at select property line locations and roadside locations within the facility, ambient PM10 at select property line locations, and VMT for all on-site traffic.

- The operational controls should be daily (PM10 related) and annual (PM and arsenic related) site-wide VMT limits. The operational VMT limits should be tiered, with tier levels related to the monitored EF and ambient concentrations. For example, the initial VMT limits would correspond to maintaining 4% silt content and 90 mg/kg arsenic in the silt. Should these silt and arsenic levels not be maintained, VMT operational limits shall be decreased, proportionately, to a lower VMT limited operational tier. Simultaneously, should PM, PM-arsenic or PM10 monitoring exceed ambient criteria, VMT limits should be lowered accordingly. There should be provisions to refine the tier levels at two year intervals, as site-specific data are obtained.

10.0 **RECOMMENDATION**

With respect to reviewing this T-RACT application, IDEQ is obligated to:

> **e.** If the Department determines that the applicant has proposed T-RACT, the Department shall determine which of the options, or combination of options, will result in the lowest emission of toxic air pollutants, develop the emission standards constituting T-RACT and incorporate the emission standards into the permit to construct. (5-1-94)
>
> **f.** If the Department determines that the applicant has not proposed T-RACT, the Department shall disapprove the submittal. If the submittal is disapproved, the applicant may supplement its submittal or demonstrate preconstruction compliance through a different method provided in Section 210. If the applicant does not supplement its submittal or demonstrate preconstruction compliance through a different method provided in Section 210, the Department shall deny the permit. (6-30-95)

This application is clearly deficient with respect to T-RACT and IDEQ should disapprove the Application for, at least, the following considerations:

- It based on PTE emissions that have not been calculated using conservative emission factors.

- The emissions used to support modeling are based on inappropriate multi-year averages and do not reflect PTE or T-RACT.

- The proposed operational limits on mine production will have no practical constraint on facility operations, emissions or ambient impacts.

- The post-model multi-year and lifetime averaging of exposures are inappropriate, as this facility's 16-year life of mine is not entitled to expend a receptor's equivalent 70- year of allowable exposure.

- Correctly applied, direct comparison of predicted maximum annual average ambient arsenic concentrations to the AACC shows a 30 factor exceedance, or 3 times the T- RACT AACC.

- Considerably higher levels of operational constraints will be required to support T- RACT. These limits are likely to require reductions in the proposed MODPRO2 levels of operations.

- The Permit Conditions are largely unenforceable, do not require any effective monitoring, or provisions for corrective actions, should the Applicant's assurances prove unachievable.

DEQ Response:

How DEQ reviews impacts associated with the proposed SGP is governed by *Idaho Air Rules* pertaining to permit applicability and permit issuance. While commenters may not agree with approaches directed by *Idaho Air Rules*, DEQ does not have latitude to deviate from what is established by rule. Comments suggesting the inappropriateness of approaches mandated by rules are outside the scope of this project and responses will not be provided.

As discussed previously, although some degree of uncertainty is present in all emission factors used in estimation emissions, all emission factors were adequately supported and the approach of estimating PTE at design capacity for combustion sources and at maximum throughputs for process sources was considered a conservative approach. The use of representative performance test data was determined to be valid and accepted by DEQ.

T-RACT is an emission standard based on the lowest emission of toxic air pollutants that a particular source is capable of meeting by the application of control technology that is reasonably available, as determined by DEQ, considering technological and economic feasibility. T-RACT is an allowable analysis to demonstrate preconstruction compliance for toxic air pollutants (IDAPA 58.01.01.210.12) that PRI has used to demonstrate compliance for arsenic.

Carcinogenic AACCs are expressed as annual averages, but as stated in DEQ's response to Comment 27, the definition of *Toxic Air Pollutant Carcinogenic Increments* in *Idaho Air Rules* Section 005.125, states, "Those ambient air quality increments based on the probability of developing excess cancers over a seventy (70) year lifetime exposure to one (1) microgram per cubic meter (1 $\mu g/m^3$) of a given carcinogen and expressed in terms of a screening emission level or an acceptable ambient concentration for a carcinogenic toxic air pollutant." Since the AACCs are based on a 70-year exposure, use of a 5-year averaging period is appropriate.

DEQ has incorporated requirements to monitor and record operational parameters that are limited in the permit, thereby making them practically enforceable.

OTHER COMMENTS

Comment 42 - ICL/SSFS: Mining/Processing Throughput Limits

The draft permit contains several throughput limits as defined in Permit Conditions 3.5 and 3.6. These conditions are artificial production limits on the facility, and will not have a bearing on the actual emissions being produced once the mine is simultaneously mining and also processing from stockpiled material. We have concerns that these artificial production limits are not actually enforceable in any way by IDEQ. Furthermore, we do not have any assurances that these artificial production limits will remain the same throughout the entire life of mine. For example, Figure 3.9 of the proposed mine plan[17] initiates and concludes with low rates over the 16 years of the mine with higher rates in the middle, making a five-year rolling average (like what is proposed in Permit Condition 3.5) meaningless in terms of limiting production.

Permit conditions should also be developed that establish throughput limits on the refining facilities and haul roads themselves, not just hauling and excavation tonnages. This is because the design capacity of the refining facilities exceeds the mine production capacity, and new ore could theoretically come in from other sources and be refined/processed at Stibnite. Without specific throughput limits on the refining process, those added emissions would not be considered.

Lastly, because IDEQ treats TAPs emissions on an incremental rather than cumulative basis, we can envision problems arising in a scenario where this facility gets permitted at the current throughput limits but then asks for an expansion five years down the road. If they are then permitted for an expansion, any increases in TAPs emissions will be permitted on a standalone basis rather than cumulatively on top of what was initially permitted. Ultimately, we are concerned that this is an approach the Applicant could use to circumvent being permitted as a TAPs Major Source in this initial PTC.

IDEQ should:

- Indicate how they plan to enforce these throughput limits and include additional measures in the permit to this effect.
- Add throughput limits for the refining and processing facilities.

DEQ Response:

27 As discussed previously in the Representativeness and Uncertainty of Emissions section, maximum hourly and daily activity rates were used to estimate the maximum 24hour and annual emission rates, and fugitive dust control requirements, emission rate limits, material activity rate limits, and supporting testing and monitoring, recordkeeping, and reporting (MRR) requirements were established as synthetic minor limits for the purposes of limiting facility-wide emissions of $PM/PM_{10}/PM_{2.5}$ to below 250 T/yr PSD applicability thresholds and Title V 100 T/yr applicability thresholds. These limits were also established for the purposes of limiting facility-wide emissions of single and total HAP to below HAP major source applicability thresholds (10/25 T/yr), and to ensure compliance with all NAAQS. Limits were established consistent with current DEQ guidance and the estimates of emissions and underlying assumptions were supported to the satisfaction of DEQ.

28 Enforceable monitoring, recordkeeping, and reporting requirements were established in the permit. $PM/PM_{10}/PM_{2.5}$ emissions limits for point sources were established with supporting activity rate limits and MRR requirements. While emissions limits and emission factors are not commonly included in the permit for fugitive sources, activity rate limits and MRR requirements were established for those sources that were identified as process rate-limiting (as summarized in Table 1.1 of the permit). These activity rate limits serve as surrogate emissions limits for PM, PM_{10}, $PM_{2.5}$, HAP and TAP from fugitive sources. Any emission increases or changes proposed after permit issuance will need to be evaluated as to whether they may require modification or revision of the PTC.

Comment 43 - NPT: Adverse impacts of dust control abatement on other resources

The Tribe is concerned about the impacts of dust abatement chemicals on soils, vegetation, and wildlife. As it is DEQ's mission to protect human health and the quality of Idaho's air, land, and water, the Tribe is including this concern with these comments on the PTC.

Magnesium chloride (MgCb) and MgCh-lignin sulfonate products used to suppress dust on roadsides can damage vegetation foliage, alter soil quality, move in roadside drainages of up to 98 m from roads, and accumulate over time, often to toxic concentrations, in trees and soils.[1] High MgCh soil concentrations from application caused mortality of Douglas-fir, lodgepole, ponderosa, and limber pines, and aspen in just two to four years.[2] Considering the life of the Project, the Tribe is concerned about long-term consequences to soils and vegetation from dust abatement chemicals.

Water is a scarce commodity in the project area. We are concerned that the limited quantity of water available is insufficient to meet permit conditions for use of water in fugitive dust control and water spraying for ore processing, and aggregate and concrete production. The quality of water is also a concern. The water source for dust control is proposed to be surface water diversion from the East Fork of the South Fork of the Salmon River, groundwater, and runoff ponds. USGS sampling indicates elevated arsenic in these waters.[3] Water quality should not create additional environmental burden if contaminated waters are used to water roads. This should have been considered in the T-RACT determination as described in IDAPA 58.01.01.210.14.

DEQ Response:

As described in the Technical Analysis section of the Statement of Basis and supporting documents, the proposed emissions and impacts of criteria, hazardous, and toxic air pollutants from various sources at the facility were evaluated by DEQ and determined to comply with applicable preconstruction requirements required for issuance of a permit to construct (PTC).

Comment 44 - NPT: Process flow description does not reflect applicant operations

Statement of Basis Facility Information Description and Figure 2 DIAGRAM OF PROCESS FLOWS are not updated to reflect Project operations.

DEQ Response:

Figure 2 in the Statement of Basis is representative of the processes modeled for compliance with the NAAQS which includes processes Sb1 and Sb2. The processes were removed from the permit, and no HAP or TAP emissions will be generated in the new Sb circuit.

Comment 45 - NPT: Limestone values are misleading

The limestone mineralogy is expressed as median concentration values from 98 samples, yet it appears that all 98 samples came from one single core MGI-17-431. This is misleading, and we question if the metal concentrations used in the emissions inventory coming from the 55,000 ore samples are also incorrectly characterized.

DEQ Response:

As described previously in the Representativeness and Uncertainty of Emissions section, metal hazardous air pollutant (HAP) and toxic air pollutant (TAP) emissions from process materials were based on median measured metal concentration profiles from onsite core samples of ore and limestone materials, including 98 samples of PRI limestone and over 55,000 samples of PRI ore. PRI has confirmed that ore samples were taken primarily from the mineralized zones of the PRI pits and were representative for the purposes of estimating emissions. PRI

has confirmed that the use of mineralized metal profiles is conservative when compared to low-mineralization materials such as development rock and clean gravel and it is pretty typical that approximately 100 samples come from each core.

Comment 46 - NPT: No accounting for winter impacts on water controls

Permit condition 3.12 requires water control for ore processing crusher and conveyer at all times. Permit condition 5.10 also requires water control for portable crushing and screening at all times. When water freezes during low temperatures, water control will not be feasible. Therefore, each ore processing crusher and conveyor (3.12) and each portable crushing and screening plant (5.10) should not operate at temperatures below freezing or there will be no control of fugitives from these emission units (EUs). If any chemical(s) is added to the water to lower freezing and thus extend ability to use water control, they and their effects should be disclosed. Please address these concerns about freezing-weather operations for these permit conditions.

DEQ Response:

As discussed previously in the response to comment 3, modeling analyses for the project, prior to refined adjustments, shows all modeled PM_{10} violations occur during the winter (Statement of Basis, Appendix B) where emissions and background levels are likely overestimated. Data provided in the SGP baseline study specify an average snow depth of 21-68 inches and an average precipitation of 6.0 inches at the project site during this period. Therefore, fugitive dust emissions from emission units and roads during high-modeled impact hours could be overestimated. Permit condition 3.12 references Permit conditions 2.1 through 2.6. Permit condition 2.6 requires a FDCP which at a minimum contains requirements to apply water or suitable dust suppressant chemicals to transfer points, screening operations, and crushing operations as necessary to control fugitive dust.

Comment 47 - NPT: Clarification needed on 3.9 Prill Loading Limit

Permit condition 3.9 Prill Loading Limit is unclear: "The permittee shall not load in excess of 200 T/day nor and 9,000 T/yr of prill (ammonium nitrate) to the prill silos." The use of"nor and" is confusing. Please clarify the intent of this section.

DEQ Response:

As a result of the public comment, Permit Condition 3.9 has been revised to remove “nor”. The permit condition is intended to limit the prill loading to 200 T/day and 9,000 T/yr.

Comment 48 - NPT: Comments on Table 1.1 Regulated Sources

Table 1.1 in the permit lists all sources of regulated emission in the permit. For clarity it would be easier to follow the permit and check limits for all the EUs if their Source ID No. were carried over from Table 1.1 to the remaining tables throughout the permit. Additionally, it is unclear if the control efficiency and maximum process rates listed in Table 1.1 are enforceable. The comments that follow are from checking the source ID listed in Table 1.1 for consistency in the permit and Statement of Basis.

- For the Mercury Retort and Induction Melting Furnace, Table 1.1 has a maximum process rate of 1,000 lb/batch and 21 T/yr. Monitoring in permit conditions 4.22 and 4.23 does not include monitoring of batch rather only weight is monitored. If only weight is recorded there is no criteria to measure compliance with the batch limitation.
- The emission units LS9-LS12 are missing a permit operating limit to ensure maximum process rate of 267 T/day.
- Statement of Basis application scope lists PS in ore processing. Assuming PS is PS1-2- L/U, in Table 1.1 of the permit, they (PS1-2-L/U) are listed under mining.
- Rock dumps and storage piles are missing from the Statement of Basis application scope.

- In Table 1.1 of the permit all mining sources except Prill Silos (PS1-2-L/U) have FCDP listed as Control Equipment. In Table 3.1 Mining and Ore Processing Control Device Descriptions some sources retain the FDCP as a listed Control Equipment (Drilling and Blasting) while others do not (Excavating and hauling activities) and some sources do not appear at all in Table 3.1 (rock dumps and storage piles).
- Although there is a facility-wide fugitive dust control and permit conditions 3.10 and 5.9 direct permittee to control fugitive dust, Reasonable Control and FDCP are listed in Table 1.1, but are missing from corresponding Tables for Control Description Descriptions for the following EUs: OC1-OC13, PCSP1, PCSP2, CM.
- For EUs EDG1-3 in Table 1.1, please allow for better performance control equipment, we suggest modifying EPA Tier 2 technologies to "EPA Tier 2 technologies or better".

DEQ Response:

The Mercury Retort and Induction Melting Furnace have a design limit of 1000 lb/batch as seen in the application. The monitoring requirements in Permit Conditions 4.22 and 4.23 require monitoring in lb/day. The mercury retort runs for 24 hours so therefore lb/batch and lb/day are the same measurement.

Lime production limits for LK, LCR, and LS-L/U are limited by the Parallel Flow Regenerative Kiln output limit in Permit Condition 5.5. As can been seen in the Lime Production Flow Diagram in the application, 267 tpd in the maximum capacity and input to the Kiln (LS9-LS12). DEQ chose to limit the output of the Kiln as seen in Permit Condition 5.5 (169 T/day).

As a result of the public comment, rock dumps and storage piles have been added under the Statement of Basis' application scope section to ensure all activities are included. Prill silos have been moved from ore processing operations to the mining activities under the Statement of Basis' application scope section to ensure consistency with Table 1.1 of the PTC.

As a result of the public comment, Table 3.1 of the PTC has been revised to include reasonable control and FDCP as control devices for the excavating and hauling activities as well as all other emission sources in the Table (OC1 – OC13). Rock dumps and storage piles have been added to Table 3.1 with the corresponding control devices of reasonable control and FDCP. Table 5.2 has been revised to include reasonable control and FDCP as control devices for the Aggregate Production Plant Emissions Units/Processes (PCSP1 and PCSP2) as well as the Central Mix Plant (CM). The Prill Silos (PS1-2-L/U) are not controlled under the FDCP as the material can be explosive and are treated differently.

Emission units EDG1-3 in Table 1.1 are specified to be EPA Tier 2 certified engines but there is no prohibition on the units meeting emissions limits more stringent than those required of EPA Tier 2 certified engines.

Comment 49 - TIFO: Conclusions of fourth comment submittal

- Each of the Permit to Construct (PTC) applications and Operating Permits proposed to date have lacked an objective treatment of potential emissions and ambient impacts.
- The initial proposals largely ignored massive emissions of toxic and hazardous air pollutants.
- Revisions of the PTC analyses have shown that approval of the previously proposed permits would have allowed significant exceedances of health standards; with no provision for monitoring, measurement, corrective action, or opportunity to seek federal relief.
- Significant emission sources excluded from Source Classification calculations as mining fugitive emissions could be mis-classified and considered as attendant to included mineral processing point or federally listed sources. IDEQ should carefully review these sources for inclusion in total emissions compared to Major Source thresholds.
- Significant under-estimation of haul road fugitive PTE emissions continues in this PTC. The estimates are not conservative as required by Idaho Code. IDEQs claim the Applicant's intentions to operate below design capacity is not a conservative emission estimate. Calculating PTE at design capacity has been

standard practice since the inception of the Clean Air Act. IDEQ conflates this long-held principle with the requirement to use conservative data in estimating AP-42 unpaved road emission estimates.

- The current proposed PTC continues to underestimate potential emissions, but acknowledges when using these minimal estimates, that compliance with health standards is not achievable with reasonably available control technologies (RACT).
- This application requests T-RACT relief from compliance with the cancer-related health standards, in contrast to the previous PTC version assertions of meeting all standards and being protective of public health, using the same controls.
- The additional operational controls (T-RACT) offered to guarantee meeting the relaxed standard require reducing the facility's allowable emission by 57%. Both the calculations supporting the required emission reduction and efficacy of the underlying operational controls are insufficient, rely on inappropriate averaging and dilution techniques, and impose no enforceable reduction in emissions or ambient air quality improvements. Greater reductions in emissions and substantial production curtailments will be required to achieve compliance.
- Alleging compliance with carcinogenic health risk standard in this PTC required multiple dilution techniques including i) using non-conservative emission factors, ii) requesting T-RACT relief from the health standard, iii) inappropriate averaging of T- RACT arsenic emissions, and iv) two levels of inappropriate post-modeling averaging of ambient air concentrations; resulting in order-of-magnitude under-predictions of arsenic exposures.
- The refined air quality modeling underlying the T-RACT analysis suggests that the massive disturbance of toxic arsenic contemplated, in this proposed multiple open-pit mining and co-located mineral processing operation, cannot meet air quality criteria in the complex terrain and challenging environmental setting of Stibnite.
- This is the third draft attempt to bring this insufficient PTC application into compliance. In the public interest IDEQ should dis-approve the PTC and require a new Application that objectively presents the emissions and controls required to comply with State and federal requirements.

DEQ Response:

29 As discussed in previous responses, maximum hourly and daily activity rates were used to estimate the maximum 24hour and annual emission rates, and Fugitive Dust, Emissions Limits, material activity rate limits, and supporting testing and monitoring, recordkeeping, and reporting (MRR) requirements were established as synthetic minor limits for the purposes of limiting facility-wide emissions of $PM/PM_{10}/PM_{2.5}$ to below 250 T/yr PSD applicability thresholds and Title V 100 T/yr applicability thresholds. These limits were also established for the purposes of limiting facility-wide emissions of single and total HAP to below HAP major source applicability thresholds (10/25 T/yr), and to ensure compliance with all NAAQS. Limits were established consistent with current DEQ guidance and the estimates of emissions and underlying assumptions were supported to the satisfaction of DEQ.

30

DEQ contends that the operational limits on mine production are sufficient, reasonable, and appropriate to ensure compliance with applicable requirements including National Ambient Air Quality Standards (NAAQS) at a sufficient level of confidence to support permit issuance. Relevant conditions include material throughput and operational limits (Permit Conditions 3.3-3.9, 4.5-4.12, 5.4-5.9, 6.3), emissions limits (Permit Conditions 4.3-4.4, 5.3), control device requirements (Permit Conditions 3.10-3.12, 4.13-4.17, 5.10-5.16), and testing (Permit Condition 4.33) requirements. To ensure enforceability of each of these requirements, supporting testing and monitoring, recordkeeping, and reporting (MRR) requirements were also included.

In accordance with IDAPA 58.01.01.006. a stationary source is defined as any building, structure, facility, emissions unit, or installation which emits or may emit any air pollutant. The fugitive emissions shall not be considered in determining whether a permit is required unless required by federal law. For New Sources Review permitting purposes, the fugitive emissions shall not be considered in determining whether the facility is major unless the facility is a designated facility per IDAPA 58.01.01.008.10.c.i. A gold mine is not a listed designated facility under IDAPA 58.01.01.006.30 and therefore fugitive emissions are not considered. Fugitive emissions of criteria pollutants are counted toward PSD classification from designated

facilities such as the lime plant. Lime plant fugitive emissions are quantified under the PSD Classification section of the Statement of Basis.

For Title V permitting purposes arsenic is a HAP and arsenic fugitive emissions from haul roads do count towards the major source determination of 10 tons per year of any HAP and 25 tons per year for any combination of HAP. Accounting for water and chemical dust suppressant control efficiencies and use of the equations cited from AP-42 Section 13.2.2 (11/2006) for unpaved roads and site-specific silt values supports an arsenic HAP PTE from the haul roads of 30.3 tons per year (T/yr) for uncontrolled emissions (above 20 T/yr as described in the Statement of Basis) and 2.03 T/yr for controlled emissions. Despite the noted limitations of using AP-42, these equations remain commonly used and accepted by DEQ.

As discussed previously in the Representativeness and Uncertainty of Emissions section above, the estimates of emissions and underlying assumptions were supported to the satisfaction of DEQ, and sufficient information was provided to demonstrate preconstruction compliance with applicable TAP and mercury standards and to support facility classifications. Key assumptions identified in this section and by the commenter (including 93.3% control efficiency for haul roads) were confirmed by PRI and accepted by DEQ, and were the basis of the facility classifications.

T-RACT is an emission standard based on the lowest emission of toxic air pollutants that a particular source is capable of meeting by the application of control technology that is reasonably available, as determined by DEQ, considering technological and economic feasibility. T-RACT is an allowable analysis to demonstrate preconstruction compliance for toxic air pollutants (IDAPA 58.01.01.210.12) that PRI has used to demonstrate compliance for arsenic.

SECOND PUBLIC COMMENT PERIOD

DEQ provided a second public comment period on the proposed PTC for PRI from February 18 – March 19, 2021, in accordance with IDAPA 58.01.01.209.01.c. During this period, comments were submitted in response to DEQ's proposed action. Public comments regarding the technical and regulatory analyses and the air quality aspects of the proposed permit are summarized below. Questions, comments, and suggestions received during the comment period that did not relate to the air quality aspects of the permit application, the Department's technical analysis, or the proposed permit were not addressed. It is also noted that many of the topics discussed during the second public comment period were addressed in the third public comment period and therefore have not been included below.

Comment 1 – A. Michaels: Environmental impacts

DEQ seeks comment on draft permit to construct for Midas Gold Idaho Inc.'s Stibnite Mine. I am reading through the Statement of Basis and seeing things like chemical treatment (lime, caustic soda, hydrogen peroxide, copper sulfate, etc.), lime production, concrete manufacturing, diesel, gas, and more. Seriously? Do we want to introduce these things into this area - again and in excess of what was likely used in the mining process in the past? Have you seen the other mine sites around the area (Cinnabar) and how horrible they look? The environmental toll is devastating. Please don't allow more mining in this area. Let this area heal from the wounds already inflicted rather than add more.

And Meadow Creek runs right through the site which flows to a high mountain like, Meadow Creek Lake. Please consider the aquatic species, birds, and other animals that drink and or live in the water that will be impacted by the mine operation.

DEQ Response:

As described in the Technical Analysis section of the Statement of Basis and supporting documents, the proposed emissions and impacts of criteria, hazardous, and toxic air pollutants from chemical treatment, lime production, concrete manufacturing, and diesel and gas storage and combustion were evaluated by DEQ and determined to comply with applicable preconstruction requirements required for issuance of a permit to construct (PTC).

Comment 2 – PRI: Cyanide emissions and monitoring

General Comment: Conditions in the draft permit to construct for cyanide emissions were first reviewed by Perpetua during this public comment period. The Department proposed an annual emissions limit for cyanide of 1.99 tons per year (Proposed Condition 4.4) and proposed operating constraints atypical of other mining projects (Proposed Condition 4.5). The proposed emission limit reflects Perpetua's estimate of actual emissions during normal operations, as presented in the application. Perpetua requests an emissions limit that ensures compliance with the minor source threshold for hazardous air pollutants (<10 tons per year) and affords operational flexibility. In addition, Perpetua requests a monitoring approach to collect data (pH and free cyanide concentrations) to use in calculations that confirm compliance with the emission limit. Specific language is suggested below to revise Proposed Conditions 4.4 and 4.18. Consistent with this approach Perpetua requests deletion of Proposed Condition 4.5 and Table 4.3 that impose process limits on pH and free cyanide because these values may vary during normal operations (making compliance with operating limits challenging); however, Perpetua can control operations to ensure compliance with the annual HAP emissions limit.

Specific Comments: To ensure compliance with the HAP minor source emissions limit, Perpetua proposes the revisions to proposed sections noted below, plus deletion of the operational constraints.

Emission Limits

4.4 Cyanide and Carbon Disulfide Emissions Limits

Facility-wide emissions shall not exceed 0.063 tons per year of carbon disulfide and 2.4 tons per year of cyanide

compounds. Compliance with the annual 2.4 ton per year limit shall be demonstrated on a rolling twelve-month basis as prescribed in Condition 4.18.

[Justification for revised emission limit: the revised emission limit establishes a compliance margin consistent with DEQ practice of approximately 20% over the actual emission during normal operations presented in the Application.]

Operating Limits [Perpetua proposes deletion of Proposed Condition 4.5 and Table 4.3]

[Justification for deleted operating limits: mines are not typically required to adhere to pH and free CN enforceable limits because the process conditions and material characteristics are variable; demonstrating compliance with the new emission limit in Proposed Condition 4.4 (2.4 tons per year) is now reflected in Proposed Condition 4.18 (Monitoring and Recordkeeping).]

Monitoring and Recordkeeping

4.18 Cyanide Specifications Monitoring

Each day, the permittee shall monitor and record the pH and free cyanide concentration level(s) in grams per cubic meter (g/m^3) from each cyanide leach and detox tank and use this information to determine compliance with the 2.4 tons per year emissions limit in Condition 4.4.

Each month, the permittee shall monitor and record the pH and free cyanide concentration level(s) in grams per cubic meter (g/m^3) from each tailings reclaim stream and use this information to determine compliance with the 2.4 tons per year emissions limit in Condition 4.4.

The recorded daily and monthly information shall be used to determine compliance with the 2.4 tons per year emissions limit in Condition 4.4 on a rolling twelve-month basis using Equation 1:

Equation 1

$$r_v = k_g \alpha_0 C_l H A F_a F_w$$

Where,

r_v = hydrogen cyanide emissions from surface (g/s)

k_g = gas phase mass transfer coefficient (m/s)

α_0 = non-ionized cyanide fraction determined from pH and pK_a (ionization coefficient)

C_l = total liquid phase free cyanide concentration (g/m^3)

H = Henry's Law Coefficient (g/m^3 per g/m^3)

A = process surface area (m^2)

F_a = area factor

F_w = wind factor

The devices and methodologies used to measure and free cyanide concentration, pH, and other variables of Equation 1 shall be identified in the O&M Manual.

[Justification for revised monitoring and recordkeeping: recording operating parameters and calculating emissions on a rolling 12-month basis will confirm continuous compliance with the new (2.4 tons per year) cyanide emission limit in Proposed Condition 4.4.]

DEQ Response:

Permit Condition 4.18 (cyanide emissions limit compliance monitoring) and Permit Condition 2.20 (O&M manual requirements) were updated consistent with the request for emissions tracking for operational flexibility. For clarification purposes, Permit Condition 4.5 (facilitywide carbon disulfide emissions limit) was separated

from Permit Condition 4.4 (facility-wide cyanide emissions limit); both limits remain unchanged and were established consistent with emissions estimates included in the application.

All emissions limits, reagent usage, and process limits in the permit were established based on the emissions estimates presented in the application as potential emissions (PTE). It was considered reasonable and appropriate to allow for monitoring of actual process parameters and monthly estimation of emissions to comply with the facility-wide cyanide emissions limit. With emissions tracking, although pH and concentration process limits were removed, monitoring of these and temperature were included on a daily basis to ensure that all inputs necessary for calculating emissions are monitored. The equation for estimating cyanide emissions was included and variables cited in the O&M manual requirements.

Comment 3 – PRI: Editorial corrections

*General Comment***:** Perpetua requests several editorial corrections for proposed permit terms.

Specific Comments: The Source ID No. and Source description lists "CIP Leach 1-4 Carbon-in-Pulp Leach Tanks," "CIL 1-6 Carbon-in-Leach Tanks," "CIP 1-6 Carbon-in-Pulp Tanks," and "CN Detox 1-2 Cyanide Detox Tanks" (Proposed Condition 1.2). To provide configuration and operational flexibility, Perpetua requests that this equipment be grouped under a single Source ID No. labeled "CN Tanks" with a single Source description of "Cyanide Leach and Detox Tanks" as shown below.

Source ID No.	Source	Control Equipment	Maximum Process Rate
CN Tanks	Cyanide Leach and Detox Tanks	Chemical Treatment for maintaining pH	n/a

A maximum process rate is listed with the CIL and CIP tanks of "1,700 T/yr PAX" (Proposed Condition 1.2). This information more appropriately fits with the floatation circuit. Please revise as shown below.

Source ID No.	Source	Control Equipment	Maximum Process Rate
Float Tanks	Floatation tanks	None	1,700 T/yr PAX

Please revise Proposed Condition 2.20, Bullet 6 of 7 to read: "Permit Conditions 3.53.8, 4.8, 4.12, and 5.45.8." Please revise Proposed Condition 2.20, Bullet 7 of 7 from "each tailings stream" to "each tailings reclaim stream." The reclaim streams are used to measure the bulk solution of the tailings facility.

DEQ Response:

Permit Conditions 1.2 (Table 1.1) and 2.20 were updated. Updates were consistent with potassium amyl xanthate (PAX) being used and carbon disulfide emitted in the floatation circuit, and cyanide being used and emitted in the cyanide leach tanks, detox tanks, electrowinning cells and pregnant solution tank, and barren tanks. The referenced permit numbers and description of the tailings reclaim streams were also updated as requested, and correction made that the rate monitored for the electrowinning cells and pregnant solution tank is a volumetric flow rate. The emissions calculations associated with reagent usage were presented as potential emissions (PTE) in the application, and as such increasing the facilitywide emissions limit for cyanide and compounds to accommodate a surplus compliance margin was not supported.

In implementing emissions tracking as described in the response to the previous comment, monitoring and recording of parameters necessary for estimating emissions from the Cyanide Leach Tanks and Cyanide Detox tanks was also required (e.g., quantity of tanks, tank dimensions, pH, temperature, and cyanide concentration).

Comment 4 – SSFS: Non-carcinogenic TAP analyses underestimated the emissions rates of acute exposure to iron and aluminum from fugitive dust.

The basic underpredictions of fugitive emissions due to the use of unreasonably low silt content value, as

discussed above, indicate that the true potential to emit other IDAPA § 585 TAPs, such as iron oxides and aluminum, could also be significantly underpredicted. Calculations of IDAPA § 585 TAP increments also suffer from cherry-picking of data so as to make it appear that emissions will comply with the stated increments in IDAPA §58.01.01.585.

According to IDEQ guidance, IDAPA § 585 TAPs exposure limits should be calculated from the maximum potential impacts over 24 hours for comparison against the acute impact limits. Modeling pollutants with short-term ambient air standards requires the use of a potential emissions rate that occurs over the duration of that averaging period, which for IDAPA § 585 TAPs is a maximum daily emissions. This would require conservative estimates that are well above the median rate of emissions; in other words, emission rates should be based on a concentration much higher than the median, and closer to the 90th percentile of the concentration of the pollutant in the source material.

The analyses of the short-term effects of iron and aluminum emissions here, however, were based on the median concentrations of those metals in the development rock samples in the assays, thus potentially significantly underestimating the predicted emission rates. Additionally, compounding factors, such as an underestimation of silt content value, enrichment from physical effects of heavy road traffic, and deposition (which increases TAP concentrations in surface materials over time), and basing emissions on PM rather than PM10, have all contributed to an underestimation of emission rates.

Moreover, it is unclear - because there is no development rock management plan and no specified preferred alternative by the Forest Service - exactly what material will be used for haul roads. As discussed above, one alternative in the DEIS proposes using development rock as well as spent ore disposal area material, while the MODPRO2 - which is yet to be evaluated by the Forest Service - only mentions the use of development rock. This uncertainty and lack of planning calls into question the data presented in the permit to construct and Statement of Basis.

The data presented in the application for the permit to construct already indicate that ambient air concentrations of iron will increase by 14.1%, and 5.5% for aluminum. IDEQ's review of these analyses in the Statement of Basis indicates impacts as high as 27% for iron and 10% for aluminum. It is likely, based on the discussion above, that a new analysis of the impacts of iron and aluminum would show that emissions would cause exceedances of the ACC ambient impact limits that go beyond the emission limits established in IDAPA 58.01.01.585 for non carcinogenic TAPs, creating a noncompliant ambient impact and unacceptable public health inhalation risk.

Conclusion

Based on the comments above, SSFS asks that IDEQ deny this draft permit to construct.

DEQ Response:

As discussed previously in the Representativeness and Uncertainty of Emissions section, the estimates of emissions and underlying assumptions were supported to the satisfaction of DEQ, and sufficient information was provided to demonstrate preconstruction compliance with non-carcinogenic TAP requirements. Key assumptions identified in this section and by the commenter (including 93.3% control efficiency for haul roads, 4% silt content, and use of median concentrations including for iron and aluminum) were confirmed by PRI and accepted by DEQ, and it was not demonstrated that the alternative underlying assumptions presented were more accurate or appropriate than data provided by PRI and accepted by DEQ. Although a median value of sampled silt percentages of roadway material was used in emission estimates presented in the application, DEQ recognizes the importance of the silt content parameter in the estimation of emissions. Since compliance with the 24-hour PM_{10} National Ambient Air Quality Standards (NAAQS) is the primary driver of NAAQS compliance, minimizing variability of the parameter is very important to ensure NAAQS compliance. To achieve this, the permit will limit *maximum silt content* to 4.0 %, as specified in Section 3.13 Haul Road

Capping of the PTC as well as associated monitoring and recordkeeping. PRI has confirmed that the use of mineralized metal profiles is conservative when compared to low-mineralization materials such as development rock and clean gravel.

Despite the noted limitations of using AP-42, these equations remain commonly used and accepted by DEQ. And while the use of an average or 90th percentile value is a more conservative approach (for silt content and/or metal concentrations), the use of site-specific median values combined with estimating and modeling PTE at design capacity and maximum activity rates was considered a sufficiently conservative approach and is commonly accepted by DEQ. Maximum hourly and daily activity rates were used to estimate the maximum 24 hour and annual emission rates. The use of enrichment factors has not been required, and DEQ is unaware of any prior instances in which such factors were applied.

FIRST PUBLIC COMMENT PERIOD

DEQ provided a first public comment period on the proposed PTC for PRI from September 10 – October 12, 2020, in accordance with IDAPA 58.01.01.209.01.c. During this period, comments were submitted in response to DEQ's proposed action. **P**ublic comments regarding the technical and regulatory analyses and the air quality aspects of the proposed permit are summarized below. Questions, comments, and suggestions received during the comment period that did not relate to the air quality aspects of the permit application, the Department's technical analysis, or the proposed permit were not addressed. It is also noted that many of the topics discussed during the first public comment period were addressed in the second and third public comment periods and therefore have not been included below.

Comment 1 – PRI: Editorial corrections

Condition 2.6: The condition currently references "(Permit Conditions 2.1–2.4)." With the addition of Condition 2.5, the reference may need to be updated to "(Permit Conditions 2.1–2.5)."

DEQ Response:

Permit Condition 2.6 was revised to correct the condition referenced to Permit Condition 2.5.

Comment 2 – PRI: Editorial corrections

Condition 2.20: Please correct the condition cross-reference from "0" to "5.3."

DEQ Response:

Permit Condition 2.20 was revised to correct the condition referenced to Permit Condition 5.3.

Comment 3 – PRI: Editorial corrections

Condition 3.2: Please correct the table cross-reference from "1.1" to "3.1."

DEQ Response:

Permit Condition 3.2 was revised to correct the table referenced to Table 3.1.

Comment 4 – PRI: Visible emission monitoring frequency

Condition 4.34: Please change the visible emission monitoring frequency from "each test run" to "each test." This request is made based on industry-standard practices and review of similar requirements in other permits. Monitoring frequency of once per each test run seems excessive and unnecessary as these source types typically do not generate visible emissions.

DEQ Response:

Permit Condition 4.34 was revised to reduce the frequency of visible emissions monitoring to once per test. The proposed frequency was considered reasonable and appropriate for capturing representative emissions during each performance test. This is also consistent with DEQ source testing guidance.

Comment 5 – TIFO and ICL: Toxic metals

With regard to toxic metals, the screening analysis indicates potential exceedance of carcinogenic and non-carcinogenic toxicity criteria for arsenic (As), antimony (Sb), cadmium (Cd), nickel (Ni), and mercury (Hg). Despite considerable uncharacterized uncertainties in the source terms and emissions estimates that cannot

be appropriately evaluated without a representative material balance for toxic metals, DEQ has dismissed any concern relative to these toxins based on modeling results.

This facility anticipates mining and processing an estimated 200 to 600 tons of Hg, 200K to 1M tons of Sb, 400K to 1M tons of As. Approximately 85% of the Sb and some undetermined fraction of the Hg will exit the site as product. The remaining toxic metals will be discharged to various environmental media, sinks, and repositories on-site or shipped to hazardous waste facilities. The applicant projects that the most significant thermal source on the site will exhaust 0.2 pounds per year (lb/yr) of Hg over 20 years to the atmosphere. This extraordinary level of control must be verified by material balance calculations to be relied upon. The applicant has not produced a material balance for toxics, and DEQ has not assessed the overall coherence of toxic metal pathways necessary to verify the applicant's assertions.

It seems that the draft permit does not require measurement, monitoring, reporting, or testing of toxic metals either in the process streams, emissions, or releases from the operations during the entire 20-year life of mining, milling, and refining. With respect to toxic metals, the permit only requires the applicant to operate the equipment in conformance with manufacturer's recommendations with the implicit assumption that this will result in health-protective Hg, Sb, As, Cd, and Ni ambient concentrations. If this interpretation is correct, then neither the emission estimates nor ambient metals concentrations will be verified by DEQ. This conclusion should be reconsidered after thorough review of a material balance.

DEQ Response:

A response and HAP/TAP application addendum were submitted by PRI that included new HAP and TAP emission estimates, new and revised TAP increment compliance demonstrations, and a sourceby-source inventory of HAP and TAP emissions. After exclusion of sources addressed by NSPS and/or NESHAP, applicable emission sources from concrete production and HVAC were evaluated for compliance with TAP increments, and compliance with TAP provisions was demonstrated. After exclusion of sources within a source category subject to an area source NESHAP (40 CFR 63), emissions from the remaining applicable nonfugitive sources in aggregate production, concrete production, and HVAC were evaluated for compliance with the Mercury Emission Standard (Table 6).

Any uncertainties in metal HAP and TAP emission estimates are not expected to affect classification as a HAP minor source or to affect compliance with TAP provisions. Although some degree of uncertainty is present in all emission factors used in estimating emissions, all emission factors were adequately supported and the approach of estimating PTE at design capacity for combustion sources and at maximum throughputs for process sources was considered a conservative approach. The use of representative performance test data (i.e., autoclave emissions data from Nevada operations) was determined to be valid and accepted by DEQ.

Comment 6 – TIFO: NDEP

The application makes several references to similar operations in Nevada regulated by the Nevada Division of Environmental Protection (NDEP). However, there are significant differences between the DEQ and NDEP regulatory approaches that could question DEQ's reliance on data from the Nevada operations cited. NDEP guidance cites AP-42 and material balances as the two main sources for developing emission factors for the mining industry.

According to NDEP website information sources, NDEP requirements are significantly more stringent than DEQ's. NDEP has implemented the Nevada Mercury Control Program (NMCP) that applies Hg emissions controls on thermal units located at precious metal mines that include both the EPA promulgated NESHAP Subpart 7E and additional NMCP permitting conditions. NMCP requires that all precious metal processing facilities that operate, construct, or modify a thermal unit that emits Hg must apply for, and obtain, a Mercury Operating Permit to Construct. DEQ is requiring only the minimal federal requirements and a generic PTC. NESHAP Subpart 7E sets Hg emission limits for three source categories that are groups of units promulgated in 2013; two of which apply to this application. NMCP requires unitlevel emission limits that are periodically re-evaluated for applicable sources. DEQ relies on alleged similar NDEP emission reports to assess NESHAP

Subpart 7E compliance, with Hg emission data presented from two Nevada operations (Goldstrike and Twin Creeks) to show that these facilities are in compliance with allowable limits.

This somewhat convoluted analysis portends that 2 autoclave examples from Nevada operations show that these facilities are, respectively, utilizing 0.2% to 10.9% of the 84 lb/ton allowable Hg emission; and 14.2% to 27.4% of the allowable 0.8 lb/ton concentrate carbon-based mercury retort emission limit. It is then assumed a nominal 10.0% and 20.0%, respectively, will be utilized at Stibnite. This results in an estimated 21.34 lb/yr emissions from the autoclave and 3.36 lb/yr retort emissions. The ** footnote suggests the actual autoclave emissions will be an extremely low 0.2 lb/yr.

The assertion that these two facilities operate in compliance with the federal portion of the Nevada permit is not conclusive evidence that the Stibnite facility will meet the standard without showing that the ore composition, process parameters and operational factors are comparable.

NESHAP Subpart 7E Mercury Sources

Subpart 7E Description	**Oper. ton/yr**	**% of Subpart 7E hr/yr**	**for Controlled Systems**	**Hg Emissions* lb/hr**	**Controlled Hg Emissions* lb/yr**	**ton/yr**
Autoclave	** 0.107	8,760	10.0%	0.002	21.34	0.011
Refinery Sources (Kiln, EW, Retort, Furnace)	0.008	1,248	20.0%	0.003	3.36	0.002
Total 7439-97-6	0.115			0.005	24.70	0.012

*Based on Similar Source Hg Reporting Levels provided below

**Expected actual emissions from Autoclave: 0.0105 g/hr, 2.3E-05 lb/hr, 0.20 lb/yr (M3 2019)

Similar Source Hg Reporting Levels
Goldstrike Autoclaves 2 & 3 (2015 & 2016 Hg Reports) = 10.9%
Twin Creeks Autoclaves 1 & 2 (2015 & 2016 Hg Reports) = 0.2%
Goldstrike Refinery (2015 & 2016 Hg Reports) = 14.3%
Twin Creeks Refinery (2015 & 2016 Hg Reports) = 27.4%

Review of the cited sources is confusing. There is an obvious and considerable difference in the two example reported values with no explanation for the difference or why the nominal values for the analysis were selected. The State of Nevada regulates more than 35 mines with applicable thermal process units, and has accumulated hundreds of emission test results. There is no indication in the DEQ application as to why these two particular test results were offered to demonstrate compliance with the applicable NESHAP requirements. The Goldstrike autoclaves report 32 lb/yr in 2016 and a facility-wide release of 271 lb/yr and has ranged from 166 to 709 lb/yr over the previous decade. The unusually low 0.2 lb/yr attributed to (M3 2019) is an undated and unlabeled excel sheet attachment to an email requesting various process information with the single cited value in a column title “Final Cleaned Autoclave Vent Offgas to Atmosphere.” It is not discernable from the referenced material what facility or process stream this test result applies to and any indication is appropriate for consideration in relation to the Stibnite proposal.

The application also references pages from the Nevada Operating permit. The NDEP Barrick Goldstrike Mine Class 1 Permit is 148 pages and does not include an antimony facility. The Draft DEQ Permit, in contrast, is 34 pages and requires almost no toxic metal monitoring, testing, reporting or assessment during the life of the mining operation.

Additional comments were provided discussing the relative jurisdictional risk of other states to that of Idaho.

DEQ Response:

PRI confirmed in the response to a request for additional information that the emissions data from Barrick Goldstrike Mines relied upon to estimate emissions is representative of the proposed autoclave and process, and that the remaining thermal source will not be constructed and will be replaced instead by a dewatering/packaging circuit. As a result, the antimony process dryer and bagging operation emission sources Sb1 and Sb2 were removed from the permit.

While it is acknowledged that there are differences between Idaho and Nevada regulatory programs and requirements, compliance with applicable federal regulations and state Rules for the Control of Air Pollution in Idaho (Rules) are required to obtain a PTC. Beyond the explicit Hg emission limits for sources in NESHAP Subpart 7E, HAP and TAP particulate metals are regulated indirectly (i.e., surrogate limits) via facility wide fugitive dust requirements, material throughput and operational limits, PM emission limits, and control device requirements. DEQ views these limits as sufficient to ensure compliance with applicable HAP and TAP requirements based on estimates of potential emissions and predicted modeled TAP concentrations, and the accuracy of autoclave and refinery emission sources estimates will ultimately be determined via testing as required by NESHAP Subpart 7E.

Comment 7 – NPT: Fugitive emissions from the tailings storage facility

The permit does not, but must, include the potential for fugitive emissions from the tailings storage facility. There are no fugitive emissions from the tailings storage facility in the emissions inventory or appended to the Statement of Basis. Significant fugitive emissions were seen from the tailings storage facility of the Thompson Creek Mine based on an aerial tour of the Thompson Creek Mine, and similar emissions are expected from the project. In addition to PM10 emissions, fugitive tailings would have higher metals and cyanide concentrations than other fugitive emissions at the mine and would thus be more injurious to the environment. The potential to emit concentrations of PM10, metals, and cyanide from the tailings storage facility should be included in the emissions inventory and modeled emissions scenarios and appropriate emissions controls should be identified in the permit.

DEQ Response:

A response and HAP/TAP application addendum were submitted by PRI that included new HAP and TAP emission estimates, including cyanide and carbon disulfide from the TSF (tailings storage facility). In the response to a request for additional information, PRI confirmed it will have one TSF as identified in Figure 1 of the PTC application, in the Meadow Creek drainage upstream of the Hangar Flats pit and adjacent to (west of) the Hanger Flats Development Rock Storage Facility (DRSF). The TSF has the potential to emit mercury and hydrogen cyanide (HCN) due to evaporative flux. Spent ore from the mill will be pumped (not hauled) to the TSF as thickened tailings slurry. This process will not create criteria pollutant nor HAP/TAP emissions. The majority of the TSF surface will be either wet beach or a supernatant liquid, with some dry areas. PM from dry beach areas was estimated using EPA's wind erosion equations in AP-42 Section 13.2.5, Industrial Wind Erosion. These equations predicted that a fastest-mile wind speed of over 19 meters per second (m/s) is required to cause windblown dust from a flat, dry tailings surface. Based on SGP onsite meteorological data, the highest fastest-mile wind speed recorded was only 12.5 m/s, resulting in no estimated emissions of windblown dust and dust metal emissions from the TSF. While these emission estimates were supported, reasonable precautions to minimize dust from any high-wind events forecast to exceed 25 mph (11.2 m/s) is required in the permit (Permit Condition 2.5).

Comment 8 – NPT: Mercury emissions from the lime kiln

Mercury emissions from the lime kiln are not quantified. Although there are no Hg limits or controls proposed for emission units associated with the lime production in the permit, there is Hg in the carbonate rock at Stibnite and Hg in the limestone will be released from the lime kiln. Mercury emissions should be accurately characterized, and there should be controls for Hg on the lime kiln regardless of the legal loopholes in the Idaho Administrative Procedures Act rules.

DEQ Response:

A response and HAP/TAP application addendum were submitted by PRI that included new HAP and TAP emission estimates, including emissions from the lime kiln based on a metals concentration profile of the source limestone.

Mercury emissions from the lime kiln were estimated by assuming all mercury in the limestone feed is volatilized and emitted. For each non mercury metal HAP and TAP, emissions from the lime kiln were calculated as PM emissions multiplied by the median metal concentration measured.

As detailed in the Mercury Emission Standard section of the Statement of Basis, as a source category lime manufacturing plants are subject to NESHAP 40 CFR 63, Subpart AAAAA (5A) and as such HAP emissions from the lime kiln (including mercury) are therefore exempt from this standard. Although there are no NSPS and NESHAP standards applicable to the SGP lime kiln, a baghouse control device was proposed and is required for the lime kiln (Permit Condition 5.11).

Comment 9 – NPT: Fugitive dust and VOC emissions from the on-site landfarm

The potential for fugitive dust and volatile organic compound ("VOC") emissions from the on-site landfarm has not been included in the emissions inventory. The Project will be operating a landfarm onsite, as identified in the Forest Service Stibnite Gold Project Draft Environmental Impact Statement (EIS). As identified by the Federal Remediation Technologies Roundtable, "landfarming sites must be managed properly to prevent both on-site and off-site issues with contamination. Leachate collection, fugitive dust emission control, adequate monitoring, and environmental safeguards are required." Landfarm emissions should be characterized and subject to facility-wide fugitive dust and VOC control requirements.

DEQ Response:

Although identified as a possible onsite activity in the Plan of Restoration and Operations (PRO), PRI did not propose landfarming activities at the SGP within the PTC application. In the response to a request for additional information, PRI confirmed that landfarming activities are not currently planned. As a result, these activities are not authorized by the PTC. Any activities or operating scenarios not regulated by the permit or otherwise addressed in the application are not expressly permitted, and any changes proposed after permit issuance will need to be evaluated as to whether they may require modification or revision of the PTC.

Comment 10 – NPT: Modeling assumptions

The modeling assumptions used for the access road are incorrect. The modeling assumptions in Table 29 of the Statement of Basis state the access road length is 1.6 miles within the Project boundary, however, the access road proposed by Midas Gold is longer, either three or four miles in length depending on the option.

DEQ Response:

The source ACCRD (Access Road) listed in Table 28 of the Ambient Air Quality Impact Analyses Review Memorandum (Appendix B to the Statement of Basis), refers to the access road portion within the SGP operations boundary that runs from the south gate to the process area. ACCRD is characterized by dust emissions generated from travel of maintenance equipment, light-duty pickup trucks and buses used for employee, visitor, and contractor transportation, and heavy-duty trucks used for cargo (including fuel, consumables, machine parts, ore processing supplies, ore concentrate, etc.) and services (including food supplies, trash, recyclables, etc.) transportation. ACCRD was represented in the model as a series of LINE sources laid along the actual route. The length of ACCRD is 1.6 miles (verified by DEQ by comparing a graphical representation of the modeling input file to aerial photographs on Google Earth) and does not change with modeling scenarios.

Comment 11 – NPT: Density of limestone

The density of limestone in the modeling is unrealistically low at 1.09 g/cm3. A more universally accepted range for limestone density should be used in the modeling.

DEQ Response:

There were 15 emission sources that were modeled using a limestone density of 1.09 g/cm3 ("limestone, dust" in The Engineering Toolbox): LS1-LS12, LSBM, LK, and LCR. The Engineering Toolbox lists a higher density of 1.36 g/cm3 for "limestone, crushed." An argument could be made that this higher density value is more appropriate for some of those 15 emission sources. However, a lower density is the more conservative assumption because it allows material to remain airborne for a longer period of time. Hence, theoretically a lower limestone density suggests higher modeled concentrations. To satisfy the commenter's concern, DEQ performed a sensitivity analysis using a density of 2.74 g/cm3 for those 15 emission sources (while keeping everything else in the model constant). This density value is on the higher end for solid limestone. Results from DEQ's sensitivity analyses show that the modeled particulate concentrations remain unchanged. This is consistent with DEQ's source group analyses in Table 27 of the Ambient Air Quality Impact Analyses Review Memorandum (Appendix B to the Statement of Basis), which show that process/ancillary sources (such as those 15 emission sources) contribute an inconsequential amount to the modeled design concentrations.

Comment 12 – NPT: Commence construction

If Midas Gold does not commence construction of an emissions unit within two years, and an extension to the PTC permit is needed, DEQ should re-open the tribal and public comment period. Midas Gold is sure to be revising its proposed construction and operations scenarios during that time, which will lead to revisions in emissions scenarios and updated PTC permit application submissions. DEQ should provide the public with the opportunity to comment on a PTC permit renewal and any updated application materials submitted by Midas Gold since its original application.

DEQ Response:

General Provision 7.5 states that the permit will expire if construction has not commenced within two years of permit issuance. If construction has not commenced, any request would be evaluated by DEQ for any additional applicable requirements prior to granting an extension.

Comment 13 – ICL: Publicly available report and records

Inspection reports and permit compliance records need to be publicly available on the DEQ website. We will also be asking the Forest Service to provide a link to the DEQ website as part of the Forest Service's implementation and monitoring website. Posting this already-existing information on the agency webpages will eliminate the need for Public Records Requests and increase both project transparency and applicant accountability.

DEQ Response:

At this time, only issued permitting documents relating to air quality are posted online on DEQ's "Issued Permits and Water Quality Certifications" webpage.

Application materials (and Tier I permit-required plans) are posted during the public comment period for each respective permitting action on DEQ's "Public Comment Opportunities" webpage, and inspection reports and compliance documents are not currently posted online.

As public records, DEQ encourages interested parties to request copies of such documents. Public record requests can be made online at DEQ's "Public Records Request" webpage.

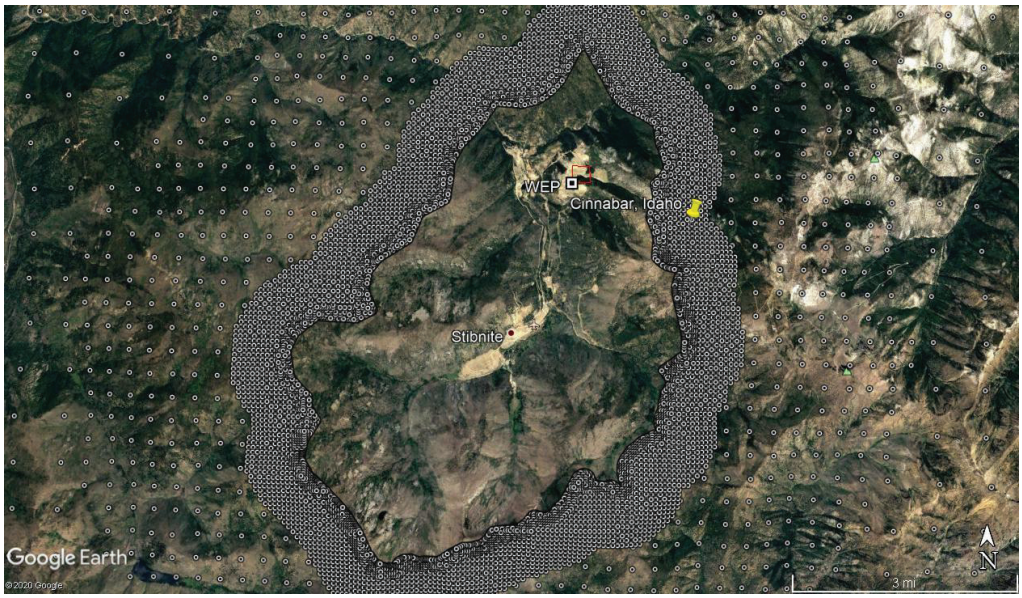
Comment 14 – SSFS: Impact analysis

The impact analysis underestimates potential emissions by assuming the emissions scenario will be the same throughout the entire life of mining.

Emissions from blasting, mining, and materials management were modeled as a volume source inside a pit at year seven, after several years of mining will have deepened the pits. Emissions escaping from the pits from blasting and associated ore transport and handling would be greater and have more impact per volume of ore processed in the earlier years when pits are less deep. Emissions may also vary due to spatial distribution over the different years the mine is in operation. Thus, the predicted ambient air quality impacts may be underestimated by not analyzing the maximum potential daily emissions during earlier years when the pits are less deep or not analyzing the different spatial distribution or potentially different concentrations from one pit and disposal area to the next.

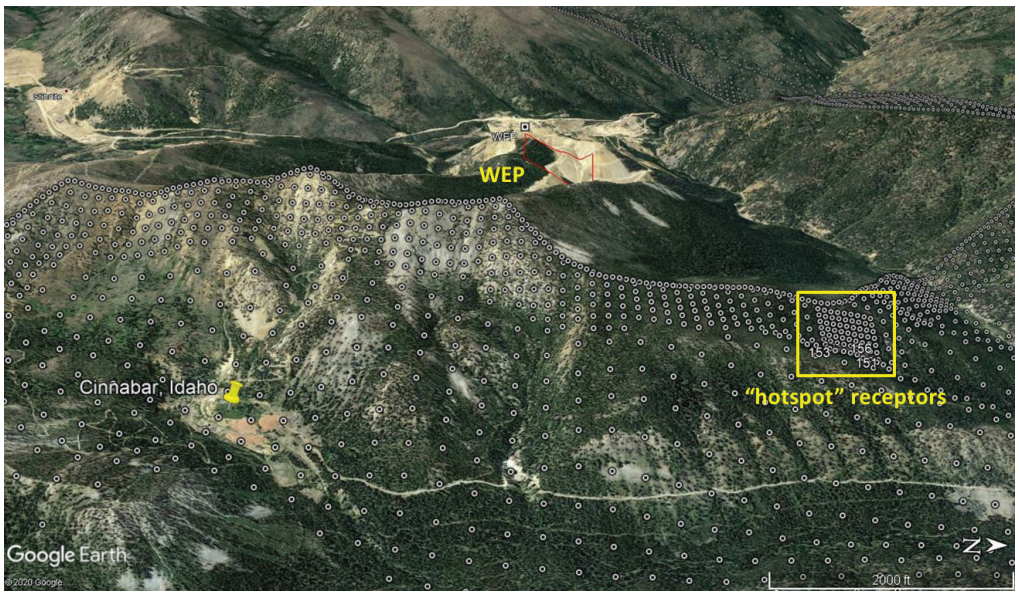
DEQ Response:

Emissions from mining operations (drilling, blasting, material extraction and movement, mobile mine machinery use, and other ancillary sources) vary for each year of the life of the mine (LOM). However, for the modeling analyses, the mining operation potential emissions were estimated using conservatively high maximum activity rates as limited in the permit and summarized in Table 3 of the Ambient Air Quality Impact Analyses Review Memorandum (Appendix B to the Statement of Basis), (i.e., extracting and hauling 180,000 tons per day (T/day) of ore or development rock). The maximum mine production rate is approximately 42.7 MMT/yr; however, a maximum daily production rate of 180,000 T/day used for potential emission calculations results in a conservatively higher production rate of approximately 65.7 MMT/yr, approximately 50 percent higher than the projected production rate. Also, the modeled emissions were based on maximum short-term activity rates occurring continuously, including blasting emissions based on one blast occurring every hour for the applicable 1-hour standards, and two blasts occurring every day for the applicable 24-hour standards. Actual blasting is not expected to exceed one blast per day.



Accurately accounting for all potential configurations is effectively impossible. DEQ contends that other conservative assumptions in analyses (such as assuming that design value modeled values occur simultaneously with design value background concentration values) will offset any unintended underestimation of emissions that occur because of uncertainties and variabilities.

Comment 15 – SSFS: Cinnabar site



The impacts analysis failed to consider particulate ambient air concentrations at the Cinnabar site. The permit application proposes mining rates of 180,000 tons material per day from the West End pit. The West End pit is located in the Sugar Creek drainage about two kilometers northeast of Cinnabar Peak. Modeling shows that particulate ambient air concentrations at Cinnabar Peak would exceed NAAQS limits and qualitatively show that lower mining rates at the West End pit of about 120,000 tons per day would be required in winter to barely comply with ambient air quality standards. There is no demonstration of NAAQS compliance for winter conditions. Therefore, a permit that allows operations during winter conditions cannot be issued. (If the permit applicant argues that the scenario modeled isn't representative, the burden is on the applicant to provide a representative modeling analysis. If there is less activity in the winter, then there would be more activity in the warmer seasons where there would be a serious potential for dust to reach the annual levels throughout. The draft permit's dust control efforts would be challenged to meet the levels modeled and needed to show compliance assuming 93% control efficiency.)

DEQ Response:

The figure below shows the location of West End Pit (WEP) with respect to Cinnabar. It shows that WEP is located to the west, not northeast, of Cinnabar.

The figure below (note that north is facing to the right) shows the locations of WEP, Cinnabar, and the hotspot receptors that show modeled violations of 24-hour PM10 NAAQS when using the BULKRN met dataset.

To evaluate the degree of NAAQS compliance confidence for 24-hour PM_{10}, DEQ performed a weight-of-evidence analysis as described in Section 4.1.4 of the Ambient Air Quality Impact Analyses Review Memorandum (Appendix B to the Statement of Basis). NAAQS compliance was demonstrated in the application using meteorological data processed with an EPA-approved method using regional cloud cover to calculate stability parameters rather than site-specific monitored solar radiation and measured temperature differences with height.

All modeled violations for 24-hour PM_{10} shown by sensitivity analyses, using BULKRN met data at a proposed mining rate of 180,000 tons material per day (T/day), occur during winter. During winter, fugitive road dust emissions are likely overestimated because of the higher moisture content of material handled or driven over. The permit requires at least 93.3% control of maximum potential fugitive emissions, but the fugitive emissions may in fact be controlled by more than that, especially during winter and periods of precipitation. Also, background concentrations in such remote areas during winter are generally much lower because of the absence

of wildfires and dust-generating sources. Background PM_{10} concentrations represent the higher end of the distribution. Accounting for reduced fugitive emissions during wintertime conditions and accounting for lower background concentrations will easily demonstrate compliance with the 24-hour PM_{10} NAAQS without the need to rerun the model for wintertime conditions. The 180,000 T/yr mining rate was established as a permit limit (Permit Condition 3.5) and is reflected in the modeling for all months of operation.

DEQ is confident that operation of the SGP will not cause or contribute to a violation of NAAQS. This is based on: (1) the submitted application materials and analyses, (2) DEQ's supplemental analyses, and (3) the assumption that the facility is constructed and operated as described in the application and limited by the PTC.

Comment 16 – SSFS: Modeling topography

Modeling using straight-line dispersion of emissions fails to account for the topography of the area, and results in an underestimation of the impacts. The near-field analyses of impacts within 10 kilometers of the project site all assume straight-line dispersion based upon onsite surface winds measured in a central location within the project area, and are only representative of a small area near the monitoring station. Actual dispersion in this area is terrain driven, flowing up, down, and around valleys, and over ridges to the next valley. Assessing impacts using straight-line dispersion therefore may not reflect impacts at all locations and actually underestimate impacts of emissions.

DEQ Response:

DEQ concurs with the commenter that dispersion in complex mountainous terrain is not well characterized by straight-lined Gaussian dispersion models utilizing a single wind direction and speed. DEQ also concurs that a potentially more accurate way to assess impacts of a source in complex terrain would be to use a more refined model with terrain-influenced meteorology and pollutant concentration "memory" from one time-step to the next, such as CALPUFF or other puff models. The objective of the air impact analysis is to satisfactorily evaluate whether the proposed project will not cause a violation of an applicable air quality standard or increment.

The Gaussian, straight-line model AERMOD has been identified by EPA as the "regulatory guideline model" for stationary source permitting, as established in 40 CFR 51, Appendix W (Guideline on Air Quality Models). AERMOD was used by PRI to evaluate NAAQS and TAP increment compliance, and DEQ contends that it is appropriate for this purpose. DEQ also contends that results obtained, using the input parameters described in the application, assure compliance with a high degree of confidence, thereby justifying permit issuance. Also, the PRI PTC is a minor source permit, and use of resource-intensive models such as CALPUFF would be overly burdensome for such projects.

Straight-line Gaussian dispersion models tend to over-predict impacts in complex terrain, especially with increasing distance from the source. However, improved algorithms in the AERMOD model do address terrain effects at a reasonably conservative (over prediction of concentrations) level. Also, studies have generally demonstrated that Gaussian models perform reasonably well at estimating the magnitude of maximum impacts, especially at longer averaging periods; however, they perform poorly at predicting the location and time of maximum impacts. The EPA approved AERMOD Gaussian model has been established as acceptably accurate for assessing air quality impacts from stationary sources, even in rather complex terrain.

Comment 17 – SSFS: Hg from terrestrial sources

The impact analysis fails to account for release of Hg from terrestrial sources. The impacts analysis does not account for Hg respiration from vegetation after uptake. Uptake of Hg by vegetation is the largest point of entry for atmospheric Hg into terrestrial environments. Due to the long history of mining in the area, the predicted impact from respiration is 19% above background levels. The impact analysis did not account for this potential release of Hg.

DEQ Response:

Mercury modeling was not performed by the applicant for the PTC application because it was not required by regulation.

Comment 18 – SSFS: Post-mining conditions

There are no air impact analyses regarding post-mining conditions. The entire air quality analysis says nothing about post-mining conditions, other than the applicant will attempt to revegetate. Because of the climate, metals, and chemicals in the area, there will be limits to the effectiveness of revegetation. The area will remain a source of dust and erosion contaminated with heavy metals. The permit should account for this source of emissions.

DEQ Response:

DEQ's requirement for permit issuance is to assure that all operations performed will not cause a violation of NAAQS or a TAP increment. DEQ is confident that emissions and impacts to ambient air resulting from post-mining conditions will be less than those associated with activities during active mining or ore processing.

In the response to a request for additional information, PRI confirmed that post-mining activities at the SGP will not commence until mining is completed in approximately 12 years or more. Post-mining activities will remain subject to permit conditions, including pertinent facility-wide conditions such as fugitive dust, visible emissions, and odor requirements (Permit Conditions 2.1–2.15) and operating limits such as the hauling limit (Permit Condition 3.5). Any activities or operating scenarios not regulated by the permit or otherwise addressed in the application are not expressly permitted, and any changes proposed after permit issuance will need to be evaluated as to whether they may require modification or revision of the PTC.

Comment 19 – NPT: Post-mining conditions

Permit Condition 2.1 should include secondary NAAQS factors when considering what are reasonable precautions. In addition to "...proximity of dust-emitting operations to human habitations and/or activities and atmospheric conditions which might affect the movement of PM...," DEQ should include public welfare protection, proximity to critical habitats, and potential for damage to the environment.

DEQ Response:

PTC permit issuance requires demonstration of compliance with NAAQS and TAP increments. As stated in Section 4.1.2 of the Ambient Air Quality Impact Analyses Review Memorandum (Appendix B to the Statement of Basis), "Modeling for ozone and secondary $PM_{2.5}$ were not performed for this minor stationary source. These analyses are typically associated with applications for major stationary sources. Nonetheless, taking the ratio of the VOC, NO_x, and SO_2 emissions from the SGP facility by the emissions and resulting concentrations of O_3 and secondary $PM_{2.5}$ from EPA's modeled emission rates for precursors (MERPs) guidance yields estimated O_3 and secondary $PM_{2.5}$ concentrations of less than 1 ppb of O_3 and less than 0.1 $\mu g/m^3$ of $PM_{2.5}$ (24-hour and annual) for the SGP facility. These estimated concentrations have a negligible effect on compliance demonstration with the NAAQS."

Comment 20 – NPT: Recordkeeping

There is discrepancy in frequency of the recordkeeping Permit Condition 2.2 ("each day") and inspection Permit Condition 2.4 ("every 12 hours"). Recordkeeping frequency should be adjusted to match the inspection frequency.

DEQ Response:

Permit Condition 2.4 was updated for consistency with the inspection frequency as requested and to ensure that

fugitive emissions are reasonably controlled.

Comment 21 – NPT: Winter conditions

Prior to onset of winter conditions each year, the condition of the haul and access roads should be assessed before freeze-up and required maintenance needed to maintain the roads through the winter months should be performed, and any preventative dust suppression activities should be completed before the roads are frozen and liquid application of suppressants or water are unrealistic.

DEQ Response:

Permit Condition 2.6 was updated as requested to include this requirement to help ensure that fugitive emissions are reasonably controlled.

As discussed previously, DEQ believes as suggested that frequent monitoring (at least once every 12 hours) will be required to ensure sufficient application of chemical and water dust suppression and that this is a reasonable precaution in advance of the winter season to minimize fugitive dust from roadways.

Comment 22 – NPT: Designate employees

DEQ should require the permittee to designate specific employees to be the on-site visible and fugitive emissions observers solely responsible for fulfilling the ongoing PTC permit requirements of conducting the required test methods and procedures of EPA Reference Method 9 and Method 22, initiating any appropriate corrective actions, and completing and maintaining recordkeeping.

DEQ Response:

Although designation of specific employees is not required by the permit or by regulation, training on the specified methods is required for observers. Because certification is required for Method 9, only trained employees will be able to perform once-per-day observations of point sources as required by Permit Condition 2.10. Similarly, only employees with an understanding of the procedures of Method 22 will be able to perform the 12-hourly observations of fugitive sources as required by Permit Condition 2.4.

Comment 23 – NPT: Completeness requirement

DEQ should have a 95% completeness requirement for recordkeeping of fugitive and visible emissions inspection records.

DEQ Response:

The permit requires that records be maintained at all times to ensure compliance (General Provision 7.10) and that records be retained for a period of five years.

Comment 24 – NPT: AMP

The Statement of Basis refers to an Access Control Plan (ACP) on page 39 and an Access Management Plan (AMP) on page 24, while the PTC permit refers to an Access Management Plan (AMP) on pages 9 and 10. If these are the same plans, we suggest DEQ be consistent in the naming of this plan.

DEQ Response:

The Statement of Basis was updated for consistency with the permit, with all instances now referencing the Access Management Plan as intended.

Comment 25 – TIFO: COC impacts

Both the NAAQS and COC-related analyses provided are largely performed for “average” conditions.

Numerous EPA guidance and sound scientific practice indicate that analyses of potential COC impacts should be conducted at expected typical (central tendency) and reasonable maximum concentrations, with appropriate discussion of the uncertainty and likelihood of worst-case conditions. Even if the input values were shown to be coherent, the modeling presented in the PTC fails with regard to worst case analyses. Even qualitative evaluation for COCs falls short, as there is no discussion of the uncertainty associated with the assertions and conclusions.

DEQ Response:

Permit issuance requires the application demonstrate to DEQ's satisfaction that impacts of applicable pollutants from applicable sources not exceed established standards, as stated in IDAPA 58.01.01.203.02 and 203.03. Agency "satisfaction" represents high confidence of compliance with standards, but it does not require certainty. Also, IDAPA 58.01.01.202.02 (Application Procedures, Estimates of Ambient Concentrations) requires that "All estimates of ambient concentrations shall be based on the applicable air quality models, data bases, and other requirements specified in 40 CFR 51, Appendix W (Guideline on Air Quality Models)." Appendix W dictates the models to be used for air permitting, including those programs that process hourly meteorological data and terrain data used in the models. DEQ-specific guidance and procedures are also provided in the *Idaho Air Modeling Guideline* (*State of Idaho Guideline for Performing Air Quality Impact Analyses*, Idaho Department of Environmental Quality, September 2013, State of Idaho DEQ Air Doc. ID AQ-011. Available at http://www.deq.idaho.gov/media/1029/modeling-guideline.pdf).

The analyses to evaluate compliance must be performed using established methods and data to the extent such methods/data are reasonably representative and available. The following are considered in evaluating whether the compliance demonstration is to DEQ "satisfaction":

- Consistency of methods/data used with requirements of Appendix W and the *Idaho Air Modeling Guideline*.
- Accuracy or conservatism of emission estimates, considering potential uncertainty in estimates and variability in parameters affecting emissions. Permit-required control measures, and associated verification of such measures, affect DEQ confidence of emission estimates.
- Modeled impact levels, the extent of elevated impacts, and the frequency of elevated impacts.
- Potential for exposure. Although the ambient air standards and TAP increments must be met at all ambient air locations, DEQ reviewers exercise a higher degree of scrutiny when modeled levels approach standards and have the potential to impact areas where people are likely to be present, including homes, schools, businesses, and hospitals.

The analyses performed for permit issuance differ from those performed for risk assessments and similar analyses. DEQ does not attempt to characterize the uncertainty and variability in results and analytical input variables beyond that needed to attain agency satisfaction of compliance. Furthermore, the application and the Ambient Air Quality Impact Analyses Review Memorandum (Appendix B to the Statement of Basis), discuss the uncertainty and variability in key variables at an appropriate level considering the magnitude and extent of impacts.

Comment 26 – ICL: Reports and records

Inspection reports, air quality monitoring data, and permit compliance records need to be publicly available on the DEQ website. We will also be asking the Forest Service to provide a link to the DEQ website as part of the Forest Service's implementation and monitoring website. Posting this already-existing information on the agency webpages will eliminate the need for superfluous Public Records Requests and increase both project transparency and applicant accountability.

Based on the information provided in our comments, we request that DEQ return the application to Midas Gold as incomplete. Once Midas Gold has resubmitted a complete application and DEQ has made the appropriate modifications to the permit, the permit should be re-noticed for public comment.

DEQ Response:

As discussed previously, issued permitting documents relating to air quality are posted online on DEQ's "Issued Permits and Water Quality Certifications" webpage.

Application materials (and Tier I permit-required plans) are posted during the public comment period for each respective permitting action on DEQ's "Public Comment Opportunities" webpage.

Because updates to the application, the proposed permit, and technical review were made, an additional 30-day public comment period will also be provided to allow for review and comment on these updates.

RE: Proposed permit to construct for Perpetua Resources (PTC No. P-2019.0047)

Dear Ms. Wetzel:

Thank you for considering our latest comments regarding the proposed permit to construct for the Perpetua Resources ("the Applicant") Stibnite Gold Project (PTC No. P-2019.0047). We also thank IDEQ for extending the public comment period by an additional 30 days upon request. The Idaho Conservation League and Save the South Fork Salmon have previously (individually) submitted three rounds of comments on this proposed permit that we incorporate by reference in these comments. For this round of comments, our organizations have decided to submit joint comments to IDEQ. Representatives from both groups also attended IDEQ's informational meeting on March 2, 2022, and had subsequent conversations with IDEQ staff regarding this permit. These comments also incorporate points from technical comments submitted separately by Ian von Lindern, P.E. PhD, from the TerraGraphics International Foundation.

Since 1973, the Idaho Conservation League ("ICL") has been Idaho's leading voice for clean water, clean air, and wilderness – values that are the foundation for Idaho's extraordinary quality of life. As a 501(c)(3) nonprofit organization, ICL works to protect these values through public education, outreach, advocacy, and policy development. ICL is Idaho's largest state-based conservation organization and represents over 35,000 supporters, many of whom have a deep personal interest in protecting Idaho's human health and environment. The Stibnite Gold Project is of significant concern to our members and supporters, leading ICL to be engaged on nearly every aspect of this project's regulatory permitting.

Save the South Salmon ("SSFS") is a community-based citizens' organization, headquartered in Valley County, Idaho, dedicated to protecting the South Fork of the Salmon River watershed, its outstanding and remarkable natural values, and the economies that depend on those values. SSFS's members and supporters have a strong interest in protecting natural resources, maintaining recreational opportunities and access, and ensuring future generations can enjoy and benefit from these resources and opportunities in the South Fork of the Salmon River watershed. SSFS's members and supporters have participated in the Stibnite Gold Project environmental review process under the National Environmental Policy Act since the Payette National Forest opened the scoping comment period in 2017, and have made significant investments in time and resources to better understand the Stibnite Gold Project and the impacts it might have on the quality of the air, water, and land of the South Fork of the Salmon River watershed.

We continue to have significant concerns about whether this permit would be protective of human health and if the permit is in accordance with state and federal regulations given the significant uncertainty in the emissions inventory and calculations. Accordingly, we once again urge IDEQ to deny Perpetua's current application for a permit to construct and require a new application that objectively presents the emissions and controls required to comply with State and Federal requirements. We are forwarding these comments to the U.S. Forest Service and Environmental Protection Agency as well. We appreciate your consideration of our comments and look forward to continued dialogue with IDEQ on this matter.

Sincerely,

Josh Johnson

ICL/SSFS Comments on the Permit to Construct for Perpetua Resources

General Comments

ICL and SSFS appreciate the significant amount of work that IDEQ staff have put into this permit thus far. We recognize that this is an exceedingly complex and difficult application to review from both a technical and regulatory perspective. Nevertheless, there remain a number of substantial deficiencies in this application that require critical review. Despite the substantial modifications that have been made to the draft permit thus far, we remain very concerned that this permit will not adequately protect air quality and public health.

The following analyses are the fourth round of public comments offered on three revisions of the proposed Permit to Construct (PTC) and Draft Operating Permit for the Stibnite Gold Project. Some progress has been achieved in securing health and environmental protectiveness through this lengthy review process. However, despite IDEQ's persistent attempts to obtain objective and transparent submittals from the Applicant, this patchwork approach to upgrade an inherently deficient application is eroding public trust in the process to provide for health and environmental safeguards. This third and latest PTC submittal continues the same unsettling pattern of minimal, insufficient, and vague calculations; ineffective monitoring; and lack of provisions for enforcement and corrective actions.

It is also worth noting that it is unusual for a PTC application for this type of project on federal lands to be considered and potentially approved prior to receiving approval from the Forest Service through the National Environmental Policy Act (NEPA) process. The Applicant is attempting to secure both State and Federal approvals simultaneously. Generally, the Federal approval dictates the type of facility that is acceptable, followed by state implementation of the required controls. The Applicant is submitting confusing and inconsistent air pollution emission claims to the different regulators, hampering the transparency required for the public to understand and comment in both forums. Additionally, the project has already, and will likely continue to, change substantially through the NEPA process - necessarily forcing changes to any prior PTC approval as well.

Conservatism

We have continued concern with IDEQ's position on conservative analyses and uncertainty in emissions calculations. IDEQ's response to previous critiques of emission calculations states:

> "… (the) approach of estimating potential emissions (PTE) at design capacity and maximum activity rates was considered a sufficiently conservative approach. Maximum hourly and daily activity rates were used to estimate the maximum 24-hour and annual

> emission rates, and emissions were modeled based on these maximum short-term activity rates occurring continuously every day."

IDEQ is conflating the "conservative" strategy long inherent in the PTC process with the conservative analyses required in estimating the potential to emit (PTE). Even if IDEQ uses a "conservative" strategy, the agency is still using non-conservative model input parameters for the emissions calculations. PTCs have been based on design PTE calculated using "maximum 24-hour and annual emission rates, and emissions modeled based on these maximum short-term activity rates occurring continuously every day" since the inception of the Clean Air Act (CAA). Comparing these required conservative rates to the Applicant's "good intentions" to operate below design capacity is not a conservative approach. The CAA has long recognized that any facility may change management, exploit additional resources, accept feedstock from adjacent properties, or numerous other production scenarios that could utilize design capacity.

IDEQ's *Guidelines for Performing Ambient Impact Analyses* states:

> "To demonstrate compliance, potential emissions must be used in the modeling analyses rather than future projected actual emissions. The maximum emission rate for each averaging period must be identified. For example, PM2.5 has both a 24 hour and annual standard. If a source will only operate 7000 hours per year, but can operate for 24 hours in a single 24 hour period, then different emission rates would be modeled for the 24 hour and annual standard" (Section 6.4.1).

The analyses for impacts for pollutants with averaging periods less than annual are not using maximum potential emissions over those short-term averaging periods. Annual emission impact analyses were also based upon an estimate of the five-year average of projected actual emissions. In assuring the appropriate level of health protectiveness, the permit process is, and has always been, designed to assure compliance at design capacity.

With respect to the use of AP-42 Emission Factors in calculating the PTE, IDEQ regulations require that "screening engineering analyses use unrefined conservative data." (6-30-95). Moreover, IDEQ guidance ranks the use of AP-42 as a last choice, with the least reliable data, and the greatest potential to underestimate emissions.[1] Accordingly, it is incumbent on IDEQ to require use of conservative emission factors. Accepting promises that intended operations will not exploit the full design capacity of the facility is not a substitute for utilizing conservative emissions factors in calculating PTE emissions.

[1] "Emissions Data Hierarchy." https://www2.deq.idaho.gov/admin/LEIA/api/document/download/5521

Facility Classification

In the Statement of Basis (SOB), IDEQ classified this facility as a synthetic minor source (SM) for PM, PM10, and PM2.5 and Class B for Hazardous Air Pollutants (HAPs). A number of comments by ICL, SSFS, and other reviewers address instances where we believe that HAP emissions continue to be underestimated. Once IDEQ completes the appropriate analyses and calculations to verify the PM and HAP emissions, the agency should assess whether the source still meets the requirements of a synthetic minor.

The Applicant and IDEQ calculations show that this facility will also emit >30,000 tons per year (TPY) of uncontrolled PM (removing the 90% control on hauling fugitive emissions + the emissions total for uncontrolled point sources) and 3,655 TPY of permitted PM point source + fugitive emissions (Table 3, SOB). However, IDEQ contends the Major Source classification of 100 TPY is not met despite the apparent 36-fold exceedance. IDEQ continues to ignore 3,569 TPY of permitted PTE PM fugitive emissions from mining operations (97.6% of total controlled PM by the Applicant's calculation) and 986 TPY of associated PM10 fugitive emissions. This clear exclusion of significant emissions from regulatory constraints is a major concern for us. Furthermore, this determination avoids the federal oversight that this permit would be afforded if classified properly as a Major Source.

To avoid including the fugitive emissions sources, IDEQ apparently relies on IDAPA 58.01.01.220.01:

> *For purposes of Sections 220 through 223, fugitive emissions shall not be considered in determining whether a source meets the applicable exemption criteria unless required by federal law.*

Accepting the Applicant's and IDEQ assertions, the current classification determination for this facility as a synthetic minor source is based on merely 2.4% of the total PM emissions. If only 13.6 TPY (0.4%) of the excluded PM fugitive emissions were included in the source classification determination, the facility would be a Class A Major Source, subject to federal review.

In the interest of health and environmental responsibility, it is imperative that the IDEQ consider all emissions including mining fugitive impacts and classify this a Major Category A Source. The only comparable facilities operating in the U.S. at this time, in Nevada, are Class 1 Major Sources according to the same criteria as Idaho's designation, even though most of the Nevada facilities do not include onsite gold ore processing. Idahoans should be afforded the same level of air quality protection as Nevadans.

Even by IDEQ exclusion criteria, some of the ignored sources asserted to be "mining fugitives" should be considered as mineral processing activity emissions controlled with and attendant to specific point sources included in the source classification determination. Significant percentages of mine ores are trucked to stockpiles and placed in storage to be processed months or years later. Alleged mine fugitive emissions also include significant on-site hauling associated with the Portable Crusher and Screening Plant. Some of this hauling is related to the lime plant and gold ore refinery operations, which are specifically listed by federal rules as requiring inclusion of fugitive emission in determining source classification.

> *Subchapter C Part 70.3(d). Fugitive emissions from a part 70 source shall be included in the permit application and the part 70 permit in the same manner as stack emissions, regardless of whether the source category in question is included in the list of sources contained in the definition of major source.*

This rule should be interpreted that if any portion of the emissions is due to a listed source, then all emissions from that source should be included in the source classification determination.

These alleged "excluded mine fugitive" sources alone (not including On-site Hauling) exceed 270 TPY PM. If only 5% of these activities were considered attendant to listed sources or mineral processing and stockpile point source operations (as opposed to mining) then the Major A Source Category threshold would be met. Unfortunately, it is not possible for us or other reviewers to quantify these sources from the available emission inventories. Fugitive emissions were reportedly estimated for a dozen different operational scenarios. However, Table 7 of the SOB and the example calculations provided use scenario W-3, because it is the maximum total PM emissions. This scenario is heavily weighted toward exploitation of the West End Pits, and provides little information to assess the potential emissions associated with those sources that might not be exempt on closer examination.

Examination of the W3 scenario also shows that the 2,901 TPY of PM estimated for On-Site Hauling is 100% attributed to hauling emissions from the West End Pit to the Hangar Flat DRSF. This is the main process stream for limestone feeding the lime plant, gold oxidation circuit, neutralization of waste streams, etc. This scenario also attributes zero hauling emissions from stockpiles to crushers. It is not possible to ascertain from these data how much of the fugitive emissions are attendant to these listed sources or are attendant to mineral processing point sources. However, the W3 scenario does not encompass other haul routes that will be used as part of the mining operation; therefore, the total PM emissions attributed to hauling would be expected to be greater than 2,901 TPY.

These observations suggest that IDEQ's reliance on operational scenarios designed to support modeling analyses to assess fugitive exclusion from Source Classification has allowed listed and point source attendant emissions to be misclassified as excluded mining fugitives. Misclassification of only a tiny percentage of the massive excluded emissions prevents Major Source determination and federal review of key portions of this PTC. The ambient impact analysis must consider the potential impacts of any operational scenario allowable under the federal approval process and the IDEQ permit.

Lastly, the classification of the facility as a synthetic minor source for criteria pollutants and HAPs is hugely dependent upon the facility consistently attaining the target 93.3% fugitive dust control effectiveness. A facility that does not have legally enforceable conditions to ensure those fugitive dust controls, which IDEQ states will be challenging to show continual compliance with, should be considered a major source. Enforceability is extremely important because without enforceable limits, the source otherwise has the potential to emit criteria pollutants in amounts that are at or above the threshold for a major source.

IDEQ should:

- Carefully review these fugitive emission claims with regard to the exclusion criteria, and publicly disclose the review.
- Update the source classification determination for this facility based on these comments.
- Ensure total consistency between project processes and activities approved in the air permit with those that would be approved in the federal approval process.

Dust Control Efficiency

IDEQ states in this permit that the Applicant will have to achieve a dust control efficiency of at least 93.3% on the haul roads in order to achieve air quality compliance, yet the agency has not provided sufficient evidence that such a high target is attainable or practically enforceable. In Appendix G of the Statement of Basis, IDEQ discusses the T-RACT Analysis, including dust control efficiency. We have reviewed the references listed in Appendix G, Table 10 of other facilities with determinations of 90% or greater control efficiency for unpaved roads. Upon investigation of these references through the EPA's Clean Air Technology Center database,[2] we found that only 1 of the 10 facilities referenced actually has *verified* compliance of achieving at least 90% control efficiency. The other nine facilities listed in Table 10 had either unverified or unknown compliance with that permit condition. In addition, only one of these facilities is actually a gold mining operation and therefore most of these references should not be used as a point of comparison to the Stibnite project.

[2] https://cfpub.epa.gov/rblc/index.cfm?action=Search.BasicSearch&lang=en

Listed Facilities in Appendix G, Table 10
AK Donlin Gold Project AK-0084 water/chem 90% (unverified/unknown compliance)
AR Turk Power Plant AR-0094 water/chem 90% (unverified/unknown compliance)
CO Rio Grande Portland Cement Corp. CO-0043 water/chem 90% (unverified/unknown compliance)
IN Nucor Steel IN-0034 chem 90% (unverified/unknown compliance)
LA Nucor Steel Louisiana LA-0239 water/chem 90% (unverified/unknown compliance)
MO Lafarge Corp. MO-0048 chem 90% (unverified/unknown compliance)
NV Sloan Quarry NV-0045 chem 98% (compliance verified)
NV Nellis Air Force Base NV-0047 water/chem 90% (unverified/unknown compliance)
OH Unlimited Concrete OH-0126 water/chem 90% (unverified/unknown compliance)
OH Unlimited Concrete OH-0131 water/chem 90% (unverified/unknown compliance)

According to the T-RACT analysis, the Applicant has eliminated paving as a control mechanism due to it being deemed too costly, instead selecting the application of a chemical dust suppressant supplemented by frequent watering. However, there is no assurance that other facilities of this size and nature have been able to achieve this high bar for dust control efficiency. IDEQ itself states on page 22 of the Statement of Basis that "it may prove challenging to consistently and continuously achieve the targeted level of fugitive dust control for emissions from traffic on unpaved roadways, with over 55 miles of haul truck routes within the mining operations boundary, a fleet of 32 haul trucks weighing between 37 and 357 tons, and a targeted dust control efficiency of 93.3% accomplished by application of both dust suppressant and water controls." Because the fugitive dust control efficiency is not practically attainable or enforceable, this facility should not be classified as a non-major source.

IDEQ should:

- Rigorously evaluate if the 93.3% dust control efficiency target is realistically attainable by the Applicant. If not, reclassify the facility as a major source.
- Include enforceable provisions in the permit to hold the Applicant to continuous achievement of that dust control efficiency level.
- Adjust emission calculations for ore handling and processing activities when temperatures are below freezing and proposed water controls would not be practical.

Fugitive Dust Control Plan

The Fugitive Dust Control Plan (FDCP) continues to be an area of significant concern for us. IDEQ has required the applicant to complete this plan as a condition of this permit. However, despite the FDCP clearly being a crux of the applicant's air quality compliance, the public will not have the opportunity to review and comment on this plan. We once again formally request the opportunity to do so. Furthermore, the permit specifies that the FDCP shall be submitted within 60 days of permit issuance. In this case, the permit would be approved without IDEQ or the public knowing specifically how the applicant will attain this aggressive standard of dust

control. For instance, we have no indication of how the applicant will suppress fugitive emissions sources other than roads.

Given that the specifics of the FDCP are crucial to ascertaining exactly how the applicant will achieve the lofty 93.3% dust control efficiency required to achieve compliance, and how enforceable the limits are, this permit should not be approved until a FDCP is submitted to IDEQ, reviewed by both IDEQ, EPA, and the public, and approved or denied pending modifications. A review of the FDCP prior to permit issuance is necessary to ensure compliance with air quality standards. If approved, the salient points of FDCP should be incorporated in the permit as clearly enforceable limits. This permit cannot be issued without enforceable provisions and limits to ensure that the high bar of fugitive dust control will actually be attained at the Stibnite Gold Project.

IDEQ should:

- Allow for public review and comment on the Fugitive Dust Control Plan *before* it is finalized.
- Incorporate clear, enforceable limits for fugitive dust control into this permit *before* any potential approval.

T-RACT

In this latest iteration of the permit, the T-RACT control measures were applied to meet human health criteria for airborne toxics. A T-RACT application is an admission that compliance with environmental health criteria is not feasible with reasonably available control technology (RACT). This is in contrast to prior IDEQ assertions that all standards would be met with available technology. The previous submittals also assured the public there were no environmental or health concerns associated with Toxic Air Pollutants (TAPs) compliance. This proposal requests exemptions from those standards. It is both confusing and concerning that IDEQ has modified its position from no significant impact to requiring T-RACT without disclosing the analyses that support these conclusions.

Before granting T-RACT, IDEQ should require the Applicant to address the feasibility of achieving compliance through more aggressive application of the current RACT proposed for particulate control, and require the necessary supporting calculations regarding environmental, cost, and energy impacts. These analyses should be based on appropriate RACT emissions and should identify the levels of control necessary for compliance with the AACC.

For detailed technical comments on T-RACT, we refer IDEQ to Section 8.0 of the comments submitted by Ian von Lindern, P.E. PhD, from the TerraGraphics International Foundation. To

summarize his technical comments, IDEQ should disapprove this T-RACT submittal in accordance with IDAPA 58.01.01.14 based on the following considerations:

- The emissions used to support modeling are based on inappropriate multi-year averages and do not reflect the PTE or T-RACT.
- The proposed operational limits on mine production will have no practical constraint on facility operations, emissions, or ambient impacts.
- The lifetime averaging of exposure is inappropriate. Just because this facility proposes to have "only" a 16-year life of mine, the Applicant is not therefore entitled to expend a receptor's equivalent 70 years of allowable exposure with regards to cancer risk.
- If the direct comparison of predicted maximum annual average ambient arsenic concentrations to the AACC is correctly applied, it shows a 30-factor exceedance, or 3 times the T-RACT AACC.
- Considerably higher levels of operational constraints will be required to support T-RACT. These limits are likely to require reductions in the proposed MODPRO2 levels of operations.
- The T-RACT controls are largely unenforceable, do not require any effective monitoring, or provisions for corrective actions, should the Applicant's assurances prove unachievable.
- The T-RACT analysis does not address the requirements in IDAPA 58.01.01.210.14.c.ii to access "the environmental impacts caused by the control technology that can not be mitigated, including, but not limited to, water pollution" despite the massive amounts of magnesium chloride and associated products that would be required to achieve the unprecedented dust control effectiveness proposed.

This relaxation of health protections deserves intensive review, public involvement, and consideration by other regulators. We are concerned that the repetitive nature of this PTC review undermines public awareness regarding the significance of this major change in strategy regarding emissions control from this facility as well as the health implications of relaxing health standards.

PM/PM10 Monitoring

In order to make this air permit practically enforceable, IDEQ must require that the Applicant install a PM/PM10 monitoring system on site at the ambient air boundary to ensure that PM/PM10 NAAQS are not violated. This step is warranted because of the uncertainty surrounding dust control efficiency and emissions factors associated with this project. To our knowledge, it is neither technologically or financially infeasible for the Applicant to install this monitoring. Additionally, IDEQ should include penalties and corrective actions in the permit that would be triggered if this monitoring system shows NAAQS violations occurring at the ambient

air boundary. These penalties should entail a mandatory reduction in mining and processing throughput.

IDEQ should:

- Add a permit condition that requires the Applicant to install a comprehensive continuous PM/PM10 monitoring system on site.
- Add enforceably penalties and corrective actions to the permit that are triggered if this monitoring system ever indicates that NAAQS are being exceeded.

Ambient Air Boundary Determination

We are concerned that the exclusion of the public access road between Stibnite Road at Sugar Creek and Thunder Mountain Road at Meadow Creek from the regulatory definition of ambient air is inconsistent with Clean Air Act's definition of ambient air,[3] EPA's long-standing policy that allows excluding certain areas of a source's property from ambient air,[4] and EPA's most recent revised policy for ambient air.[5] Allowing the public to access this road, even under the conditions of the Stibnite Road Access Management Plan, may result in acute exposure of the public to hazardous air conditions.

EPA's long-standing policy has been to exempt "the atmosphere over land owned or controlled by the source and to which public access is precluded by a fence or other physical barriers" from ambient air requirements.[6] In 2019, recognizing advances in surveillance and monitoring capabilities, EPA revised the "fence or other physical barriers element of this ambient air policy while maintaining public health protection" to allow stationary sources to use "other types of measures "to support exclusion of an area from ambient air."[7] Key to this policy revision was the fact that "legal" access – whether the public has the right or permission to enter a specific property – did not change the definition of ambient air. In other words, "if 'ambient air' is defined as that to which the general public has access, then that to which the general public does not have access is not ambient air."[8]

[7] Memorandum to Revised Policy; Revised Policy at 2.

[8] Revised Policy at 6.

Under this permit, the general public would have access to the road through the project area and not be entirely precluded from using it throughout the life of the mine. Based on EPA's policy, since the general public would have access, albeit restricted, the road is ambient air. The Response to Comments justifies this exclusion because "[t]he roadway is completely within the boundary of the mine," "[u]se of the roadway by [the public] is completely at the discretion of PRI and will be tightly controlled," and the public "will be considered [business invitees] of PRI."[9] This rationale cannot be reconciled with EPA's policy.

The EPA Revised Policy explains:

> "The EPA's view is that the general public has legal access to areas that are owned and controlled by parties other than the owner or operator of a stationary source. The EPA continues to view the "general public" to include any person(s) other than those who are permitted access to the property as employees or business invitees of a specific stationary source (including trespassers)."[10]

In other words, people that are traveling on the road through the mine site to access public (Forest Service) property are members of the general public. The Applicant's attempt to label the public as "guests of PRI"[11] is disingenuous and "would expand the exclusion beyond reason and deny the protection of the NAAQS to large numbers of people."[12] The fact that these "guests" would "abide by access and safety procedures established by PRI" is meaningless in terms of protecting the public from exposure to hazardous air conditions. There are no air quality monitors on the road because it has been excluded from ambient air.[13] Thus, it will not be known to those traveling on the road what type of acute exposure to air pollutants will result.

Moreover, IDEQ's own definition of "ambient air" is "[t]hat portion of the atmosphere, external to buildings, to which the general public has access."[14] The public access road through the project area fits that definition exactly. In addition, IDEQ's Modeling Guidelines[15] for determining the ambient air boundary demonstrate that this public road should <u>not</u> be excluded from the ambient air boundary:

- "It shall be assumed that the air within the facility boundaries is ambient air unless the facility can demonstrate that public access is precluded." Here, although public access

[9] IDEQ, *Air Quality Permitting 2nd Response to Public Comments* (June 4, 2021) at 7 ("Response to Comments").

[15] IDEQ, *Guideline for Performing Air Quality Impact Analyses* (July 2021) at 37-38.

might be controlled, it will not be precluded. Filing for required federal permits acknowledges that the Applicant does not have the right to preclude public access across the project site. Thus the road should not be excluded from an ambient air analysis.

- "For the purpose of defining ambient air, the 'general public' is considered anyone not directly associated with the facility. In general, if someone present at the site would not be subject to OSHA or other worker exposure regulations, then they are considered as the general public." People passing through the facility to access public land on the other side of the project area are not "directly associated with the facility" and would not be "subject to OSHA or other worker exposure regulations" and therefore are the general public

- "If the facility is not controlled by a physical barrier AND/OR general public access is not discouraged by the type of area, size of the facility, or the remoteness of the facility location, then the ambient air boundary is determined to be inside the property boundary." The Applicant does not propose a physical barrier. General public access is not discouraged by the items listed above. Access to these public lands is long-standing, an important part of Valley County's recreational experience, and acknowledged in fillings for federal permits.

- "Is the general public allowed on site as a part of a right-of-way easement or a common service road? If "yes," then the right-of-way is determined to be ambient air." The public is allowed access through the site because it is a public road. The Applicant cannot completely preclude public access.

IDEQ precedent, reaffirmed as recently as 2021, makes it clear that a public right-of-way access through a project area is considered – not excluded from – ambient air, and regulatory analyses of the potential impacts along that road must show compliance with all ambient impact limits for averaging periods under one year. This determination has been applied by IDEQ for public roads, non-navigable rivers, and railroad tracks. Here, the general public would be allowed access through the mine site on a public road that the Applicant does not have the right to completely deny access. There is no indication that this public road should be treated any differently from past projects. Nothing in the ambient air impact assessments supporting this permit includes any analysis of the impacts on the road through the project area.

IDEQ should:

- Reassess the ambient air boundary determination and model ambient air concentrations along public access routes.

TAPs Mass Balance

We recommend that IDEQ develop a material balance for TAPs to inform and assist the agency in assessing the quality and uncertainty inherent in the data underlying the Applicant's assertions. Many other states specifically require a material balance for criteria pollutants, HAPs, and TAPs. IDEQ's response reiterates the same "conservative" claim:

> "While a material balance is a useful approach to developing emission estimates, it is not a requirement, and the use of maximum activity rates and representative performance test data to estimate and model emissions is commonly accepted by DEQ. While the use of an average or maximum value is a more conservative approach, the use of site-specific median values combined with estimating and modeling PTE at design capacity and maximum activity rates was considered a sufficiently conservative approach."

IDEQ's own TAPs guidance, however, specifies the use of AP-42 and mass balance techniques:

> "Determine if a new (constructed after June 30, 1995) emission unit has the potential to emit a TAP listed in IDAPA 58.01.01.585 (Rules Section 585) or IDAPA 58.0101.586 (Rules Section 586). Potential toxic air pollutants can be determined by reviewing commonly available emission factors, such as EPA's AP-42, or calculating emissions using a mass balance."

Mass balance analyses would be invaluable in enhancing regulators' and the public's ability to follow and review emission calculations, and designing appropriate operational limitations and controls for this PTC.

IDEQ should:

- Require a facility-wide mass balance for TAPs in subsequent submittals for this PTC.

Arsenic Emissions

The proposed Stibnite Gold Project clearly presents hazardous concerns associated with toxic metal releases. Arsenic and mercury are of particular concern due to their high toxicity and importance in the metallurgical processes. This facility will potentially emit 170 to 360 TPY of arsenic. About 85-90% of the uncontrolled arsenic emissions are proposed to be contained or captured by proposed controls and approximately 13 to 38 TPY will be released to the atmosphere as fine particulate (controlled PTE). The PTC Application underestimates these emissions by a factor of 5.6 to 12 times by our calculations (see previous public comments on version 2 of this PTC), and asserts arsenic emissions of about 30 TPY PTE uncontrolled and 2.4 TPY controlled PTE. Most of this mischaracterization is associated with road dust suspended from the massive volume of heavy trucks moving thousands of loads of arsenical contaminated materials across the site. The Applicant apparently achieves this low estimate by using minimal

emission factors and particulate arsenic content, and claiming an unprecedented capability to control 93.3% of the road dust through chemical suppressants and watering.

An in-depth review of the Emissions Inventory reveals there are several factors that have not been given appropriate treatment in developing the arsenic emissions totals. We incorporate our detailed prior comments on this matter by reference into this latest round of comments and continue to have significant concerns that the arsenic emissions from this facility are being grossly underestimated.

The underestimation of fugitive dust emissions from haul roads resulting from the use of non-conservative modeling parameters is exacerbated when one considers that there appear to be three largely unaccounted for processes that will increase the arsenic content of haul road related fugitive dust emissions over time: 1) haul truck spillage of ore or waste rock containing higher arsenic content than the surface aggregate, 2) an increase in silt-sized particles in the haul road surface layer due to traffic wear, and 3) the application of dust abatement water sourced from the East Fork South Fork of the Salmon River containing elevated levels of arsenic.

Silt Content

As IDEQ has acknowledged in their response to comments, there are three key data-based variables used in estimating controlled, unpaved road arsenic emissions: silt content, arsenic content of the silt, and control efficiency. We remain concerned that using a 4% silt content for surface aggregate material for haul roads is too low according to scientific literature. Using a lower than reasonable silt content results in an underestimation of fugitive dust emissions. In its response to comments, IDEQ failed to provide a rationale for why the Applicant's assumption that a 4% silt content was appropriate in this case when EPA's publication AP-42 (that IDEQ relies on for other purposes) provides a mean silt content range for industrial unpaved haul roads of 5.8 to 24%.

Table 13.2.2-1. TYPICAL SILT CONTENT VALUES OF SURFACE			
AP-42	MATERIAL ON INDUSTRIAL UNPAVED ROADS		
		All Gravel Road	Haul Roads
	Industry Types	18	4
	No. Sites	53	10
	No. Samples	272	58
	Minimum	4.3%	5.8%
	Maximum	24.0%	24.0%
	Average	10.1%	11.6%
	Median	8.4%	8.4%
	Geomean	8.8%	9.9%

The mean silt content range reported in AP-42 is consistent with other scientific literature. Tannant and Regensberg's *Guidelines for Haul Road Design* (2001), for example, provides guidelines for haul road surface material properties (Section 5.1.1, pg. 58) and recommend a range of 5-10% fines (material passing a #200 sieve). They cite two separate studies stating 5-15% and 5-10% respectively to support this guideline. We have not been able to find any evidence for *functional* haul road surface material having less than 5% silt content. The following table summarizes plausible values for three variables at this site. These values are rated as minimal, typical, and conservative emissions factors.

Comparison of Characteristic Values for Key Variables Used in Calculating Particulate and Arsenic Emissions from Gravel Haul Roads				
Characteristic	Silt Content	Silt Content	As Content	Control
Values	All Gravel Roads	Haul Roads	ppm	%- Emitted
AP-42 Minimal	4.3%	5.8%	909	10%
AP-42 Typical	8.8%	9.9%	1231	15%
AP-42 Conservative	10.1%	11.6%	1812	20%
Midas PRI	4%	4%	667	6.7%

In each case, the Applicant has used less than minimal values. Our concern is that reliance on an unrealistically low silt content value combined with the need for extremely aggressive fugitive dust control efficiencies raises the significant likelihood that this permit may exceed National Ambient Air Quality Standards for particulate matter. IDEQ's response to comments simply states that the assumption for a 4% silt content was "confirmed by PRI and accepted by DEQ."[16]

[16] Response to Comments at 62.

But there is no discussion on what basis DEQ accepted this value for silt content and there is no stated rationale for why a higher silt content that is recommended in scientific literature does not apply to this particular haul road.

IDEQ should:

- Reassess emissions calculations and fugitive dust control efficiencies using a more realistic silt content for haul roads.

Mining/Processing Throughput Limits

The draft permit contains several throughput limits as defined in Permit Conditions 3.5 and 3.6. These conditions are artificial production limits on the facility, and will not have a bearing on the actual emissions being produced once the mine is simultaneously mining and also processing from stockpiled material. We have concerns that these artificial production limits are not actually enforceable in any way by IDEQ. Furthermore, we do not have any assurances that these artificial production limits will remain the same throughout the entire life of mine. For example, Figure 3.9 of the proposed mine plan[17] initiates and concludes with low rates over the 16 years of the mine with higher rates in the middle, making a five-year rolling average (like what is proposed in Permit Condition 3.5) meaningless in terms of limiting production.

Permit conditions should also be developed that establish throughput limits on the refining facilities and haul roads themselves, not just hauling and excavation tonnages. This is because the design capacity of the refining facilities exceeds the mine production capacity, and new ore could theoretically come in from other sources and be refined/processed at Stibnite. Without specific throughput limits on the refining process, those added emissions would not be considered.

Lastly, because IDEQ treats TAPs emissions on an incremental rather than cumulative basis, we can envision problems arising in a scenario where this facility gets permitted at the current throughput limits but then asks for an expansion five years down the road. If they are then permitted for an expansion, any increases in TAPs emissions will be permitted on a standalone basis rather than cumulatively on top of what was initially permitted. Ultimately, we are concerned that this is an approach the Applicant could use to circumvent being permitted as a TAPs Major Source in this initial PTC.

[17] STIBNITE GOLD PROJECT: REFINED PROPOSED ACTION – MODPRO2, Perpetua Resources Idaho Inc. October 15, 2021.

IDEQ should:

- Indicate how they plan to enforce these throughput limits and include additional measures in the permit to this effect.
- Add throughput limits for the refining and processing facilities.

In summary, we once again urge IDEQ to deny Perpetua's current application for a permit to construct and require a new application that objectively presents the emissions and controls required to comply with State and Federal requirements.

Nez Perce

TRIBAL EXECUTIVE COMMITTEE
P.O. BOX 305 • LAPWAI, IDAHO 83540 • (208) 843-2253

March 14, 2022

Submitted via email to: kelli.wetzel@deq.idaho.gov

Re: ***Nez Perce Tribe's Comments on Perpetua Resources Idaho, Inc., Stibnite Gold Project, Updated Proposed Permit to Construct and Operate an Air Pollution-Emitting Source (Docket No. AQ-1700)***

Dear Ms. Wetzel:

On behalf of the Nez Perce Tribe ("Tribe"), I submit this letter and accompanying technical comments on the updated proposed permit to construct and operate an air pollution-emitting source ("updated PTC") for Perpetua Resources Idaho, Inc., ("PRI") proposed Stibnite Gold Project ("Project") located at the intersection of Forest Service Roads NF-374 and NF-412, Docket No. AQ-1700. The Tribe's comments supplement the comments it previously submitted on October 12 and November 10, 2020 and on March 18, 2021.

The Tribe would like to acknowledge the additional effort undertaken by the Idaho Department of Environmental Quality ("DEQ") to address substantive comments received during previous public comment periods concerning the emissions of hazardous air pollutants ("HAP") and toxic air pollutants ("TAP") and the lime plant status determination. The Tribe would also like to thank DEQ for extending the public comment period by an additional 30 days. The original 30-day comment period was inadequate to provide the Tribe and the public sufficient time to review PRI's new reports and the revisions to the draft PTC and Statement of Basis.

The Tribe has reviewed the DEQ response to comments, updated proposed permit and technical review for the Project. For the reasons outlined in the attached technical comments, the Tribe disagrees with DEQ's determination to issue the proposed permit. DEQ has not adequately resolved the questions and concerns submitted by the Tribe, and, therefore, has not demonstrated that constructing and operating an open-pit gold mine, on-site ore processing, ore concentration and refining, and ancillary equipment would be achievable without causing or contributing to a violation of the National Ambient Air Quality Standards ("NAAQS") for PM10. Project activities

will therefore injure or unreasonably affect human or animal life or vegetation and the Tribe's Treaty-reserved resources, and DEQ must accordingly not issue the proposed permit to PRI.

The Nez Perce Tribe appreciates this opportunity to provide these comments on the updated PTC. If you have any questions or require clarification from the Tribe, please do not hesitate to contact Julie Simpson, Air Quality Program Coordinator, Environmental Restoration & Waste Management Division, Nez Perce Tribe, at (208) 621-3818 or Mike Lopez, Senior Staff Attorney, Nez Perce Tribe Office of Legal Counsel, at 208-843-7355.

Sincerely,

Samuel N. Penney

NEZ PERCE TRIBE'S COMMENTS ON AQ-1700
PERPETUA RESOURCES IDAHO, INC., STIBNITE GOLD PROJECT,
UPDATED PROPOSED PERMIT TO CONSTRUCT AND OPERATE
AN AIR POLLUTION-EMITTING SOURCE

The Nez Perce Tribe ("Tribe") submits the following comments on Perpetua Resources Idaho, Inc.'s updated proposed permit to construct and operation an air pollution-emitting source for the Stibnite Gold Project. The Tribe's comments supplement the comments it previously submitted on October 12 and November 10, 2020 and on March 18, 2021.

DEQ's reliance on a 93.3% fugitive dust control efficiency to ensure compliance with permit requirements and for the Project to be classified as a synthetic minor source is unsupported

Permit conditions must ensure compliance and enforceability, and DEQ has not demonstrated evidence that a 93.3% fugitive dust control efficiency is attainable or practically enforceable. DEQ has not provided any case studies that a 93.3% fugitive dust control efficiency can be met through a combination of chemical suppressant and added water. Not only is the 93.3% control efficiency requirement not backed up by supporting technically accurate documentation to be possible in the real world, permit conditions are not written so that it is possible to verify compliance and document violations when enforcement would be necessary. DEQ is, therefore, unable to ensure that permit conditions can be met.

DEQ also relies on the unproved 93.3% fugitive dust control efficiency for the Project to be considered a synthetic minor for facility-wide emissions of PM/PM_{10}/PM2.5 to be below 250 tons/yr PSD applicability thresholds, Title V 100 tons/yr applicability thresholds, and to limit facility-wide emissions of single and total HAP to below HAP major source applicability thresholds of 10/25 tons/yr. As described above, because the 93.3% fugitive dust control efficiency is not practically achievable or enforceable, the Project does not meet the standard to avoid classification as a major source for PSD, Title V, and HAP.

The state of Idaho's internal controls and program resources are inadequate to guarantee permit conditions will be met

The PTC lacks sufficient monitoring for enforcement and compliance to ensure that permit conditions are met. In the Tribe's March 18, 2021 comment letter, the Tribe states that a once every two years inspection schedule and response by phone was woefully insufficient to ensure the Project is meeting the 93.3 percent fugitive dust control permit requirements that guarantee human life, animal life, and vegetation, and the Tribe's Treaty-reserved resources are not injured or unreasonably affected. DEQ now states that the inspection schedule will be even more insufficient – at a rate of once every five years.

Meteorological data used in the modeling came from on-site monitoring at one location. With the complex terrain of the site, the inputs to the modelling will not be representative of the actual weather throughout the entire mining site over the life of the mine. With that in mind, fenceline monitoring should be a requirement to ensure compliance with the PM10 NAAQS, if the permit is issued.

As described in our November 10, 2020 comments, additional monitoring (real-time continuous, federal reference PM2.5 and PM10 monitoring, web cameras, aerial drones, and collocation of meteorological monitoring) and weekly on-site inspections are necessary for DEQ to accomplish its responsibilities under the Clean Air Act to implement and enforce permit conditions and ensure the NAAQS are not violated.

Concerns with Fugitive Dust Control Plan (FDCP), Operations and Maintenance Manual (O&M), Access Management Plan (AMP), and Haul Road Cap Plan (HRCP) submission and review process

These plans are key to holding Project emissions at or below assumed emissions in the emissions inventory and modeling used to determine the source applicability of the Project. Any assumptions, including emission controls, need a practically enforceable permit requirement to keep the Project a synthetic minor for PSD, Title V, and HAP. As these plans are not yet written, and their associated permit conditions not included in the PTC, the PTC is not practically enforceable.

Our understanding is that the first opportunity for meaningful comment on the FDCP, O&M, AMP, and HRCP will be when a Tier I air operating permit is drafted. Strict adherence to these plans is critical to ensuring compliance, and only giving the public the opportunity to review and comment on these plans when the Tier I air operating permit is drafted, and every five years thereafter, is inadequate.

Adverse impacts of dust control abatement on other resources

The Tribe is concerned about the impacts of dust abatement chemicals on soils, vegetation, and wildlife. As it is DEQ's mission to protect human health and the quality of Idaho's air, land, and water, the Tribe is including this concern with these comments on the PTC.

Magnesium chloride ($MgCl_2$) and $MgCl_2$-lignin sulfonate products used to suppress dust on roadsides can damage vegetation foliage, alter soil quality, move in roadside drainages of up to 98 m from roads, and accumulate over time, often to toxic concentrations, in trees and soils.[1] High $MgCl_2$ soil concentrations from application caused mortality of Douglas-fir, lodgepole, ponderosa, and limber pines, and aspen in just two to four years.[2] Considering the life of the Project, the Tribe is concerned about long-term consequences to soils and vegetation from dust abatement chemicals.

Water is a scarce commodity in the project area. We are concerned that the limited quantity of water available is insufficient to meet permit conditions for use of water in fugitive dust control and water spraying for ore processing, and aggregate and concrete production. The quality of water is also a concern. The water source for dust control is proposed to be surface water

[1] Goodrich, B. A., et al., Condition of Soils and Vegetation along Roads Treated with Magnesium Chloride for Dust Suppression (Water, Air, and Soil Pollution 198, 165-188) (2009).
[2] Goodrich, B. A. and Jacobi. W. R. 2012. Foliar damage, ion content, and mortality rate of five common roadside tree species heated with soil applications of Magnesium Chloride. Water, Air, and Soil Pollution 223:847-862.

diversion from the East Fork of the South Fork of the Salmon River, groundwater, and runoff ponds. USGS sampling indicates elevated arsenic in these waters.[3] Water quality should not create additional environmental burden if contaminated waters are used to water roads. This should have been considered in the T-RACT determination as described in IDAPA 58.01.01.210.14.

Concerns with Permit Condition 2.20 O&M Manual

Permit condition 2.20 requires the permittee to develop and maintain an Operation and Maintenance (O&M) manual to ensure compliance with emission limits and the control equipment maintenance and operation general provision. The Tribe has the following concerns about section 2.20:

- Please explain why the O&M manual is termed a "manual" and not a "plan", and please justify why the O&M manual does not require approval by DEQ when DEQ approval is required for the FDCP, AMP and HRCP plans.

- Please explain the rationale for the O&M manual being due 60 days after startup of any process equipment, unlike the 60 days after permit issuance required for the FDCP, AMP, and HRCP plans.

- The O&M permit condition, 2.20, states a once per month visible emission (VE) inspection requirement for wet scrubber, carbon filter, baghouse, and bin vents, but permit condition 2.10 requires the following VE inspection: "Each day during daylight hours and under normal operating conditions, the permittee shall conduct a facility-wide inspection of potential point sources of visible emissions including stacks, vents, and functionally equivalent openings." Since wet scrubber, carbon filter, baghouse, and bin vents have openings, the VE inspection requirement for this control equipment should be the same as permit condition 2.10.

Concerns with Permit Condition 3.11 Drilling Rigs Dust Control System

We appreciate that DEQ has added controls for the drilling activities. However, the details in actually achieving the 90% control are to be included in an O&M manual which will be developed after the PTC permit is issued. If DEQ relied on vendor-stated control efficiencies, there should be testing requirements included in the PTC to validate the emissions controls.

Concerns with Permit Condition 3.13 Haul Road Capping

The addition of permit condition 3.13 Haul Road Capping is appreciated. However, haul road surfaces will degrade over time. Because the arsenic concentration in the roadbed will come from both the road material itself and spilled ore, DEQ should require periodic testing of both silt and arsenic content of the road bed to validate assumptions underlying the estimated emissions and assure the representativeness of the emission factors used. Periodic measurement would

[3] Baldwin, A.K., and Etheridge, A.B., 2019, Arsenic, antimony, mercury, and water temperature in streams near Stibnite mining area, central Idaho, 2011–17: U.S. Geological Survey Scientific Investigations Report 2019-5072, 20 p., plus appendix, https://doi.org/10.3133/sir20195072.

increase confidence that the NAAQS are being protected (PM_{10} from haul road fugitives) and fugitive arsenic is being controlled. We suggest use of most conservative average arsenic concentration in the quartzite used. In the 55,000 ore samples presented, that would be the mean, not the median as proposed in 3.13. Please explain in better detail how DEQ justified the assumption that 50% of the vehicle miles traveled (VMT) will occur on low-arsenic capped haul roads and what level of detail will be required in the HRCP such that the emission limits are enforceable.

Process flow description does not reflect applicant operations

Statement of Basis Facility Information Description and Figure 2 DIAGRAM OF PROCESS FLOWS are not updated to reflect Project operations.

Limestone values are misleading

The limestone mineralogy is expressed as median concentration values from 98 samples, yet it appears that all 98 samples came from one single core MGI-17-431. This is misleading, and we question if the metal concentrations used in the emissions inventory coming from the 55,000 ore samples are also incorrectly characterized.

Emissions estimate values are not sufficiently conservative

DEQ should use conservative values for all emission estimates. For any emission factor (EF) requiring an average value, the most conservative average value should be used to protect human health. Examples include the silt content for used in EF for Haul Road fugitives and the metal concentrations in the ore for HAP/TAP. The median is only a statistical number. The arithmetic mean is most commonly considered the average.

In the Statement of Basis it states, "It is noted that PRI projected actual annual production at approximately 42.7 million T/yr, or 65% of the permitted annual production limit of 65.7 million T/yr (Permit Condition 3.5), and that as a result actual emissions are expected to be lower than presented." The 65.7 MT/y value comes from 180,000 T/day for 365 days, however, permit condition 3.5 also has a 135,000 T/day limit based on a 5-year rolling average. Thus the actual permit limit is 49.3 MT/y (135,000 T/day x 365 day/y). Therefore, the projected actual annual production is closer to 87% (42.7/49.3) of the permitted annual production limit. The permit is less protective than DEQ has presented.

Concerns about fugitive dust controls

The FDCP plan is key for the facility to reach the 93.3% fugitive dust control that allows DEQ to demonstrate the facility is a synthetic minor. We are concerned that the use of such non-specific permit requirement terms of "as necessary" and "periodic" is not practical enforceability.

We are very concerned about PRI's commitment to 93.3% control for fugitives on haul roads. In Facility Comment #10, PRI asked for a change from a twice daily to a monthly frequency for permit condition 2.4 fugitive emission inspection. A monthly inspection frequency is woefully inadequate. We appreciate that DEQ has retained the twice daily inspection frequency.

PET 658

REC 1024

Retention of records should exceed five years. The records of FDCP are key to compliance checking and it is plausible that inspection frequency will exceed 5 years. The description of the facility information in the Statement of Basis states "the SGP will include three years of pre-mining development and construction activities, followed by an operating mine life of approximately 12 years." And permit condition 2.24 states "In accordance with IDAPA 58.01.01.313.01.b., the permittee shall submit a complete application to DEQ at the address provided (Permit Condition 2.26) for an initial Tier I operating permit within 12 months of becoming a Tier I source or commencing operation." Therefore, it is very plausible the facility will operate for 4 years or more before an operating permit is issued. If compliance inspection is every 5 years, earthmoving activities at the mine may go for 9 years before any compliance check is made by DEQ.

Permit condition 2.5 includes a 10% opacity trigger: "Fugitive dust control measures shall be applied to haul roads on a frequency such that visible emissions from vehicle traffic on a haul road do not exceed 10% opacity". We are unaware of any study showing that a 10% opacity limit ensures a 93.3% fugitive dust control efficiency. A more protective trigger would be an instantaneous see/no-see. Any trigger, to be sufficiently evaluated, should specify a timeframe for measurement (example: instantaneous or 15 second), a location, and when to take the opacity reading (example: immediately after a loaded ore truck passes near surface of the road bed). Additionally, with over 55 miles of haul roads, there should be multiple locations being monitored during each inspection.

Regular testing requirements needed for process and control equipment

Permit Conditions 2.20–2.21 require developing and complying with the requirements of an O&M manual to ensure compliance with control equipment maintenance and operation general provisions (Permit Condition 7.2). Documentation of as-built process equipment specifications and control equipment performance guarantees and establishing control equipment operating parameters and procedures were required, since these were relied upon in the development of emissions inventories, and in the evaluation of ambient air impacts in the modeling analyses. Compliance is ensured by complying with monitoring and recordkeeping requirements. There should be regular testing required to confirm process and control equipment are operating/performing to the specifications, guarantees, and parameters identified in the PTC application.

Antimony hauling not sufficiently characterized

The mineral products from the proposed Stibnite Gold Project are gold and antimony, accounting for 1 and 99% by mass, respectively. In earlier versions of the PTC, the antimony concentrated was going to be dried and bagged, and then was proposed to be dewatered and packaged wet. Page six of the Statement of Basis states, "The metal-recovery process from ore will include conventional crushing and grinding, followed by froth-flotation circuits that will generate separate gold-silver and antimony-silver concentrates. The antimony-silver concentrate will be shipped offsite for refining…". In Footnote c) of Table 3 in the Statement of Basis, it states that "In the response to a request for additional information, PRI confirmed that antimony process dryer and bagging operation emission sources (Sb1 and Sb2) initially proposed would be

replaced by a dewatering/packaging circuit. As a result, these emission sources have been removed from the permit and post-project PTE." Please include documentation confirming there are no air emissions associated with removing the antimony-silver concentrate from the site and how hauling the antimony concentrate from the processing area to the property boundary is accurately accounted for in the emissions inventory for the permit. If no market for the antimony is found and the concentrate is either stockpiled, stored on-site, or hauled to the tailings storage facility, emissions from this concentrate should be reevaluated.

No accounting for winter impacts on water controls

Permit condition 3.12 requires water control for ore processing crusher and conveyer at all times. Permit condition 5.10 also requires water control for portable crushing and screening at all times. When water freezes during low temperatures, water control will not be feasible. Therefore, each ore processing crusher and conveyor (3.12) and each portable crushing and screening plant (5.10) should not operate at temperatures below freezing or there will be no control of fugitives from these emission units (EUs). If any chemical(s) is added to the water to lower freezing and thus extend ability to use water control, they and their effects should be disclosed. Please address these concerns about freezing-weather operations for these permit conditions.

Clarification needed on 3.9 Prill Loading Limit

Permit condition 3.9 Prill Loading Limit is unclear: "The permittee shall not load in excess of 200 T/day nor and 9,000 T/yr of prill (ammonium nitrate) to the prill silos." The use of "nor and" is confusing. Please clarify the intent of this section.

Comments on Table 1.1 Regulated Sources

Table 1.1 in the permit lists all source of regulated emission in the permit. For clarity it would be easier to follow the permit and check limits for all the EUs if their Source ID No. were carried over from Table 1.1 to the remaining tables throughout the permit. Additionally, it is unclear if the control efficiency and maximum process rates listed in Table 1.1 are enforceable. The comments that follow are from checking the source ID listed in Table 1.1 for consistency in the permit and Statement of Basis.

- For the Mercury Retort and Induction Melting Furnace, Table 1.1 has a maximum process rate of 1,000 lb/batch and 21 T/yr. Monitoring in permit conditions 4.22 and 4.23 does not include monitoring of batch rather only weight is monitored. If only weight is recorded there is no criteria to measure compliance with the batch limitation.

- The emission units LS9-LS12 are missing a permit operating limit to ensure maximum process rate of 267 T/day.

- Statement of Basis application scope lists PS in ore processing. Assuming PS is PS1-2-L/U, in Table 1.1 of the permit, they (PS1-2-L/U) are listed under mining.

- Rock dumps and storage piles are missing from the Statement of Basis application scope.

- In Table 1.1 of the permit all mining sources except Prill Silos (PS1-2-L/U) have FCDP listed as Control Equipment. In Table 3.1 Mining and Ore Processing Control Device Descriptions some sources retain the FDCP as a listed Control Equipment (Drilling and Blasting) while others do not (Excavating and hauling activities) and some sources do not appear at all in Table 3.1 (rock dumps and storage piles).

- Although there is a facility-wide fugitive dust control and permit conditions 3.10 and 5.9 direct permittee to control fugitive dust, Reasonable Control and FDCP are listed in Table 1.1, but are missing from corresponding Tables for Control Description Descriptions for the following EUs: OC1-OC13, PCSP1, PCSP2, CM.

- For EUs EDG1-3 in Table 1.1, please allow for better performance control equipment, we suggest modifying EPA Tier 2 technologies to "EPA Tier 2 technologies or better".

Representativeness of the emission factors

The applicability determination depends on the emissions inventory (EI). The EI depends on the proposed processes and the EFs used to characterized these activities. There are instances where we are concerned that inappropriate EFs have been used. The EFs for the ore processing come from AP 42 chapter 11.19 Crushed Stone Processing and Pulverized Mineral Processing. The AP-42 chapter 11.24 Metallic Minerals Processing might be a better representation for the OC1-OC13. In all cases, the most conservative EFs should be used.

When an EF has a control efficiency built into it, the permit should specify conditions to assure equipment will employ the same controls to assure the representativeness of the EF. Permit conditions do not clearly specify this.

DEQ has erred in its interpretation of EPA's Revised Policy on Exclusions from "Ambient Air"[4] for the public access road through the mine site

The public access road between Stibnite Road at Sugar Creek and Thunder Mountain Road at Meadow Creek should not be excluded from the regulatory definition of ambient air. This road is intended to allow public access, not preclude it. EPA's revised Ambient Air Policy describes conditions by which the public is to be excluded from an area controlled by a source and which would then justify excluding an area for purposes of analyzing the source's impact on ambient air. Controlling public access on the public access road between Stibnite Road at Sugar Creek and Thunder Mountain Road at Meadow Creek, as is described Section 3.3.10 of the Statement of Basis, Appendix B Ambient Air Quality Impact Analyses Review Memorandum, consists of providing "controlled through-site access that is safe, provides travel-time comparable to current conditions and is consistent with the United States Forest Service travel management plan."[5] Controlling public access through a site is not excluding public access to a site, thus the EPA

[5] Morrie Lewis and Kelli Wetzel, *Statement of Basis: Permit to Construct No. P-2019.0047, Project ID 62288, Appendix B: Ambient Air Quality Impact Analysis Review Memorandum*, pp. 55-56, (Jan. 6, 2022), https://www2.deq.idaho.gov/admin/LEIA/api/document/download/16522.

revised Ambient Air Policy does not apply, and, therefore, the public access road should be considered ambient air.

As the public access road is ambient air, all emissions, modeling, and controls must be characterized and considered, and subject to the NAAQS.

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY

AIR & RADIATION
DIVISION

March 16, 2022

Ms. Kelli Wetzel
Idaho Department of Environmental Quality
1410 North Hilton
Boise, Idaho 83706-1255

Re: Perpetua Resources, Inc., Stibnite, Idaho, Docket No. AQ-1700

Dear Ms. Wetzel:

The U.S. Environmental Protection Agency (EPA), Region 10 has reviewed the proposed permit to construct and operate an open-pit gold mine located in Stibnite, Idaho, for Perpetua Resources Idaho, Inc. Docket No. AQ-1700. In addition to the proposed permit, the EPA has reviewed the proposed Statement of Basis, Response to Comments, and application materials, including the Stibnite Permit to Construct Application dated June 23, 2020, and the Stibnite Permit to Construct Application – TAP Addendum dated October 5, 2021, and submits the enclosed comments.

We would like to acknowledge the challenges presented when developing a mining air permit and Idaho's efforts to address the EPA's and other interested parties' substantive comments that were received during the previous public comment periods. The EPA remains concerned that the proposed permit does not include accurate permit conditions that are enforceable as a practical matter and that would achieve the objective of limiting the project's potential to emit such that it would be a synthetic minor source for the PSD construction permit program and Title V operating permit program as well as assure compliance with the applicable National Ambient Air Quality Standards (NAAQS).

The EPA appreciates the opportunity to review the proposed permit and is available to assist in the development of accurate, practically enforceable permit conditions sufficient to assure continuous compliance with the synthetic minor emission limits necessary to avoid major source permitting under PSD and Title V and also assure compliance with the applicable NAAQS. Please contact Bryan Holtrop at holtrop.bryan@epa.gov or (206) 553-4473 if you have any questions or would like to arrange a discussion of our comments.

Sincerely

KELLY MCFADDEN

Air Permit and Toxics Branch

cc: Mr. Mike Simon
Idaho Department of Environmental Quality

EPA'S COMMENTS ON DOCKET NO. AQ-1700
PERPETUA RESOURCES IDAHO, INC., STIBNITE GOLD PROJECT,
PROPOSED PERMIT TO CONSTRUCT AND OPERATE
AN AIR POLLUTION-EMITTING SOURCE
March 16, 2022

The U.S. Environmental Protection Agency, Region 10 has reviewed the proposed permit to construct and operate an open-pit gold mine located in Stibnite, Idaho, for Perpetua Resources Idaho, Inc. In addition to the proposed permit, the EPA has reviewed the proposed Statement of Basis, Response to Comments, and application materials, including the Stibnite Permit to Construct Application dated June 23, 2020, and the Stibnite Permit to Construct Application – TAP Addendum dated October 5, 2021.

As discussed in detail below, EPA has two overarching concerns: (1) the draft permit may not limit the source's potential to emit (PTE) to below prevention of significant deterioration (PSD) and Title V major source thresholds in a manner that is enforceable as a practical matter; and (2) the draft permit may not ensure the source will not cause or significantly contribute to a violation of the National Ambient Air Quality Standards.

General Requirements

EPA's longstanding position is that a permit limitation can legally restrict a source's PTE[1] if it meets two criteria: 1) the limitation is federally enforceable or legally and practicably enforceable by a state or local air pollution control agency; and 2) it is enforceable as a practical matter.[2]

In general, practical enforceability for a source-specific permit means that the provision must specify: (1) a technically accurate limitation and the portions of the source subject to the limitation; (2) the time period for the limitation (hourly, daily, monthly, annually); and (3) the method to determine compliance including appropriate monitoring, record keeping and reporting.[3] EPA made these comments in its March 19, 2021, comment letter to IDEQ regarding the previous Perpetua draft.

With respect to NAAQS compliance, in accordance with IDAPA 58.01.01.203.02: "No permit to construct shall be granted for a new or modified source unless the application shows to the satisfaction of the Department all of the following: NAAQS. The stationary source or

[1] IDAPA Section 58.01.01.107 (incorporating the definition of "potential to emit" in 40 C.F.R. § 52.21(b) and 40 C.F.R. Part 70; see also 58.01.01.006.88;

[3] John S. Seitz, "Options for Limiting the Potential to Emit (PTE) of a Stationary Source Under Section 112 and Title V of the Clean Air Act" (Jan. 25, 1995) ("Seitz Memo") at 5-6; Kathie Stein, "Guidance on Enforceability Requirements for Limiting Potential to Emit through SIP and § 112 Rules and General Permits" (January 25, 1995) ("Stein Memo") at 6; *In re Shell Offshore, Inc.*, 15 E.A.D. 526, 551 (March 30, 2012); Reclassification of Major Sources as Area Sources Under Section 112 of the Clean Air Act, 84 FR 36304, 36318 (July 26, 2019).

modification would not cause or significantly contribute to a violation of any ambient air quality standard." See also 40 CFR 52.670(c).

Limiting PTE for PSD, Title V (including HAP) and NAAQS Purposes

Many of the emission limits in the permit are derived from emissions factors. Similarly, the permit assumes control efficiencies for certain emission sources. However, the permit lacks conditions incorporating the numerous assumptions and parameters associated with the emissions factors and control efficiencies. Emission factors include numerous operating assumptions and variables regarding the source. Accordingly, the permit should contain conditions to ensure the operating assumptions and variables underlying the emission factor accurately reflect site-specific conditions and are enforceable.[4] Similarly, when permits require add-on controls operated at a specified efficiency level, permit writers should include, so that the operating efficiency condition is enforceable as a practical matter, those operating parameters and assumptions which the permitting agency depended upon to determine that the control equipment would have a given efficiency.[5]

The permit record does not demonstrate that the emission factors used to estimate the source's PTE and derive the emission limits are technically accurate. Emission factors used to derive a PTE limitation must be technically accurate.[6] In general, AP-42 emissions factors are based on averages and are not intended for establishing source-specific limits.[7] When using AP-42 emissions factors to establish limits on PTE, EPA recommends using these emissions factors only when source specific emissions factors are not available and selecting conservatively higher emissions factors.[8]

EPA states in AP-42, "Before simply applying AP-42 emission factors to predict emissions from new or proposed sources, or to make other source-specific emission assessments, the user should review the latest literature and technology to be aware of circumstances that might cause such sources to exhibit emission characteristics different from those of other, typical existing sources. Care should be taken to assure that the subject source type and design, controls, and raw material input are those of the source(s) analyzed to produce the emission factor. This fact should be

[4] Hunt Memo at 7-8; See also Peabody Western Coal, 12 E.A.D. at 38 n.38; In the Matter of Yuhuang Chemical Inc. Methanol Plant St. James Parish, Louisiana, Title V Petition Response Order, No. VI-2015-03 (August 31, 2016) ("Yuhuang Order") at 19, 28.

[5] Hunt Memo at 7, 20-21; see also Cash Creek General LLC, Title V Petition Response Order, No. IV-2010-4 (June 22, 2012) ("Cash Creek Order") at 17, 26 (granting in part because the permittee's claims of 90% control efficiency of PM emissions from storage piles and associated roadways was unsubstantiated and the permit lacked any requirements governing frequency of wet suppression, atmospheric or operations conditions under which wet suppression should applied the time of day that wet or chemical suppression should be applied, or the amount that should be applied).

[6] Peabody Western Coal, 12 E.A.D. at 39; *see also* In re Shell Offshore, Inc. 15 E.A.D. at 559; Yuhuang Order at 19, 28.

[7] Peabody Western Coal, 12 E.A.D. at 38 ("Peabody not only proposes to rely on the AP-42 factors to establish both its PTE limit and to demonstrate compliance with that limit, Peabody compounds the potential inaccuracy of this approach by using unverified emission control assumptions in both calculations."); see also John S. Seitz and Eric Schaeffer, "Potential to Emit (PTE) Guidance for Specific Source Categories" (April 14, 1998) at 4 n.4.

[8] In re Shell Offshore, Inc. 15 E.A.D. at 559.

considered, as well as the age of the information and the user's knowledge of technology advances."[9]

When permits contain emissions, production or operational PTE limitations, they should also have monitoring, recordkeeping, and reporting requirements that allow a permitting agency to verify a source's compliance with its limits.[10] The permit should provide for the collecting, maintaining, and reporting of information necessary to determine emissions of each pollutant as well as compliance with operating parameters.[11] The permit must include conditions that clearly specify the monitoring requirements and how the permittee must demonstrate compliance via the monitoring requirements.[12]

Limiting PTE for the Ore Processing and Lime Plant Operations for PSD, Title 5 (including HAP), Title V, and NAAQS Purposes

The Permit does not appear to specify technically accurate emission limitations and the portions of the source subject to the limitation because: (i) the permit may not adequately require compliance with all PTE emission limits for each emission source or include PTE emissions limits representing all emissions sources, (ii) the permit record may not adequately demonstrate that the emission limits are based on accurate emissions factors, and (iii) the permit may not contain monitoring, recordkeeping, and reporting conditions sufficient to ensure compliance with all emission limits and associated controls.

Examples of these specific issues with respect to the Ore Processing and Lime Plant Operations include, but may not be limited to, the following:

Ore Processing PTE Limitations**:**

1. A PTE limitation appears to be needed to restrict the amount of ore material storage piles consistent with the emission estimates in the permit application.
2. Per Table 1.1, the 80% control efficiency applicable to the associated ore storage piles, and source ID. No. OC9, OC10 and OC11 is not included.
3. Per the application Ore Processing Diagram (Figure 1), the 108 ton per day (tpd) process rate associated with the Sb Drying and Bagging, the 7.5 tpd process rate associated with the Carbon Regeneration, and the 6,980 tpd rate associated with the Autoclave are not included.
4. Per the application Ore Processing Diagram (Figure 1), emission sources Sb1 and Sb2 are not included in Table 1.1 or specified in the permit conditions.

Ore Processing PTE Emission Factors:

5. Some of the PTE limitations may not be technically accurate because they are not based on emission factors that are representative of the emission sources. For example, AP-42 Section 11.24 Metallic Minerals Processing emission factors applies to the processing of hard ores including gold. However, the application uses AP-42 emissions factors from Section 11.19.2 Crushed Stone Processing that is applicable to non-metallic mineral processing. The

[9] AP-42 Volume I at 4.
[10] Hunt Memo at 17; In re Shell Offshore, Inc. 15 E.A.D. at 551.
[11] 84 Fed. Reg. 36,304, 36,320.
[12] Yuhuang Order at 21.

permitting record does not provide a reasoned explanation as to why emission factors from Section 11.24 were selected over those from Section 11.19.2.

Ore Processing Monitoring, Recordkeeping and Reporting Requirements:

6. The monitoring method does not appear to specify how and where the PTE limitations will be measured consistent with the application's emissions calculations. For example, Permit Condition 3.18 specifies "The devices and methodologies used to measure weights shall be identified in the O&M Manual" for determining compliance with the input to the primary crusher. Per the application, this monitoring should apply at OC1 (Loader Transfer of ORE to Grizzly) and not OC7 (Primary Crusher) as specified in the permit condition. The permit also does not specify generally how the weight is measured such as by a truck scale or some other method but is to be developed in an O&M Manual after the permit is issued and is not enforceable to this permit condition (see permit conditions 2.20 and 2.21). The permit must include all monitoring, recordkeeping and reporting necessary to assure compliance with the permit emission limitations and applicable requirements. This comment is also applicable to permit conditions 3.16 through 3.20, 4.18 through 4.32, 4.34, and 5.16 through 5.24.
7. IDEQ required monitoring of baghouse pressure drop to assure compliance in permit condition 4.31. Though pressure drop monitoring can be an indicator of the source's maintenance program, monitoring experts within EPA have concluded that pressure drop is not a reliable approach for monitoring baghouse compliance. Alternatives to pressure drop include opacity monitoring/readings and bag leak detectors. Bag leak detectors are a good alternative for baghouses that require a more rigorous level of scrutiny than periodic observations provide. These monitoring techniques can be combined with a good operation and maintenance program to assure compliance. This comment is also applicable to permit conditions 5.21, 5.22, and 5.23.

Lime Plant PTE Limitations:

8. The following PTE limitations specified in Table 1.1 and the application do not appear to be included in the permit including: 267 tpd applicable to LK, LCR, and LS-L/U; 250 tpd applicable to LS1-L/U and MillS2-L/U; 1,000 tpd applicable to ACS1, ACS2, and ACS3; 500 tpd applicable to ACS4; and 70,000 tons per year applicable to LS1-L/U, MillS2-L/U, ACS1-L/U, ACS2-L/U, AC3-L/U and ACS4-L/U.
9. The PTE limitation of 1,130 tpd of limestone in permit condition 5.4 may not be technically accurate as it does not appear to account for all of the emissions sources comprising the lime plant subject to PSD and Title V permitting limits of a 100 tons per year. For example, the limestone mining activities (e.g., drilling, blasting, excavating, hauling, and storage piles) and all of the lime plant processing emission units and activities shown in the application's Figure 2 do not appear to be included in the emissions estimates. These emission units presented in Figure 2 include the dump truck unloading, stationary grizzly, rock breaker, primary crusher feed hopper, vibrating grizzly feeder, and the emission units and activities following the limestone ball mill and lime slaker (e.g., Milk of Lime Distribution Tank). Emissions from those aspects of the limestone handling and processing that would not happen if the lime plant did not exist must be accounted for as support activities to the lime plant. Furthermore, if the mining of limestone (including overburden removal) would not be done if the lime plant did not exist, emissions from those activities must also be included with the lime plant emission inventory. For example, IDEQ's SOB and Perpetua's letter

dated September 23, 2021, indicates that the limestone is overburden excavated from the Middle Marble Geologic Unit (MMGU) located in the northwest portion of the West End Pit and that the overburden must be removed to access the gold ore. However, Midas Gold documents from 2016 and 2020 indicate, contrary to this information, that the MMGU is located in the northeast portion of the West End Pit, is located beneath a 30 ft- to 250 ft-thick quartzite unit and requires the addition of a haul road to transport limestone to the lime plant processing facility. Because the limestone deposits are buried 30 to 250 feet below the surface, as noted above, it appears more than 1,130 tpd of material would need to be excavated to access the limestone deposit.

10. IDEQ's PSD applicability analysis in the Statement of Basis (SOB) does not appear to include all of these emission sources or provide the necessary information to support their Lime Plant PSD emission estimates.

Lime Plant PTE Emission Factors:

11. IDEQ's SOB Table 10 PSD emission estimates may not be technically accurate because they do not appear to be based on emission factors that are representative of the emission sources. For example, AP-42 Section 11.17 Lime Manufacturing emission factors applies to the processing of lime derived from marble. However, the application uses AP-42 emissions factors from Section 11.19.2 Crushed Stone Processing. In addition, the limestone excavating emission estimates (Material Load & Unload) appear to use emission factors from Section 11.19.2 Crushed Stone Processing instead of Section 11.9 Western Surface Coal Mining emission factors that are representative and specific to mining excavation activities. The permitting record does not explain why emission factors from 11.19.2 were selected over those from 11.17 and 11.9. If IDEQ does not have a good technical reason for their selection of emission factors, consistent with comment #5, the most conservative emission factor should be used for emission units that make verification difficult. Comment 19 would also apply to fugitive dust emissions resulting from limestone mining sources including limestone drilling, blasting, excavating, and haul road activities.

Lime Plant Monitoring, Recordkeeping, and Reporting (MRR) Requirements:

12. Consistent with comment #6 for ore processing, the lime plant MRR requirements appear to be unenforceable as Permit Condition 5.16 specifies "the permittee shall monitor and record" using the "devices and methodologies… identified in the O&M Manual" for the PTE limitation associated with the limestone primary crusher. The permit must include all monitoring, recordkeeping and reporting necessary to assure compliance with the permit emission limitations and applicable requirements.
13. If the O&M Manual is used to provide the monitoring, recordkeeping, and reporting (MRR) requirements for the applicable PTE limitations then the O&M Manual would need to be reviewed and approved by IDEQ, available for review during the public comment period and must be enforceable at all times upon issuance of the permit. Also, any changes to the O&M Manual that that would make the approved MRR requirements less stringent would be subject to the same IDEQ and public review approval process and need to be enforceable at all times upon issuance of the revised permit.

Other PTE Limitations:

14. Central Mixer Loading (Source ID No. CM) controls are unspecified in Table 1.1 and the permit consistent with the emission estimates in the permitting record.
15. Engine PTE limitations specifying the capacity of 1,000 bkW for the three emergency generators (EDG1, EDG2, and EDG3) should be specified in the permit. Also, the monitoring and recordkeeping requirement specified in permit condition 6.3 should include all hours of operation, not just non-emergency operating hours, and specify the devices and methodologies by which the monitoring and recordkeeping will be achieved.

Limiting PTE of the Mining Fugitive Dust Emissions for NAAQS and Title V HAP Purposes

The permit does not ensure that the fugitive dust emissions related to the mining of ore and limestone will not cause or significantly contribute to a violation of the NAAQS or exceedance of the Title V HAP major source permitting thresholds. The emission limits necessary to ensure compliance with the NAAQS and Title V HAP applicability limits do not appear to be enforceable as a practical matter. In particular (1) achieving 93.3% control efficiency for fugitive dust resulting from mining activities (excavation and haul roads) and 90% control efficiency for drilling activities are critical to ensuring no violation of the NAAQS and Title V HAP limits, (2) the permit does not contain the conditions necessary to ensure the permittee achieves those efficiencies at all times and (3) the permit record does not demonstrate that those efficiencies are achievable based on the site-specific conditions at the Perpetua mine. EPA made similar comments in its March 19, 2021, comment letter to IDEQ regarding the previous Perpetua draft.

Examples of these specific issues include, but may not be limited to, the following:

Mining Fugitive Dust PTE Permit Limitations**:**

16. PTE limitations consistent with the 93.3% control efficiency applicable to haul road and access road do not appear to be specified in the permit conditions. These PTE limitations may include permit conditions requiring control measures such as how frequently chemical suppressant supplemented with watering must be applied, the atmospheric and operational conditions under which magnesium chloride supplemented with watering should be applied, the time of day that magnesium chloride supplemented with watering should be applied, and/or the amount that should be applied. [13] The permit requires that fugitive road dust PTE limitations such as those indicated above are to be developed by the permittee after the permit is issued. The permit also allows these types of PTE limitations to be changed without IDEQ review and approval. PTE limitations addressing the 93.3% control efficiency must be reviewed and approved by IDEQ, subject to review by the public during the public comment period and must be enforceable at all times upon the issuance of the initial permit. Also, any changes to the approved PTE limitations after the permit is issued that are less stringent must go through IDEQ public review and approval and must be enforceable at all times upon the issuance of the revised permit.
17. PTE limitations to achieve a 93.3% control efficiency for fugitive dust emissions associated with the mining excavation activities as specified in Table 1.1 and Table 3.1 do not appear to be specified in the permit conditions. Although permit condition 3.10 requires the "permittee

[13] See Cash Creek Order at 17, 26.

shall control emissions from mining… emission sources (Table 3.1) in accordance with the Fugitive Dust Control Plan." it does not specify what those controls are and as such are unenforceable. These control measures must be specified as part of the permit consistent with the permitting record and subject to review during the public comment period. In addition, these control measures must be enforceable at all times upon issuance of the permit. Any changes that are less stringent than the approved control measures made after the initial permit is issued must be proposed for review using public notice procedures and must be enforceable at all times upon issuance of the revised permit.

18. To make the PTE limitations enforceable as a practical matter, the permit should include the parameters and assumptions used to develop the fugitive dust emission factors estimates for the haul roads and access roads (see AP-42 Section 13.2.2, Equation 1a).[14] Per AP-42 and the application, these parameters and assumptions include surface material silt content (%), mean vehicle weight (tons), speed limit (mph), and daily vehicle miles travelled.

Mining PTE Fugitive Dust Control Efficiencies and Emissions Factors:

19. IDEQ's permitting record does not appear to provide support for a 93.3% control efficiency applicable to fugitive dust emissions resulting from mining excavation operations and haul roads. IDEQ's permitting record cites three studies that address the control efficiencies associated with fugitive dust emissions associated with haul roads but not mining excavation activities. Based on these studies, IDEQ concludes that applying magnesium chloride will achieve a control efficiency of 90%. However, IDEQ's permitting record does not provide a reasoned analysis consistent with AP-42's control effectiveness factors (or equivalent) that this control efficiency and associated control measures identified by these studies would be representative of Perpetua's mining operation. In addition, IDEQ's permitting record does not identify the specific study details that support their conclusion and does not include copies of these studies for review during public comment period. (see Appendix A, Air Sciences 2020 application, page 339 of 421). IDEQ's permitting record indicates that a control efficiency of 90% is also supported by control efficiency limits established for 10 projects in the EPA RACT/BACT/LAER Clearinghouse (RBLC) database. However, IDEQ's permitting record does not provide a reasoned analysis consistent with AP-42's control effectiveness factors (or equivalent) that the control efficiencies and associated control measures identified by these permitting projects would be representative of Perpetua's mining operation. In addition, IDEQ's permitting record does not identify the specific details from the permitting projects and associated documentation that support their conclusions (IDEQ's 2021 TAP Addendum, page 37 of 226). Moreover, IDEQ's permitting record does not provide any technical studies showing that the supplementing magnesium chloride with watering will improve the control efficiency of magnesium chloride. Lastly, IDEQ's permitting record does not appear to provide support for a 10% opacity associated with a 93.3% control efficiency for haul roads as established in Permit Condition 2.5. To support the 93.3% claim of road dust control efficiency, a see-no see approach to opacity monitoring may be more appropriate.
20. IDEQ estimated fugitive dust emissions from haul roads based on a 4.0% surface material silt content.[15] However, the arithmetic average silt content for haul roads based on Perpetua's site-specific data is 4.3%. The silt content value can have a significant impact on the

[14] See footnotes 4 through 6, above.
[15] Statement of Basis at page 27 and Appendix A.

representativeness and conservativeness of the emissions factor and, thus, emissions estimate.[16] Use of the 4.3% average value results in about 7% more fugitive dust emissions from the haul roads than estimated using the median value. IDEQ's modeling sensitivity study showed values just below the NAAQS, such that an 7% increase in fugitive dust from haul roads would have resulted in 24-hour PM10 NAAQS violations. AP-42 values for similar operations show a wide range of silt fractions, with average values around 8% silt fraction for mine haul roads. The permit record does not include an adequate justification for using the 4.0% silt content figure to derive the fugitive dust haul roads emissions factor and whether a 4.3% is representative for the haul roads including inside the open pits.

21. As noted in Comment #15 and #16, the mining excavation PTE limitation of 180,000 tpd may not be technically accurate because it is not based on emission factors that are representative of mining emission sources. For example, AP-42 Section 11.9 Western Surface Coal Mining Section includes emission factors applicable to mining excavation operations. However, the application appears to use AP-42 emissions factors from Section 11.19.2 Crushed Stone Processing for truck loading and unloading of crushed stone.

Mining Fugitive Dust Monitoring, Recordkeeping, and Reporting Requirements:

22. No monitoring, recordkeeping and reporting (MRR) requirements appear to be specified for the excavation mining controls required by permit conditions 3.10 to ensure their enforceability.
23. No monitoring, recordkeeping, and reporting requirements appear to be specified for the 90% control efficiency applicable to the drilling activities required in permit condition 3.11.
24. The monitoring methods associated with the haul roads appear to be unenforceable as they do not specify how the monitoring and recordkeeping demonstrating compliance with the applicable PTE limitations will be achieved. For example, Permit Condition 3.16 specifies "the permittee shall monitor and record" using the "devices and methodologies… identified in the O&M Manual" for the PTE limitation associated with the 180,000 tpd hauling PTE limitation in permit condition 3.5. The permit must include all monitoring, recordkeeping and reporting necessary to assure compliance with the permit emission limitations and applicable requirements. The permit must include all monitoring, recordkeeping and reporting necessary to assure compliance with the permit emission limitations and applicable requirements.
25. Given the high level of uncertainty in the assumptions and requirements to ensure compliance with the PM10 24-hr NAAQS, the addition of post-construction ambient monitoring requirements is highly prudent. IDEQ may be able to require post-construction monitoring when determined to be necessary to determine the effect a stationary source may have on air quality in the vicinity of the source, especially when there is high uncertainty in project air quality impacts determined from modeling. The EPA recommends IDEQ add a permit requirement for the source to deploy a fenceline PM10 monitoring network, in a manner determined to be adequate by IDEQ, to demonstrate 24-hour and annual PM10 NAAQS compliance.

Mining Access Management Plan (AMP) for NAAQS Purposes:

26. Permit Condition 2.7 requires the development of an Access Management Plan (AMP) to address whether the NAAQS apply to the mine's access road through the Perpetua Mining

[16] AP-42 Chapter 13.2.2-4.

site given the extent of public access allowed. Permit Condition 2.8 allows the AMP to be developed after the permit is issued and does not require the AMP to be enforceable. For the AMP to preclude the applicability of the NAAQS along the access road, the AMP must be reviewed and approved by IDEQ, subject to review by the public during the public comment period and must be enforceable at all times upon issuance of the initial permit. Any changes to the AMP that are less stringent than the approved AMP must be reviewed and approved by IDEQ, subject to review by the public, and enforceable at all times upon issuance of the revised permit.

27. Given the unique situation with a public access road traversing the mine site, the key assumptions, parameters, and methodologies used to preclude public access from the mine site must be fully disclosed in the permit record and the necessary requirements be included in the permit and available for public review and comment. The State assumes measures taken to preclude public access will be appropriate and adequately comply with EPA's Revised Policy on Exclusions from Ambient Air (as specified in the December 2, 2019, memo from Andrew Wheeler to the EPA Regional Administrators). Section 2.7 of the permit provides requirements for the source to develop a plan to preclude public access, but these requirements offer a range of measures the source may choose to implement and are therefore ambiguous. Without full disclosure in the record of the exact measures and permit requirements to ensure compliance with national ambient air policy, it is not clear if the public access road can be excluded from ambient air protections. The state needs to provide sufficient justification to demonstrate the measures and requirements to preclude public access and ensure members of the public traversing the road can be classified as "guests of the mine" sufficiently complies with national ambient air policy. Given the uniqueness and ambiguity of the situation, a petition to the EPA national ambient air policy team for review and concurrence with the State's findings could be warranted.

Mining Dust Haul Road Capping Plan (HRCP) for NAAQS and Title V HAP Purposes:

28. Permit Condition 3.13 requires the development of a Haul Road Capping Plan (HRCP) to address fugitive dust emissions from the haul roads and development rock storage facilities after the permit is issued.
29. To the extent that this plan is being relied upon to limit fugitive dust emissions for Title V HAP applicability and NAAQS compliance purposes, the HRCP would need to be reviewed and approved by IDEQ prior to the public comment period, subject to review during the public comment period, and enforceable upon the issuance of the initial permit. Also, any changes to the HRCP after the permit is issued and that are less stringent than the approved HRCP would need IDEQ approval and public review and be enforceable at all times after the revised permit is issued. There does not appear to be a reason that the HRCP can't be developed and incorporated into the permit now.

Seattle, WA 98101-3144

REGIONAL
ADMINISTRATOR'S
DIVISION

January 10, 2023

Linda Jackson
Payette Forest Supervisor
Stibnite Gold Project
500 N. Mission Street, Building 2
McCall, Idaho 83638

Dear Linda Jackson:

The U.S. Environmental Protection Agency has reviewed the U.S. Forest Service's October 2022 Draft Supplemental Environmental Impact Statement (DSEIS) for the Stibnite Gold Project (CEQ Number 20220154, EPA R10 Project Number 17-0013-AFS). EPA has conducted its review pursuant to the National Environmental Policy Act and our review authority under Section 309 of the Clean Air Act. The CAA Section 309 role is unique to EPA and requires EPA to review and comment publicly on any proposed federal action subject to NEPA's environmental impact statement requirement.

As a Cooperating Agency, EPA is supporting the Forest Service in the EIS development including review and comment on administrative drafts of EIS documents. EPA provided Draft EIS comments to the Forest Service in November 2020. Most recently EPA has supported the preparation of the DSEIS for the revised proposal submitted by the project proponent, Perpetua Resources Ltd (formerly Midas Gold Idaho, Inc), which includes the Forest Service eliminating two of the previous DEIS action alternatives from further consideration.

The DSEIS evaluates the potential environmental impacts associated with mining operations located on the Payette and Boise National Forests in central Idaho. The proposed project will produce gold and silver doré, and antimony concentrate for commercial sale. The project includes three open pits, an ore processing facility, a lime plant and associated limestone mining, development rock storage facilities, a tailings storage facility, a water treatment facility, access and haul roads, electrical transmission lines, and other support infrastructure and facilities. The mine life will be 20 years, not including post reclamation monitoring, with active mining and ore processing occurring over approximately 15 years. The DSEIS identifies and evaluates a No Action Alternative and two Action Alternatives: 1) 2021 Modified Mine Plan (2021 MMP) Alternative, representing the Proposed Action and identified as the Agency Preferred Alternative, and 2) Johnson Creek Route Alternative.

EPA appreciates that the DSEIS addresses many concerns and recommendations raised in our earlier review of the project documents. Additionally, EPA identified environmental concerns and deficiencies in the analysis that should be addressed in the Final EIS. Our attached Detailed Comments include recommendations for protecting air quality, surface water and groundwater quality, stream temperatures, wetland and riparian resources, fish habitat, and communities with environmental justice concerns; addressing impacts from soil contaminants and reclamation cover materials, geological hazards, and greenhouse gas emissions; and additional analysis to strengthen the assessment of impacts between the different mine access routes/road alternatives and modeling for different parameters.

Key recommendations for the FEIS include:

- Clearly and sharply defining impacts from the mine access routes/road alternatives.
- Monitoring for fugitive dust and particulate matter air emissions, assessing airborne arsenic impacts, confirming consistency across proposed state and federal air quality measures, and addressing possible underestimations of mercury deposition.
- Addressing suitability of soils for reclamation and effects of soil contaminants on surface water quality.
- Implementing effective monitoring, corrective actions, and addressing uncertainty for effects to stream temperature.
- Ensuring impacts from groundwater and surface water contaminants (e.g., mercury, methylmercury, arsenic, and antimony) are not underestimated when demonstrating compliance with the Clean Water Act and determining if additional mitigation measures for potential impacts are needed.
- Including an estimated financial assurance amount and mechanism, the disclosure of which is particularly important in this project given the long-term water management needs at the site (including post-closure).
- Establishing an Independent Tailings Review Board (ITRB) for the tailings storage facility including the buttress dam and conducting regular independent reviews as a mitigation measure to ensure geotechnical stability and protection of surface resources.
- Including continuous monitoring and inspections to address uncertainty and potential underestimation of indirect impacts and functional loss to wetlands and riparian resources.
- Supplementing the environmental justice analysis with EJScreen and considering mitigation measures for impacts including but not limited to loss of access and effects to subsistence.
- For climate change:
    - Including science-based greenhouse gas emissions reduction targets.
    - Assessing the social cost of carbon.
    - Incorporating adaptation in project features, such as stream crossings, reconstruction, and riparian cover.

Thank you for the opportunity to review the DSEIS for this project. We appreciate the constructive ongoing engagement with the Forest Service during the NEPA process and look forward to working with you as you prepare the FEIS. If you have questions about this review, please contact Susan Sturges of my staff at 206-553-2117 and sturges.susan@epa.gov, or me, at (206) 553-1774 or at chu.rebecca@epa.gov.

Sincerely,

REBECCA CHU

Alternatives Analysis – Burntlog Route and the Johnson Creek Alternative

The material summarized in the Executive Summary and in Table 2.8.1 Alternative Comparison and Impact Summary[1] indicate that the Burntlog Route may result in greater impacts on several environmental and economic indicators, than as generally presented for the 2021 MMP Alternative (which includes the Burntlog Route). Examples include more greenhouse gas (GHG) emissions, soil impacts, stream crossings, forest disturbance, wetland loss, wildlife habitat disturbances, new roads, ground disturbance, impact on historical properties, higher inconsistency with designated Recreation Opportunity Spectrum, and lower contributions to employment trends. Further, the 2021 MMP Alternative will likely: impact roadless characteristics in three inventories roadless areas; increase non-native plant species spread; and create construction noise into the Frank Church River of No Return Wilderness. As the proposed mine access routes (Burntlog Route and the Johnson Creek Route Alternative) are the primary difference between the two Action Alternatives, EPA recommends the FEIS clearly and sharply define issues related to each access route and ensure the assessments are accurately reflected across the different sections.

Potential Impacts to Air Quality

Idaho Department of Environmental Quality (IDEQ) Air Quality Permit to Construct (PTC)

The DSEIS indicates on June 17, 2022, IDEQ issued a final PTC and Statement of Basis (SOB) stating that the Stibnite Gold Project (SGP) will not require a Title V permit.[2] Further that "[a] determination was made by the State of Idaho that the SGP satisfies the requirements of the PTC program, based on demonstration of the SGP's potential emissions and controls. This was based on the complete air emissions inventory of stationary sources that was submitted by Perpetua as part of its application to the IDEQ for an air quality permit."[3]

EPA formally commented during the public review process for IDEQ's draft air quality PTC that the draft PTC did not appear to sufficiently limit annual emissions to allow the SGP to avoid being subject to the Title V and Prevention of Significant Deterioration (PSD) programs and assure compliance with the National Ambient Air Quality Standards.[4] EPA continues to review the final PTC for compliance with the CAA. As a Cooperating Agency for this project's EIS, EPA shared our March 2022 draft PTC comments with the Forest Service. EPA recommends the FEIS include a summary of EPA's public comments. EPA is available to meet with the Forest Service and IDEQ, who is also a NEPA cooperating agency, to discuss our concerns and answer any questions.

[1] (DSEIS, p. 2-136).
[2] (DSEIS, p. 3-35).
[3] (DSEIS, p. 3-37).
[4] McFadden, Kelly. (March 16, 2022). [Letter from Kelly McFadden, US EPA Region 10 to Kelli Wetzel, Idaho Department of Environmental Quality, 2022].

Enclosure of Main Ore Processing Facility and Coarse Ore Stockpile

The DSEIS indicates the main ore processing facility building and coarse ore stockpile will be enclosed.[5] EPA notes that IDEQ's PTC does not include stipulations that the main ore processing facility building and coarse ore stockpile will be enclosed. Given the inconsistency, EPA recommends the FEIS clarify whether the main ore processing facility building and coarse ore stockpile will be enclosed, which EPA supports to reduce dust. If the main ore processing facility building and coarse ore stock will not be enclosed, correct its description throughout the FEIS. EPA also recommends adjusting the assessment analysis to account for the change.

Bag House Dust Collectors

The DSEIS indicates water sprays and/or bag house dust collectors will be installed at the ore-crushing system and at ore reclaim feeders that deliver ore to the grinding circuit.[6] EPA notes that IDEQ's PTC does not include baghouse dust collectors within the ore-crushing system and at ore reclaim feeders. EPA recommends that the FEIS clarify the measures that will be taken for the SGP, and adjust any inconsistencies in the FEIS, including the assessment analysis to account for the change.

Title V Permit

Regarding the DSEIS statement "[t]he regulation establishes mercury emissions limitations and work practice standards to control mercury emissions from gold production processes." [7] EPA recommends evaluating if this regulation would require a Title V permit for the SGP. If so, EPA recommends adding the following sentence in the same paragraph "This regulation also requires that the SGP obtain a Title V permit. See 40 CFR 63.11640(d). This requirement is separate and independent from whether a Title V permit is needed based on the project's potential air emissions."

Fugitive Dust and Particulate Matter (PM) Monitoring

Table 2.4-12 in the DSEIS indicates "[t]he Proponent will prepare a dust mitigation plan with appropriate schedule or triggers for control deemed adequate by IDEQ to achieve the level of control of 93 percent of dust (as submitted in the proponent's draft application for Permit to Construct from IDEQ). Alternatively, the proponent could employ particulate matter or opacity monitors deemed adequate by IDEQ and the Forest Service and immediately apply water or chemical dust control when PM or opacity monitors reach levels within 10 percent of the threshold determined by IDEQ."[8]

Since the final PTC has been issued by IDEQ, EPA recommends changing the reference to the draft application to a reference to the PTC for the FEIS. PTC permit condition 2.6 requires the proponent to develop and maintain a Fugitive Dust Control Plan (FDCP) and permit conditions 1.2 and 3.2 specifies 93% dust control must be met for the haul roads. The FDCP was not provided in the PTC before it was issued and has not been available for public review. EPA recommends the FEIS include a draft of the FDCP as an appendix or publicly available reference document.

The IDEQ PTC does not contain any requirements for PM monitoring as is stated above in the first paragraph. The EPA has recommended PM10 monitoring in previous cooperating agency NEPA comments and in comments to IDEQ during the draft air permit comment period.

---

[5] (DSEIS, p. 4-36).
[6] (DSEIS, p.4-36).
[7] (DSEIS, p. 3-36).
[8] (DSEIS, p. 2-94).

For the FEIS, EPA continues to recommend continuous PM10 monitoring at the facility fenceline, as a mitigation measure and integral part of the FDCP, to ensure the project will not cause a violation of the primary and secondary National Ambient Air Quality Standards. Monitoring is justified based on the high range of uncertainty in the estimates of fugitive dust emissions and high potential of potential impacts to resources in the project area.

Though the DSEIS modeling indicates that PM10 impacts will be below the NAAQS, the modeling was based on numerous assumptions, including achieving a 93% control efficiency on fugitive dust emitted from haul roads. Small errors and uncertainties in the emission inventory assumptions could lead to significantly more fugitive dust emissions than estimated. In its prior comments to IDEQ, EPA raised concerns about the feasibility and enforceability of achieving the 93% control efficiency.[9] PM10 monitoring would help to verify the estimated emissions in the assessments were correct or provide a measurement tool to gauge the effectiveness of post-project mitigation to address excessive emissions.

Access Road

The DSEIS states "[t]he EPA Region X has indicated that the access road could possibly be excluded from ambient air if sufficient measures are taken to comply with the 2019 revised policy (EPA 2019a)."[10] EPA recommends disclosing that formal EPA policy review of the proposed ambient air boundary was not requested by the state and was not conducted. The EPA does not typically engage in formal review of the ambient air boundary during NEPA review and usually only conducts such a review upon request of the state during air permitting.

For the FEIS, EPA suggests the following to add to the paragraph: "Exclusion of the public access road from ambient air protections is a unique case that relies on measures assumed to meet the standards inferred in the 2019 revised ambient air policy. However, a formal EPA policy review of the ambient air boundary for the project has not been conducted nor requested. A formal review is not necessarily required. The EPA did provide formal comment on IDEQ's air quality PTC recommending a review be requested by the state and that initial measures in the PTC were too ambiguous to determine compliance with the revised ambient air policy."

Arsenic Screening Analysis

The EPA continues to have concern that the arsenic screening analysis underestimates cumulative impacts of airborne arsenic to the environment in the vicinity of the project. The results presented on page 4-46 of the DSEIS, and Table 4.3-13 are compared to an annual acceptable ambient concentration for a carcinogen (AACC), the Idaho toxics screening threshold. However, this screening threshold is not necessarily intended to be compared against a 70-year lifetime scenario where 57 years of the period assumes zero exposure. The threshold is an annual average used for screening, prescribed as a de-minimus value based on lifetime risk. Under IDEQ's hazardous air pollutant program, in practice, project impacts from the maximum year of emissions would typically be compared to the annual average AACC for arsenic.

If the impacts were determined using annual average emissions during the period of the project only, the resulting arsenic concentrations would exceed the AACC. There is significant uncertainty in the

[9] McFadden, Kelly. (March 16, 2022). [Letter from Kelly McFadden, US EPA Region 10 to Kelli Wetzel, Idaho Department of Environmental Quality, 2022].

[10] (DSEIS, p. 3-30).

emission rates of fugitive dust associated with the project such that arsenic emissions could be underpredicted.

Based on these concerns, the EPA continues to recommend the FEIS include an expanded cumulative analysis to disclose project airborne arsenic impacts to the environment.

Retort Emissions

The DSEIS states "[t]he retort emissions are based on an average of two refinery reports in 2015/2016 (NDEP 2015, 2016). The corresponding calculations are 20 percent of the retort standard of 0.8 lb/ton."[11]

The process by which these emissions are derived is unclear. The two referenced documents (NDEP 2015, 2016) contain emission values for over 25 mining operations in Nevada. Depending on the mine, the emissions can be less than 1 lb/year to greater than 500 lbs/year. For the FEIS, EPA recommends providing information on which two refinery reports were averaged and why those two were selected to best represent conditions at Stibnite.

Gaseous Elemental Mercury (Hg0) Emissions

The DSEIS indicates that gaseous elemental Hg0 emission sources at the SGP will be controlled by activated carbon absorbers.[12] If Hg0 emissions are controlled by the activated carbon absorbers, EPA recommends the FEIS clarify if this means that the 13.6 lb/year of Hg released from the SGP project will consist of particulate bound and oxidized Hg. EPA further recommends clarifying for the AERMOD assessment, if all 13.6 lbs of Hg are included in this modeling.

Underestimations of Total Hg Deposition

The DSEIS states "[t]his analysis indicates a maximum estimated increase in Hg deposition rate of 0.4 percent or less of the existing background rate. However, it should be recognized that this rate underestimates the total Hg deposition, as the mechanism of Hg0 flux is not included in the screening model."[13]

While we appreciate the inclusion of the sentence indicating a reason why this percent increase is underestimated; the reason listed is only part of the reason for the underestimation. As mentioned in a previous section, the background Hg deposition values based on data from more than 10 years ago is also biased high due to subsequent emission controls. Therefore, the 0.4% increase underestimates Hg deposition because 1) it does not include Hg0 deposition; and 2) the background deposition rates are overestimated for current conditions.

Generally, when developing an EIS on the impacts of a proposed mine, the preference is to develop conservative estimates of potential impacts and provide caveats as to why these impacts may be overpredicted. For this SEIS there are several instances where impacts are underpredicted and then caveats are added indicating that there is a low bias in the analysis. The problem with this approach is that impacts may not be identified and properly mitigated. EPA suggests adjusting the Hg deposition assessment for the FEIS to conservatively estimate the potential impacts and then provide caveats as to why these impacts are likely overpredicted.

---

[11] (DSEIS, p. 4-40).
[12] (DSEIS, p. 4-50).
[13] (DSEIS, p. 4-50).

Contribution Above Estimated Hg Background

Table 4.3-18 SGP Contribution Above Estimated Hg Background indicates that SGP will result in Hg deposition of 0.056 g/km2/year. However, an earlier Table (4.3-6) indicates that the mine will release 13.6 lbs per year of Hg. The previous statement that Hg0 emissions will be controlled suggests that 13.6 lbs represents releases of oxidized and particulate bound fractions which will be deposited relatively locally.

Of the 6,200 grams of Hg released (which is mostly or entirely Hg2+ and HgP according to the previous statement in the SEIS), AERMOD predicts only 0.056 g/year is deposited with a square km. There seems to be a disconnect between the species of Hg emitted, the amount of Hg emitted, and the amount being deposited locally within this analysis. EPA recommends reevaluating these analyses, making appropriate corrections for the FEIS, and if potential significant deposition is identified, mitigating to reduce impacts.

Soils and Reclamation Cover Materials

Reclamation Cover Material

Table 2.4.-12 in the DSEIS indicates that reclamation cover material (e.g., growth media) used in places including but not limited to the TSF and tailings storage facility buttress (TSFB) would be evaluated for contaminants prior to use during reclamation. Acceptable metal/contaminant concentrations and sampling and testing would be documented in a sampling and analysis plan developed prior to reclamation. [14]

EPA recommends that the FEIS disclose the concentration limits that would be required by the Forest Service since these are directly relevant to the evaluation of environmental impacts for the project, including the analysis of the availability of and suitability of cover material (metals) and the analysis of potential reclamation and closure/post- closure impacts to wetlands, waters, wildlife, aquatic resources, and public health in subsequent EIS sections.

We have provided this same comment on previous versions of this section and the NEPA specialist report and reiterate the recommendation to disclose this information to support conclusions regarding impacts and mitigation effectiveness.

Suitable Soil Types for Reclamation

Under Suitable Soil Types for Reclamation, the DSEIS states "[t]he soils in this SMU [soil map unit typic halosparists (cTH)] also have elevated antimony, arsenic, and mercury concentrations (Tetra Tech 2021a)."[15] EPA recommends the FEIS discuss how soils with elevated concentrations of antimony, arsenic and mercury will impact predicted water quality concentrations of these contaminants. EPA also recommends specifying whether these values are elevated when compared to other background soils or in relation to soil criteria.

Soil Contamination/Chemistry

The DSEIS states "[t]he mean concentrations of antimony (14.88 ppm within a range of 0.04 to 2,580 ppm) and mercury (0.972 ppm within a range of 0.005 to 283 ppm) from the samples are high but are still within the highest screening-level phytotoxicity criteria concentrations from various literature

[14] (DSEIS, p.2-97).
[15] (DSEIS, p. 3-81).

references and federal agencies in U.S. and Canada cited in the Reclamation and Closure Plan (Tetra Tech 2021a)."[16]

While these concentrations may be below phytotoxicity criteria, EPA recommends the FEIS evaluate how elevated soil concentrations will impact surface water quality in the Environmental Consequences section of the FEIS.

Surface Water and Groundwater Quality

Riparian Vegetation Zones

The DSEIS includes a measure to establish 18-foot-wide vegetation zones consisting of willow, spruce, and other riparian species that effectively shade stream flows in the restored and native stream channels in the mine area.[17] Studies over the years have shown that riparian vegetation located outside of an 18-foot buffer is a critical component of riparian vegetation stream shade production. [18,19] That is, restored riparian buffer widths would need to be much wider than 18 feet to produce levels of stream shade that would result in the predicted post-closure stream temperature conditions illustrated in Figure 4.9-27. The DSEIS references to the Environmental Monitoring and Management Plan (EMMP) framework, however, specific actions were not provided that described how full potential stream shading from riparian vegetation within the Riparian Conservation Area[20] will be achieved for riparian areas located outside of 18 feet from the stream.

EPA recommends the FEIS include specific management and protection that will be implemented to ensure (shade producing) riparian vegetation is promoted outside of 18 feet from the stream. Describe the specific planned efforts to eliminate anthropogenic disturbance, and promotion of riparian restoration, within the entire riparian zone, including the "outer" riparian zone associated with stream shade production (i.e., outside of 18 feet from the stream).

Stream Temperature

The DSEIS states that predicted long-term post-closure cool stream temperature conditions depend on the successful implementation of "the lined Stibnite Lake lacustrine feature above the cover of the Yellow Pine pit backfill to moderate maximum stream temperatures."[21]

"Cooling" temperature properties of this lake is dependent on lake water residence time and depth,[22] both of which are impacted by upstream sediment delivery.[23] That is, sediment transport into the lake can result in sediment deposition on the lake bottom, reducing the water depth, and subsequently decreasing the lake residence time. Specifically, it was reported that "about 90 percent of coarse-grained sediment derived from upgradient is deposited in the Yellow Pine pit" along with approximately 20 percent of the fine-grained sediment (<0.0625 millimeter in diameter), and "[t]hus, the Yellow Pine pit

[16] (DSEIS, p. 3-85).
[17] (DSEIS, p. 4-269).
[18] Groom, J. D., Madsen, L. J., Jones, J. E., & Giovanini, J. N. (2018). Informing changes to riparian forestry rules with a Bayesian hierarchical model. Forest Ecology and Management, 419, 17-30.
[19] Barnowe-Meyer, S., Bilby, R., Groom, J., Lunde, C., Richardson, J., & Stednick, J. (2021). Review of current and proposed riparian management zone prescriptions in meeting westside Washington State anti-degradation temperature criterion FINAL REPORT.
[20] (DSEIS, p. 3-250).
[21] (DSEIS, p. 4-269).
[22] (DSEIS, p.4-274).
[23] (DSEIS, p.3-191)

is an effective sediment trap for coarse-grained particles but does not have a long enough residence time to deposit the majority of the fine-grained sediment load." In addition, "most of the sediment load discharged from the Meadow Creek reach is deposited in the Yellow Pine pit lake".[24]

Unless otherwise determined through modeling analysis, it can be expected that these same sediment transport/deposition dynamics will occur with the created East Fork South Fork Salmon River (EFSFSR)/Stibnite Lake complex. In addition, this material also highlights the likely need to understand sediment loading and transport in the EFSFSR watershed to maintain the future Stibnite Lake attributes that lead to "cooling" water temperatures.

Several potential sediment reduction and management measures are introduced on DSEIS page 4-274, and it is stated that the effectiveness of these measures will be evaluated through the EMMP. However, the EMMP does not provide specific examples on how current and future sediment loading is evaluated (i.e., status monitoring), as well as evaluate the effectiveness of the proposed actions to address any future sediment "issue" (i.e., effectiveness monitoring).

EPA recommends the FEIS include implementation of detailed monitoring strategies that will: 1) monitor and quantify the sources and amount of sediment loading (including both chronic and episodic) entering the EFSFSR river system upstream of the Stibnite Lake; 2) evaluate the transport of both suspended and bedload transport in the stream network upstream of the Stibnite Lake; and 3) monitor sediment deposition and bathometry conditions in Stibnite Lake.

Information collected as part of this monitoring effort is necessary to: 1) determine if a problem exists associated with excessive sediment loading and/or deposition in Stibnite Lake, and 2) provide the necessary information to produce plans intended to adequately address any future corrective action to address excessive sediment loading and/or deposition in Stibnite Lake.

EPA also recommends the FEIS include detailed corrective action strategies that outline actions to: 1) correct/eliminate any future "elevated" sediment sources (similar to what is proposed to excessive sediment from Blowout Creek[25]); 2) correct/eliminate the transport of the bed load and "coarse" sediment load that has entered the river network; and 3) potential mitigation measures to address potential future "shallowing" of Stibnite Lake resulting from sediment deposition.

Significant Temperature Mitigation Feature

Figure 4.9-27 illustrates that the most significant temperature mitigation feature in the EFSFSR river watershed is located between the TSFB and the East Fork Meadow Creek (EFMC). Specifically, modeled stream temperatures post mine closure (i.e., end of year 27) decrease up to 7° C within this short reach, which results in lower temperature to continue downstream in the EFSFSR.[26] The DSEIS later reports that without this upstream temperature reduction "stream temperatures downstream of the Yellow Pine pit area could also be greater than existing conditions."[27] The DSEIS lists several possible reasons for this "significant" stream cooling reach: 1) resumption of "baseline" cool groundwater discharge; 2) increase stream shade; and 3) underdrain flow from the TSF.[28]

---

[24] (DSEIS, p. 3-191).
[25] (DSEIS, p. 2-62).
[26] (DSEIS, p. 4-272).
[27] (DSEIS, 4-281).
[28] (DSEIS, p. 4-271).

PET 681

REC 1047

It is unlikely that the first two factors outlined on page 4-271 are meaningful factors in the creation of the "significant" stream cooling zone between the TSFB and the EFMC. The dashed line in Figure 4.9-27 indicates that stream temperatures currently increase within this reach, indicating that "baseline" groundwater influences within this reach are likely a relatively minor factor towards the creation of the "significant" temperature reduction zone. Additionally, it is unlikely that increase shade within this reach will result in the "significant" stream cooling zone because stream shade does not "cool" a river/stream. Stream shade reduces the amount of solar heat load (i.e., sun light) from reaching the stream water, and this lower heat load can result in a gradual loss of heat energy (i.e., temperature reduction) through the relatively slow evaporation/convection processes.

It is possible that cool underdrain flow from the TSF added into this stream reach could physically "dilute" the warm stream water advecting from upstream. The amount of cooling would be dependent on the volume and temperature of these underdrain inputs.

EPA recommends the FEIS: 1) provide additional analysis describing the potential uncertainty that the "cooling" feature will function as predicted, 2) ensure proposed monitoring assesses if the "cooling" feature functions as predicted, and 3) include a description of potential mitigation/corrective actions if the "cooling" feature does not occur as expected.

An acknowledgment of potential uncertainty of predicted ground water discharge volumes and "restored" shade conditions is on page 4-281. However, as described above, these two factors are unlikely a significant source of the cool water within the TSFB and the EFMC reach of Meadow Creek. The potential uncertainty associated with the predictions of the magnitude and duration of the cool underdrain flows were not provided in the DSEIS. Material presented on Page 2-56 indicates that these underdrain flows may be unavailable for stream cooling within this reach due to 1) the potential need for it to be treated prior to discharge into the stream; and/or 2) the potential need for it to be used as makeup water for the mill process. Thus, EPA recommends the FEIS include evaluations in this assessment that describe the potential uncertainty associated with the magnitude and duration of the predicted underdrain flows.

The DSEIS does not discuss potential mitigation measures associated with a lower production and/or elevated temperatures of the expected underdrain flows discharging into the "significant" stream cooling zone between the TSFB and the EFMC. EPA recommends the FEIS include evaluations in this assessment that describe potential mitigation/corrective actions needed to address any loss or reduced effectiveness from the underdrain flows expected within this reach.

Groundwater Analyte Concentrations

The DSEIS indicates groundwater analyte concentrations beneath the mine site, particularly in the vicinity of the TSF, TSFB, Hangar Flats pit backfill, and Yellow Pine pit backfill are expected to increase in response to constituent leaching from development rock. Existing groundwater in those areas typically does not meet regulatory criteria for use as drinking water due primarily to arsenic and antimony concentrations.[29]

To adequately describe the nature and extent of additional groundwater contamination contributed by SGP, EPA recommends the FEIS include a summary that describes the magnitude of groundwater concentrations above current baseline conditions and the geographic extent (in feet) over which baseline

[29] (DSEIS, p. ES-15).

concentrations are exceeded. Figures which depict the extent and magnitude of groundwater concentration changes in relation to mine facilities would be particularly helpful to disclose groundwater impacts.

Surface Water Methylmercury (MeHg) Concentrations

The DSEIS states "MeHg concentrations in SGP site streams are not appreciably different from those reported by the USGS nationwide study, and that historical mining activity in the analysis area has not increased MeHg concentrations above those observed at similar reference locations throughout the U.S."[30]

It is accurate that the USGS nationwide study did not identify an increase in MeHg in basins containing mines; however, the FEIS will need to include a caveat that this study only included one sample location from Idaho, and that location was outside of the Stibnite study area. As such, the statement that mining activity has not increased MeHg above "similar reference locations" is inaccurate. Instead, EPA recommends the FEIS state that MeHg concentrations in the Stibnite area were similar to those observed in non-mining impacted watersheds throughout the US.

It is important when comparing MeHg concentrations to other areas that these be interpreted in the context of the dissolved organic carbon (DOC) and sulfate levels present. The national USGS study referred to includes measures of these parameters. Because the amount of MeHg generated by an ecosystem is influenced by both DOC and sulfate, EPA recommends the FEIS include a comparison of not just the MeHg values, but the MeHg values in relation to existing DOC and sulfate concentrations in the Stibnite area and how those compare to other streams in the national assessment.

Major Ions, pH, and Total Dissolved Solids (TDS)

In the Surface Water - Major Ions, pH, and TDS section of the DSEIS,[31] EPA recommends the FEIS include in this discussion the levels of sulfate under existing conditions. This information is included in Table 3.9.9, but the significance and trends of this data are not described. Because the levels of sulfate may increase because of mining activity and there are important links between sulfate levels and MeHg production, EPA recommends the FEIS include a description of current sulfate levels. From the table, it appears that most sulfate levels are quite low (<10 mg/L), especially when compared to the national average from the USGS study at 45.9 mg/L.

Chemical Release Rates Temperature Correction

The DSEIS states "[t]he source terms were then scaled to field conditions to account for differences in reaction rates, temperatures, and liquid-to-solid ratios between laboratory tests and field conditions."[32]

EPA notes that the temperature correction will likely underestimate leaching rates encountered at the mine site. The Arrhenius equation is based on pyrite oxidation and is not specific to other metal/element release rates. Several metals have been shown to have higher release rates at lower temperatures.[33]

In addition to the inherent uncertainties in applying the temperature correction factor, an annual air temperature of 2.6°C should not be used for scaling. The annual average incorporates many months of sub-zero temperatures into this average when water is frozen and aqueous geochemical reactions are not occurring. A more conservative annual average would be based only on time periods when the

[30] (DSEIS, p. 3-188).
[31] (DSEIS, p. 3-176).
[32] (DSEIS, p. 4-182).
[33] SRK Consulting. 2006. Cold Temperature Effects of Geochemical Weathering.

temperature was greater than 0°C. A slightly less conservative approach would be based on an average that substituted 0's for time periods when the temperature was negative. In addition, temperatures below the surface are often higher than air temperatures, especially when they are insulated with snow cover. Furthermore, chemical reactions are exothermic and can also contribute to increases in subsurface temperatures in geochemically active areas. In addition, under future climatic conditions, the temperature is predicted to increase.

Overall, for the FEIS, EPA recommends the chemical release rates not be corrected for temperature during the water quality modeling.

Effects of Deposited Mercury to Watershed

The DSEIS indicates actual local mercury deposition rates from project emissions depend on the fractions of particulate versus gaseous mercury emissions. Particulate emissions generally deposit on the ground surface nearer to their source while gaseous emissions tend to deposit farther from the source or potentially become part of global atmospheric mercury burden.[34]

We appreciate this information being mentioned in the water quality section of the DSEIS. In the air section of the DSEIS, it suggests that most Hg0 will be captured, which suggests that most of the 13.6 lbs/year (6,200 g/year) that is released will be Hg2+ and HgP which would deposit locally. However, the results of the AERMOD predictions indicate that a much smaller amount or mercury (0.056 g/year) will be deposited within a square km around the mine site. There seems to be a disconnect between the amount and species of mercury emitted and the amount being deposited to the local watershed. EPA recommends the FEIS assess the potential for enhanced local deposition of Hg2+ and HgP of mercury to the local watershed and how this will impact water concentrations.

Ratios of Stream Mercury Loads to Atmospheric Mercury Deposition Rates

The DSEIS states "[r]atios of stream mercury loads to atmospheric mercury deposition rates have been reported in watersheds affected by gold and silver mining (Domagalski et al. 2016)... Therefore, aerial deposition would have a minor to moderate, long-term effect on particulate mercury loads in streams within the project area watershed."[35]

It is unclear what ratios are being used in the analysis that led to the conclusion of minor to moderate impacts. An earlier version of the DSEIS document stated that "[r]eported ratios of stream mercury loads to atmospheric mercury deposition rates have been reported to be approximately 50-to-1 in watersheds affected by gold and silver mining with a drainage areas less than 500 square kilometers (Domagalski et al. 2016). Application of that ratio to the total mass of mercury emission would suggest that aerial deposition could contribute up to approximately 0.3 pounds per year to streams within the watershed during the operations period, primarily in the form of particulate mercury."

At that time, the EPA commented the ratio of 50 to 1 is not applicable to this situation. Domagalski et al, 2016 is suggesting that the stream Hg loads are 50 times higher than the atmospheric deposition load due to the contribution of non-atmospheric sources in the watershed.

Applying the Domagalski ratio of 50 to 1, would indicate that deposition from the mine releases would be 0.006 pounds/ year and then multiplying value by 50 to come up with 0.3 pounds/year. But this large

[34] (DSEIS, p. 4-252).
[35] (DSEIS, p. 4-259).

multiplier is a function of untreated mine waste in the watersheds that is overwhelming the atmospheric deposition. This is not applicable to conditions presented in the DSEIS.

Our concern is that the DSEIS flips the intention of the 50 to 1 ratio to suggest that only 2% of atmospherically deposited mercury makes its ways into streams. This is inaccurate and opposite of what is presented in Domagalski for gold-silver mine impacted watersheds.

While the DSEIS does not make specific reference to the ratio used in the analysis, EPA remains concerned about the basis of the analysis that used the Domagalski ratio of 50 to 1 for these conclusions. EPA recommends the FEIS reassess the ratio used and make corrections accordingly.

Ratio to Predict Future MeHg Concentrations

The DSEIS states "a ratio method to estimate methylmercury concentrations from predicted total mercury concentrations was applied per the approach and data collection by Holloway et al. (2017) that showed methylmercury concentrations were up to two percent of total mercury concentrations in samples from Sugar Creek and the East Fork SFSR."[36]

EPA recommends the FEIS clarify if the ratio from Holloway is based on dissolved or whole water mercury concentrations and recommends utilizing dissolved concentrations since this is the form that is predicted to be released from the mine operations (i.e., "Predictive modeling indicates that mine facilities and water treatment would contribute dissolved mercury to surface waters primarily during the operating and early post-closure periods")

Also, the Holloway ratio is based on existing conditions between mercury and MeHg and will underpredict ratios that may exist if carbon and/or sulfate levels are increased.

Overall, using this ratio to predict future MeHg concentrations likely results in an underprediction of the impacts. For the FEIS, EPA recommends reassessing the use of this ratio and adjusting the assessment accordingly to avoid underpredicting impacts.

Model Sensitivity and Uncertainty

Air Temperature Correction Factors

The DSEIS states "[a]ir temperature correction factors used to scale laboratory reaction rates to field conditions by the model could underestimate actual reaction rates and chemical releases from mined materials, and hence, surface water quality impacts."[37]

We appreciate that the potential for underestimating reactions rates due to the temperature correction factor is mentioned in the DSEIS. However, for the FEIS, EPA suggests that the model be run without the temperature correction factor applied to the chemical source terms in order to provide an upper bound of leaching potential. In general, EPA suggests a preference to overpredict environmental impacts with a caveat that the predictions may be conservative rather than the other way around.

Later the DSEIS mentions "[t]he model is most sensitive to …increasing the reaction temperature" and "increasing the reaction temperature in mined materials and pit walls was shown to produce higher post-closure arsenic concentrations in the pit lakes and downstream assessment nodes."

---

[36] (DSEIS, p. 4-259).
[37] (DSEIS, p. 4-279).

Presumably, "increasing the reaction temperature" refers to using the humidity cell test (HCT) results that were obtained from the lab (at 25°C) without decreasing the reaction temperature to reflect the annual average measured at the mine site (2.6 °C). EPA recommends the FEIS provide details clarifying if they were still decreased from the lab, but less than had been done originally. It should also be taken into consideration that under future climate conditions, the annual average air temperature at the mine may increase, which would result in an underpredictions of chemical releases rates if the current rates are based on the average of historical temperature.

Presumably these results represent uncorrected laboratory-based source terms, as opposed to a dataset where the reaction temperature has been increased beyond what was measured in the lab. Given that the temperature correction factor was a significant variable impacting the water quality predictions (i.e. correcting the chemical release rates measured at 25 °C down to 2.6 °C), this underscores our comments for the FEIS to include the uncorrected rates in the model predictions unless specific evidence can be provided to support the use of the temperature corrections.

Atmospheric Mercury Deposition

The DSEIS states "[t]he surface water quality model predictions do not include mass loading inputs from permitted IPDES outfalls that would be required for the SGP. Additionally, mercury inputs from atmospheric deposition caused by the SGP have not been considered in the model. These additional loads were discussed qualitatively or semi-quantitatively in the analysis above but could modify future analyte concentrations compared to predicted values."[38]

As mentioned above, we appreciate disclosing this information in the DSEIS; however, for the FEIS, EPA recommends accounting for atmospheric deposition in the water quality predictions to provide a wholistic assessment of water quality impacts.

Site-wide Water Chemistry (SWWC) Model-predicted Concentrations

The DSEIS states "[m]odel-predicted concentrations generated by the SWWC Model are for the dissolved fraction only and may underpredict concentration levels for constituents such as mercury that have been shown to occur in particulate form."[39]

As mentioned previously, we appreciate disclosing this information in the DSEIS; however, for the FEIS, EPA recommends a preference to account for whole water concentrations (which is reflective of the 12 ng/L chronic criteria value for mercury).

There are multiple aspects of the analysis in the DSEIS where the estimated impacts represent underpredictions. While each individual aspect may represent a relatively minor underpredictions, collectively they could add up to the impacts to air and water being significantly higher than what is anticipated in the DSEIS. As noted in the comments above, we recommend that underpredictions be remedied to develop conservative predictions of water quality impacts. This is important in order to disclose impacts more accurately and also to ensure that water management, control, and treatment plans will be effective at protecting water quality.

[38] (DSEIS, p. 4-279).
[39] (DSEIS, p. 4-279).

Mitigation Measures for Mercury

Mercury concentrations in West End Creek will increase from the baseline of approximately 4 ng/l to approximately 53 ng/l during mining operations (for 10 years).[40] This represents an increase in mercury loading and likely impairment to West End Creek, which is fully supporting its beneficial uses and is a high-quality water under Idaho's antidegradation policy. Additionally, it will also increase loading downstream to Sugar Creek, which is already listed as impaired under Clean Water Act Section 303(d) for mercury. The increase is due to the diversion of West End Creek, which is a result of the proposed SGP. Even though West End Creek is elevated in mercury above the proposed West End pit, by diverting the Creek and mining the pit, the SGP is resulting in an increase in the amount of mercury into lower West End Creek and Sugar Creek from current conditions. For the FEIS, EPA recommends that a mitigation measure be developed to avoid the predicted mercury water quality standard exceedances during operations or offset the additional amount of mercury being added to the system (e.g., by removing other mercury sources) to avoid further water quality degradation. Because mercury is bioaccumulative, effects to the system will likely extend beyond the lifespan of the SGP.

Financial Assurance

According to the DSEIS, calculation of the initial bond amount would be completed following the Record of Decision (ROD) when enough information is available to adequately and accurately perform the calculation.[41] EPA continues to recommend that the FEIS provide a more specific discussion of the estimated financial assurance amount and mechanism, particularly given the water management needs at the site (including post-closure). This would provide a basis for evaluating whether the planned reclamation and closure activities would be effective (funded) in the event of a bankruptcy or compliance issues. Other mining EISs have included financial assurance estimates that comport with the draft reclamation and closure plans and acknowledge that the final financial assurance would be determined after the ROD. For example, see the Donlin Gold Project EIS, the Haile Gold Project EIS, and the Northmet Project EIS. This level of disclosure is also important for the SGP. Failure to obtain sufficient financial assurance at the Stibnite Mine Site in the past has resulted in significant, unaddressed contamination at the Site. If not for the NEPA process, there would be no public disclosure of financial assurance estimates. We understand that draft estimates are currently available.

Geologic Resources and Geotechnical Hazards

Mitigation Measures for Geotechnical Stability

The SDEIS analysis does not recommend any additional geotechnical stability mitigation measures beyond those identified in Section 2.4.9. Although the TSF dam is designed to meet and exceed regulatory stability criteria, recent studies of dam failures have established that the dominant cause of failures arises from deficiencies in engineering practice associated with the spectrum of activities embraced by design, construction, quality control, and quality assurance.[42] Therefore, there is credible information highlighting that, even assuming that the dam and buttress are adequately designed, dam incidents could still happen due to human-caused errors during construction and operations. A best practice to mitigate this, is the establishment of an Independent Tailings Review Board (ITRB) and regular independent reviews during design, construction, operations, and closure. An ITRB and regular

[40] (DSEIS, p.4-251).
[41] (DSEIS, p. 2-91).
[42] Morgenstern, N.R. 2018. Geotechnical Risk, Regulation, and Public Policy. Soils and Rocks, São Paulo, 41(2): 107-129.

independent review is a best practice for new tailings dam facilities (with high or greater consequence classifications) in the Global Industry Standard on Tailings Management.[43]

The State of Idaho's dam safety regulations do not appear to require independent review. Therefore, we recommend that the FEIS include a requirement that an ITRB be established and regularly conduct independent reviews as a mitigation measure to ensure geotechnical stability, including during seismic events, and protection of surface resources. We note that the Forest Service is requiring establishment of an ITRB in RODs for the Pinto Valley Mine (AZ) and Kensington Mine (AK), based on the global standard and FEMA Federal Guidelines for Dam Safety Risk Management.

Geotechnical Stability of Mine Access Roads

When comparing geotechnical stability related to mass wasting events (i.e., landslides, rockfalls, and avalanche paths) of the 2021 MMP Alternative's Burntlog Route and the Johnson Creek Route Alternative, EPA recommends the FEIS consider the implementation of proposed environmental design features (EDFs) for the two Action Alternatives in the alternatives analysis. For example, for existing areas of landslides and rockfalls, geotechnical design considerations and improvements to existing roads with EDFs could address the issues raised as concerns for the Johnson Creek Route Alternative with geotechnical stability potentially improving as a result of the alternative. EPA also recommends that the FEIS clearly state in Section 4.2.2.3 Johnson Creek Route Alternative that the EDFs proposed for the 2021 MMP Alternative's Burntlog Route also apply to the Johnson Creek Route Alternative.

Existing Versus New Stream Crossings from Mine Access Roads

Throughout the DSEIS, the number of estimated stream crossings for mine access roads are compared between the alternatives, but the context of these stream crossings (i.e., existing versus new) is not generally included in these analyses. For example, new stream crossings where a road did not previously exist has a different impact than reconstruction of current road stream crossings to higher environmental protection standards which may result in an improvement of aquatic conditions/upstream access. Where appropriate to meaningfully distinguish impacts between alternatives, in addition to estimated number of stream crossings, EPA recommends the FEIS evaluates the potential impacts from stream crossings that considers potential different responses associated with existing stream crossings and new stream crossings.

Impact Assessment of Public Access of Burntlog Route

According to the DSEIS, Burntlog Route will be open to public use[44]and it is not apparent that the 2021 MMP Alternative will necessarily promote the separation of the general public and heavy mining equipment during operations along Burntlog Route when compared to Johnson Creek Route Alternative. Accordingly, during operations the public will potentially have access and use the same roads as large mining equipment for both Action Alternatives. Therefore, EPA recommends that potential public safety risks and potential accidents resulting from public use of these road networks are assessed similarly for both Action Alternatives. EPA also recommends that this assessment accounts for the effects of proposed improvements to the road network that are described for the Johnson Creek Route Alternative (i.e., "wider roads, more cut/fill sections, and more switchbacks") when comparing these two alternatives.

[43] International Council on Mining & Metals, UN Environment Programme, Principles for Responsible Investment, August 2020.

[44] For example, (DSEIS, pgs. 2-18, 2-20, and 4-34).

Fish Resources and Fish Habitat

Fish Exposure to Interim Conditions

The DSEIS includes a summary of measures to avoid and minimize impacts to fish habitat and describes the fishway (with trap and haul capability) and direct and indirect impacts to individual fish.[45] Measures such as removal or blockage of access will be taken to ensure fish are not exposed to mining activities that are known to be potentially harmful or lethal such as noise and vibration. The DSEIS is unclear about whether reaches that are in sub-optimal/poor condition are accessible to fish (with consideration to both anadromous and non-anadromous salmonids). Fish will have access to the active area, if the fishway provides upstream and downstream passage as planned. The DSEIS indicates fish will have access to stream reaches recently impacted and have marginal/poor condition in terms of habitat quality, stability, temperature, etc.[46] EPA recommends the FEIS clarify whether there will be fish access to recently reclaimed reaches in marginal/poor condition and discuss related control measures to ensure fish protection.

Stream Construction and Enhancements

Successful stream reclamations and enhancements are constructed to function in relative equilibrium with inputs/transport of wood, water, and sediment/bedload that vary in time and space. Therefore, design and construction are dependent on adequate modeling of these three inputs. Even with careful effort, risk of improper function can result leading to negative outcomes, such as erosion, incision, bed aggradation, channel widening, etc. This risk has been acknowledged in the DSEIS stream design report.[47] Once completed, these stream constructions/restorations require ongoing evaluation and monitoring to ensure proper function until they are established and stable.

EPA encourages that the FEIS include the best available data and modeling methods for the stream reclamation/enhancement effort. EPA further recommends following a rigorous monitoring effort, particularly following large precipitation events (e.g., rain-on-snow) to ensure that this restoration can be realized in the long-term. We recommend that these measures be identified and committed to in the FEIS.

Mitigation for Tissue-based Mercury Criteria Exceedances

The DSEIS states "[f]or mercury, while the predicted concentrations do not exceed the aquatic life criterion based on water column, it is uncertain whether incremental change in water column concentrations beyond baseline would cause fish tissue concentrations to exceed the tissue-based criterion."[48]

This uncertainty directly relates to whether the SGP would result in exceedances of Idaho's EPA-approved fish tissue-based human health criterion for mercury. The 2014 NMFS Biological Opinion for Idaho's water quality standards for toxics concluded that the aquatic life criterion is not protective of aquatic life and that it is unlikely to be protective of the human health fish tissue criterion. Therefore, EPA recommends that this uncertainty be addressed by including a mitigation measure to section 4.12.3 that would require mercury monitoring and analysis to determine whether the incremental changes could result in exceedances of the tissue-based mercury human health criterion over time and that adaptive

---

[45] (SDEIS, pg. 2-107, 2-119 -120, and 4-334).

[46] (SDEIS, p. 4-334).

[47] Perpetua Resources. Sept. 2021. Stibnite Gold Project– Stream Design Report. Prepared by Rio Applied Science and Engineering, Boise, Idaho.

[48] (DSEIS, p. 4-438).

management occur if exceedances are predicted. EPA also recommends the FEIS include this mitigation along with a list of potential adaptive management measures or mercury offsets.

Access and Transportation

Context for Disturbance by Past Mining Activities

The DSEIS states "[t]here would be a long-term loss of access to land for exercising treaty rights within the Operations Area Boundary while the lands are occupied for mining; however, lands within the Operations Area Boundary have been highly disturbed by past mining activities."[49] EPA notes that the statement "lands within the Operations Area Boundary have been highly disturbed by past mining activities" does not serve a purpose in the context of public access and how it affects impacted Tribes without additional context. The first half of the sentence speaks to the loss of access to the land, and the underlined portion shifts to land disturbance and not access.

As written, it seems to suggest that additional land disturbance will not be as impactful to Tribes because the land has already been disturbed in the past. For the FEIS, EPA suggests either removing the identified portion of the text, or providing additional context after it, to clarify that past impacts to the land do not justify or reduce the concerns associated with future land disturbances.

Wetlands and Riparian Resources

Uncertainty and Underestimation of Indirect Effects

Regarding "[f]unctional loss due to other indirect effects, including changes in hydrology, water quality, and increase dust and/or mercury deposition has been examined through inspection of dewatering drawdown and distance to roadways, but is difficult to quantify precisely. As a result, functional units that would be lost if these indirect effects occur, may be underestimated."[50]

To address these uncertainties and underestimation of impacts, EPA recommends the FEIS include a mitigation measure to Section 4.12.2 that would require continuous monitoring and inspections to determine whether there are incremental changes that are contributing additional impacts to hydrology, water quality, increased dust/mercury deposition, etc. that are indicative of additional functional loss to wetlands or riparian resources. EPA further recommends that the monitoring and inspections be used to identify if additional best management practices, adaptive management, and/or compensatory mitigation are needed during project operations.

Conceptual Stream and Wetland Mitigation Plan

The DSEIS provides little information about the overall objectives and elements of the proposed Conceptual Stream and Wetland Mitigation Plan compared to descriptions of the other proposed mitigation plans developed for other resources. EPA recommends the FEIS provide more details about the actions proposed in this mitigation plan that demonstrates that this plan will provides adequate and appropriate compensatory mitigation. Language like what is found on page 4-322 (Section 4.11.3 - Mitigation Measures) – "Perpetua proposes to accomplish compensatory mitigation for impacts to wetlands through a combination of mitigation bank credits in the North Fork Payette subbasin and permittee-responsible on-site mitigation within the SFSR subbasin (Tetra Tech 2021b)", would be helpful to summarize earlier in the FEIS, such as in the Stibnite Gold Mitigation Plan section of the Alternatives chapter.

---

[49] (DSEIS, p. 4-492).

[50] (DSEIS, p. 4-308).

Environmental Justice

EJScreen

The Forest Service employs a clear methodology for identifying people of color and low-income populations in the SEIS analysis and considers the need for a state-specific threshold to identify these communities. In addition to the methodology outlined by the Forest Service, EPA continues to recommend the FEIS supplement the analysis by including an EJScreen analysis and considering its datasets with the most recent version of EJScreen, EJScreen 2.1.[51] EPA considers a project to be in an area of potential environmental justice (EJ) concern when an EJScreen for the impacted area shows one or more of the EJ Indexes at or above the 80th percentile in the nation and/or state.

Traditional Ecological Knowledge

EPA appreciates that the DSEIS includes ethnographies of the analysis area prepared by the Nez Perce Tribe, the Shoshone-Paiute Tribes, and the Shoshone-Bannock Tribes. EPA recommends the FEIS include the identification, inclusion, and integration of Traditional Ecological Knowledge (TEK) into the NEPA analysis. In addition to anticipated impacts from the project, as well as traditional hunting and land use patterns in the area, this can include the collection of local and traditional knowledge concerning the affected environment and could be used to support the understanding of how climate change has impacted local environmental resources and subsistence resources. In addition to reviewing any pertinent traditional environmental knowledge currently available, additional studies and outreach may be conducted as necessary to clearly identify potential impacts, including cumulative impacts, from the proposed project and project alternatives, and help inform avoidance, minimization, and compensation strategies across affected environmental resources. As an example, this could include potential impacts from increased noise and air emissions that may affect fish and wildlife that are of cultural and subsistence importance to communities with EJ concerns.

Mitigation

EPA notes that the DSEIS indicates that at this time, no mitigation measures have been identified for Environmental Justice and for several of the resource sections that are relevant to Environmental Justice. For the FEIS, EPA recommends including mitigation measures developed upon contribution and feedback from the communities with EJ concerns if the information can be publicly disclosed, or alternatively, note that mitigation measures have been developed or are contingent upon contribution and feedback from the communities with EJ concerns.

Access Mitigation

The ~14,221 acres of public lands within the Operations Area Boundary will become inaccessible to communities with EJ concerns. This restricted access has potential to result in additional adverse and disproportionate impacts by limiting subsistence or traditional use by communities with EJ concerns, including tribal members and indigenous peoples.[52] The DSEIS indicates that the action alternatives will remove access to a culturally important area for approximately 20 years.[53] The DSEIS indicates that a mitigation measure for access impact would be incorporated into any decision on the SGP due to long-term loss of access to land while the lands are occupied for mining.[54]

---

[51] https://www.epa.gov/ejscreen, accessed 1/10/2023.
[52] (DSEIS, p. 4-620).
[53] (DSEIS, p. 4-623).
[54] (DSEIS, p. 4-669 and 4-672).

To the extent information can be publicly disclosed, EPA recommends including in the FEIS additional information on proposed access mitigation. EPA continues to recommend working with communities with EJ concerns to identify priority areas that will be affected by SGP, and using input from these communities to identify access opportunities, develop mitigation plans, and developing plan to restore access at the conclusion of the project. If there is interest from communities with EJ concerns in maintaining partial access to specific high-priority areas within the Operations Area Boundary, then EPA encourages Forest Service to work with these communities and the project proponent to determine specific times that may be reserved for safe access, if possible.

Replacement Cost Method for Subsistence Foods

EPA recommends that the Forest Service consider the potential use of the replacement cost method (RCM) to quantify the monetary cost of replacing subsistence foods that may be lost because of SGP activities. RCM is a standard technique for evaluating the dollar value of an ecosystem service.[55] Subsistence harvest patterns could be disrupted by harvesters' self-imposed restrictions on resources considered to be tainted, or as a result of space-use conflicts (e.g., increased number of users resulting from changes to access), or due to the temporarily avoidance of subsistence use areas due to noise impacts and habitat loss expected from construction and operation. When subsistence foods are not available, nutritionally comparable substitutes must be purchased, placing a direct financial burden on subsistence users in the form of lost harvest, as well as an indirect burden from stranded assets that users purchase for harvest activities (e.g., fishing or hunting equipment, 4x4 vehicles). EPA recommends that Forest Service work with communities with EJ concerns to consider potentially developing and adopting mitigation measures that will compensate for potential losses in harvest using the RCM.

Climate Change

NEPA Guidance on Consideration of Greenhouse Gas Emissions and Climate Change

On January 9, 2023, Council on Environmental Quality (CEQ) published interim guidance to assist federal agencies in assessing and disclosing climate change impacts during environmental reviews.[56] CEQ developed this guidance in response to EO 13990, *Protecting Public Health and the Environment and Restoring Science to Tackle the Climate Crisis*. The interim guidance is effective immediately. CEQ indicated that agencies should use this interim guidance to inform the NEPA review for all new proposed actions and may use it for evaluations in process, as agencies deem appropriate, such as informing the consideration of alternatives or help address comments raised through the public comment process. EPA recommends the FEIS apply the interim guidance as appropriate, to ensure robust consideration of potential climate impacts, mitigation, and adaptation issues.

Science-based GHG Reductions Targets

The analysis in the DSEIS compares project emissions to Idaho state-level emissions as a percentage. EPA recommends the FEIS compare project emissions to science based GHG reductions targets. The United States has established a Paris-agreement target to reduce net GHG emissions economy-wide by 50-52% below 2005 levels, consistent with a pathway to net-zero by 2050. EO 14057 establishes a policy for the federal government to lead by example in order to achieve a carbon-pollution free electricity sector by 2035 and net-zero emissions economy-wide by no later than 2050. These and other policies reflect science based GHG reduction goals to avoid the worst impacts of climate change.

[55] (Brown & Burch, 1992; Hougner, Colding, & Soderqvist, 2006).

[56] https://www.federalregister.gov/documents/2023/01/09/2023-00158/national-environmental-policy-act-guidance-on-consideration-of-greenhouse-gas-emissions-and-climate, accessed 1/10/2023.

EPA recommends the FEIS discussion include whether and to what extent the estimated GHG emissions from the proposed alternatives are consistent with achieving these science based national GHG reduction targets and any relevant state or local goals.

Social Cost of Carbon

The DSEIS notes "[f]or purposes of this analysis, qualitative analysis is appropriate because quantifying the relative costs and benefits of the alternatives is not practically feasible and would be subject to high uncertainty as described below."[57] However, the DSEIS calculates estimates of direct and indirect emissions, and these estimates can be used to monetize those emissions using the Social Cost of Greenhouse Gases (SG-GHG). EPA encourages lead agencies to monetize impacts of GHG emissions using SG-GHG estimates in NEPA analyses. For transparency, EPA recommends the FEIS assess the climate impacts and disclose climate damages of the proposed project using the SC-GHG, which reflect the best available science and methodologies to monetize the value of net changes in direct and indirect GHG emissions resulting from a proposed action to society.

Estimated Emissions Speciated by Gas

The SDEIS presents estimates in CO_2e and not speciated by gas (CO_2, CH_4 and N_2O). To ensure transparency of the analysis, EPA recommends presenting emissions estimates individually by GHG, as well as aggregated in terms of total CO_2e in the FEIS.

Additionally, the DSEIS indicates that approximately 99.9 percent of all processing GHG emissions are CO_2. Similarly, construction, mining and commuting CO_2 emissions comprise approximately 99 percent of the total GHG emissions from those activities.[58] EPA recommends the FEIS include data to support this statement. Specifically, EPA recommends providing data showing the amount of each GHG emitted from each emission source (i.e., the activities included in Tables 4.4-2a and 4.4-2b).

Direct and Indirect GHG Emissions

EPA recommends including a data table in the FEIS to support the DSEIS statement that the direct and indirect GHG emissions are only a small increase over the current regional GHG emissions.[59] Much of the information to develop this table is already in the SEIS, but it is found in various sections and with differing units (e.g., MMT CO_2 (e) vs. tons CO_2 (e)). As an example, to produce a table to support this statement, Tables 4.4-2a and 4.4-2b could be augmented to include the estimated indirect emissions and the current Idaho GHG emissions inventory.

Access Road Alternatives

The DSEIS indicates that the magnitude of the GHG emissions difference between the access road alternatives will be small compared to total SGP construction emissions during the construction phase.[60] EPA recommends the FEIS support this statement with data demonstrating that the Johnson Creek Alternative has similar GHG emissions to the 2021 MMP Alternative. Preferably, the emissions data for this alternative would be presented the same as it is in Tables 4.4-2a and 4.4-2b so that the alternatives can be meaningfully compared.

---

[57] (DSEIS, p. 4-60).
[58] (DSEIS, p. 4-65).
[59] (DSEIS, p. 4-67).
[60] (DSEIS, p. 4-73).

Integration of Climate Science

Flow (quantity and timing), summer air temperatures, and snowpack are likely to be substantially different over the span of this project (i.e., the next 15 to 20 years or longer) due to climate change. Further, conditions from that point in time into the future will be even further from estimates that are based on past conditions. It does not appear that climate change related concepts/forecasting/modeling are incorporated in the relevant sections of the DSEIS beyond the acknowledgement that climate change presents uncertainty.[61] For example, the DSEIS indicates the 100-year flood recurrence interval has been the standard approach in culvert sizing,[62] but it is now important to state future projections of high flow magnitude to conservatively account for climate change; and that modeled flow future conditions are based on historic condition.[63]

For the FEIS, EPA recommends incorporating state-of-the-climate science forecasting/modeling to estimate local climate conditions for proposed work that uses estimates of flow, air temperature, and snowpack. Examples of activities that would benefit from sophisticated forecasting would be road crossings design, stream reconstruction, and growth of riparian vegetation for stream temperature attainment. If site specific models and data are not available, consider incorporating climate science literature/information to inform and adjust existing models to conservatively adjust for climate change. Consider climate science projections (knowledge from the literature, forecasting/modeling) in aspects for both ongoing and postmining operations.

Proposed Action and Alternatives

Agency Preferred Alternative

Rationale of 2021 MMP Identification

The Executive Summary highlights three reasons the Forest Service identified the 2021 MMP Alternative as the Agency Preferred Alternative, but the first two bullets (i.e., incorporates water management and closure activities to reduce the duration of long-term water treatment requirements and incorporate measures to manage stream temperatures) are also true for the Johnson Creek Alternative since the mining portion of the Action Alternatives are the same. Similarly, Section 2.7 highlights eight reasons the Forest Service identified the 2021 MMP as the Agency Preferred Alternative, but the first two are also true for Johnson Creek Alternative. For the FEIS, since the Action Alternatives differ by proposed mine access routes, EPA recommends replacing these first two reasons with other primary reasons that are exclusive for the 2021 MMP.

The Agency Preferred Alternative sections in the Executive Summary and Chapter 2, as presented, appear to imply that the Agency Preferred Alternative is environmentally superior to the Johnson Creek Alternative. For transparency, EPA recommends the FEIS provide additional context for the selection, such as if the reasons highlighted were given preference or prioritized over other potential negative impacts.

Least Environmentally Damaging Alternative (LEDPA)

Because the U.S. Army Corps of Engineers is planning to use this EIS to support its CWA Section 404 analysis, EPA recommends that the FEIS discuss whether the Agency Preferred Alternative is also the LEDPA.

[61] (DSEIS, p.4-280).
[62] (DSEIS, p.4-264).
[63] (DSEIS, p.4-326).

Environmentally Preferrable Alternative
EPA recommends the FEIS describe the criteria which will be used to ultimately determine the environmentally preferable alternative under NEPA.

Specific Comments – DSEIS

Ore Processing

- The DSEIS indicates grinding will occur within an enclosed building to reduce noise levels and facilitate maintenance of the milling equipment.[64] EPA recommends the FEIS confirm if the ore processing building will be enclosed, and if not, correct its description throughout the FEIS. EPA notes a similar statement regarding an enclosed ore processing facility building is included in the Environmental Design Features on page 2-112.

- The DSEIS indicates the limestone crusher, screens, conveyors, and feed bins would not be enclosed. Dust would be controlled in a similar manner to the ore crushing and conveying process using water sprays and/or bag house dust collectors.[65] EPA recommends FEIS confirm if the limestone processing would be controlled like the ore processing operation, and if so, correct its description throughout the FEIS.

Tailings Storage Facility

- Regarding "[t]he TSF would be designed and operated as a closed-circuit, zero-discharge facility meaning no tailings water would be discharged to the surface water or groundwater except in compliance with applicable permits and regulations"[66] and "[w]ater from the TSF and TSF Buttress underdrains may be discharged from two outfalls shown on Figure 2.4-15,…"[67]

  The first sentence implies that there will be no discharge from the TSF. Based on the other two sentences, this appears to be accurate for operational conditions, but not for closure. Therefore, for the FEIS, EPA recommends revising the first sentence as follows: "… no tailings water would be discharged during mining operations,…"

Dry Stack Tailings

- The DSEIS indicates the use of the dry stack method of tailings disposal was evaluated and determined to be technically and economically infeasible.[68] An additional consideration in the determination to not fully evaluate a dry stack option is that stability of the proposed TSF is enhanced by the waste rock buttress so the stability advantage of a dry stack over a tailings impoundment is not as prominent for the SGP as it might be for other projects. We recommend that this consideration be included in the FEIS.

Agency Preferred Alternative

- The rationale for Agency Preferred Alternative in Section 2.7 raises two travelway distances (i.e., 0.5 miles and 100ft) in comparison for potential spill contamination, sedimentation, and

[64] (DSEIS, p. 2-48).
[65] (DSEIS, p. 3-48).
[66] (DSEIS, p. 2-57).
[67] (DSEIS, p. 2-67).
[68] (DSEIS, p. 2-130).

turbidity to streams during operations.[69] As there is very likely covariance (i.e., connection) between the two travelway distance zones and that these two zones could be repeating the same information, EPA suggests the FEIS use only one distance zone in this comparison.

Table 2.8-1 Alternative Comparison and Impact Summary (for 2021 MMP)

- The DSEIS indicates low flow will be reduced at some locations during some periods of the SGP operations.[70] EPA recommends the FEIS add a sentence to the table describing how far downstream (in feet or miles) from the SGP low flow conditions would occur so that the geographic extent of low flow impacts to the EFSFSR are clearly disclosed. Note that this comment also applies to the same sentence on page ES-14.

- In the summary table 2.8-1 2021 MMP, the TSF area groundwater summary provides the estimated changes in groundwater concentrations.[71] EPA recommends the FEIS describe how far from each facility the groundwater concentrations would remain elevated above the baseline so that the geographic extent of groundwater contamination caused by the SGP is disclosed.

- The DSEIS states, "[f]or mercury, while the predicted concentrations do not exceed the aquatic life criterion based on water column, it is uncertain whether incremental change in water column concentrations beyond baseline would cause fish tissue concentrations to exceed the tissue-based criterion."[72] EPA recommends the FEIS add this sentence to the summary table 2.8-1 2021 MMP, for surface water quality since it relates to uncertainties associated with achieving Idaho's fish tissue-based mercury water quality criterion for human health.

- According to pg. 4-308, "[f]unctional loss due to other indirect effects, including changes in hydrology, water quality, and increase dust and/or mercury deposition has been examined through inspection of dewatering drawdown and distance to roadways, but is difficult to quantify precisely. As a result, functional units that would be lost if these indirect effects occur, may be underestimated." EPA recommends adding this statement or something similar to the summary table 2.8-1 2021 MMP, Wetlands for the FEIS. Otherwise, the exact acres of wetlands lost or changed provided in the table imply a level of certainty that does not exist since indirect (secondary) impacts are underestimated and not quantified. In addition, we recommend that a similar uncertainty statement be added to the Executive Summary on page ES-17.

Air Quality

- The SDEIS indicates deposition of mercury, and nitrogen and sulfur species were predicted to be less than Significant Impact Levels (SILs).[73] EPA notes that SILs are air quality screening thresholds not applicable to deposition of pollutants, so this statement is incorrect. For the FEIS, EPA recommends replacing this term with "applicable screening thresholds," or another appropriate term.

- The DSEIS states "SILs are defined concentrations of criteria pollutants in the ambient air that are considered inconsequential in comparison to the NAAQS. A project impact shown to be

[69] (DSEIS, p. 2-133).
[70] (DSEIS, p. 2-141).
[71] (DSEIS, p. 2-143).
[72] (DSEIS, p. 4-438).
[73] (DSEIS, p. ES-9).

below a SIL can be presumed to not cause or contribute to the violation of a NAAQS."[74] The first sentence in this paragraph is misleading. For the FEIS, EPA suggests the following language replace the first sentence: "SILs are screening thresholds of criteria air pollutant concentrations considered by the EPA as a level of de minimis impact to air quality. SILs are primarily used in air quality modeling assessments, where a project impact shown to be below a SIL can be presumed to not cause or contribute to the violation of a NAAQS."

- EPA recommends the FEIS clarify or note in Section 3.3.2 why the much larger "far-field" region's scope is of importance to the Tribes,[75] given the potential impacts of poor ambient air quality to wilderness areas of Tribal and cultural significance.

- The DSEIS states "[t]he New Source Review process requires facilities to undergo an EPA pre-construction review if they propose building new facilities or modifying existing facilities that would result in a "significant increase" of criteria pollutants per 40 CFR § 52.2376."[76] For the FEIS, EPA recommends changing the regulatory cite from "52.2376" to "52.21" and "criteria pollutants" to "regulated NSR pollutants."

- The DSEIS states "[a]pplicability of the PSD program to the SGP depends on the magnitude of annual emissions for criteria pollutants."[77] We recommend the FEIS revise this sentence to be more precise: "Applicability of the PSD program to the SGP depends on the project's potential to emit regulated NSR pollutants. Applicability is determined using maximum potential annual potential emissions of the project for each NSR pollutant."

- The DSEIS states "… the 2021 MMP analysis did include an assessment of the significance of SGP air quality impacts by comparison to the Class II PSD increments."[78] EPA suggests the FEIS add an additional sentence to disclose why the PSD increment is selected as a threshold to assess the significance of air quality impacts. For example, additional language could state: "The PSD increments may provide a reasonable significance threshold for NEPA assessment because, under the Clean Air Act, significant air quality deterioration is recognized to occur when the amount of new air pollution from a new or modified source would exceed the applicable PSD increment."

- The DSEIS includes a statement "…consistent with best available control technology for new surface mining and processing operations"[79] which is incorrect. The project did not go through BACT review under the IDEQ PTC process because it did not go through major-source PSD permitting. EPA recommends removing the reference to BACT in the FEIS. A similar statement is included at the top of page 4-59 which EPA recommends revising to remove the reference to BACT.

---

[74] (DSEIS, p. 4-27).
[75] (DSEIS, p. 3-30).
[76] (DSEIS, p. 3-34).
[77] (DSEIS, p.3-35).
[78] (DSEIS, p. 4-28).
[79] (DSEIS, p. 4-35).

- EPA suggests the FEIS revise the second sentence on page 4-38 to read "As shown in Table 4.3-4, *IDEQ determined that* these emissions are less than the annual threshold of 100 tpy that would trigger Title V or 250 tpy for PSD permitting status."

- Regarding DSEIS statement on page 4-43 "…it also is unlikely the SGP would cause or contribute to a violation of a PSD increment" and Table 4.3-9 column heading "PSD Increment Compliance", it is important to disclose that comparison to the PSD increment threshold in the EIS is not to determine compliance to the standard (this is not a full regulatory assessment of increment consumption) but as a measure of the significance of project impacts to air quality for purposes of NEPA review. Therefore, we recommend the FEIS add a sentence to state the results instead indicate the project does not cause a significant deterioration of air quality. Also, EPA suggests changing the column header for Table 4.3-9 from "PSD increment compliance" to more appropriate wording such as "Results below threshold" or something similar to show the comparison is used to judge significance of project impacts rather than compliance with a regulatory threshold.

- For the DSEIS statement "[t]he most recent measurements were between 2007 and 2010 and are provided in Table 3.3-10 to serve as an estimate of historical Hg deposition in the region surrounding the SGP area,"[80] EPA recommends the FEIS add the word "wet" before deposition to specify that these data do not include dry deposition.

- For Table 3.3-10 Historical Annual Average Concentration and Mercury Deposition Rates – Three Idaho MDN Sites,[81] EPA recommends the FEIS add "in precipitation" to this Table title.

- The DSEIS indicates the nearest geographic site to the SGP area is no longer active but was active from December 2008 to August 14, 2017.[82] For the FEIS, EPA recommends specifying that the nearest site is over 500 km away.

- EPA notes that the Table (3.3-11) Annual Average Mercury Concentration – Salt Lake City AMNet Site[83] contains an important error. The Table reports that the overall mean gaseous elemental mercury (GEM) concentrations is 12.91 ng/m3. This value is not accurate. All yearly averages shown above in the Table are less than 2.5 ng/m3; and if taking an overall mean of the annual means the value would be 1.88 ng/m3 which is much lower than the 12.91 ng/m3 value currently included in the Table. It appears that the values for particle bound mercury (PBM)2.5 and GEM were switched, because the PBM2.5 value listed is lower than all of the annual reported concentrations. EPA recommends the FEIS correct the error accordingly.

- Regarding the DSEIS statement "[e]stimates of these emissions were based on regulatory compliance emission test results available for several gold mines in Nevada that use the same type of extraction process (Nevada Division of Environmental Protection 2006, 2015, 2016),"[84] for the FEIS, EPA recommends the FEIS add whether the mercury content of the ore was significantly different in the comparison between Stibnite and the Nevada mines.

---

[80] (DSEIS, p. 3-47).
[81] (DSEIS, p. 3-56).
[82] (DSEIS, p. 3-56).
[83] (DSEIS, p. 3-57).
[84] (DSEIS, p. 4-25).

- The DSEIS states "[f]urther speciation of the particulate forms of Hg is possible such as fine [particle-borne Hg (HgP)], which is analogous to filterable and condensable PM10. Essentially, the PM10 associated with HgP is the mercury bound within the particles of the particulate smaller than 10 microns. Appropriate particle distribution of mercury can be established using proper test methods and techniques, but the overall percentage of HgP compared to total Hg is small, with HgP PM10 being even less (~14.1 percent vs 2.4 percent from a coal boiler as an example) (Peng 2021). However, as discussed below, and in further detail in Section 4.3.4.2, the approach applied for this analysis did not speciate HgP."[85] EPA notes that this statement appears superfluous, given that particulate bound Hg was not further speciated in the analysis. EPA suggests the FEIS include some context for why this information is included or consider removing it.

Surface Water and Groundwater Water Quality

- The SDEIS states that for copper and mercury, impacts may be minimal but uncertainties in predicting future conditions exist.[86] EPA recommends the FEIS describe the mitigation and monitoring that will occur to reduce the uncertainties and actions that would be taken if impacts are more than minimal and result in exceedances of Idaho's CWA aquatic life criteria for copper and mercury.

- For the FEIS, EPA recommends noting in a footnote of the Table 3.9-6a Average MWMP Results – Development Rock and Ore and in the text that refers to the Table[87] that the detection limit used for this test for mercury (100-200 ng/L) is significantly above the CWA aquatic life criterion of 12 ng/L. Therefore, while some concentrations were above 200 ng/L, when values were less than this it does not indicate that the leachate would meet criteria. The same comment also applies to cadmium, copper, selenium, silver, thallium and lead. If similar issues also exist in other Tables in the text, EPA recommends adding a similar note indicating where the detection limit of the analysis is above the regulatory criteria level.

- The DSEIS indicates, under existing conditions, streams in the SGP area (except for West End Creek) are listed as impaired in accordance with CWA Section 303(d). The causes for listing of these waters are associated with arsenic (plus antimony and mercury at some locations) for exceedances of Idaho's water quality standards (WQS). Operational and post-closure concentrations of these elements in the East Fork SFSR are predicted to be comparable to or less than the existing conditions.[88] EPA recommends the FEIS add a sentence to this statement in the Executive Summary that identifies that under the proposed action West End Creek is predicted to exceed Idaho's CWA mercury aquatic life criterion for approximately 10 years during operation. The predicted mercury Idaho CWA WQS exceedances are described in the main text of the SDEIS, but we recommend that they also be identified in the Executive Summary.

- For Table 3.9-10b, [89] EPA recommends the FEIS add Idaho's CWA mercury criteria to the table header row as is done for the other constituents.

---

[85] (DSEIS, p. 4-30).
[86] (DSEIS, p. ES-16).
[87] (DSEIS, p. 3-160).
[88] (DSEIS, p. ES-15).
[89] (DSEIS, p. 3-183).

- Since cyanide is predicted to be elevated in the tailings pond,[90] EPA recommends the FEIS include cyanide in Table 4.9.6. Predicted TSF Surface Water Chemistry so that predicted cyanide concentrations are disclosed.

- EPA recommends the FEIS add cyanide to Table 4.9-8 Predicted Groundwater Chemistry Underlying the TSF for the same reason as above.

Fish Resources and Fish Habitat

- The DSEIS states "[t]he SGP area could experience natural climate change impacts to fish resources…"[91] EPA recommends the FEIS clarify and/or rephrase this sentence to either remove "natural" from the sentence or clearly identify what is meant by "natural climate change."

1 Introduction

1.1 Overview

This guideline is intended to assist air permit applicants, air quality specialists, and others who are reasonably proficient at performing atmospheric dispersion modeling analyses, in understanding the Idaho Department of Environmental Quality's (DEQ's) expectations for performing ambient air quality impact analyses associated with air quality permitting. This guideline does not have the force and effect of a rule and is not intended to supersede statutory or regulatory requirements or recommendations of the state of Idaho or the Environmental Protection Agency (EPA). It is provided as general guidance and does not alter the discretionary authority of DEQ to protect public health.

A working-level knowledge of air pollutant dispersion and air quality assessment is needed to understand and use this guideline. Applicants not proficient in atmospheric dispersion modeling are encouraged to use environmental consultants specializing in air quality modeling or other sufficiently experienced professionals having such modeling capabilities. DEQ does not have available resources to educate applicants or consultants in the fundamentals of performing atmospheric pollutant dispersion modeling analyses.

DEQ staff will not recommend a specific consultant; however, DEQ may provide a list of consultants used by applicants for recent permit applications for which dispersion modeling was required. Recent permit applications, DEQ-issued permits, and the Statement of Basis for issued permits are available on DEQ's website, and consultants used by specific applicants are often identified in application materials and the DEQ modeling memorandum (the modeling review memorandum is typically included as an appendix to the Statement of Basis). DEQ may perform the atmospheric dispersion modeling analyses for applicants in some circumstances. Section 1.2 of this guideline describes cases in which DEQ may perform the analyses.

Table 1 provides a basic step-by-step description of an air quality impact analysis, with specific sections of this guideline referenced for each step.

The purpose of an air quality impact analysis, performed in support of an air quality permit application, is to demonstrate that all applicable ambient air quality standards will be met if a proposed project is implemented or to demonstrate an existing facility's compliance with the standards.

Demonstration of compliance with the National Ambient Air Quality Standards (NAAQS), toxic air pollutant (TAP) increments, and prevention of significant deterioration (PSD) increments is required by the state of Idaho for permit issuance and certain exemptions. DEQ has determined this demonstration generally requires the applicant to perform air quality impact analyses using an atmospheric dispersion model, referred to as modeling analyses in this guideline.

The extent of the required modeling analyses will vary from one project to another depending on the type and magnitude of emissions and applicability of specific permitting requirements. For simple facilities (e.g., few sources and buildings), compliance may be shown by using screening- level techniques, including a screening-level model. No further analyses will be required if compliance can be adequately demonstrated with the use of an appropriate screening technique. Projects for which compliance cannot be demonstrated using screening techniques must use more refined methods. Complex multi-point emitting sources or sources with unusual pollutant dispersion environments, for

which screening techniques are not appropriate, are also required to use more refined modeling techniques. Facilities submitting applications for which the PSD requirements are applicable are required to perform more extensive analyses than when submitting a minor source application. This guideline focuses on the requirements for non-PSD applications. Facilities submitting a PSD application should refer to the New Source Review Workshop Manual (EPA 1990) and other available materials from EPA for additional guidance and should consult with DEQ before performing the required analyses.

This guideline follows the Rules for the Control of Air Pollution in Idaho (IDAPA 58.01.01 {Idaho Air Rules}), EPA guidance in the New Source Review Workshop Manual (EPA 1990), and the Guideline on Air Quality Models (EPA 2005). The 2005 version of the Guideline on Air Quality Models was used to develop this version of the guideline. However, the most current version of the Guideline on Air Quality Models should always be used when evaluating appropriate methods and data for a specific project.

The Guideline on Air Quality Models specifies:

"…air quality modeling techniques that should be applied to State Implementation Plan (SIP) revisions for existing sources and to new source reviews (NSR), including prevention of significant deterioration (PSD). Applicable only to criteria pollutants, it is intended for use by EPA Regional Offices, in judging the adequacy of modeling analyses performed by EPA, State and local agencies and by industry. The guidance is appropriate for use by other Federal agencies and by State agencies with air quality and land management responsibilities."

DEQ highly recommends that a modeling protocol be developed and submitted to DEQ for approval before performing any modeling analyses. A DEQ-approved protocol will help assure that methods and data used in the modeling analyses are appropriate and will be acceptable to DEQ reviewers. Guidance on the contents of a protocol is provided in Section 6.1.

Table 1. Sections of the Guideline Used in Performing an Air Impact Analysis

Step in Air Impact Analysis	Section
1) Determine whether professional assistance is needed for performance of the air impact analyses?	1.1, 1.2, 2.0
2) Review general modeling requirements and develop a methodology.	5.0, 6.0
3) Calculate the emissions increase for modeling applicability purposes.	3.3, 6.3
4) Determine whether dispersion modeling is required – compare applicability inventory to modeling thresholds.	3.1, 3.2
5) Select the appropriate model.	6.2, 5.0
6) Set up the modeling analysis, including facility layout, buildings, ambient air boundary, receptors, and elevation data.	6.4.3, 6.4.4, 6.4.5, 6.5, 6.6, 6.7, 6.9
7) Select meteorological data.	6.8
8) Determine background concentrations.	6.10
9) Prepare and submit protocol, and obtain DEQ approval.	6.1
10) Calculate emissions for significant impact analyses and TAPs analyses.	5.1.1, 6.3, 6.3.1, 6.3.2, 6.3.3, 6.4.1
11) Calculate/obtain emissions release parameters and document.	6.4.2
12) Evaluate model results for significant impact analyses and TAPs analyses.	4.1, 4.2, 4.3, 6.11
13) Calculate emissions for cumulative NAAQS analyses and document.	5.1.2, 6.3.1, 6.3.2, 6.3.3, 6.4.1
14) Evaluate model results for cumulative NAAQS analyses.	4.1, 6.11.1
15) Perform comprehensive quality assurance/control of the analyses and evaluation of results.	2.0, 6.11.2
16) Prepare permit application and modeling report.	6.12, 7.0

1.2 Responsibility for Modeling Analyses

The accuracy and representativeness of methods and data used in the modeling analyses is the responsibility of the applicant. DEQ may provide applicants with appropriate meteorological data (not always preprocessed and ready for model input) and default background pollutant concentration values, as described later in this guideline.

DEQ modeling staff may assist applicants or may perform the required modeling analyses in some instances. The following are cases in which DEQ may perform the modeling analyses for permit applicants:

- Renewal of a Tier II operating permit. If a facility has not been modified since issuance of a previous Tier II operating permit, DEQ may use the previously performed modeling results to demonstrate compliance with NAAQS. Previously conducted modeling analyses will not be acceptable if DEQ identifies errors in methods or data used, or if the model used is substantially outdated, such that compliance with NAAQS may be questionable. Changes in applicable standards would also trigger the need to remodel the facility.
- DEQ has current modeling files for the facility. In instances where DEQ has a current model for the facility, slight changes to account for a new source or modification can sometimes be easily made by DEQ modeling staff. The applicant will be responsible for providing, justifying, and

documenting all input parameters needed to adequately address the proposed changes. Modeling analyses performed by DEQ staff will be done outside of the regulatory time limit for permit application review and will be dependent on DEQ staff workload. The applicant must include justification and documentation of all parameters, even those provided in previously submitted analyses. DEQ's permitting process requires that each application be a complete package in itself and not merely reference previously submitted applications.
If compliance with standards cannot be easily demonstrated by DEQ's analyses it will be the applicant's responsibility to conduct more refined analyses.

- Simplistic modeling analyses for small businesses. DEQ may conduct the modeling analyses for small business in situations where there are a small number of sources and a simple facility layout. These decisions will be made on a case- by-case basis and will depend on current DEQ workload.

Modeling analyses performed by DEQ for permit applicants will typically be done outside of the regulatory review process and any review timelines. Data and results will typically be forwarded to the applicant for their review when the analyses are completed by DEQ staff. The applicant will then combine those analyses with other components of the application and submit the complete application to DEQ to initiate the agency review process.

Permit applicants will be responsible for submitting the following information/data to enable DEQ to perform modeling analyses:

- Detailed description of operations and equipment used.
- Requested allowable emissions rates for all criteria pollutants and TAPs for all applicable averaging periods.
- Maximum operational and material processing rates.
- Site description and scaled site plot plan, including a detailed description of any structures. Universal Transverse Mercator (UTM) coordinates, with the applicable datum listed, must be provided for all building corners, and heights of all building tiers must be provided.
- Emissions point information (stack location in UTM coordinates with the applicable datum listed, stack height, stack diameter, stack gas temperature, and flow rate) with thorough justification and documentation of such information.

If DEQ's analyses do not initially demonstrate compliance with applicable standards, it will be the applicant's responsibility to refine the analyses to achieve an adequate compliance demonstration.

DEQ has developed, or is in the process of developing, specific modeling approaches for several industrial types. For example, DEQ has conducted non-site-specific modeling for truck-mix concrete batch plants and portable hot-mix asphalt plants; and no source- specific modeling is require for these plants if they meet the production rate limits, minimum stack parameter specifications, and setback distances from specific receptors. DEQ air dispersion modeling staff should be consulted regarding availability and details of industry-specific modeling approaches.

2 Use of the Modeling Guideline

2.1 This Guideline Most Useful in Common Instances

This modeling guideline is presented as suggestions and instructions for performing a modeling analysis in the most common instances. The methods and data presented are not appropriate for all sources,

locations, and/or situations, and use of a method presented in the guideline does not necessarily assure DEQ approval of the method. DEQ may approve or require methods and/or data differing from those presented in this guideline, depending on the characteristics of the specific situation.

2.2 Level of Knowledge Required to Use This Guideline

This guideline is not intended to educate permit applicants or consultants in the basic principles of atmospheric dispersion or in the operation of various dispersion models, as stated in Section 1.1. A wide variety of commercially available courses are available for applicants to develop the level of knowledge needed to correctly perform pollutant dispersion modeling analyses.

If your specialist (your staff) or consultant and cannot easily answer the following questions, they may not be adequately skilled to properly perform an air impact analysis involving dispersion modeling for air permitting purposes:

1. Have you performed an atmospheric dispersion modeling analysis within the last five years?
2. Do you understand why a stack with a horizontal or rain-capped release is sometimes modeled using a stack flow velocity of 0.001 meters per second?
3. Do you know what a significant impact is, and its implications for modeled impacts?
4. Do you know when background concentrations are used in a modeling analysis and when they are not?
5. Do you understand the difference between a significant impact analysis and a cumulative NAAQS impact analysis?
6. Do you know what surface roughness, Bowen ratio, and surface albedo are and how they are used in the model programs and preprocessor programs?
7. Do you understand the difference in how point sources, area sources, and volume sources are treated in AERMOD, SCREEN3, and/or AERSCREEN?
8. Do you know whether AERMOD uses daily or hourly meteorological data?

Permitting regulations require the applicant to demonstrate that emissions will not cause or significantly contribute to a violation of a standard. The regulations do not require that the analyses estimate actual impacts to the greatest degree possible. Therefore, it is advised that applicants use reasonably conservative data and methods to demonstrate compliance – data and methods that both DEQ and the applicant agree will generate impacts greater than those that would be reasonably expected. However, overly conservative estimates of input parameters, especially emission quantities, may substantially overstate impacts. This could result in the inappropriate applicability of certain requirements and/or the imposition of unnecessary permit provisions and restrictions.

Use of unrealistic release parameters, such as stack flow rates or stack gas temperatures, could shift the location of maximum impacts. In situations where the modeling analyses involve numerous sources, this could result in either under-estimation or over-estimation of combined impacts. Therefore, it is recommended that reasonably accurate release parameters be used when modeling multiple sources, rather than overly conservative parameters. In some instances, where reasonably expected parameters are highly variable, it may be more appropriate to use multiple operational scenarios to evaluate the effects of varying parameters.

3 Requirements to Perform Air Impact Analyses

This section outlines the permitting requirement to demonstrate compliance with NAAQS and TAP increments, and it describes when project-specific air impact modeling analyses are needed for issuance of a PTC or Tier II Operating Permit. It discusses pollutant-specific regulatory applicability, regulatory requirements for permit issuance, and calculation of emission increases for project modeling applicability.

3.1 Air Impact Analysis Regulatory Requirements for Permit Issuance

3.1.1 NAAQS and TAP Compliance Demonstration Requirements

Idaho Air Rules Section 203.02 states that "no permit to construct shall be granted for a new or modified stationary source or modified stationary source unless the applicant shows to the satisfaction of the Department" that the source or modification "would not cause or significantly contribute to a violation of any ambient air quality standard." Section 203.03 similarly requires that no permit be issued unless it is demonstrated through the use of methods in Section 210 that the source or modification would not "injure or unreasonably affect human or animal life or vegetation as required by Section 161."

Air impact analyses are also required for the issuance of Tier II Operating Permits, with requirements of Idaho Air Rules Section 403.02 mirroring Section 203.02 for PTCs. There are no TAP impact analysis requirements for Tier II Operating Permits.

3.1.2 Below Regulatory Concern Exemption from Demonstration Requirement

Certain projects may be exempt from the requirement to demonstrate compliance with NAAQS or TAP increments. If a project would qualify for a Below Regulatory Concern (BRC) permit exemption as per Idaho Air Rules Section 221 if it were not for potential annual emissions of one or more pollutants exceeding the BRC threshold of 10 percent of emissions defined by Idaho Air Rules as "significant," then a NAAQS compliance demonstration may not be required for those pollutants with emissions below BRC levels. DEQ's regulatory interpretation policy of exemption provisions of Idaho Air Rules Section 221.01 is that: "A DEQ NAAQS compliance assertion will not be made by the DEQ modeling group for specific criteria pollutants having a project emissions increase below BRC levels, provided the proposed project would have qualified for a Category I Exemption for BRC emissions quantities except for the emissions of another criteria pollutant.[1]" The interpretation policy also states that the exemption criteria of uncontrolled potential to emit (PTE) not to exceed 100 ton/year (Idaho Air Rules Section 220.01.a.i) is not applicable when evaluating whether a NAAQS impact analysis is required. A permit will be issued limiting PTE below 100 ton/year, thereby negating the need to maintain calculated uncontrolled PTE under 100 ton/year.

The BRC exemption cannot generally be used to exempt a project from a pollutant-specific NAAQS compliance demonstration where a PTC is required for the action regardless of emission quantities, such as the modification of an existing emission or throughput limit.

However, in this instance, if post-project facility-wide annual emissions of the criteria pollutant are also below BRC thresholds, then a NAAQS compliance demonstration is not required.

3.1.3 Regulatory Requirements of the Air Impact Analyses

Once a permit is required for a proposed project, an air impact analysis is required for permit issuance unless the pollutant can be exempt from the requirement to demonstrate compliance with NAAQS and TAP increments, as described above in Section 3.1.2. Idaho Air Rules Section 203 for PTCs and Section 403 for Tier II Operating Permits require that air impact analyses demonstrate compliance with NAAQS and TAP increments "to the satisfaction of the Department." A key consideration is what constitutes DEQ satisfaction of compliance.

Use of unquestionably-conservative methods and data for all components of the analyses will generate predicted impacts that demonstrate compliance at near complete certainty. As analyses move back from methods and data that are highly conservative, then the certainty of NAAQS and TAP increment compliance decreases. Determining the point at which analyses no longer satisfactorily demonstrate compliance then becomes an important concern. This point is not defined in the regulations. DEQ asserts that a satisfactory compliance demonstration is an analysis where NAAQS and TAPs increment compliance is "highly confident," considering all variability and uncertainty in analytical methods and data.

The confidence level of compliance with air quality standards will be affected by the following:

- Magnitude and spatial extent of modeled impacts in comparison to applicable thresholds or standards.
- Potential for public exposure to impacts exceeding standards.
- Representativeness of meteorological data used, and the accuracy/conservatism of meteorological data processing methods used.
- Uncertainty and variability of estimated emissions. Emissions that will be verified by source testing will be considered as near certainty, while emissions based on low-ranked AP-42 factors (which usually represent an average across the industry) will be considered as low confidence.
- Method used to account for atmospheric chemistry (NO/NOx chemistry primarily).
- Representativeness and conservatism of background concentrations (note that using design value background levels with design value modeled results is more conservative for short-averaging periods than for annual averaging periods).
- Level of conservatism in modeling expected operational scenarios (handling variable load conditions, multiple intermittent sources, etc.).
- Representativeness/conservatism of methods used to handle complex emission points such as fugitive releases.
- Handling of building downwash.
- Handling of complex terrain.
- Methods use to hand co-contributing sources in a cumulative impact analysis.

3.2 Emission Thresholds Triggering Site-Specific Impact Analyses

Emission quantities from a source directly affect pollutant impacts to ambient air, and therefore affect the likelihood of a source to cause or contribute to a violation of an ambient air quality standard. Where emission rates are minimal, DEQ can be highly confident that the source will not cause or contribute to a standard violation without performing an impact analysis using pollutant dispersion modeling. Screening Emission Levels (ELs) are specified in the Idaho Air Rules as a de *minimis* TAP emission quantity, below which compliance with the TAP increment is assured. De *minimis* levels for criteria pollutants are not specified in Idaho Air Rules. However, this section presents criteria pollutant de *minimis* levels that DEQ

asserts will reasonably assure NAAQS compliance for various circumstances. These levels were established using the professional judgement of DEQ scientists and engineers, combined with results from computerized pollutant dispersion models for various generic configurations.

DEQ established emission de *minimis* levels as a function of the Significant Emission Rates (SERs) defined in Idaho Air Rules Section 005.108. The SERs are expressed as annual emission rates. To use SERs for NAAQS with short-term averaging periods, the SER is divided by 8,760 hours/year and compared to maximum hourly emissions for 1-hour standards or maximum daily emissions divided by 24 for 24-hour standards. DEQ also developed Significant Impact Level (SIL) thresholds for modification projects; emissions less than these rates are reasonably assured to have impacts less than the applicable SIL. SIL thresholds were developed by DEQ using dispersion modeling analyses of a generic facility with one point source.

Whether a specific emission quantity can cause or contribute to a violation greatly depends on whether those emissions occur from a new facility or are added to those of an existing facility, and whether the existing facility has recently demonstrated NAAQS compliance on a facility- wide basis through dispersion modeling. The confidence of NAAQS compliance is high where project emissions occur from a proposed new facility in an attainment area and predicted emission quantities are low. NAAQS compliance confidence is also high for projects at existing facilities where facility-wide air impact analyses were recently performed and emissions associated with the modification are minimal. Even if the increase in emissions at a previously modeled existing facility could cause impacts exceeding the SIL, it is unlikely that impacts could exceed the NAAQS when combined with co-contributing sources and background concentrations. This is because any high impacts from new sources are not likely to coincide in time and space with high impacts from the existing facility. In the unlikely event that such minimal emissions combine with a high background concentration and impacts from nearby sources to produce an impact exceeding the NAAQS, it is likely that such impacts would only occur in a small area, would only occur for limited periods, and would not affect areas where sensitive individuals could be present.

A modeling applicability threshold assuring project impacts less than the SIL is used for modification projects to facilities where facility-wide NAAQS compliance demonstrations have not been recently performed. This threshold assures with high confidence that the project will not significantly contribute to any potentially existing NAAQS violation. These threshold values were based on modeling of a generic DEQ-generated facility, using the AERMOD regulatory model with Idaho meteorological data. The analyses used the following parameters: stack height = 10 meters; stack diameter = 0.5 meters; velocity at stack exit = 10 meters/second; stack gas temperature at exit = 200 ^{o}F; ambient air is at a distance of 100 meters from the stack; the stack is centered on a 10 meter square building, 5 meters high. The SIL thresholds are emission rates that, when modeled using the generic DEQ-generated facility, result in impacts just below the applicable SIL.

Figures 1 and 2 show the project-specific air impact analysis applicability determination process for new facilities and modifications to existing facilities, respectively. This process should only be used for projects proposed in attainment or unclassifiable areas. DEQ should be consulted if a proposed project is located in a non-attainment area. Also, if DEQ observes project-specific conditions that suggest a threshold is not appropriate or protective of NAAQS, then DEQ may require project-specific air impact modeling even though emissions are below the listed threshold.

Table 2 lists the modeling applicability threshold values referenced in Figures 1 and 2.

Table 2. Modeling Applicability Thresholds (values in pounds/hour[(a)])

Pollutant and Averaging Period	SIL Threshold	BRC	1/8 SER	1/4 SER	SER
CO 1-hr	84	2.3[b,c]	2.9[b]	5.7[b]	100 ton/yr
CO 8-hr	26	2.3[b,c]	2.9[b]	5.7[b]	100 ton/yr
NO_2 1-hr	0.38	0.91[c]	1.14	2.3	40 ton/yr
NO_2 ann	0.43 (1.9 ton/yr)	4.0 ton/yr	5.0 ton/yr	10.0 ton/yr	40 ton/yr
SO_2 1-hr	0.40	0.91[c]	1.14	2.3	40 ton/yr
PM_{10} 24-hr	0.32	0.34[c]	0.43	0.86	15 ton/yr
$PM_{2.5}$ 24-hr	0.092	0.23[c]	0.29	0.57	10 ton/yr
$PM_{2.5}$ ann	0.085 (0.37ton/yr)	1.00 ton/yr	1.25 ton/yr	2.5 ton/yr	10 ton/yr
Pb 3-month	0.00102 (0.73 lb/mon)	9.9 lb/mon	12.3 lb/mon	24.7 lb/mon	0.6 ton/yr

a) Values in pounds/hour as averaged over the averaging period of the NAAQS, unless noted otherwise. Pound/hour values listed as a function of the SER were calculated by dividing the annual SER value by 8,760.

b) These values are more restrictive than the SIL Threshold. Therefore, the SIL Threshold may be used in place of these values.

c) BRC is based only on annual emissions. The pounds/hour values listed as BRC for short term standards are the annual BRC rate divided by 8,760 hours/year. Annual emissions from the project should be divided by 8,760 hours/year and then compared to the listed pounds/hour BRC threshold to evaluate whether the project can be exempt from NAAQS compliance demonstration requirements for the applicable pollutant.

d) These values are more restrictive than the SIL Threshold. Therefore, the SIL Threshold may be used in place of these values.

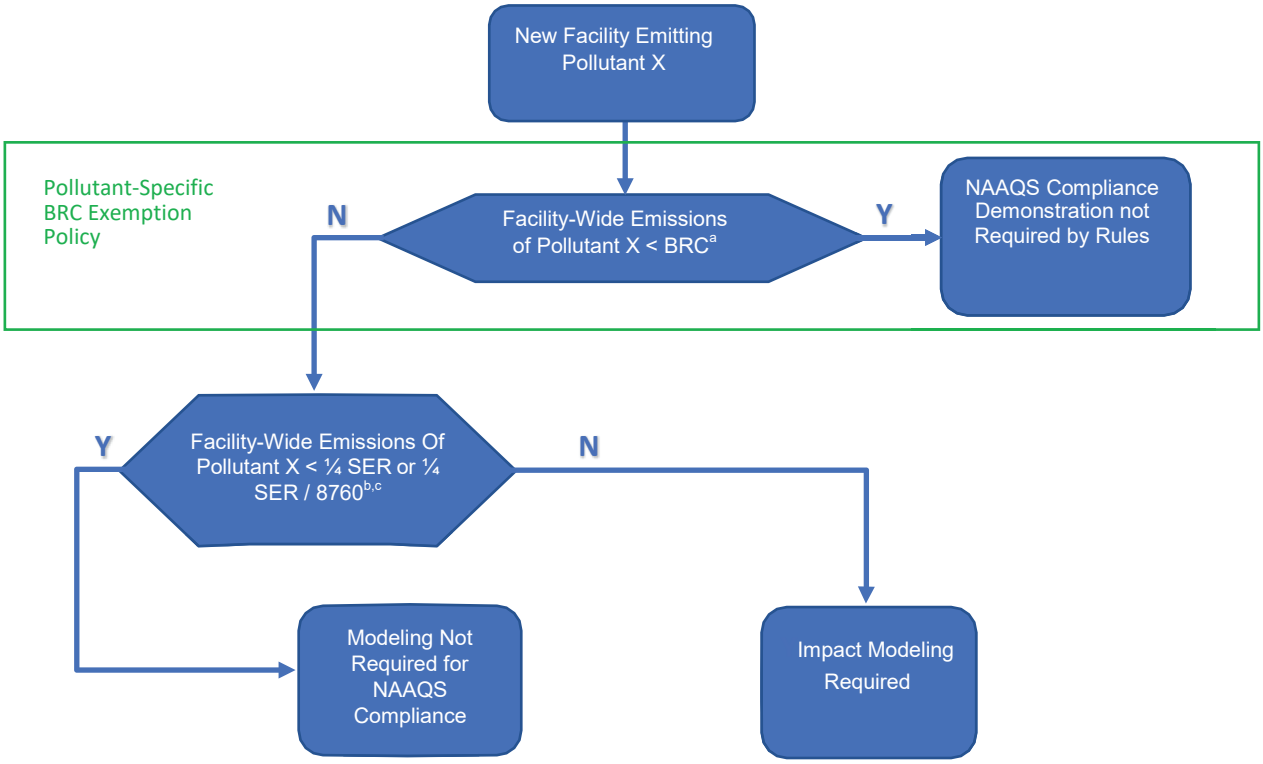

Figure 1. Pollutant-Specific Modeling Applicability Flow Chart for New Facilities in Attainment or Unclassifiable Areas

a) This evaluation is DEQ's regulatory interpretation of permit exemption rules, as described in: *Policy on NAAQS Compliance Demonstration Requirements*. Idaho Department of Environmental Quality Policy Memorandum. July 11, 2014. The evaluation is based only on annual emissions, and emissions qualifying as "fugitive" as defined by Idaho Air Rules for permit applicability are not included in the evaluation. Example: A company proposes to construct a widget maker facility. The project would qualify for a BRC permitting exemption under Idaho Air Rules Section 221.01, with emissions of Pollutant X below the BRC threshold, except that emissions of Pollutant Y exceed the BRC threshold and trigger the requirement to obtain a PTC. By DEQ regulatory interpretation, a NAAQS compliance demonstration for Pollutant X is not required by Idaho Air Rules for permit issuance.

b) Emissions calculated according to DEQ-specified methods. Fugitive emissions associated with the project are included in this evaluation. The threshold of 1/4 SER is applicable to NAAQS regulated on an annual average; and 1/4 SER/8760 is applicable to NAAQS on a short-term average, with the pound/hour threshold value compared to the maximum potential/allowable emission for the averaging period divided by the hours in the averaging period.

c) If DEQ observes project-specific conditions that suggest these thresholds are not appropriate or protective of NAAQS, then DEQ may require project-specific air impact modeling even though emissions are below listed thresholds.

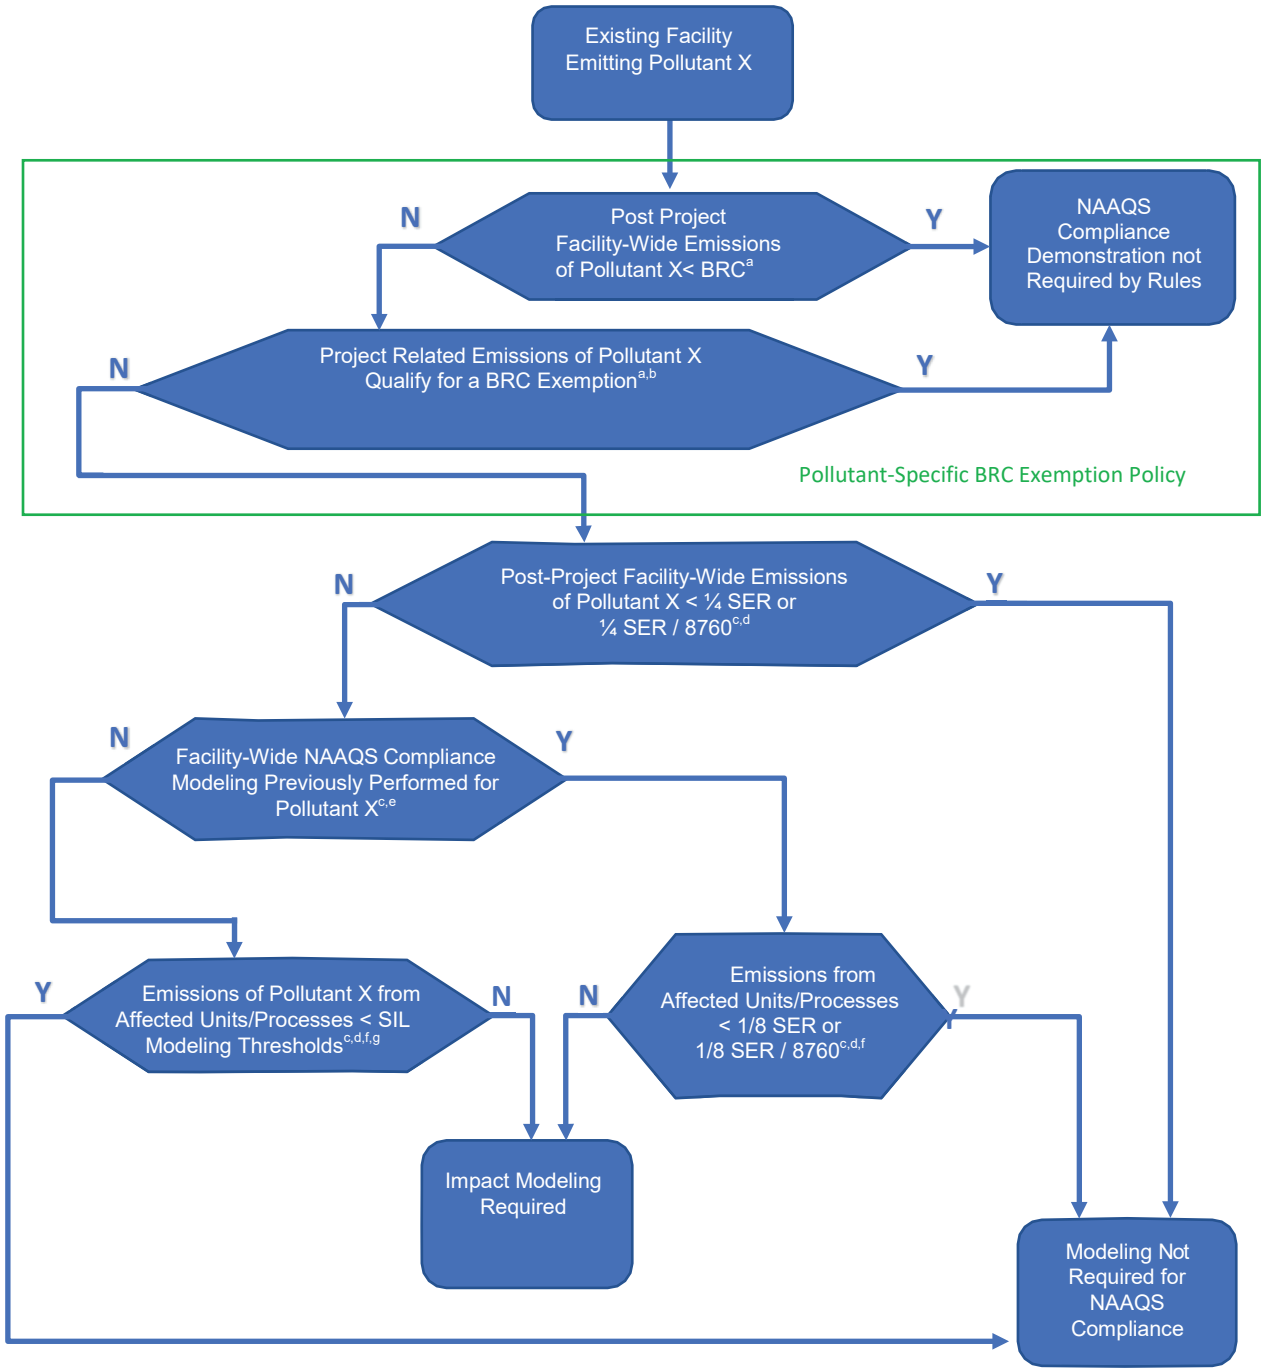

Figure 2 Pollutant-Specific Modeling Applicability Flow Chart for Modifications to Existing Facilities in Attainment or Unclassifiable Areas

a) This evaluation is DEQ's regulatory interpretation of permit exemption rules, as described in: Policy on NAAQS Compliance Demonstration Requirements. Idaho Department of Environmental Quality Policy Memorandum. July 11, 2014. The evaluation is based only on annual emissions, and emissions qualifying as "fugitive" as defined by Idaho Air Rules for permit applicability are not included in the evaluation.

b) Examples:

1. A company proposes to construct a widget maker at their existing facility. The project would qualify for a BRC permitting exemption under Idaho Air Rules Section 221.01, with emissions of Pollutant X below the BRC threshold, except emissions of Pollutant Y exceed the BRC threshold and trigger the

requirement to obtain a PTC. By DEQ regulatory interpretation, a NAAQS compliance demonstration for Pollutant X is not required by Idaho Air Rules for permit issuance.

2. A facility proposes to increase production at their existing, permitted widget maker. The existing permit limits widget production at 50 widgets per hour. The project proposes to increase production to 100 widgets per hour. The increase in emissions of Pollutant X is below the BRC threshold, but total emissions of Pollutant X from the unit are above the BRC threshold. A NAAQS compliance demonstration for Pollutant X is required because the project could not qualify for a permitting exemption, regardless of the emissions from other pollutants. The modification requires changing an existing permit condition, and therefore, could not qualify for a BRC exemption.

c) Fugitive emissions associated with the project are included in this evaluation.

d) If DEQ observes project-specific conditions that suggest these thresholds are not appropriate or protective of NAAQS, then DEQ may require project-specific air impact modeling even though emissions are below listed thresholds.

e) This applies if facility-wide modeling of the specific pollutant was performed for the averaging period of the NAAQS. Facility-wide modeling may be associated with a past permitting project or performed independently, and it may conservatively use allowable emissions or a more-refined reflection of actual emissions. Modeling must have been approved by DEQ, performed within the previous five years, be representative of the existing facility and operations, and include the pollutant of interest.

f) Emissions increase calculated according to DEQ-specified methods, including methods to handle projects involving relaxation of an emission-affecting permit limit.

g) SIL Modeling Threshold based on modeling of a generic hypothetical source.

3.3 Emission Increase Calculation for Project-Specific Modeling Applicability

Whether project-specific air impact modeling is required for a project depends on the increase in emissions resulting from implementation of the project. The emission increase for a new facility is simply the sum of potential or permit-allowable emissions from all emission sources associated with the project. The emission increase for a modification is defined in Idaho Air Rules as “the amount by which projected actual emissions exceed baseline actual emissions of an emissions unit.” Section 3.3.2 provides more details on calculating the emission increase associated with modifications for modeling applicability.

The following types of emissions sources should be included in the modeling applicability calculation:

- All emissions sources that may be included in the permitting analyses or the issued permit, regardless of whether those sources may have (or will be issued) emissions or operating limits. Sources that are exempt from permitting as per Idaho Air Rules Section 220-223 must normally be included in the modeling applicability calculation. DEQ’s modeling group should be consulted if there are questions regarding the inclusion or exclusion of emission sources in the modeling applicability determination.
- Process fugitive emissions from material handling, processing, etc. Fugitive emissions from vehicle traffic on facility roadways and wind erosion emissions from storage piles will not typically be considered for minor source permitting applicability unless DEQ determines such sources may have a substantial contribution to ambient concentrations. Mining facilities are typically in this category where such fugitive sources must be included.
- Intermittent sources such as batch processes, flaring, bin dumping, engine testing, etc. Emissions of NOx from intermittent testing of engines powering emergency generators and fire suppression water pumps can typically be excluded from the modeling applicability

determination for 1-hour NO2 NAAQS compliance demonstrations. Appendix A provides DEQ's final guidance on the modeling of NOx from intermittent testing and maintenance operations of engines powering emergency generators and fire suppression water pumps.

Sections 3.3.1 and 3.3.2 describe how emission quantities should be calculated for various scenarios to evaluate the need to conduct project-specific impact modeling. The modeling applicability emission inventory (used to determine whether modeling is needed) may be different than the modeling analysis emission inventory (used to conduct a significant impact analysis), as explained in Section 6.3.1.

3.3.1 Determining Whether Modeling is Needed for a New Source or Facility

Proposed allowable emissions, as specified in a permit application or calculated as potential to emit, of all new emissions sources will be used to evaluate the need for modeling a proposed new emissions source or new facility. No emission sources are typically exempt from the evaluation of whether modeling is needed. Also, any reductions in emissions at a different source cannot be considered at the modeling applicability stage.

3.3.2 Determining Whether Modeling is Needed for Modifications

Air impact modeling requirements for a modification hinge on the quantity of increased emissions that could occur as a result of the modification. For the purpose of project-specific applicability for performing an air impact analysis, any emission decreases are not typically considered. Creditable decreases may be considered in air impact modeling performed once the requirement to perform impact modeling has been established. If removal of an existing source or installation of control equipment on a source occurs concurrently with a modification, the emission reduction associated with such activities will not typically be considered in the evaluation of whether emissions exceed modeling applicability thresholds.

Emission increases for a modification must be carefully calculated to obtain an accurate or conservative assessment. From a regulatory standpoint, "Emissions Increase" is defined in Idaho Air Rules Section 007.04 as, "The amount by which projected actual emissions exceed baseline actual emissions of an emissions unit." Baseline actual emissions are a best-estimate of emissions that could realistically occur by operation of the source before modification. If the source is permitted, such emissions may be those allowed under the restrictions of the existing permit (using best available emission estimation methods and considering the permit limits that are the most restrictive to emission-causing operations). The following should be considered when calculating baseline actual emissions to evaluate the need for project-specific modeling:

- For a given process, the same emission calculation method and emission-affecting assumptions should be used for baseline actuals as is used for calculating future permit allowables, unless there are changes in the process that necessitate using different methods and assumptions. A change in emission factors or methods used to estimate emissions from a given process cannot be used to reduce the change in emissions associated with a proposed modification.
- Emissions considered as a conservative estimate for post-project allowable emissions (over-estimation of emissions), will result in an overestimate of baseline actual emissions for future projects. This may then result in an underestimation of the future project emission increase. DEQ approval of a conservatively high emission estimate of a source for initial permitting may not be appropriate for calculating baseline emissions for a future modification. However, the same emission factor or estimation method should be used for a given process, as noted in the previous bullet. For example, if a project involves increasing allowable throughput and the

emission generating mechanism does not change, the same emission factor should be used for both baseline actual emissions and post-project allowable emissions. Also, the applicant should use a factor they are confident does not underestimate post-project allowable emissions, even if it is suspected use of the factor overstates baseline actual emissions.

- Permit applicants should not simply use emission factors and other emission-affecting parameters from previous air impact analyses as a representation of baseline actual conditions. Many previous analyses were only required to demonstrate that the project will not cause a violation, and this was often accomplished by using simplistic estimates that substantially overestimate emissions. More accurate and updated emission rate data and release parameter information are frequently available for a source after initial permit issuance. This results from performance tests or from changes in emission factors. Baseline actual emissions should generally be calculated using the most accurate methods available. Overestimating baseline emissions will result in underestimation of the change in emissions resulting from a modification.
- Full operational levels (as allowed by the existing permit) can be considered in the calculation of baseline actual emissions, provided the facility/equipment could have accommodated such a level of operation. For example, a certain unit has a throughput limit of 1,000 units per day, and operational records indicate that only a maximum of 900 units per day has been processed. Baseline emissions can be calculated by assuming 1,000 units per day if it can be demonstrated that the facility could effectively attain those levels without a facility modification.
- Many permits contain both specific emission limits and limits on production. Baseline emissions must be based on the most restrictive limitation in the permit. As an example, consider a case where source testing has demonstrated that emissions per unit of production are lower than anticipated during initial permitting. As part of a proposed modification, the facility would like to raise the allowable production rate but not change the permitted emission rate. In this case, there will be an increase in allowable emissions because there is an increase in throughput. However, the applicant may calculate the increase in emissions using an updated emission factor that is based on recent source testing.

Future projected actual emissions will simply be permit-allowable emissions. Conservative emission estimates that overstate these emissions are acceptable and encouraged to facilitate expeditious DEQ approval of the modeling-applicability calculation.

Relaxation of Existing Permit Restrictions

Some modification projects involve the relaxation of an existing emission-affecting permit restriction, such as throughput limit, limit on hours of operation, material restriction on the type of material processed, or a direct emissions limit. In these cases, especially where the existing limit was needed to assure compliance with a NAAQS or a TAP increment, DEQ may require that the entirety of emissions from the unit be considered for modeling applicability rather than the increase alone. This approach is used because of the following:

- An increase in emissions at an existing emission point is more likely to cause or contribute to a NAAQS or TAP increment violation than if those emissions occurred at a new point. This is because emissions at two separate points must have overlapping plumes for their impacts to be additive.
- If a limit was needed on an emission point to assure NAAQS or TAP increment compliance, then increasing emissions at such a point would likely cause a violation.

This approach is intended to address potential "sham" permitting. A sham permit occurs when a facility originally intends to operate at a certain level, and equipment permitted is fully capable of operating at such levels, but NAAQS or TAP increment compliance cannot be demonstrated. As a result, the facility is issued a permit limit on the source(s) to assure compliance. Sometime after permit issuance, the facility then submits a permit application to relax the limit, addressing only the increase from the previous limit for impact analyses. This approach effectively circumvents the requirement to comply with NAAQS and/or TAP increments. To address this concern, the emission increase is calculated using a baseline associated with the facility prior to issuance of the permit establishing the limit that the facility now proposes to relax.

Generally, DEQ will use a 5-year period during which a project that involves relaxation of a limit (without a physical change at the facility) will be considered an adjustment/correction of previous permitting project rather than a new project. The emission increase will be calculated using the base emissions allowable prior to the previous permitting project (the project that established the limit to be relaxed) and the new proposed limit.

Replacement Projects

The need for modeling replacement projects that do not qualify as routine replacement is based on total allowable emissions from the proposed new source. The decrease in emissions associated with the removal of the old equipment is not generally considered for modeling applicability.

For example, if a sawmill proposes replacing an existing kiln with a new kiln (not routine replacement), modeling applicability would be based on the proposed allowable emissions of the new kiln without any consideration of the decrease in emissions associated with removal of the older kiln. The creditable emissions decrease associated with the kiln removed can be used in the air impact modeling to offset the emissions from the new kiln, modeled as negative values to evaluate the net impact of the project.

Modification of a Permitted Source

This scenario involves alteration of an existing and permitted emissions source. The need for modeling is normally based on the emission increase as determined by the difference between baseline actual emissions and future projected emissions (permit allowables). However, if the modification alters the release characteristics of the source (temperature, stack gas flow rate, stack height, etc.), then the entire allowable emissions from the modified source must be included for the purpose of modeling applicability. If the emission release characteristics do not change, then the applicable emissions will be considered as the increase resulting from the modification. An example of this is increased emissions-generating activities (that do not affect the temperature or volume of air exhausted) in a room where air is exhausted to the atmosphere through an existing stack. The emissions increase would be calculated as the difference between the current emissions rate and the new proposed allowable emissions rate. Determining the need for project-specific air impact modeling based on only the increase in emissions is approved by DEQ on a case-by-case basis, considering whether the point of release and release characteristics are very similar between the existing and modified emissions points.

A permit is not specifically required for instances where physical changes made at a facility affect dispersion but do not meet the definition of a "modification." Although such changes do not typically require a permit, they do effectively invalidate any dispersion modeling analyses performed prior to those changes and could alter the NAAQS compliance status of the facility. In some cases, DEQ may request facilities to perform air quality dispersion modeling analyses to affirm compliance with applicable standards.

4 Applicable Standards

This section discusses the applicable standards for assessing impacts on ambient air.

4.1 Criteria Pollutants

Table 3 lists the significant impact levels (SILs) used to determine whether or not the proposed project would have a significant impact on the air quality in the area. The proposed project has a significant impact on the ambient air quality if the resulting ambient concentrations exceed these levels due to an emissions increase.

Table 4 presents the NAAQS which are incorporated by reference (IBR) into Idaho Air Rules Section 107.03.b. Typically, there is about a year of lag time between when a new NAAQS is promulgated by EPA and the time when it is IBR into Idaho Air Rules. A NAAQS compliance demonstration involving modeling analyses for a specific standard is only required for permits issued after the date the standard is IBR into Idaho Air Rules. In cases where a NAAQS has been promulgated by EPA but not yet IBR to Idaho Air Rules, DEQ should be consulted for a determination on what specific analyses may be required for permit issuance.

Table 3. Significant Impact Levels (IDAPA 58.01.01.006)

Pollutant	Averaging Time	Significant Impact Levels (µg/m^3)[a]
CO	1-hour	2000
CO	8-hour	500
NO2	1-hour	4 ppb[b,c] (7.5 µg/m^3)[d]
NO2	Annual	1.0
SO2	1-hour	3 ppb[e] (7.9 µg/m^3)[d]
SO2	3-hour	25
SO2	24-hour	5
SO2	Annual	1.0
PM_{10}	24-hour	5.0
PM_{10}	Annual	1.0
$PM_{2.5}$	24-hour	1.2
$PM_{2.5}$	Annual	0.3[f]

a) Micrograms per cubic meter

b) ppb - parts per billion

c) Interim SIL (EPA 2010a)

d) µg/m3 value calculated for standard conditions

e) Interim SIL (EPA 2010b)

f) This value is the upper limit as listed in 40 CFR 51.165(b)(2). Without monitoring data supporting this value, DEQ will use the 0.2 µg/m^3 value recommended by EPA (EPA 2018)

Table 4. National Ambient Air Quality Standards

Pollutant	Averaging Time	Standard (µg/m^3)[a]
CO	1-hour	40,000[b]
CO	8-hour	10,000[b]
NO2	1-hour	100 ppb [c] (188 µg/m3)
NO2	Annual	100[d]
SO2	1-hour	75 ppb[e] (196 µg/m3)
SO2	3-hour	1,300[b]
SO2	24-hour	365[b]
SO2	Annual	80[c]
PM_{10}	24-hour	150[f]
PM_{10}	Annual	50[g]
$PM_{2.5}$	24-hour	35[h]
$PM_{2.5}$	Annual	12[i]
Pb	Quarterly	1.5[j]
Pb	3-month	0.15[k]

a) Micrograms per cubic meter.
b) Not to be exceeded more than once per year.
c) Three-year average of the 98th percentile of the annual distribution of 1-hour average daily maximum concentrations not to exceed standard.
d) Not to be exceeded in any calendar year.
e) Three-year average of the 99th percentile of the annual distribution of 1-hour average daily maximum concentrations not to exceed standard.
f) Never expected to be exceeded more than once in any calendar year.
g) Standard has been revoked.
h) Three-year average of the 98th percentile of the annual distribution of 24-hour average concentrations not to exceed standard,
i) Three-year average of the annual mean concentrations not to exceed standard.
j) Not to be exceeded in any quarter of any calendar year.
k) Not to be exceeded in any 3-month rolling average of any calendar year.

4.2 TAPs Increments

Applicable TAPs increments are listed in Idaho Air Rules Section 585 for non-carcinogens (AACs) and 586 for carcinogens (AACCs). The tables found in these sections of Idaho Air Rules list the ELs in pounds per hour (lb/hr) as well as the AACs for non-carcinogens and AACCs for carcinogens. Note that the concentrations for the non-carcinogens are in units of milligrams per cubic meter (mg/m3) and the concentrations for carcinogens are in units of micrograms per cubic meter (□g/m3).

4.3 Toxics

Idaho Air Rules Section 161 states, “Any contaminant which is by its nature toxic to human or animal life or vegetation shall not be emitted in such quantities or concentrations as to alone, or in combination with other contaminants, injure or unreasonably affect human or animal life or vegetation.” DEQ may

require toxics analyses as a case-by-case basis in instances where DEQ suspects impacts of toxics may have an unacceptable impact.

5 Modeling Methodology

The required level of analysis will generally depend on the complexity of the proposed construction or modification, surrounding emissions sources and terrain features, current air quality levels, and classification (attainment vs non-attainment) in the impact area. Screening techniques may be adequate for simplistic or isolated sources. Screening techniques are not appropriate in complex situations such as a large number of buildings in the immediate area that create downwash for a point source or the presence of complex terrain within the modeling domain. More refined modeling will be necessary when screening modeling is inappropriate or cannot demonstrate compliance with applicable air quality impact limits.

5.1 Requirements for Permit Applications

As recommended by EPA (EPA 1990), dispersion modeling analysis generally involves two distinct phases. The first phase is the preliminary analysis, also known as the significant impact analysis; the second phase is the full impact analysis, also known as the cumulative NAAQS analysis. These analyses may be performed with either a simple “screening model” or with a more complex “refined model.” A flowchart showing the general modeling methodology for permit modeling is presented in Figure 3.

5.1.1 Significant Impact Analysis

In the significant impact level (SIL) analysis, the highest estimated concentration in ambient air is compared to the SILs in Table 3. A five-year mean of the highest estimated concentration from each year can be used in the SIL analysis for pollutants with probabilistic standards. These pollutants include 24-hour PM2.5, annual PM2.5, 1-hour NO2, and 1-hour SO2. Only the changes in emissions associated with the proposed project are modeled in the significant impact analysis for new sources or modifications. Impacts from nearby and other background sources, including background concentrations, are not considered in the significant impact analysis. Section 6.3 provides guidance on sources and emissions to include in the significant impact analysis. No further analysis is generally required for the NAAQS or PSD increments if the estimated concentration is below applicable SILs. The source or modification is determined to have a significant impact on ambient air if the estimated impact exceeds the SILs. In this case, a cumulative NAAQS analysis will be necessary to demonstrate to the satisfaction of DEQ that the stationary source or modification would not cause or significantly contribute to a violation of any ambient air quality standard. Also, if DEQ has information that indicates existing facility emissions may not meet NAAQS, then DEQ may require the facility to demonstrate full NAAQS compliance at the time of the current permitting action or a later date.

The ambient concentration due to any proposed construction or modification cannot exceed the SILs listed in Table 3 for minor stationary sources in non-attainment areas (NAAs). Offsets are required even if the ambient impacts are below the SILs for major stationary sources or major modifications at major stationary sources in NAAs. The DEQ air modeling coordinator should be contacted for locations of NAAs in Idaho.

5.1.2 Cumulative NAAQS Analysis

In a cumulative NAAQS analysis, the scope of the analysis is expanded from the significant impact analysis to include impacts from all other sources at the facility and background concentrations. Assessing impacts from potential co-contributing sources may also be required in the cumulative NAAQS analyses. It is the applicant's responsibility to identify potential co- contributing sources. The factors to be reviewed include the type of source, distance between the facilities, location of potential impact, pollutants emitted, and emission rates of pollutants of interest. If impacts of neighboring sources, on receptors showing a significant impact from the sources subject to the permitting action, are not adequately accounted for by the background concentration used, then emissions from those sources must be modeled.

When conducting cumulative NAAQS modeling, the sources not explicitly included in the model (e.g., mobile sources; small, stationary sources; some fugitive sources; and large, distant sources) are accounted for by adding a background concentration representative of the air quality in the area. Background concentrations are based on ambient air monitoring data collected in the area or from similar areas determined to be reasonably representative. Section 6.10 provides a more detailed discussion of appropriate background concentrations. Background concentrations must account for all impacts not accounted for by sources specifically modeled. Current default background concentrations must be obtained from a DEQ air quality modeler.

Modeling assessments for major new source/modifications subject to the PSD program, and where project emissions cause an impact exceeding SILs, must include emissions from all point sources within the radius of significant impact and all sources outside the radius of significant impact that cause a significant impact within the radius of significant impact.

5.2 Additional Requirements for PSD Applications

Major facilities subject to PSD rules have many more responsibilities in the permitting process. DEQ engineers and analysts make the final determination of PSD applicability. If the proposed project is subject to PSD, the applicant should consult with DEQ during the early phases of the project development. If the proposed project is subject to PSD, the applicant should consult with DEQ during the early phases of the project development. This guideline only provides a brief summary of the PSD permitting program.

A PSD review is required if a proposed new facility is defined as a designated facility (Table 5) and emits or has projected actual emissions, after controls, of 100 tons per year (T/yr) or more of any regulated air pollutant. If the new facility is not one of the types listed in Table 5, then a PSD review is required if the facility emits or has projected actual emissions, after controls, of 250 T/yr or more of any regulated air pollutant. For PSD review, the potential to emit is defined as the maximum capacity of a stationary source to emit a pollutant under its physical and operational design (defined in Idaho Air Rules Section 006). A PSD review is also required if proposed emissions from a modification to an existing PSD major source are greater than the significant emissions rates listed in Table 6.

The location of the facility is important, as it determines the applicable increment of allowable air quality deterioration. Other factors, such as the topography and meteorology of the area and the proximity to a Class I area (specified areas of pristine air quality such as certain national parks, wilderness areas, etc.) or NAA, also determine the control requirements. The allowable increments, as of the publication of this document, for Class I, II, and III areas are listed in Table 7. Additional increment

limits can be promulgated by the EPA or DEQ, so it remains the applicant's responsibility to verify applicable PSD increment limits. The Class I areas in Idaho and surrounding states are shown in Appendix B. The remainder of the state is currently designated as Class II. There are no Class III areas in Idaho.

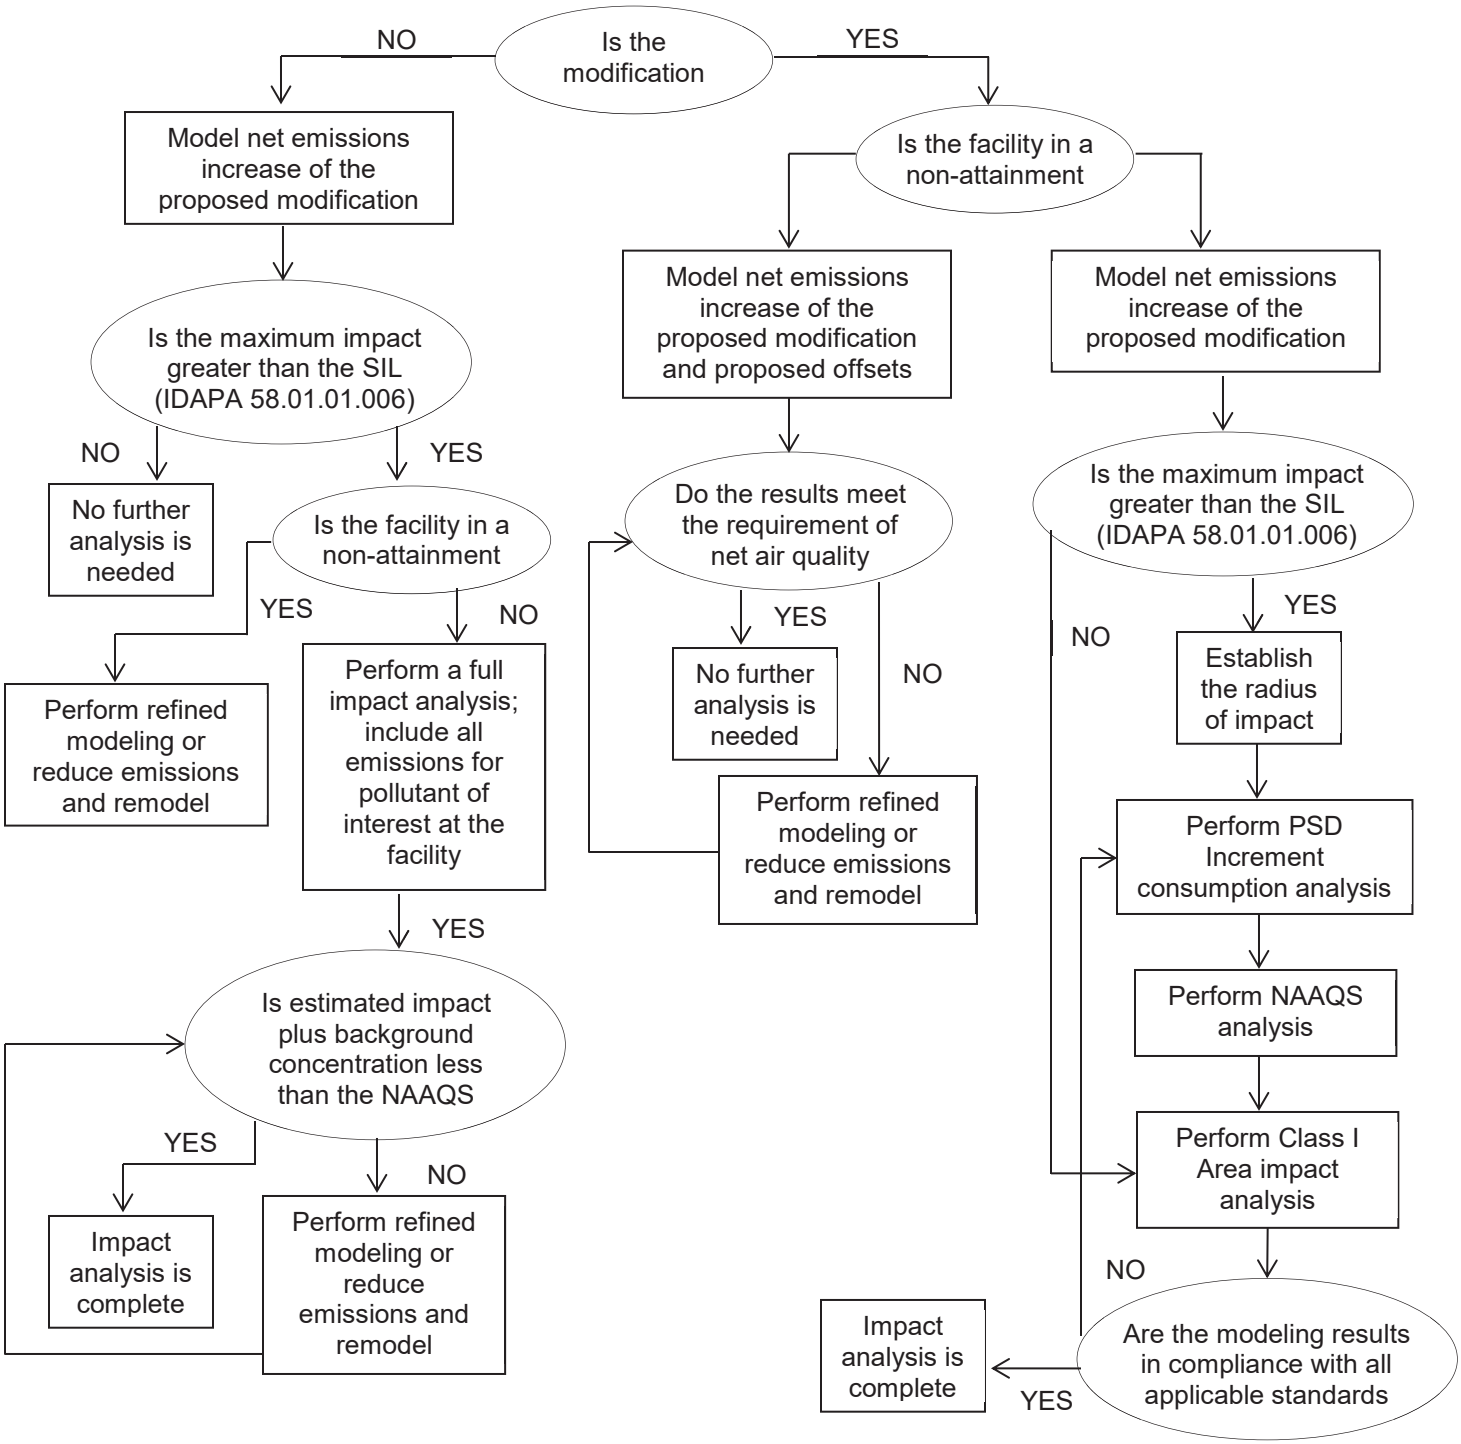

Figure 3. Flow Chart for Criteria Pollutant Ambient Impact Analysis for Permit to Construct Application

Pre-construction air quality is determined through ambient air monitoring. In some cases, there may already be enough data to establish the baseline. However, the applicant may be required to conduct up to one year of ambient monitoring at strategic locations if monitoring data are not available for the source area of the proposed construction site. Pre-construction monitoring will automatically be required if the model-predicted impact of the proposed source exceeds the levels in Table 8 and there are no current ambient air monitoring data available. DEQ may require pre-construction monitoring in other situations.

The following additional analyses are required in PSD applications:

- PSD increment consumption
- Class I area visibility and Air Quality Related Values (AQRVs) analysis
- Growth analysis
- Ambient air quality impact analysis (during construction)
- Soils and vegetation impacts
- Visibility impairment (in impact area, separate from the Class I area visibility analysis)

Refer to the *New Source Review Workshop Manual* (EPA 1990) for additional guidance.

Designated Facility Types as found in IDAPA.58.01.01.006:

1. Fossil fuel-fired, steam electric plants of more than 250 million British thermal units (Btu)per hour heat input
2. Coal cleaning plants (with thermal dryers)
3. Kraft pulp mills
4. Portland cement plants
5. Primary zinc smelters
6. Iron and steel mill plants
7. Primary aluminum ore reduction plants
8. Primary copper smelters
9. Municipal incinerators capable of charging more than 250 tons of refuse per day
10. Hydrofluoric acid plants
11. Sulfuric acid plants
12. Nitric acid plants
13. Petroleum refineries
14. Lime plants
15. Phosphate rock processing plants
16. Coke oven batteries
17. Sulfur recovery plants
18. Carbon black plants (furnace process)
19. Primary lead smelters
20. Fuel conversion plants
21. Sintering plants
22. Secondary metal production plants
23. Chemical process plants
24. Fossil fuel boilers (or combination thereof) totaling more than 250 million Btu/hour heat input
25. Petroleum storage and transfer units with a total storage capacity exceeding 300,000 barrels
26. Taconite ore processing plants
27. Glass fiber processing plants
28. Charcoal production plants

Table 5. Significant Emissions Rates (40 CFR 52.21 (b)(23); IDAPA 58.01.01.006)[a]

Pollutant	Emission Rate (T/yr)
CO	100
NOX	40
SO2	40
PM_{10}	15
$PM_{2.5}$	10 (40)[b]
Particulate matter	25
Ozone (VOC)	40 (of VOCs)
Pb	0.6
Asbestos	0.007
Beryllium	0.0004
Mercury	0.1
Vinyl chloride	1
Fluorides	3
Sulfuric Acid Mist	7
Hydrogen Sulfide (H_2S)	10
Total Reduced Sulfur (including H_2S)	10
Radionuclides from facilities regulated under40 CFR Par 61, Subpart H	0.1 mrem/yr
Reduced sulfur compounds (Including H_2S)	10
Any other pollutant regulated under the Clean Air Act including radionuclides	Any emission rate
Each regulated pollutant (from a major facility or major modification)	Emission rate that causes air quality impact of 1 µg/m3 or greater (24-hour basis) in any Class I area located within 10

a) A PSD review is required if the operation is modified and actual emissions of a pollutant will be greater than shown above

b) SO_2, NOx, and VOCs as precursors

Table 6. Prevention of Significant Deterioration Increment Limits

Pollutant	Averaging Period	Class I (µg/m^3)	Class II(µg/m^3)	Class III (µg/m^3)
NO_2	Annual[c]	2.5	25	50
SO_2	Annual[b]	2	20	40
SO_2	24-hour[c]	5	91	182
SO_2	3-hour[c]	25	512	700
PM_{10}	Annual[b]	4	17	34
PM_{10}	24-hour[c]	8	30	60
$PM_{2.5}$	Annual[b]	1	4	8
$PM_{2.5}$	24-hour[c]	2	9	18

a) The Class I, II, and III areas are defined and shown in Appendix A.

b) Never to be exceeded.
c) Not to be exceeded more than once a year.

Table 7. Modeled Impacts Above which Preconstruction Monitoring cannot be Exempted for PSD-Applicable Projects

Pollutant	Ambient Concentration ($\mu g/m^3$)	Averaging Period
CO	575	8-hour
NO2	14	Annual
SO2	13	24-hour
PM10	10	24-hour
PM2.5	4	24-hour
Ozone	100 T/yr increase of VOCs	N/A
Pb	0.1	Quarterly
Mercury	0.25	24-hour
Beryllium	0.0001	24-hour
Fluorides	0.25	24-hour
Vinyl chloride	15	24-hour
Hydrogen sulfide	0.2	1-hour

5.3 Facility Emission Cap (FEC) Permit Modeling

Contact DEQ for guidance on modeling requirements for FEC permits. In general, the modeling submitted must support all possible future emissions rates sources, and facility configuration.

6 Performing a Modeling Analysis

An application will be considered incomplete if it lacks sufficient information and/or a valid modeling analysis, supported by adequate documentation and justification of methods and data. Appendix C includes a copy of the DEQ modeling checklist, which is designed to help the applicant prepare the information necessary for a complete modeling package.

The procedures in this document, as well as the EPA documents *Guideline on Air Quality Models* (EPA 2005), *New Source Review Workshop Manual* (EPA 1990), and other more issue- specific guidance should typically be followed when conducting the modeling analysis. These documents provide guidance on appropriate model applications. DEQ will work with the applicant to determine acceptable impact assessment procedures where EPA or state policies are not clear cut or involve case-by-case review.

6.1 Modeling Protocol

Applicants are highly advised to contact the DEQ stationary source air quality modeling supervisor at (208) 373-0502 and submit a modeling protocol, as suggested in the modeling checklist (Appendix C), to ensure appropriate models, meteorological data, background concentrations, and procedures are applied. Use of a modeling protocol is a key component of DEQ's permit streamlining program, which

focuses on establishing mutually agreed upon methods and data prior to permit application submittal. This approach substantially reduces DEQ review time and the potential for the application to be determined incomplete or the permit denied because of problems with the modeling analyses.

The content of the modeling protocol is dependent on the type of permit application. A modeling protocol for a new, major source or a major modification at a major facility will be more detailed than one for a new, minor source or a minor modification. A modeling protocol checklist is presented in Appendix D. A description of the general methodology, as well as justification for assumptions and data used, should be included in the modeling protocol.

A modeling protocol, in written form and agreed upon by DEQ, provides the applicant the assurance that their approach and methodology as described will be accepted. However, the approval of a modeling protocol is not meant to imply approval of a completed modeling analysis. The facility should submit as much detailed information as possible in the modeling protocol to increase the likelihood of having the modeling analysis approved. The applicant should prepare the application with the understanding that DEQ will require a higher degree of documentation/justification of data and methods in cases where modeled concentrations are very near regulatory thresholds/standards.

A modeling protocol may be submitted in hard-copy format or may be emailed to the DEQ stationary source modeling coordinator. DEQ will typically provide comments on or approval of the protocol within two weeks from the date the protocol was received.

The following are key issues that should be addressed in the protocol:

- Ambient air boundary. It is the applicant's responsibility to accurately evaluate the ambient air boundary and identify any unique situations affecting the ambient air boundary that may exist at the facility. Such unique situations may include rivers bisecting the facility, easements or public roadways bisecting the facility, railways, lease agreements, and operating a business where the general public is allowed on site. See Section 6.5.
- Justification/documentation of stack parameters. The protocol should thoroughly describe how emissions release parameters (flow rates and stack temperatures) were measured or estimated, if such data are available at that time. A simple indication that parameters were checked will not be accepted as documentation and justification. Calculations of initial dispersion coefficients for volume sources should be provided such that DEQ reviewers can easily and quickly verify the values. See Section 6.4.2.
- Design concentrations. The protocol should clearly state what modeled concentrations will be used to evaluate compliance. For example, the maximum of 6th highest modeled concentrations at each receptor is typically used as the PM10 24-hour design value when modeling a five-year data set. See Section 6.11.1.
- Meteorological data. If meteorological data are not provided by DEQ, the applicant should thoroughly justify selection of the data, demonstrating how the data used are representative for the application site. The protocol should also describe the quality of the data, clearly demonstrating the data are adequate for use in an air impact analysis. See Section 6.8.
- Receptor grid. The receptor grid spacing proposed for the analyses should be thoroughly described. See Section 6.6.
- Background concentrations. Within the protocol, the applicant may either propose appropriate background concentrations or request that DEQ provide reasonably conservative background concentrations. See Section 6.10.
- Unique circumstances or scenarios used in the analyses. Any atypical conditions associated with the site or the project that could affect the results of the air impact analyses, or DEQ's approval

of the project, should be described in the protocol. Protocol approval only assures acceptability that those conditions or issues accurately described in the protocol are acceptable.

6.2 Choosing the Appropriate Models

Air quality models approved by the EPA for regulatory use are required (Idaho Air Rules Section 202.02 and 402.03). The DEQ modeling coordinator should be consulted to discuss or verify the model most appropriate for the release being simulated. Factors to consider when determining the appropriate model include, but are not limited to, type of release (e.g., elevated point or area), downwash, location of ambient air, meteorological conditions (e.g., stagnation), and availability of meteorological data. All modeling must use the current versions of models recommended in the EPA's *Guideline on Air Quality Models* (EPA 2005). Many of these models can be found on the EPA's Support Center for Regulatory Air Models (SCRAM) website (http://www.epa.gov/ttn/scram). Modeling performed with older versions may be rejected. Any modification or alteration of a guideline model must be approved by DEQ and, in most instances, the EPA. Approval of the use of other models is completely at the discretion of DEQ. When alternative models are used, DEQ may require the submittal of additional data (e.g., sensitivity analysis) for verification. The use of proprietary models (those models that are not available free of charge to the public) is generally not allowed for the demonstration of compliance with NAAQS, PSD increment, or TAPs increments. Proprietary graphical user interfaces (GUIs) that use unaltered publicly available regulatory models are not considered proprietary models. Results generated by such GUIs will be accepted provided input and output files are submitted and such files can be readily used as input for the publicly available model without the proprietary GUI.

6.2.1 Readily Available Models

The following is a summary of the most commonly used air quality models:

AERMOD – AERMIC (American Meteorological Society/Environmental Protection Agency Regulatory Model Improvement Committee) was formed to introduce state-of-the-art modeling concepts into EPA's air quality models. AERMIC's focus is on a new platform for regulatory steady-state plume modeling. This platform includes: 1) air turbulence structure, scaling, and concepts; 2) treatment of both surface and elevated sources; and 3) simple and complex terrain. The modeling system has three components: AERMOD - the air dispersion model; AERMET - the meteorological data preprocessor; and AERMAP - the terrain data preprocessor. AERMOD is the replacement model for ISCST3.

AERSCREEN – AERSCREEN is the screening-level model for applications where AERMOD would be appropriate.

SCREEN3 – SCREEN3 is a screening version of the ISCST3 model.

SCREEN3 is not considered an acceptable screening model for AERMOD, which is the model replacing ISCST3. *Analyses performed with SCREEN3 will no longer be accepted by DEQ for permitting purposes in most instances.*

CTSCREEN – (Complex Terrain Screening model) –A screening technique when complex terrain is important. CTSCREEN is a screening version of the CTDMPLUS model. CTSCREEN and CTDMPLUS are the same basic model. The primary difference is that CTSCREEN uses

an extensive array of predetermined meteorological conditions where site-specific meteorological data are not available.

AERMOD is considered a more refined model for complex terrain. AERSCREEN incorporates the same terrain algorithms as AERMOD, and may yield more favorable results than CTSCREEN.

ISCST3 – (Industrial Source Complex Model) – Historically, the most commonly used refined Gaussian plume model.

ISCST3 has been replaced as an EPA guideline model by AERMOD. *DEQ will generally no longer accept air quality analyses conducted with ISCST3 for permitting purposes.*

CTDMPLUS – (Complex Terrain Dispersion Model Plus Algorithms for Unstable Situations) – A refined air quality model for use in all atmospheric stabilities with sources located in or near complex topography. Since the model accounts for the three-dimensional nature of plume and terrain interaction, it requires detailed terrain and meteorological data that are representative of the modeling domain.

CALPUFF – A multi-layer, multi-species, non-steady-state, puff dispersion model that simulates the effects of time- and space-varying meteorological conditions on pollutant transport, transformation, and removal. CALPUFF is most commonly used to assess impacts on Class I areas and is applied at distances over 50 kilometers. It includes algorithms for subgrid scale effects (such as terrain impingement), as well as longer range effects (such as pollutant removal due to wet scavenging and dry deposition, chemical transformation, and visibility effects of particulate matter concentrations).

CALPUFF is not an EPA-approved model for near-field impact assessment (within 50 kilometers of a source). Any use of CALPUFF in the near-field must be thoroughly justified and approved specifically by DEQ and often by EPA.

VISCREEN – A screening model to assess visibility impacts on Class I areas. Calculates the potential impact of a plume of specified emissions for specific transport and dispersion conditions.

Screening models, such as SCREEN3 and AERSCREEN, are used to simulate the probable worst-case condition under normal, maximum operating conditions. They are generally simplistic representations, typically taking less computer time and yielding conservative impact predictions. A screening analysis must follow EPA guidance in *Screening Procedures for Estimating the Air Quality Impact of Stationary Sources, Revised* (EPA 1992) or any current EPA guidance for AERSCREEN. If a properly conducted screening analysis does not indicate an exceedance of the ambient standards from a proposed construction or modification, then a more refined analysis is not necessary to adequately demonstrate compliance.

6.2.2 Replacement of ISC by AERMOD

AERMOD was promulgated as the replacement model for ISC. During the one-year transitional period, between November 2005 and November 2006, applicants could use either ISCST3 or AERMOD to demonstrate compliance. After that, ISCST3 was no longer a guideline model and analyses conducted with ISCST3 were not typically accepted by DEQ.

There are several modeling scenarios that are problematic when using AERMOD:

1. Hot, buoyant plumes released horizontally or with a rain cap. With ISCST3 the typical approach is to set the exit velocity to 0.01 or 0.001 meters per second (m/sec) to effectively eliminate the plume vertical momentum flux, then increase the exit diameter to a point where the modeled volumetric flow is equal to that of the source. This approach cannot be used for AERMOD if plume downwash is considered because downwash behavior is a function of stack diameter in the PRIME downwash algorithm within AERMOD.

   Modeling with the actual stack diameter and a 0.001 m/sec exit velocity is recommended as a conservative measure. This method effectively eliminates vertical momentum of the plume; however, it also eliminates thermal buoyancy effects. In some instances, hand calculations of plume rise, using those equations in the AERMOD algorithms, may show that thermal buoyancy is overwhelmingly the dominant plume rise mechanism. In such cases, the source may be modeled as an uninterrupted vertical release. Use of this method or other methods should be discussed with DEQ prior to use.

   Methods to accurately model hot horizontal releases and capped vertical releases within AERMOD have been developed for Beta versions of AERMOD. Applicants should contact DEQ as to the availability of AERMOD versions to handle hot horizontal and capped releases.

2. Representative meteorological data are rather limited for many areas within Idaho. More site-specific meteorological and land surface characteristics are needed to run AERMOD than what is used for ISC. Therefore, using meteorological data from a distant station is more of a concern when using AERMOD.

   It is the applicant's responsibility to demonstrate the meteorological data used are representative of meteorological conditions at the application site. Applicants may be required to use specialized methods to demonstrate compliance in cases where available meteorological data are of questionable representativeness. Such methods could involve running additional modeling analyses using multiple meteorological data sets or otherwise providing a demonstration that use of on-site data could not reasonably be expected to give results that exceed applicable regulatory thresholds or standards.

6.3 Pollutants and Sources to be Included in the Impact Analyses

This section discusses what pollutants and sources should be included in modeling analyses submitted in support of applications for permits to construct (PTCs), Tier II operating permits, and FEC permits. Specific emissions sources that are exempt from permitting requirements are not necessarily exempt from a modeling analysis when a PTC or Tier II Operating Permit is required for other sources/reasons. DEQ modeling staff should be consulted before any emissions sources eliminated from the modeling analyses.

DEQ does have a list of activities that may be treated as "trivial" and are not required to be addressed in the permit application. In addition to the trivial activities listed below, Idaho Air Rules Section 317 list activities that are "presumptively insignificant emission units." DEQ has determined that these activities must generally be included in Tier II and PTC applications when facility-wide modeling is required. The list below was generated from an EPA white paper entitled Streamlined Development of Part 70 Permit Applications (EPA 1995).

Activities That May be Treated as "Trivial" (EPA 1995):

1. Combustion emissions from propulsion of mobile sources, except for vessel emissions from outer continental shelf sources.
2. Air-conditioning units used for human comfort that do not have applicable requirements under Title VI of the Clean Air Act.
3. Ventilating units used for human comfort that do not exhaust air pollutants into the ambient air from any manufacturing/industrial or commercial process.
4. Noncommercial food preparation.
5. Consumer use of office equipment and products, not including printers or businesses primarily involved in photographic reproduction.
6. Janitorial services and consumer use of janitorial products.
7. Internal combustion engines used for landscaping purposes.
8. Laundry activities, except for dry cleaning and steam boilers.
9. Bathroom/toilet vent emissions.
10. Emergency (backup) electrical generators at residential locations.
11. Tobacco smoking rooms and areas.
12. Blacksmith forges.
13. Plant maintenance and upkeep activities (e.g., grounds keeping, general repairs, cleaning, painting, welding, plumbing, re-tarring roofs, installing insulation, and paving parking lots) provided these activities are not conducted as part of a manufacturing process, are not related to the source's primary business activity, and do not otherwise trigger a permit modification.[(a)]
14. Repair or maintenance shop activities not related to the source's primary business activity, not including emissions from surface-coating or degreasing (solvent metal cleaning) activities, and not otherwise triggering a permit modification.
15. Portable electrical generators that can be moved by hand from one location to another.[(b)]
16. Hand-held equipment for buffing, polishing, cutting, drilling, sawing, grinding, turning or machining wood, metal or plastic.
17. Brazing, soldering and welding equipment, and cutting torches related to manufacturing and construction activities that do not result in emission of hazardous air pollutant metals.[(c)]
18. Air compressors and pneumatically operated equipment, including hand tools.
19. Batteries and battery charging stations, except at battery manufacturing plants.
20. Storage tanks, vessels, and containers holding or storing liquid substances that will not emit any volatile organic compound or hazardous air pollutant.[(d)]
21. Storage tanks, reservoirs, and pumping and handling equipment of any size containing soaps, vegetable oil, grease, animal fat, and nonvolatile aqueous salt solutions, provided appropriate lids and covers are utilized.
22. Equipment used to mix package soaps, vegetable oil, grease, animal fat, and nonvolatile aqueous salt solutions, provided appropriate lids and covers are utilized.
23. Drop hammers or hydraulic presses for forging or metalworking.
24. Equipment used exclusively to slaughter animals, but not including other equipment at slaughterhouses, such as rendering cookers, boilers, heating plants, incinerators, and electrical power generating equipment.
25. Vents from continuous emissions monitors and other analyzers.
26. Natural gas pressure-regulator vents, excluding venting at oil and gas production facilities.
27. Hand-held applicator equipment for hot-melt adhesives with no volatile organic compounds in the adhesive formulation.

28. Equipment used for surface coating, painting, dipping, or spraying operations, except those that will emit any volatile organic compound or hazardous air pollutant.
29. Carbon dioxide lasers, used only on metals and other materials that do not emit hazardous air pollutants in the process.
30. Consumer use of paper trimmers/binders.
31. Electric- or steam-heated drying ovens and autoclaves, but not the emissions from the articles or substances being processed in the ovens or autoclaves, or the boilers delivering the steam.
32. Salt baths using nonvolatile salts that do not result in emissions of any regulated air pollutant.
33. Laser trimmers using dust collection to prevent fugitive emissions.
34. Bench-scale, laboratory equipment used for physical or chemical analysis, but not for lab fume hoods or vents.[(e)]
35. Routine calibration and maintenance of laboratory equipment or other analytical instruments.
36. Equipment used for quality control/assurance or inspection purposes, including sampling equipment used to withdraw materials for analysis.
37. Hydraulic and hydrostatic testing equipment.
38. Environmental chambers not using hazardous air pollutant gasses.
39. Shock chambers.
40. Humidity chambers.
41. Solar simulators.
42. Fugitive emissions related to movement of passenger vehicles, provided the emissions are not counted for applicability purposes and any required fugitive-dust-control plan or its equivalent is submitted.
43. Process-water filtration systems and demineralizers.
44. Demineralized-water tanks and demineralizer vents.
45. Boiler-water treatment operations, not including cooling towers.
46. Oxygen scavenging (de-aeration) of water.
47. Ozone generators.
48. Fire suppression systems.
49. Emergency road flares.
50. Steam vents and safety relief valves.
51. Steam leaks.
52. Steam cleaning operations.
53. Steam sterilizers.

a) Cleaning and painting activities qualify as trivial they are not subject to volatile organic compound or hazardous air pollutant control requirements. Asphalt batch plant owners/operators must still get a permit if otherwise required.

b) “Moved by hand” means the generator can be moved without the assistance of any motorized or non-motorized vehicle, conveyance, or device.

c) Brazing, soldering and welding equipment, and cutting torches that emit hazardous air pollutant metals and are related to manufacturing and construction activities are more appropriate for treatment as insignificant activities instead of trivial activities based on size or production-level thresholds. Brazing, soldering, welding, and cutting torches that emit hazardous air pollutant metals and are directly related to plant maintenance, upkeep, and repair, or maintenance shop activities, are appropriately treated as trivial.

d) Consideration of storage tanks containing petroleum liquids or other volatile organic liquids as a trivial source should be based on size limits such as storage tank capacity and vapor pressure of liquids stored are not appropriate for this list.

e) Many lab fume hoods or vents might qualify for treatment as insignificant (depending on the applicable State Implementation Plan) or can be grouped together for purposes of description.

6.3.1 Permits to Construct

Criteria Pollutants

All increases in emissions of criteria pollutants are generally required to be accounted for in the significant impact analyses for PTC applications. However, the emissions sources and inventory used to evaluate the need for modeling, described in Section 3 of this guideline, may differ from the sources and inventory used for the significant impact analyses. All emissions changes associated with a proposed project are generally used in the significant impact analyses, including emissions reductions associated with sources removed from operation. Also, sources included in the significant impact analyses for minor source permitting may differ from sources included for PSD permitting. For minor source permitting, the significant impact analyses for criteria pollutants generally includes: all emissions increases and decreases associated with the proposed project. For PSD permitting, the net emissions increase, as defined in Idaho Air Rules Section 007, is modeled. The net emissions increase includes all increases and decreases that occurred within the previous five years or since the issuance of any PSD permit to the facility, whichever is a shorter period.

Cumulative impact analyses are required if impacts associated with the significant impact analyses exceed SILs, as described in Sections 5.1.1 and 5.1.2. A cumulative impact analysis involves modeling facility-wide emissions, modeling any co-contributing sources, and adding an appropriate background value to results.

DEQ highly suggests that applicants specify in a modeling protocol those sources to be included and/or excluded in the significant impact analyses with thorough justification and documentation. The following provides general guidance for the significant impact analyses performed for specific minor source scenarios:

- Modification to an existing emissions unit where the release parameters (flow rate, stack gas temperature, etc.) do not change. The emissions increase associated with the modification is modeled. If the existing source is currently permitted, the emissions increase will be calculated as the differences between the current permit limit (or whatever emissions rate was used in previous modeling analyses) and the future proposed limit. If the source is not currently regulated by a permit emissions limit, then current emissions should be based on actual emissions as defined by Idaho Air Rules.
- Modification to an existing emissions unit where the release parameters change as a result of the modification. Existing emissions for permitted and non-permitted sources should be calculated as described for scenario “a;” however, current emissions should be modeled as negative emissions (using the existing release parameters) and future allowable emissions modeled as positive emissions (using the new release parameters).
- Removal of, or emissions reductions from, an existing emissions unit. Emissions reductions from such units should be modeled as negative emissions to account for the net project impacts. Existing permit-allowable emissions rates may be used, or actual emissions (based on two years of operations within the previous ten years) for units not regulated by an existing emissions limit.

- Replacement or relocation of an existing emissions unit. Replaced units should be treated in the same manner as removed units, described in scenario "c."
- Addition or removal of units exempt from permitting. Units that are exempt from permitting should be included in the significant impact analyses in most instances, unless such units are considered as trivial per Table 9 in Section 6.3 of this guideline. Existing and future emissions should be based on maximum potential emissions unless otherwise directed or approved by DEQ.

TAPs

All TAPs, except those exempted under Idaho Air Rules Section 210.20, with project-total emissions increases above the DEQ TAP ELs (discussed in Section 4.0) must be included in the modeling analysis. The DEQ TAPs checklist, available on the DEQ website, should be used to demonstrate compliance with TAPs.

Fugitive Sources

Fugitive emissions are defined in Idaho Air Rules Section 006 as, "those emissions which could not reasonably pass through a stack, chimney, vent, or other functionally equivalent opening." This definition includes windblown dust from a stockpile. Generally, modeling is required for all fugitive emissions sources determined not to be unquantifiable. Fugitive emissions from vehicle traffic on roads and wind erosion from material storage piles are normally not included in the modeling analyses for minor source applications. However, DEQ may require modeling of these sources in instances where these emissions could substantially contribute to ambient concentrations and a potential exceedance of air quality standards. Process fugitive emissions such as those from material handling operations and equipment leaks should be included in the modeling analyses.

Intermittent Sources

Emissions sources that operate intermittently may be excluded from the SIL analysis and/or cumulative NAAQS analysis, approved by DEQ on a case-by-case basis, to the extent that it can be reasonably concluded that such sources could not measurably affect the compliance determination. If the intermittent sources are engines powering emergency generators or fire suppression water pumps, and operations are less than 100 hours/year for operational testing and maintenance, the sources can be excluded from compliance demonstrations for the 1-hour NO2 NAAQS, unless specifically required at the discretion of the DEQ Director. This guidance is explained in more detail in Appendix A.

Inconsequential Sources

The applicant may determine that some sources are "inconsequential" when estimating the design concentration (i.e., only contribute to a small percentage of the total, maximum, ambient impact for that project) and exclude them from the modeling analysis. If this is the case, the applicant must justify the exclusion of these sources. This justification, which is pollutant and averaging-period specific, must be based on emissions rates and a qualitative discussion of impacts. For example, if an emissions unit operates 24 hours per day but only 500 hours per year, the source may be "inconsequential" for the annual emissions, but not for the 24-hour emissions. The justification should include the following two phases:

1. Compare the emissions and operating conditions of each emissions source to the total emissions that would be modeled. If the uncontrolled emissions are "negligible" compared to the total emissions and are not expected to impact the maximum ambient concentration, the individual

PET 737
REC 1103

emissions source may be deemed as "inconsequential" and may be excluded from the modeling analysis.

Unless there are a large number of negligible sources that will substantially slow the model run time, it may be easier to include such sources in the analyses rather than provide justification for their exclusion.

2. If more than one emissions source is excluded from the modeling analysis, the total emissions of those sources excluded and the total estimated ambient concentration must be compared to the total modeled emissions and qualitatively evaluated for impacts. This will ensure that all of the excluded sources are still "inconsequential" as a whole.

Non-Attainment Areas

Facilities located in an a non-attainment area for a specified pollutant may be required to model all the emissions for that specified pollutant, even those emissions that are deemed to be inconsequential. This process will be treated on a case-by-case basis. It is recommended that the applicant meet with DEQ staff prior to beginning the modeling analysis to discuss what sources will be included.

6.3.2 Facility-Wide Tier II Operating Permits

All emissions for the entire facility, excluding those listed in Table 9, are required to be included in a facility-wide Tier II application. All criteria pollutant emissions are generally required to be included in the modeling analysis submitted with the Tier II operating permit application. Facility-wide TAPs emissions are not typically required to be included in the modeling analysis for the Tier II application. DEQ reserves the right to request additional information or analysis, including the modeling of other pollutants, under Idaho Air Rules Section 402.04, if there is a concern relative to compliance with Idaho Air Rules Section 161. Modeling of all fugitive emissions may be required if DEQ determines it necessary to protect ambient air quality standards.

As with the PTC application, the applicant may determine that some criteria pollutant sources are "inconsequential" when estimating the design concentration (i.e., only contribute to a small percentage of the total, maximum, ambient impact for that project) and exclude them from the modeling analysis. The applicant should use the process presented above in Section 6.3.1. Facilities located in non-attainment areas for a specified pollutant must contact the DEQ modeling coordinator at (208) 373-0112 prior to submitting the Tier II application. DEQ modeling staff will review the current SIP for the area to determine the appropriate level of analysis. This process will be treated on a case-by-case basis. It is recommended that the applicant meet with DEQ staff prior to beginning the modeling analysis to discuss what sources will be included.

6.3.3 FEC Permits

Permit applications utilizing a facility emissions cap (FEC) must provide sufficient modeling scenarios to reasonably assess maximum impacts of potential source configurations. The modeling requirements for these permits are facility-specific and will vary greatly depending on the operational flexibility desired by the permit applicant.

6.4 Source Information Required

This section discusses the source information that is required for a modeling analysis.

6.4.1 Emission Rates

Tables 8.1 and 8.2 in the *Guideline on Air Quality Models* (EPA 2005) present the emissions information required for air dispersion modeling. The emissions rate used in the modeling analysis must be that associated with maximum design capacity or a federally enforceable permit condition (40 CFR 51, Appendix W, Table 9-2). For a major modification, the emissions rate to be modeled in the significant impact analysis for criteria pollutants is the net emission rate increase, as defined in Idaho Air Rules Section 007. To demonstrate compliance with applicable standards, potential emissions must be used in the modeling analyses rather than future projected actual emissions. For minor modifications, the emissions modeled are the emissions changes associated with the proposed project, as described in Section 6.3.1 of this guideline. Emissions decreases are modeled as negative values in the significant impact analyses. However, in instances where NAAQS compliance may be questionable, DEQ may require facility-wide modeling even though results of the significant impact analysis indicate impacts are below SILs. When a cumulative NAAQS analysis is required, the potential emissions for all sources and, if requested, any co-contributing sources are used in the modeling analyses.

For PTCs, the project-wide emissions rate increase of TAPs is compared to the EL in Idaho Air Rules Section 585 and 586. Any TAP that has a total project emissions increase that exceeds the EL must be modeled.

The maximum emissions rate for each averaging period must be identified. For example, PM2.5 has both a 24-hour and an annual standard. If a source will only operate 7,000 hours per year but can operate for 24 hours in a single 24-hour period, then different emissions rates would be modeled for the 24-hour standard and annual standard.

If any pounds per hour emissions rate used in a modeling analysis differs from that used in the emissions inventory, the application should clearly show how the modeled rate was calculated. For example, a source has a maximum hourly emissions rate of 2.0 pounds per hour and a maximum daily operations rate of 12 hours per day (not restricted to any specific daily schedule). The modeled emissions rate for demonstrating compliance with a 24-hour standard would be 1.0 pounds per hour ((2.0 lb/hr x 12 hr/day) / 24 hr = 1.0 lb/hr).

Modeling intermittent sources in a representative and worst-case manner can present a challenge to the modeler. These sources can be modeled in two ways:

1. The allowable emissions can be modeled for a time period equal to that of the actual source. The emissions event is then selected to reasonably represent worst-case impacts or a series of potential operational scenarios are modeled.
2. The allowable emissions for the event are evenly divided over the pollutant averaging period of interest.

As an example, a mill may have fugitive PM2.5 emissions from periodic loadout of a waste bin. The emissions may occur for one hour, three times per week. Modeling must demonstrate compliance with both the 24-hour and annual standards. It is determined that only one loadout can occur during any 24-hour period. Since there is no specific time when the loadout is likely to occur, 24-hour modeling was conducted by evenly dividing the emissions from one loadout throughout the entire 24-hour period. Annual impacts were modeled by calculating annual allowable emissions, and evenly dividing those emissions among each hour of the year.

If it is known that emissions are most likely to occur during a certain time of the day, it may be appropriate to distribute emissions only over those hours of the day. The applicant should consult with DEQ modeling staff to obtain approval of such methods prior to modeling intermittent sources.

DEQ may allow exclusion of some very infrequent periodic emissions from the modeling analyses. Monthly testing of an emergency generator for 35 minutes could be an example of an infrequent periodic emissions source. Approval of excluding such sources from the modeling analyses will be made by DEQ on a case-by-case basis considering:

- The pollutant of interest and the averaging period of the standard
- Quantity of emissions from the source
- Frequency of the emissions
- Averaging period of standards associated with pollutants emitted
- Number of sources to be excluded
- Distance from source to ambient air receptors
- Nearby sensitive receptors (hospitals, schools, residences)
- Modeled impact of other sources in relation to applicable standards

As indicated in Section 6.3.1. Intermittent Sources, DEQ allows the exclusion of NOx emissions from intermittent testing and maintenance of engines powering emergency generators and fire suppression water pumps for demonstrating compliance with the 1-hour NO2 NAAQS.

6.4.2 Source Parameters

Stack parameters for each point source that are required to be modeled are as follows:

- Stack base elevation (feet or meters)
- Stack height (feet or meters)
- Stack inside diameter (feet or meters) (If the stack is not circular, use equivalent dimensions determined by Area = d2/4, where d is the stack's inner diameter)
- Stack exit velocity (meters/second) or exit flow rate (actual cubic feet per minute (acfm))
- Stack exit temperature (F or K)

Source parameters for area sources include the following:

- Source height (meters)
- Easterly dimension (meters)
- Northerly dimension (meters)
- Initial vertical dimension (meters)
- Angle from North (degrees)

Source parameters for volume sources include the following:

- Source height (meters)
- Initial horizontal dimension (meters)
- Initial vertical dimension (meters)

The application must provide detailed documentation and justification of all source parameters used in the analyses, including calculations where appropriate. Applications not providing sufficient documentation/justification of source parameters will be declared incomplete or denied. Stating that parameters were provided by the manufacturer or design engineer is not considered as adequate documentation/justification.

Flow Rates and Stack Gas Temperatures

Maximum flow rates and maximum stack gas temperatures should not typically be used in the modeling analyses unless the source predominantly operates at such a rate. Although maximum emissions are typically associated with maximum flow rates and stack gas temperatures, maximum impacts are often associated with lower emissions rates and lower stack gas flow rates and temperatures. Applicants should either use multiple scenarios of emissions, flow rates, and temperatures, or conservatively use maximum emissions with more typical stack gas flow rates and temperatures.

Submitted modeling analyses should provide detailed documentation and justification of all release parameters used in the analyses. Stack gas temperatures and flow rates substantially affect dispersion, and the application should clearly show how these parameters were calculated or measured. If gas temperatures are based on measurements made at locations other than near the stack exit, the temperature used in the model should be adjusted to derive a temperature appropriate for the stack exit. Stack gas exit velocities exceeding 50 m/sec will generally be viewed as suspect by DEQ reviewers, and greater documentation of values used will be required.

Unrealistic stack parameters submitted in applications are most commonly associated with internal combustion engines, and typically involve overly high exit velocities and stack temperatures. Applicants often use temperature and flow data obtained for the exhaust manifold rather than for the point of release to the atmosphere. Actual flows and temperatures at the release point will be substantially lower after heat loss through the walls of an exhaust pipe and through an exhaust muffler.

Stack Orientation

DEQ also requires the following be included in the application and modeling analysis:

- Orientation of the stack (horizontal or vertical)
- Indication of the presence or absence of a rain cap or other obstruction in the released flow from a stack

Stack orientation information is important because it affects the dispersion characteristics of the pollutants. If either a horizontal stack or rain cap (or other obstruction) is present, it must be accounted for in the modeling analysis, since upward plume momentum is zero because of either the obstruction or the orientation of the stack.

The method recommended by DEQ for modeling horizontal or rain-capped sources, when using the model AERMOD where downwash is not considered, is based on a procedure recommended by EPA (July 9, 1993, memorandum from Joseph A. Tikvart, Source Receptor Analysis Branch, to Ken Eng, Chief, Air Compliance Branch, Region II). The method involves setting the stack velocity to 0.001 meters per second to effectively turn off momentum plume rise. The memo also recommends turning stack tip downwash off for horizontal releases.

The recommended method for modeling point sources of non-buoyant emissions with horizontal release or vertical release with the presence of a rain cap is as follows:

1. Define the emissions source as a point source, entering in the model the actual height of release, stack gas temperature, and the Universal Transverse Mercator (UTM) coordinates.
2. Plumes from horizontal emissions releases or vertical stacks with rain caps experience no momentum induced plume rise. Set the stack gas exit velocity to 0.001 meters per second to effectively prevent the model from accounting for momentum plume rise.

3. Stack tip downwash is not appropriate for horizontally released emissions. If the emissions vent in the horizontal direction, the stack diameter can be set to 0.001 meters to prevent stack tip downwash effects. This step should not be used for sources that vent vertically with a rain cap over the stack, since the rain cap will not prevent stack tip downwash effects. The actual inside stack diameter should be used for rain-capped stacks.
4. Run the model as otherwise required.

By setting the flow velocity and/or stack diameter to 0.001, plume rise from hot, buoyant plumes is inappropriately eliminated. Since the PRIME downwash algorithm within AERMOD is affected by stack diameter, it is not acceptable to artificially increase the diameter by a substantial degree to generate a more accurate mass of hot stack gas emitted.

Non-regulatory versions of AERMOD allow the modeler to identify sources as a horizontal release or rain-capped source, and the model will consider the thermal buoyancy flux in the plume rise calculation while not considering a vertical momentum flux. To use the non- regulatory version, the actual temperature, stack diameter, and flow rate are entered into the model, then the source is identified in the AERMOD input file as a capped or horizontal release. DEQ must approve the use of any non-regulatory options in AERMOD.

Alternate methods may be approved by DEQ on a case-by-case basis if there are unique circumstances. In such cases, DEQ strongly advises that the permit applicant or consultant contact DEQ prior to modeling to discuss the issue, prepare a modeling protocol, and obtain prior approval from DEQ to use the proposed method.

Initial Plume Dimensions for Volume Sources

Initial horizontal plume dimensions for volume sources should be calculated as follows:

- Single volume source:
  $\sigma y0$ = side length of source divided by 4.3
- Line source represented as a series of volume sources (separated or adjacent):
  $\sigma y0$ = side length of source divided by 2.15

Initial vertical plume dimensions for volume sources should be calculated as follows:

- Surface based source:
  $\sigma z0$ = height of source divided by 2.15
- Elevated source on or adjacent to a building:
  $\sigma z0$ = building height divided by 2.15
- Elevated source not on or adjacent to a building:
  $\sigma z0$ = building height divided by 4.3

6.4.3 Scaled Plot Plan

A scaled plot plan showing emissions release locations, nearby buildings, property lines, fence lines, and roads is required (Section 8.1.2(b), *Guideline on Air Quality Models* (EPA 2005). The dimensions of the buildings (height, width, and length) should be noted either on the plot plan or in a table in the report. If building dimensions are listed in a table format, then it should be easy to cross-reference between the plot plan, model input file, and table.

The use of site plot plans generated directly from the modeling files does not meet the scaled plot plan submittal requirement. The submittal should include those scaled plot plans used to generate the modeling files.

6.4.4 Building Downwash Parameters

According to Section 6.2.2 in the *Guideline on Air Quality Models* (EPA 2005), the air quality impacts associated with cavity and wake effects due to the nearby building structures should be determined for any stacks with stack heights less than good engineering practice (GEP). If AERSCREEN is used with the option of entering dimensions of a single building, the building with the greatest corresponding GEP stack height should be analyzed. This may not necessarily be the building closest to the stack. When the EPA's AERMOD model is used and stacks are less than GEP stack height, building profile information is required for use in the modeling. The recommended building profile software is the EPA's *Building Profile Input Program* (BPIP). This program can also be used to determine which building should be used in the screening analysis. BPIP is available on EPA's SCRAM website.

6.4.5 Source, Building, and Receptor Coordinates and Elevations

UTM coordinates are typically used to define locations of emissions points, building corners, and receptor locations. The datum (e.g., NAD27, NAD83, WGS84) must be specified for the coordinates used, and the same datum must be used for all locations specified in the modeling analysis to assure consistency. The same coordinate system should also be used to evaluate elevations for emissions points, buildings, and receptors.

6.5 Ambient Air Boundary

The ambient air boundary must be determined before an ambient air assessment can be completed. The definition of ambient air in Idaho Air Rules Section 006 is, "that portion of the atmosphere, external to buildings, to which the general public has access." The EPA has further stated that "the exemption from ambient air is available only for the atmosphere over land owned or controlled by the source and to which public access is precluded by a fence or other physical barriers" (Costle 1980). Based on these definitions, DEQ has developed the following guidance to be used when determining the ambient air boundary for a facility.

It shall be assumed that the air within the facility boundaries is ambient air unless the facility can demonstrate that public access is precluded. The facility-proposed ambient air boundary must include justification that demonstrates the facility has reasonable control of the area and effectively precludes public access on a routine basis. The following criteria must be satisfied when developing a facility-proposed, ambient-air boundary justification. A justification must accompany the answers.

For the purpose of defining ambient air, the "general public" is considered anyone not directly associated with the facility. In general, if someone present at the site would not be subject to OSHA or other worker exposure regulations, then they are considered as the general public.

1. Facility Control
    - Is general public access precluded by a physical barrier (e.g., fence with a gate)? If "yes," the facility is assumed to be controlled and public access effectively precluded, and the ambient air boundary can be set at the fence line. Proceed to No. 2. If "no," then proceed to No. 1b. Rugged terrain or a water body is not typically considered as a physical barrier.

- Is general public access discouraged by the type of area (e.g., industrial park site away from residential or recreational areas), size of the facility (e.g., the facility is surrounded by a buffer zone that is controlled by the facility), or a remote location away from the proximity of human habitation or activities? Is the facility controlled by reasonable posting of the property with "no trespassing" signs, or reasonable patrol of the property by a security person who routinely asks trespassers to leave? If "yes" to BOTH questions, the facility is assumed to be controlled, with public access effectively precluded, and the ambient air boundary is determined to be at the property boundary. Proceed to No. 2. If "no," to EITHER question, proceed to No. 1c.
- If the facility is not controlled by a physical barrier AND/OR general public access is not discouraged by the type of area, size of the facility, or the remoteness of the facility location, then the ambient air boundary is determined to be inside the property boundary. The actual point at which the ambient air boundary occurs is dependent on several factors, such as the type of operation at the facility (e.g., are employees outside on a regular basis?) and whether employees have a clear view, from the location where the employees normally work, of the entire property (e.g., are trees blocking the sight?). The ambient air boundary is determined to be at a point where employees are not regularly present and where they do not have a clear view of the property. To meet this criteria, a very detailed description of the facility and property must be provided. If a justification cannot be provided, the ambient air boundary is determined to be all air that is external to the buildings. Proceed to No. 2.

2. Facility Business
   Is the general public invited as part of the normal business conducted on the facility site (e.g., the facility includes a commercial establishment or service provider)? If "yes," then the area into which the public is invited is determined to be ambient air. Adjust the ambient air boundary determined in No. 1. If "no," the ambient air boundary determined in No. 1 is not changed. Proceed to No. 3.
3. Right-of-Way Access
   Is the general public allowed on site as a part of a right-of-way easement or a common service road? If "yes," then the right-of-way is determined to be ambient air. Adjust the ambient air boundary determined in No. 1. If "no," the ambient air boundary determined in No. 1 is not changed. Any streams or rivers transecting a facility will be considered as ambient air at all locations between high water levels unless the applicant adequately demonstrates and documents that public access can be legally precluded. Idaho Department of Lands and Fish and Game rules governing public access should be used for such a demonstration.
4. Leased Property
   Does the facility lease a portion of their site to another industry, business, or individual OR does the facility lease property from another entity? For example, if a facility leases part of its property to a farmer for growing crops, that portion leased may be considered as ambient air. These situations are frequently complicated, and DEQ should be consulted regarding any specific case involving leased property as it affects the ambient air boundary.

Any area outside the facility's (or facilities' if they are under common ownership) control will be considered ambient air. This includes other industrial facilities. The employees of other facilities are considered to be general public for the facility in question. Evaluation of the ambient air quality must include all sources within facility control if the source or source modification exceeds the SILs defined in IDAPA 58.01.01.006 (definition of significant contribution).

6.6 Receptor Network

A receptor network establishes locations where the air dispersion model calculates a pollutant concentration. Each location is called a receptor, to represent a receptor that might be exposed to that concentration at that location. Receptors are required to be placed in all areas considered to be ambient air.

Modeling must be conducted using a sufficiently dense receptor grid to reasonably resolve the maximum modeled concentration and confidently demonstrate compliance with standards.

DEQ may determine an application incomplete or may deny a permit if DEQ is not confident the receptor grid spacing used is adequate to confidently demonstrate NAAQS compliance. DEQ may also include additional receptors during verification modeling if it is questionable whether the maximum concentrations have been resolved, and approval will not be granted if results do not comply with applicable standards. Adequacy of the receptor grid can be evaluated by reviewing a plot of modeled design value concentrations and considering the following:

- Maximum modeled concentrations in relation to a trigger value (SILs, NAAQS, or AACs/AACCs)
- Concentrations at receptors immediately adjacent to the maximum modeled concentration
- Terrain features within the modeling domain and areas beyond the domain if maximum modeled concentrations are near the boundary of the domain

6.7 Elevation Data

Terrain elevations for sources and receptors should be used when appropriate (EPA 2005). Where AERMOD is the model used to demonstrate compliance, the applicant should generally use the latest established procedures and guidance provided by EPA (see the SCRAM website on EPA's TTNWeb-Technology Transfer Network (*http://www.epa.gov/ttn/scram*). Prior to 2009, elevations of receptors, sources, and buildings used in the modeling analyses were determined from U.S. Geological Survey (USGS) Digital Elevation Model (DEM) files. AERMAP now supports processing terrain elevations from the National Elevation Dataset (NED) developed by the USGS. Since the DEM files will no longer be updated, NED represents more up-to-date and accurate data, and these should be used in preference to DEM files. These data can be downloaded in a seamless data set in GeoTiff format for use in AERMAP.

A single, consistent source of terrain data should be used to establish elevations for receptors, emissions sources, and site structures. Using different datums within a single modeling analysis can result in critical problems such as sources located beneath ground-level, buildings suspended above ground-level, or facilities located on hillsides rather than valley floors.

6.8 Meteorological Data

The meteorological data used in the modeling analysis should be representative of the meteorological conditions at the particular site of the proposed construction or modification. Section 8.3 in the *Guideline on Air Quality Models* (EPA 2005) states that representativeness of the meteorological data is dependent on the following: (1) the distance from the meteorological monitoring site to the area under consideration; (2) the complexity of the terrain surrounding both the meteorological monitoring site and the area under consideration; (3) the exposure of the meteorological monitoring site; and (4) the period of time during which data are collected.

When using AERMOD, representativeness will also depend on the similarity between the monitoring site and the application site for: 1) surface roughness; 2) land type characteristics that influence parameters such as albedo and Bowen Ratio (vegetative cover and moisture content). Consult with the DEQ air quality modeling coordinator to determine if representative meteorological data are available for the area under consideration. If the only available meteorological data are of questionable representativeness, DEQ may require applicants to perform modeling analyses using multiple meteorological data sets. Alternatively, site-specific data could be acquired by the facility. Site-specific meteorological data are typically only required for PSD applications or when DEQ has concern regarding NAAQS compliance.

The collection of site-specific meteorological data should follow the recommendations provided in *Meteorological Monitoring Guidance for Regulatory Modeling Applications* (EPA 2000), as well as Section 8.3.3 in the *Guideline on Air Quality Models* (EPA 2005). Site-specific meteorological data must be approved prior to use in a modeling analysis. Generally, following EPA recommendations and procedures is determined to be adequate for DEQ approval. To receive approval, the facility must provide DEQ staff with standard operating procedures, the quality assurance plan for operating the meteorological tower, and quality control audit reports that cover the entire year of data. DEQ will review this information and respond with either an approval or denial letter. The facility should either reference or include a copy of the approval letter when meteorological data are used in a modeling analysis. This will help to expedite the review process of the permit application. If DEQ does not approve the data for air modeling purposes, the analyses will not be approved and alternate approaches must be developed.

There are several sources of meteorological data besides on-site collected data. The National Weather Service (NWS) collects data throughout the country. Much of these data are collected at airports. These and other data are available through the National Climatic Data Center (*http://www.ncdc.noaa.gov/oa/ncdc.html*), through EPA's SCRAM website, or possibly through DEQ's modeling coordinator.

As stated in Section 8.3.1.1 in the *Guideline on Air Quality Models* (EPA 2005), the model user should "acquire enough meteorological data to ensure that worst-case meteorological conditions are adequately represented in the model results." Section 8.3.1.2 recommends using five years of NWS data or at least one year of site-specific data. If more than one year of site-specific data are available, then all years, up to five years, should be used (see Section 8.3.1.2(b) in EPA 2005). Site-specific meteorological data must be subjected to DEQ-approved quality assurance procedures.

The following should be considered when generating meteorological data with AERMET:

- Surface characteristics specified for landuse types in AERMET are based on the meteorological measurement site, not the facility application site.
- The EPA program AERSURFACE should be used, following recommendations specified in the user's guide, to define season- and sector-specific surface parameters (albedo, Bowen Ratio, and surface roughness).
- A current aerial photograph of the meteorological measurement site, or a detailed land- use map, should be used to check the accuracy of land-use files used in AERSURFACE.
- Sector-specific values of surface characteristics should be calculated for each season.
- Documentation of the surface characteristics analyses should be submitted with the application. Sufficient detail must be provided such that DEQ staff can regenerate the AERMET output meteorological files.

6.9 Land-Use Classification

Determining if the area surrounding the facility is urban or rural is necessary before a dispersion modeling analysis can be conducted correctly. Two methods of classifying an area as urban or rural are described in Section 7.2.3.c in the *Guideline on Air Quality Models* (EPA 2005). The first is the land-use method. The area is classified according to the current land usage (according to the meteorological land-use typing scheme proposed by Auer [1978]) of its surroundings in a three-kilometer (approximately 1.8-mile) radius centered at the source. If 50 percent or more of the surrounding area is classified as I1, I2, C1, R2, or R3 (using classifications listed in Auer 1978), the source would be considered an urban source. Otherwise, the source would be considered rural. Appendix E provides a summary of the meteorological land-use typing scheme proposed by Auer (1978).

A second method relies on population density. If the population density within a three-kilometer (approximately 1.8-mile) radius, centered at the facility, is greater than 750 people per square kilometer, the urban modeling option for the area can be used. However, the population density method of source classification should not be applied to highly industrialized areas. This is because highly industrialized areas typically have low population densities, but the presence of buildings and areas of asphalt and concrete make the source more urban in nature. The *Guideline on Air Quality Models*, Section 7.2.3.e, states that, of the two methods, the land-use procedure is more definitive (EPA 2005).

6.10 Background Concentrations

Section 8.2 in the *Guideline on Air Quality Models* (EPA 2005) discusses the use of background concentrations in a cumulative NAAQS analysis. Background concentrations of regulated criteria pollutants must be included in cumulative NAAQS analyses for both PSD and non-PSD applications. The modeler is required to contact DEQ prior to performing the modeling analysis to obtain the appropriate, reasonably conservative background concentration(s) for the area and time intervals of concern. A different pollutant-specific concentration is needed for each applicable averaging period.

Background concentrations are developed based on air quality monitoring data collected from the area of the proposed project or from similar areas determined to be reasonably representative. DEQ has developed applicable background concentrations for specific areas and default concentrations for areas where monitoring data are not available. Facilities may propose alternate/refined background concentrations based on their own analyses. Use of an alternate background concentration should be proposed within a modeling protocol submitted to DEQ. An alternate background concentration proposal analysis should include the following:

- Description of monitoring data proposed as representative of the proposed project area. The description should include the statistics of the data set and the quality control/assurance measures conducted for the data if data were not provided by DEQ.
- Description of all emissions sources in the area of the proposed project and sources in the area(s) where claimed representative monitoring data were obtained. This should include both point sources and area/mobile sources, and should also address emissions source density. A discussion should be provided that compares the two areas and supports the use of the monitoring data for the project site.
- A detailed assessment of the meteorology of the project area and the area where monitoring data were obtained. Differences between the areas should be assessed for the effects they may have on pollutant dispersion and concentrations in ambient air.

Air monitoring data for Idaho can be obtained at the following EPA website address: *http://www.epa.gov/air/data/index.html*. In most instances, background concentrations calculated in the following manner will be accepted by DEQ:

- 24-hour PM2.5: The maximum 3-year mean of 98th percentile of 24-hour average concentrations over 1-year periods.
- Annual PM2.5: The maximum 3-year mean of annual averages, using 5 consecutive years of data.
- Short term standards of PM10, SO2, and CO: The maximum 2nd highest monitored value over each year of applicable data.
- 1-hour NO2: The maximum 3-year mean of the 98th percentile of the daily maximum 1-hour average concentrations over 1-year periods.
- 1-hour SO2: The maximum 3-year mean of the 99th percentile of the daily maximum 1-hour average concentrations over 1-year periods.
- Annual Standards of SO2 and NO2: The maximum annual average for the applicable data. The most recent 5-year data set should be used.

Existing emissions from a facility may have a measurable impact to monitored concentrations in some instances. It is the facility's responsibility to assess their contribution to the background concentration. Prior to this assessment, a protocol must be submitted to, and approved by, DEQ. The assessment must then be done in accordance with the DEQ-approved protocol. In such cases, the facility's impact may be subtracted from the monitored value to establish an appropriate background concentration value. The following should be considered in such analyses:

- To evaluate a facility's impact on background monitored values, modeling must be performed using meteorological data collected during the same period when monitoring data were collected.
- Site-specific meteorological data must be used. These data must be highly representative for both the facility site and the monitoring site.
- Actual emissions for the period modeled must be used in the analyses.
- Monitored and modeled values must be paired in time and space; i.e. modeled values subtracted from monitoring results must be those values modeled at the site of the monitor for the averaging period associated with the monitored value.
- One suggested approach would be to start with the highest monitored value and model the facility's impact on that value. If the result is lower than the next-highest monitored value, this process should be repeated for that monitored value. This process is repeated until the highest adjusted value is greater than the next unadjusted value. The highest adjusted value is used for the background concentration.

Use of other methods to calculate a background concentration will be evaluated on a case-by- case basis. Proposals for such methods should be thoroughly described in the protocol.

6.11 Evaluation of Compliance with Standards

6.11.1 Approval Criteria

The applicant must demonstrate compliance with all other applicable impact limits in addition to demonstrating compliance with NAAQS. For PSD applications, these include impact limits for Class I areas within 300 kilometers, non-attainment area impact limits (when in or potentially significantly impacting a non-attainment area), and TAPs increment standards in Idaho Air Rules Sections 585 and

586 (when emitting TAPs above DEQ ELs). Federal land managers have the responsibility to protect the natural and cultural resources of Class I areas from adverse impacts of air pollution. Refer to the Federal Land Managers Air Quality Related Values Workgroup (FLAG) Phase I Report- Revised (USFS et al 2010). In some cases, deposition of airborne pollutants (e.g., radionuclides or fluorides, for example) or human risk pathways associated with deposition of airborne emissions may be subject to regulatory impact limits.

The highest modeled ambient concentration must be used for comparison against the SILs for all applicable criteria pollutants. A multi-year average, consistent with the years of meteorological data modeled, of the maximum modeled concentration of each year modeled can be used for the probabilistic standards, including 24-hour PM2.5, annual PM2.5, 1-hour NO2, and 1-hour SO2.

The following design concentrations must be used when demonstrating compliance with the cumulative NAAQS:

- CO
  - 1-hour averaging period – maximum of second highest ambient concentrations at each receptor
  - 8-hour averaging period – maximum of second highest ambient concentrations at each receptor
- NO2
  - 1-hour averaging period – maximum of 5-year averages (at each modeled receptor) of the 98th percentile of the annual distribution (equal to the 8th high) of maximum daily 1-hour ambient concentrations
  - Annual averaging period – maximum of ambient concentrations at each receptor
- SO2
  - 1-hour averaging period – maximum of 5-year averages (at each modeled receptor) of the 99th percentile of the annual distribution (equal to the 4th high) of maximum daily 1-hour ambient concentrations
  - 3-hour averaging period – maximum of second highest ambient concentrations at each receptor
  - 24-hour averaging period – maximum of second highest ambient concentrations at each receptor
  - Annual averaging period – maximum of ambient concentrations at each receptor
- PM10
  - 24-hour averaging period – “the projected 24-hour average concentrations will not exceed the 24-hour NAAQS more than once per year on average” (EPA 2005). The design concentration is dependent on the number of meteorological data years used in the analysis. For example, if five years of NWS data were used, then the design concentration would be the sixth highest 24-hour ambient concentration that occurred at each receptor over that five-year period.
- PM2.5
  - 24-hour averaging period – maximum of multi-year average of annual maximum 24- hour ambient concentrations at each receptor. Using the multi-year average of the 98th percentile of the annual distribution (equal to the 8th high) of 24-hour concentrations for both the modeled design value and background is not adequately conservative because background concentrations are frequently the controlling factor for PM2.5.
  - Annual Averaging Period - maximum of multi-year average of annual ambient concentrations at each receptor.

- Pb
  - Quarterly averaging period – maximum of ambient concentrations at each receptor
  - 3-month rolling average – maximum of ambient concentrations at each receptor

If meteorological data used in the analyses are of questionable representativeness, DEQ may require a more stringent design value. DEQ may also require analyses using multiple meteorological data sets to compensate somewhat for increased uncertainty.

The following design concentrations must be used when demonstrating compliance with TAPs requirements:

- Noncarcinogens – 24-hour averaging period – maximum of ambient concentrations at each receptor
- Carcinogens – total averaging period (1-5 years depending on meteorological data availability) – maximum of ambient concentrations at each receptor

6.11.2 Adequacy of Analyses Results

The submitted analyses must demonstrate to the satisfaction of DEQ that applicable emissions do not cause or significantly contribute to a violation of any air quality standard, as per Idaho Air Rules Section 203 for PTCs and Idaho Air Rules Section 403 for Tier II operating permits. Approvability of the submitted analyses will depend on the results of the analyses as well as the representativeness and quality of input data and parameters used. DEQ recognizes the uncertainty in typical dispersion modeling analyses and the variability and uncertainty associated with input parameters such as background concentrations, emission quantities, operational characteristics, etc. These uncertainties will be considered in DEQ's evaluation and determination of acceptability.

DEQ will evaluate model inputs and parameters more carefully as modeling results more closely approach applicable standards. Modeled concentrations within about 90 percent of the standard will be more closely reviewed by DEQ. At these concentrations, approval will be based on a "weight of evidence" type approach, considering the model results, input data/parameters, potentially exposed public, any monitoring requirements specified in the proposed permit, and operational variability. DEQ will not approve any modeling results that do not show compliance with applicable standards. The following provides discussion on how DEQ will evaluate compliance in situations where modeled concentrations are very near applicable standards:

- Modeled Concentrations: Results within about 90 percent of the air quality standard will generally trigger DEQ to more carefully evaluate the analyses. In some instances, the analysis may not adequately demonstrate compliance even though modeled concentrations are below a standard.
- Emissions Estimates: Estimates of emissions can be a substantial source of uncertainty and/or variability. It is important to evaluate both uncertainty in the estimate and variability, and to distinguish between them. Where estimates of maximum emissions are highly uncertain and the estimate is not necessarily conservative, DEQ may consider modeling results slightly below the standard as not adequately demonstrating compliance. Alternatively, if emissions are highly variable and the allowable emission rate is set at the maximum, DEQ will consider the likelihood of high emissions occurring concurrently with conditions of poor dispersion.
- Representativeness of Meteorological Data: Using meteorological data from a distant location where the representativeness is questionable will add to the uncertainty of the modeling analyses. Applicants may be requested by DEQ to provide a more detailed assessment of the area's meteorology and qualitative comparisons to data used in the analyses. Such assessments

should be performed by meteorologists or those having considerable knowledge in surface meteorology. In some instances, DEQ may request an applicant to install and operate a meteorological station to resolve concerns with data representativeness. In cases where meteorological data used in the analyses are of questionable representativeness, DEQ may require the use of multiple meteorological data sets in the analyses.

- Background Concentrations: Background concentrations are often a very large source of uncertainty and variability, especially for 1-hour NO2, PM10, and PM2.5, where background concentrations can be a considerable fraction of the standard. When modeled 1-hour NO2, PM10 and PM2.5 concentrations are very near the standard, applicants should review and compare the meteorological conditions associated with the modeled result and the background concentration.
- Modeled Emissions Release Parameters: Parameters characterizing the release of emissions (stack temperature, flow rate, initial plume dimensions for volume sources, etc.) greatly impact the modeling results. The conservatism of these parameters will be considered by DEQ during the review.
- Permit Requirements: As modeled concentrations approach applicable standards, DEQ may require more extensive emissions monitoring, source testing, and possibly ambient air monitoring.
- Areas with High Concentration Impacts: DEQ will consider the land use of areas where models project high concentrations. DEQ will require a higher degree of certainty for areas where there is a high potential for exposures to the public, such as actual residences, businesses, parks, etc. However, it is important to consider that dispersion models are reasonably accurate at predicting the magnitude of maximum concentrations but often perform poorly at predicting the location or time of maximum concentrations.

6.12 Air Quality Modeling Report

The applicant must supply an air quality modeling report that presents the case as to how the modeling results demonstrate compliance with all applicable air quality standards. The level of detail of the report will depend on the complexity of the proposed facility and the permitting project.

Each submitted application must be a complete package in itself. Referencing previously submitted materials, such as those submitted in an earlier application, will not generally be considered as meeting the stated requirements to provide documentation/justification of air quality analyses and data used as inputs for those analyses.

Below is an example annotated outline of an air quality modeling report. The report should thoroughly describe all aspects of the air impact analyses performed. Specific sections of this guideline should be consulted to evaluate the details needed for the modeling report regarding certain aspects of the analyses.

I Purpose

- State the purpose of the air quality modeling analyses (i.e., demonstrating compliance for a permit to construct or a Tier II operating permit).
- Provide a detailed description of regulatory requirements as they relate to modeling, citing specific applicable regulations.

II Model Description/Justification

- Discuss what model was chosen and justify why it is the appropriate model for the situation. This discussion may be very brief if the applicant is proposing to use AERMOD for near-field impacts.

III Emissions and Source Data

- Present tables showing the current (either actual or permit allowable) emission rates, future allowable emissions rates (maximum for each applicable averaging period), and the requested emission increase (future allowable minus actual or current allowable).
- If cumulative NAAQS impact analyses are required, the applicant must thoroughly document all emissions used in the model, even when such sources are not affected by the particular proposed project. Emissions calculations, source test data, and/or other information justifying the value used should be provided for all sources unless those emissions are based on a specific emissions limit presented in an issued permit.
- Provide justification for those sources and/or pollutants determined to be “inconsequential” (if applicable).
- Provide stack parameters (emissions rates, stack height, stack elevation, stack diameter, stack gas exit velocity, and stack gas exit temperature) for each modeled emissions point. Values for stack parameters should be justified and well documented, indicating whether values are estimated or measured.
- Provide a facility plot plan to scale showing the fence line, ambient air boundary, emission sources at the facility, and buildings. Include the height, width, and base elevation of each building at the facility.
- Provide UTM coordinates of all emissions points, and list the datum used.

IV Ambient air boundary

- Thoroughly describe how the public are precluded from accessing all areas excluded from the receptor network, describing any complicating ambient air issues such as rivers bisecting the facility, leasing agreements, retail sales operations at the site, right of ways, etc.

V Receptor Network

- Describe the receptor network used. Include the distance between receptors for the fine and coarse grids. Justify any deviation from minimum recommendations in EPA or state guidelines, and provide a demonstration that the receptor grid allows for resolution of the maximum modeled concentration.

VI Elevation Data

- Describe any elevation data used and the source of the information, including the datum for the coordinates used. If necessary, include a USGS 7.5-minute map showing the location of the facility. A justification must be provided if elevation data are not used.

VII Meteorological Data

- Describe the source of the meteorological data and present a representative analysis according to Section 6.8. Electronic copies of the files must be included with the modeling report if meteorological data were not provided in model-ready format to the applicant from DEQ. If site-specific data are used, provide documentation that DEQ has reviewed and approved the data.
- If the applicant has generated AERMOD input meteorological files by running AERMET, rather than using AERMOD input files provided by DEQ, supporting AERMET documentation must be submitted with the application. A detailed report on the processing of meteorological data

should be submitted, including a report on running AERSURFACE to evaluate surface characteristics and a detailed report on data collection and quality for any on-site data processed. Copies of the raw meteorological data must also be submitted to DEQ.

VIII Land-Use Classification

- State the land-use classification for the area surrounding the source and provide the justification.

IX Background Concentrations

- State whether background concentrations were used and identify the source of the information.
- If DEQ default background concentrations were not used, the report must thoroughly describe and document how background concentrations were determined.

X Evaluation of Compliance with Standards

- Include tables summarizing the air quality model output (example tables are shown in Appendix F).

XI Electronic Copies of the Modeling Files

- Provide modeling input/output files (including BPIP and meteorological data, and intermediate files generated by AERMET, AERMAP, and AERMOD) on compact disk or other means.

7 DEQ Review of Modeling Analyses

DEQ dispersion modeling staff will review the submitted air quality analyses prior to approval and issuance of the permit. Review of the analyses will occur in two phases: 1) completeness review; 2) technical review of submitted analyses. The completeness review will focus on evaluating whether the required analyses were performed and the primary components of the air quality analyses were submitted with the application. The technical review will evaluate whether the data and methods used in the analyses are accurate and appropriate for the project.

Several methods and approaches can be used by the applicant to ensure the submitted modeling analyses are approved by DEQ or, if there are problems with the analyses, such problems are identified early in the completeness review and will minimize delays to the project:

1. Submit a modeling analyses protocol prior to conducting the analyses. The protocol, as described in Section 6.1, should provide details on the proposed methods and data to the greatest degree possible.
2. Provide a detailed and well-organized modeling analyses report, as described in Section 6.12. This will allow DEQ staff to quickly assess the appropriateness and technical accuracy of the analyses. If a modeling protocol was submitted to DEQ prior to the application, a copy of the protocol and DEQ's protocol approval notification should be included with the application.
3. Provide clear justification for methods and data used, and provide supporting documentation. Calculations should be provided such that the DEQ reviewer can easily verify the calculated values.
4. Ensure that emissions sources are named consistently between the emissions inventory used for the permit application forms and the modeling analyses.

Conduct quality assurance/control measures to minimize error in the submitted analyses. The following are some measures that will help minimize or identify errors in the analyses:

- Print or view a three-dimensional representation of the sources, building, receptors, and the ambient air boundary. This will identify any errors in UTM coordinates and elevations.
- Check that all sources included in the application are included in the modeling analyses. If some sources are not included, a detailed justification should be provided. If facility-wide modeling is needed for a cumulative impact analysis, the emissions inventory of other sources, not directly addressed by the current permitting action, should be thoroughly documented.
- Emissions rates used in the modeling analyses should be identical to those listed in the permit application forms and the emissions calculation section of the application. Any differences between emissions rates should be thoroughly documented and all calculation steps should be shown. This will allow DEQ reviewers to quickly evaluate how emissions rates were calculated.

8 Summary

This document provides guidance for performing an ambient air assessment, for permitting purposes, in the state of Idaho. This document should be used in conjunction with the EPA's *Guideline on Air Quality Models* (EPA 2005) and *New Source Review Workshop Manual* (EPA 1990), and other applicable guidance materials. Following the guidance in this document, as well as EPA guidance, will help expedite DEQ's review of the application.

Appendix A. Guidance for 1-Hour NO_2 Modeling of Intermittent Sources

DEQ Guidance for Minor New Source Review Modeling of 1-Hour NO_2 from Intermittent Testing of Emergency Engines

State of Idaho
Department of Environmental Quality

September 2013

Certain industrial facilities have internal combustion (IC) engines that are used only to power emergency generators or fire-suppression pumps. These engines only operate for periodic testing and during an actual emergency. As such, these sources with intermittent emissions are difficult to model in a way that accounts for impacts in a reasonably accurate but conservative manner. As a result, Tyler Fox, leader of Environmental Protection Agency's (EPA) Air Quality Modeling Group, developed a memorandum entitled "Additional Clarification Regarding Application of Appendix W Modeling Guideline for the 1-hour NO2 National Ambient Air Quality Standard, dated March 1, 2011. The memo provides states with the flexibility to exclude certain types of sources with intermittent emissions from Appendix W modeling.

Upon a review of other states' application of the Tyler Fox memo, comments from the public and Idaho industry, an internal review of Idaho sources, NO2 background levels, and various sample model runs; DEQ has determined that Nitrogen Oxides (NOx) emissions from the intermittent operational testing of engines powering emergency generators or fire-suppression water pumps may be excluded from the project-specific significant impact level (SIL) analysis and the cumulative NAAQS analysis for 1-hour NO2, providing the annual hours of operation from testing and maintenance are less than or equal to 100 hours per engine.

This determination is applicable to minor source air permitting projects and is not limited to any specific number of engines present at a facility. The Director may require deviation from this guidance if deemed appropriate to assure compliance with 1-hour NO2 NAAQS and IDAPA 58.01.01.203 or 01.403. DEQ will determine how emergency engines are included in permits for major sources, specifically those applicable to the Prevention of Significant Deterioration (PSD) program, on a case-by-case basis.

This guidance does not have the force and effect of a rule and is not intended to supersede statutory or regulatory requirements or recommendations of the state of Idaho or EPA. This guidance may be altered upon new or revised guidance from EPA, development of new methods to appropriately handle such emissions, or new information gained from technical analyses.

Contact the DEQ stationary source air modeling coordinator at (208) 373-0112 for any questions or additional information regarding data and methods for assessing air quality impacts from intermittently operated sources.

Appendix B. Class I Areas

Class I Areas

This appendix shows Class I areas in and near Idaho. The areas represent situations where air quality impact limits are stricter than the NAAQS. The information in this appendix is current as of the date of this document. Please check with DEQ to verify if it is still current.

Area Classifications

The Class I, II, and III areas are defined below (shown in Figure 1).

1. Class I - National park, recreation, and wilderness areas that were already established when the 1977 Clean Air Act was passed, and other designated parts of the country that now benefit from high quality air and where a high priority has been established for the maintenance of pristine conditions. Additional degradation of the air is severely restricted.
2. Class II - Areas that need reasonably or moderately good air quality protection. This is presently the class designation of most areas in the United States. Increments of deterioration have been stipulated that will generally accommodate most proposed development projects.
3. Class III - Areas that can, at the discretion of the states, be designated as allowing for larger increments of air quality degradation and therefore greater growth and development potential. No Class III areas have been designated in Idaho.

The Class I areas in Idaho include the following: Hells Canyon, Sawtooth, and Selway- Bitterroot wilderness areas, Craters of the Moon National Monument, and Yellowstone National Park.

Class I areas near Idaho's borders include the following: Spokane Indian Reservation, Washington; Hells Canyon and Eagle Cap Wilderness areas, Oregon; Cabinet Mountain and Anaconda-Pintler Wilderness areas, Red Rock Lakes, and Flathead Indian Reservation, Montana; Yellowstone National Park, Montana and Wyoming; Teton National Park, Wyoming; and Jarbidge Wilderness, Nevada.

Figure A-1. Class I areas in and near Idaho.

Appendix C. Idaho DEQ Air Dispersion Modeling Checklist

Idaho DEQ Stationary Source Air Dispersion Modeling Checklist

- ☐ Reviewed the Idaho Air Quality Modeling Guideline and have determined the appropriate methods and data for use in this permitting action, contacting DEQ as needed to provide clarification.
- ☐ A modeling applicability analysis was performed for all criteria pollutants emitted by the new facility or modification, and modeling was performed for those pollutants having a total increase in emissions exceeding DEQ modeling thresholds.
- ☐ A TAPs modeling applicability analysis was performed for all TAPs emissions increases associated with the project, and TAPs modeling was performed for those TAPs having a project total emissions rate exceeding the emissions screening levels.
- ☐ Provided a description of the ambient air boundary and demonstrated how public access will be precluded from all areas excluded from ambient air.
- ☐ The receptor grid used meets minimal requirements specified by DEQ AND is adequate to reasonably resolve the maximum modeled concentration and confidently demonstrate compliance with applicable standards.
- ☐ The modeling domain used is sufficiently large to resolve the maximum impacts, accounting for impacts on distant elevated terrain.
- ☐ A scaled site plot plan was included in the application, showing emissions sources, buildings, and the ambient air boundary.
- ☐ Thoroughly documented all release parameters used in the model and provided justification for their use.
- ☐ Emissions rates provided in the emissions inventory section of the application are identical to those used in the modeling analyses or, if emissions rates are not identical, thorough justification of modeled rates has been provided.
- ☐ A cumulative NAAQS impact analysis was performed for all criteria pollutants for which modeled impacts from the significant impact analysis exceeded SILs. The cumulative NAAQS impact analysis included facility-wide emissions, emissions from any co-contributing sources, and a DEQ approved background concentration. Documentation of all emissions rates and release parameters used in the cumulative NAAQS impact analyses are provided in the application.
- ☐ Included all input and output modeling files for all pollutants and averaging periods.
- ☐ If a modeling protocol was prepared and submitted to DEQ prior to performing the air impact analyses, the protocol and DEQ's protocol approval notice is included with the application.

Appendix D. Modeling Protocol Checklists

Modeling Protocol Checklist for New Minor Sources or Minor Modifications

The following should be thoroughly addressed in a modeling protocol submitted to DEQ:
Introduction and Purpose

- General overview, facility description, description of area where facility is located.
- Project overview.
- Goals of the air quality impact analysis (i.e., demonstrate compliance for a PTC for a modification, PTC for a new facility, or a Tier II operating permit).
- Applicable regulations and requirements.
- Pollutants of concern.

Emissions and Source Data

- Description of facility processes and emissions controls affected by the permitting action.
- List of emissions points that will be included in the modeling analyses. Present a table showing current actual/allowable and future allowable emission rates (using pounds per hour rates for all applicable averaging periods) and the requested emissions increase (future allowable minus current actual or allowable).
- Good engineering practice (GEP) stack-height analysis for any stacks approaching GEP height.
- Graphic showing the facility layout: location of sources, buildings, emissions points, and fence lines.
- Description of methods used to calculate or otherwise determine source parameters (emissions rates, UTM coordinates, stack height, stack elevation, stack diameter, stack- gas exit velocity, and stack-gas exit temperature) for each source included in the modeling analyses.
- Methodology for including area and volume sources in the modeling analysis, including justification and calculations of initial dispersion coefficients and release heights.
- Methodology for including/excluding sources from the modeling analyses.

Air Quality Modeling Methodology

- Description of model selection and justification. This may be minimal in cases where the regulatory guideline model is used (AERMOD in most cases).
- Description of model setup and application
  - Model options (i.e., regulatory default). Describe and provide justification for any non-default settings.
  - Averaging periods used in the analyses and how emissions rates were calculated for specific averaging periods.
  - Land-use analysis in all cases where “urban” is used and in cases where land use is not obviously “rural.”
  - Methods used to account for building downwash in the analyses.
  - Treatment of any chemical transformations (e.g., NO to NO2) accounted for in the analyses.
  - Any other unique methods or data used.Description of how elevations of sources, buildings, and receptors were determined.
- Receptor network
  - Description of receptor grids – include methodology for ensuring the maximum concentration will be estimated
  - Discussion/justification of ambient air boundary, including a description of how the general public will be excluded from areas not considered ambient air.

- Meteorological data
  - Selection of meteorological databases – justification of appropriateness of meteorological data to area of interest
  - Meteorological data processing
  - Meteorological data analysis (e.g., wind rose)
- Background concentrations

Applicable Regulatory Limits

- Methodology for evaluation of compliance with standards (i.e., determination of design concentration)
- Significant Impact analysis
  - Comparison to SILs
  - TAPs analysis
- Cumulative NAAQS impact analysis
  - NAAQS analysis
- Presentation of results – state how the results of the modeling analysis will be displayed (i.e., list what information will be included)

Appendix E. Land-Use Classification Procedure

Land-Use Classification Procedure

See Section 8.2.8.b of *Guideline on Air Quality Models* (EPA 2001) for additional information.

1. Determine a circular area centered on the source with a radius of three kilometers.
2. Classify the land use within this area using the meteorological land-use typing scheme presented in Table D-1.
3. If land-use types I1, I2, C1, R2, and R3 account for 50 percent or more of the area, use urban dispersion coefficients; otherwise, use rural dispersion coefficients.

Table D-1. Identification and Classification of Land-Use Types (Auer 1978)

Type	Use	Structures	Vegetation
I1	Heavy Industrial	Major chemical, steel, and fabrication industries; generally 3-5 story buildings, flat roofs	Grass and tree growth extremely rare; <5% vegetation
I2	Light-moderate Industrial	Rail yards, truck depots, warehouses, industrial parks, minor fabrications; generally 1-3 story buildings, flat roofs	Very limited grass, trees almost totally absent; <5% vegetation
C1	Commercial	Office and apartment buildings, hotels; >10 story heights, flat roofs	Limited grass and trees; <15% vegetation
R1	Common residential	Single family dwellings with normal easements; generally one story, pitched roof structures; frequent driveways	Abundant grass lawns and light-moderately wooded; >70% vegetation
R2	Compact residential	Single, some multiple, family dwellings with close spacing; generally <2 story, pitched roof structures; garages (via alley), no driveways	Limited lawn size and shade trees; <30% vegetation
R3	Compact residential	Old multi-family dwellings with close (<2m) lateral separation; generally 2 story, flat roof structures; garages (via alley) and ash pits, no driveways	Limited lawn size, old established shade trees; <35% vegetation
R4	Estate residential	Expansive family dwellings on multi-acre tracts	Abundant grass lawns and lightly wooded; >80% vegetation
A1	Metropolitan natural	Major municipal, state, or federal parks, golf courses, cemeteries, campuses; occasionally single story structures	Nearly total grass and lightly wooded; >95% vegetation
A2	Agricultural natural		Local crops (e.g., corn, soybeans); >95% vegetation
A3	Undeveloped	Uncultivated; wasteland	Mostly wild grasses and weeds, lightly wooded; >90% vegetation
A4	Undeveloped rural		Heavily wooded; >95% vegetation
A5	Water surfaces	Rivers, Lakes	Not applicable

Appendix F. Example Tables for Air Quality Modeling Report

Example Tables for Air Quality Modeling Reports

This appendix contains examples of tables that are useful in presenting information in modeling reports.

Table E-1. Example Stack Parameters Table

Parameter[a]	Generator Stack	Boiler Stack
Computer Model Identifier (Alias)		
Emissions Rate (lb/hr)		
Stack Height (ft)		
Stack Diameter (ft)		
Exit Temperature (°F)		
Exit Flow Rate (acfm)		

a) Provide thorough justification/documentation of values used in the model, including calculations used to generate values.

Table E-2. Example Significant Impacts Summary ($PM_{2.5}$)

Year	5-Year Mean of Highest Annual Concentration ($\mu g/m^3$)	Radius of Significant Annual Impact (m)	5-Year Mean of Highest 24-hour Concentration ($\mu g/m^3$)	Radius of Significant 24-hour Impact (m)
1987-1991				
Significant Impact Level	0.3	Not applicable	1.2	Not applicable

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
WASHINGTON, D.C. 20460

DEC 0 2 2019

THE ADMINISTRATOR

MEMORANDUM

SUBJECT: Revised Policy on Exclusions from "Ambient Air"

FROM: Andrew R. Wheeler

TO: Regional Administrators

The U.S. Environmental Protection Agency is updating its policy on the exclusion of certain areas from the scope of "ambient air." In the context of developing and implementing national ambient air quality standards under the *Clean Air Act*, the EPA defines "ambient air" at 40 CFR § 50.1(e) as "that portion of the atmosphere, external to buildings, to which the general public has access." In applying this definition, the EPA has long followed a policy that allows excluding certain areas of a source's property, located outside of a building, from ambient air. As described in a 1980 letter from then-Administrator Douglas Costle to Senator Jennings Randolph, this "exemption from ambient air is available only for the atmosphere over land owned or controlled by the source and to which public access is precluded by a fence or other physical barriers." In the attached revised policy, I am revising the "fence or other physical barriers" element of this ambient air policy, while maintaining public health protection.

This revision to the ambient air policy, like the 1980 letter, considers as eligible for exclusion only the atmosphere over "land owned or controlled by the [stationary] source." While the 1980 letter said such areas may only be excluded when public access is precluded by "a fence or other physical barriers," this limited revision more clearly recognizes that a *fence or other physical barrier* is not the only type of measure that may be used to establish that the general public does not "have access" to an area of land that is owned or controlled by the source. These other types of measures, potentially combined with physical barriers, may be used to support exclusion of an area from ambient air. Thus, the EPA's revised ambient air policy, consistent with its discretion available under the regulatory definition of ambient air, is that *the atmosphere over land owned or controlled by the stationary source may be excluded from ambient air where the source employs measures, which may include physical barriers, that are effective in precluding access to the land by the general public.*

The revised policy reflects input from stakeholders, and the EPA expects this policy to maintain the same level of public health protection that was originally intended by the 1980 letter. For example, under the Prevention of Significant Deterioration program air quality analysis requirement, the air agency[1] must still determine, based on the administrative record for the permit, that the general public does not have access to property in order to exclude an area from ambient air.

The revised policy reflected in the attachment is neither a regulation subject to notice-and-comment rulemaking requirements nor a final agency action. This action does not amend the definition of "ambient air" in EPA regulations at 40 CFR § 50.1(e) and does not create or change any legal requirements applicable to the EPA, air agencies or the public. This policy does not of its own force determine that any specific portion of any particular source's property may be excluded from ambient air on the basis of particular measures taken to preclude public access. Determinations concerning the adequacy of such measures can only be made by the EPA or another air agency on a case-by-case basis after consideration of the relevant administrative record. Air agencies are not required to apply this policy and retain the discretion to determine whether the steps taken by a source will be adequate to preclude public access.

Please share this memorandum and the attached revised policy with air agencies in your region. For any questions regarding this memorandum and the attached revised policy, please contact Scott Mathias, Acting Director of the Air Quality Policy Division in the Office of Air Quality Planning and Standards at (919) 541-5310 or mathias.scott@epa.gov.

Attachment

[1] "Air agency" refers to a state, local or tribal air permitting agency and may also refer to the EPA, depending on the context.

Revised Policy on Exclusions from "Ambient Air"

I. INTRODUCTION

In the context of developing and implementing national ambient air quality standards under the *Clean Air Act*, the U.S. Environmental Protection Agency defines "ambient air" at 40 CFR § 50.1(e) as "that portion of the atmosphere, external to buildings, to which the general public has access."[1] The regulatory definition plainly excludes from ambient air areas inside buildings, and these areas are not addressed further in this document. In addition, the EPA has long recognized that certain areas external to buildings may be excluded from the regulatory definition of ambient air because the general public does not have access to them. Based on this interpretation, the EPA has a longstanding policy in allowing an exclusion from "ambient air" of the atmosphere over certain areas external to buildings when particular conditions are satisfied. This interpretation and policy were affirmed in a 1980 letter from Administrator Costle, which stated that the EPA was retaining "the policy that the exemption from ambient air is available only for the atmosphere over land owned or controlled by the source and to which public access is precluded by a fence or other physical barriers."[2]

The 1980 policy was criticized by those who believed that allowing exclusions of atmosphere, even on a source's own property, resulted in inadequate public health protection. In a 1989 report, the U.S. General Accounting Office reviewed the EPA's implementation of its ambient air policy and found that, in some cases, EPA Regional offices approved ambient air exclusions that allowed sources to increase pollution where air quality modeling predicted violations of the NAAQS.[3] The report recommended that the EPA "initiate a formal rulemaking process to redefine ambient air in a manner that is more protective of the environment." The report criticized the EPA for allowing the use of land acquisition to exclude such land from determinations of compliance with the NAAQS. It equated such land acquisition practices to prohibited dispersion techniques – a comparison with which the EPA has disagreed.[4]

Notwithstanding the GAO report, the EPA left the policy in the 1980 letter in place and decided neither to redefine its regulatory definition of ambient air nor to issue guidance concerning land acquisition practices. The EPA has continued to apply the policy described in the 1980 letter for nearly 40 years, and the EPA has periodically provided guidance to address the application of the policy in specific situations.

[1] *See also Train v. NRDC*, 421 U.S. 60, 65 (1975) ("'ambient air' [is] the statute's term for the outdoor air used by the general public").

[2] Letter from EPA Administrator Douglas Costle to Senator Jennings Randolph, Chairman, Committee on Environment and Public Works, December 19, 1980 (1980 letter).

[3] "Air Pollution: EPA's Ambient Air Policy Results in Additional Pollution," United States General Accounting Office, GAO/RCED-89-144, July 1989, at 14-21.

[4] Policy statement on the definition of Ambient Air, David G. Hawkins, Assistant Administrator for Air, Noise, and Radiation, Draft, January 9, 1980.

In recent years, industry representatives have argued that the longstanding ambient air policy is overly restrictive because it purports to require the use of a fence to preclude public access and justify excluding an area. These stakeholders have identified situations arising in specific types of air quality analyses (*e.g.*, Prevention of Significant Deterioration (PSD) permitting) that the EPA may not have considered when it issued the 1980 letter.[5] Industry representatives have requested that, given the advances in surveillance and monitoring capabilities and the variety of ambient air situations that have arisen since 1980, the language from the 1980 letter should be updated to more readily allow regulatory authorities to consider additional types of measures that are effective in precluding public access to a source's property, consistent with the regulatory definition of ambient air.

The EPA has reviewed the general principles expressed in the 1980 letter and has concluded, after considering a wide range of stakeholder comments, that it is reasonable to update the language from the 1980 letter that calls for the use of "a fence or other physical barriers" to preclude public access. In summary, this policy statement describes a refinement to the language of the existing policy that recognizes that a variety of measures (including, but not limited to, physical barriers) could be appropriately considered effective, depending on site-specific circumstances, to preclude public access from property owned or controlled by a source. The limited exclusion in this updated ambient air policy continues to apply only to property "owned or controlled" by the source and reflects only an update to the criteria the EPA will apply when determining whether a source effectively precludes public access to its property for purposes of analyzing the source's impact on ambient air.

A draft of the revised policy was made available for public review and comment from November 18, 2018, through January 11, 2019.[6] A total of 37 sets of comments were received from individuals and stakeholders representing state, local and tribal government agencies, industry and environmental groups. Some of the comments are discussed below. After consideration of all comments received, the EPA believes the revised policy is appropriate and will maintain public health protection. The revised policy is fully consistent with the regulatory definition of ambient air and fulfills the objective of protecting the public from exposure to potentially adverse levels of air pollution in a manner no less effective than the "fence or other physical barriers" called for under the previous policy.

II. BACKGROUND

As discussed above, the EPA's longstanding policy is based on the view that the general public does not have access to land occupied by a stationary source (or that would be occupied by a proposed stationary source or modification) when the land meets both of the following conditions: (1) the land is owned or controlled by the owner or operator of the stationary source; and (2) the land is surrounded by a fence or other physical barriers that preclude general public access. For

[5] American Forestry and Paper Association/American Wood Council, NAAQS Permitting White Paper on Flexible Procedures (September 2014) (*see* relevant discussion in sections 2 and 3).

[6] *See https://www.epa.gov/nsr/forms/draft-guidance-revised-policy-exclusions-ambient-air.*

example, under this policy, the EPA allows a PSD permit applicant to exclude from its air quality analysis the site of the proposed source where the record shows that the site is owned or controlled by the source and surrounded by a fence or other physical barriers that do not allow public access.[7]

Although not expressly stated by Administrator Costle in 1980, it is clear that these dual conditions of the policy have been fundamentally grounded on an interpretation of the regulatory phrase "to which the general public has access." In a 2007 memorandum, the EPA explained that it uses "controlled" in the context of the first condition of the policy to mean that the owner or operator of the source has the legal right to use the land, and that its land-use right includes "the power to control public access" and "the power to exclude the general public."[8] The EPA explained that the second condition calls for a source to actually take steps to preclude the general public from accessing its property "by relying on some type of physical barrier (*e.g.*, a fence, wall, or natural obstruction)." Thus, the first condition calls for a consideration of whether the general public has access in a *legal* sense (whether the owner or controller of the land has the right to preclude the general public's access), while the second condition calls for a consideration of whether the general public has access in a *practical or physical* sense (whether the general public is able to enter). The EPA also recognized that some persons that have both legal and practical access to the source's property are not necessarily considered members of the general public, such as employees of the owner or operator who work at the site, or "business invitees," such as contractors or delivery persons.[9] Of all of these aspects of the analysis, the sole change to the EPA's ambient air policy reflected in this attachment is that the EPA no longer considers "a fence or other physical barriers" to be the only type of measure available to a source in order to preclude public access in a practical or physical sense.

Over the years, the EPA has provided clarifying guidance to explain how the definition of ambient air, and the associated ambient air policy, should be applied under specific circumstances for air quality analyses, such as analyses used to demonstrate compliance with the NAAQS and PSD increments within the PSD permitting process. For example, in the aforementioned 2007 memorandum, the EPA explained how it intended to apply the definitions of "ambient air" and "building, structure, facility or installation"[10] to arrangements where a source locates on property that it leases from another entity. The EPA has provided its views in other situations, on a case-by-case basis, concerning the adequacy of certain types of fencing or other physical barriers (*e.g.*, a steep cliff or rugged terrain) based on the EPA's understanding of the core concept of "access" to source property by the public, as this term is used in the regulatory definition of ambient air.

---

[7] *See, e.g., In re Hibbing Taconite*, 2 E.A.D. 838 (Admr. 1989). In this case, the EPA's Administrator called for additional review of whether physical barriers were present at all locations around the perimeter of excluded property.
[8] Memorandum from Stephen D. Page, EPA, OAQPS, to EPA Regional Air Division Directors, "Interpretation of 'Ambient Air' in Situations Involving Leased Land Under the Regulations for Prevention of Significant Deterioration (PSD)," attachment at 2-3, June 22, 2007. The memorandum refers to the 1980 letter, but this revised policy does not affect the interpretations expressed in the 2007 memorandum, as described above.
[9] *Id.*, attachment at 5-6.
[10] *See* 40 CFR 52.21(b)(6).

In its review of individual situations, the EPA has sometimes agreed that an area may qualify for exclusion from ambient air despite the fact that the specific property or facility at issue, or a certain portion of the property or facility, was not surrounded by a fence or other physical barriers. For example, five years after the 1980 letter, the EPA allowed an ambient air exclusion based on the cumulative effect of a company's extensive property holdings, installation of fences, posting of "No Trespassing" signs, security patrolling and the rugged mountainous terrain.[11] More recently, the EPA excluded an area from ambient air based on a source's proposal to preclude public access using measures other than a fence or other physical barriers. The United States Court of Appeals for the Ninth Circuit reviewed and upheld the exclusion, finding that, although fencing or other physical barriers were not used, other methods were used to effectively preclude public access, and "[t]he essence of the EPA's regulatory definition links ambient air to public access."[12] Although that case involved permitting of a source located over water, where installation of a fence or other physical barriers was not practical, the language of the regulatory definition of ambient air does not preclude extending this reasoning to other factual situations. For example, there may be situations over land where it is also impractical or unduly burdensome to require a source to install a fence or other physical barriers when other means of precluding public access may be equally effective. The EPA has thus not read the regulatory definition to require the use of physical barriers in all cases. After evaluating the specific circumstances, the EPA has in some cases supported excluding areas of land from ambient air that were not surrounded by physical barriers. The EPA has previously recognized that public access may be effectively precluded by means other than a fence or other physical barriers and still be consistent with the regulatory definition of ambient air.

In addition to seeking assistance from the EPA in case-specific permitting situations, organizations representing permit applicants have on various occasions requested that the EPA reconsider aspects of the ambient air policy that their membership considers to be inflexible or outdated, such as the need to demonstrate NAAQS attainment on railroad tracks and roadways on or just beyond their property boundary, in areas where these organizations assert few or no members of the general public are expected to be present. These requests resurfaced in comments on the draft revised policy that was made available for informal public comment. Furthermore, some commenters argued that the EPA's historic focus on a fence or other physical barriers is outdated in that it does not address or allow consideration of additional security technology and other measures by which public access may be precluded (*e.g.*, routine security patrols, remote surveillance cameras, drones). Some commenters also pointed out that a fence or physical barriers are not mandated by the regulatory definition of ambient air and, therefore, the EPA's ambient air policy should not consider them to be the only allowable means of precluding public access. On

---

[11] *See*, 50 FR 7056, 7057 (February 20, 1985). In this instance, Kennecott maintained that public access was precluded from ambient air by a combination of rugged terrain, dense vegetation, limited perimeter fencing, no-trespassing signs and security patrols.

[12] *See REDOIL v. EPA*, 716 F.3d 1155, 1164-65 (9th Cir. 2012) (a proposed offshore drill ship in the Arctic Ocean seeking a PSD permit was allowed to exempt from ambient air a "safety zone" surrounding the ship that was established by the U.S. Coast Guard and effectively precluded public access); *see also* EPA memorandum from Phil Millam, Region X, to Randy Poteet, ARCO Alaska, Inc., titled "Arco Alaska Permit Application for Beaufort Sea Exploratory Drill Project," March 1, 1993 (EPA regional comment letter asking ARCO to certify that an exclusionary safety zone exists with reasonable zone boundary control measures for EPA to consider the area to be controlled by the source, and therefore, excluded from being considered ambient air).

the other hand, some commenters argued that the EPA's 1980 policy allowing an exemption for fenced land owned or controlled by a source was contrary to law.[13] These stakeholders argued that the regulatory definition should be revised through rulemaking to eliminate or narrow the exclusion for areas external to buildings. Other commenters argued that the draft revised policy would further loosen the existing policy and therefore would be clearly inappropriate.

III. CORE ELEMENTS OF REGULATORY DEFINITION OF "AMBIENT AIR"

Considering these views of interested stakeholders, the EPA has evaluated the terms in the regulatory definition of ambient air and identified three core conceptual elements: "access," "general public," and "external to buildings." The EPA then considered how each of these terms or phrases has been applied under the existing ambient air policy and whether additional flexibility or clarification may be appropriate, consistent with the existing regulatory definition of ambient air. The EPA concluded that it is reasonable and appropriate to update its ambient air policy[14] concerning methods for precluding public access to source property in order to facilitate greater flexibility in light of developments and experience since the 1980 letter, while at the same time ensuring that the public health protection afforded by the 1980 letter is maintained.

Consistent with past practice and the discussion above, the EPA continues to interpret the term "access" to encompass two key concepts: legal access and physical or practical access.[15] Some commenters argued that the EPA's policy should allow areas to be excluded where there is no legal access, even if there is physical access, by the general public. They argued that physically precluding public access should not be necessary under the ambient air policy because it is not specifically required by the CAA or the regulatory definition of ambient air. Commenters also argued that persons entering private property without the owner's permission are trespassers and therefore their access is unlawful and irrelevant. While the regulatory definition of "ambient air" does not use some of the terms reflected in the EPA's ambient air policy, the definition also does not explicitly exclude any area external to buildings. The exclusion for such areas is reasonably inferred as the inverse of what is affirmatively covered ("areas ... to which the general public has access"). Nor does the regulatory definition prescribe specific criteria that are in conflict with the EPA's policy. The EPA 's view is that the approach advocated by these commenters of focusing only on legal access reads the term "access" too narrowly and ignores the EPA's longstanding

---

[13] One commenter cited memoranda issued in 1972 and 1977; *see* Appendix for the EPA's response.

[14] Some commenters refer to the 1980 letter as an EPA interpretation, but it also contains statements of EPA policy. The 1980 letter stated the EPA was retaining "the existing policy" that "the exemption from ambient air is available only for the atmosphere over land owned or controlled by the source and to which public access is precluded by a fence or other physical barriers." The policy clarified how the EPA intended to apply the concept in the regulatory definition of the general public having (or not having) "access" to property (and the air above it). Although not expressly stated in Administrator Costle's letter, that letter, and this revised policy, "interpret" the regulatory definition to be inapplicable to areas outside of buildings to which the general public does not have access and read the term "access" to encompass both legal and practical access. The 1980 letter and this revised policy then proceed to provide policy guidance as to the conditions under which the EPA believes it may be appropriate for one to conclude that general public does not have such access to an area. This revised policy describes how the EPA intends to exercise its discretion to determine whether the public has access based on record-based facts (and provides guidance for others to do likewise).

[15] The word "access" has a variety of meanings. As used for applying the regulatory definition of ambient air ("atmosphere . . . to which the public has access"), the EPA believes the term encompasses both the public's *legal right* and the public's *practical ability* to enter a particular parcel of land.

PET 778

REC 1144

understanding that the general public may have access based on, not only the right, but also the ability, to enter an area.

The first aspect of the access element (*i.e.*, legal access) concerns whether the general public has the right or permission to enter a specific property. Under the ambient air policy as described in the 1980 letter, an exclusion from ambient air is available only for areas owned or controlled by the source (*i.e.*, the source has legal authority, via ownership or control, to preclude access by the public).

Although the draft revised policy did not propose any change in this element of the ambient air policy, some commenters advocated that the EPA allow exclusions of property owned or controlled by other parties. These commenters argued that the regulatory definition of "ambient air" does not mandate that the *source* own or control the land from which the public is otherwise precluded. As discussed above, the EPA's policy allowing exclusion of some areas external to buildings is not based on language in the regulatory definition mandating exclusion or providing particular criteria for such an exclusion, but rather, is inferred as the inverse of what is affirmatively covered by that definition (*i.e.*, if "ambient air" is defined as that to which the general public has access, then that to which the general public does not have access is not ambient air). The EPA's view is that the general public has legal access to areas that are owned and controlled by parties other than the owner or operator of a stationary source. The EPA continues to view the "general public" to include any person(s) other than those who are permitted access to the property as employees or business invitees of a specific stationary source (including trespassers). Although a landowner who owns a stationary source downwind of another landowner's separate stationary source may restrict public access onto his or her private property, the owner and the individuals that are permitted access to his or her downwind property are, generally speaking, members of the general public relative to the upwind stationary source. An alternative reading of "general public" that excludes all persons on any private property to which access is restricted (*e.g.*, private homeowners with fenced yards) would expand the exclusion beyond reason and deny the protection of the NAAQS to large numbers of people. This revised policy makes no change to the "owned or controlled by the source" and "general public" elements of the policy.

The second aspect of the access element (*i.e.*, physical or practical access) addresses whether the general public is able to, under actual circumstances, enter a particular parcel of land. As discussed above, the EPA stated in the 1980 letter that for an area to be excluded from ambient air, public access should be precluded by means of a fence or other physical barriers. Since 1980, the EPA has found that a natural barrier (*e.g.*, steep cliff, rugged terrain or dense vegetation), was sufficient, in the absence of a man-made barrier like a wall or fence, to prevent public access, in some situations.[16]

---

[16] *See* 50 FR 7056, 7057 (February 20, 1985). On a related issue, one commenter cited two EPA memos from 1985 and 2000 for the conclusions that "a shoreline by itself is not a sufficient barrier to public access" and "publicly accessible areas such as highways and rivers may show violations of NAAQS," respectively. The EPA believes the revised policy would not necessarily result in different conclusions, depending on the facts presented. Relevant factors for an air agency to determine whether an unfenced "shoreline" is a sufficient barrier to preclude public access across the border of a source property may include: the ability of users of the water body (*e.g.*, boaters, to access the shore in that location, whether the general public has access to the water body, and whether the source uses any additional measures, such as signage and video surveillance). Regarding a highway or river, the revised policy makes no change

Based on concerns that a physical barrier is not always needed to restrict access, the EPA invited public comments on a draft revised ambient air policy that would replace the term "a fence or other physical barriers" in the "access" element of the policy with the broader term "measures, which may include physical barriers, that are effective in deterring or precluding access to the land by the general public."[17] Some commenters agreed that "fences or other physical barriers" should not always be necessary for precluding public access.

Recognizing advances in security technologies and greater experience in the diversity of ambient air scenarios since the 1980 letter, the EPA's view is that a source can in many instances employ measures, other than fencing or other physical barriers, or in combination with fencing or other physical barriers, to effectively preclude public access. While sources often use traditional fencing at the boundary of a facility, there are examples of other measures, of which more than one may be used in combination, that have been effective in precluding public access when adequate procedures are followed (*e.g.*, video surveillance, monitoring, clear signage, routine security patrols). Furthermore, the EPA recognizes that there will be future technologies such as drones and more advanced video surveillance capabilities, that will potentially be used to preclude public access.[18]

The EPA does not regard this revision as a fundamental change to the longstanding ambient air policy. For example, under the prior policy, it was always possible for some fences to be scaled and other types of barriers to be breached.[19] The EPA agrees with commenters who stated that a fence is an effective means of precluding public access, but even a fence, depending on factors such as its height, composition, scalability, resistance to damage or tunneling and remoteness of location, will not in all conceivable situations prevent persons who desire to gain access (although

---

to the "owned or controlled by the source" element, as stated above, so the EPA generally would not expect the revised policy to change a determination of whether an area should be excluded from ambient air, where it includes "publicly accessible areas such as highways and rivers" since such areas generally are not owned or controlled by the source. Thus, the EPA sees no conflict between past policy memorandums and the revised policy.

[17] In the draft revised policy made available for public comment, the EPA used the word "deter" in addition to "preclude." This was intended to acknowledge that non-physical measures might be defeated (perhaps temporarily) by a deliberate trespasser in a manner similar to a physical obstruction, but this scenario is appropriately defined through the word "preclude" such that the word "deter" is not necessary in this context. The EPA maintains its view that any type of measure employed by a source should preclude public access to justify excluding a portion of source property from ambient air and its effectiveness in doing so should be evaluated on a case-by-case basis.

[18] By listing examples in this paragraph, the EPA does not suggest that any such measure by itself will be effective in precluding access to any particular property without procedures that ensure that the measure will be used in a manner that effectively precludes public access. Nor, by listing examples, does the EPA intend to foreclose the possibility that some other measure or measures not listed as an example might be effective in precluding access to any particular property. The determination by an air agency of whether access to any particular property is precluded is fact-based and facility-specific.

[19] One commenter argued that "the fact that even 'physical barriers' conceivably could be scaled or breached means that 'the general public has access" within the meaning of 40 CFR § 50.1(e), even if a fence or other physical barrier is used. The EPA believes that the regulatory definition is reasonably read not to require absolute certainty that no one could ever overcome a fence or other physical (or non-physical) barriers around a source. Another commenter noted that some physical barriers such as "short walls, three-rail fences, [or] easily scaled walls or fences" may be insufficient to actually prevent access. The EPA believes that the effectiveness of particular measures, whether physical or non-physical, to preclude public access should be addressed by the source and the air agency on a case-by-case basis considering the totality of the circumstances.

unlawfully) to a source's property. Generally, the air agency[20] should be satisfied that the measures proposed by the source are adequate to assure that the general public will not have access under reasonably anticipated circumstances that could occur in the area. This revised policy does not prescribe, approve, or disallow any specific types of measures (physical barriers or otherwise) that may be used to preclude public access. Rather, this revised policy calls for staff at the EPA (and other air agencies as well) to carefully assess measures proposed by a source to preclude public access under specific, factual circumstances. The goal of such an assessment is to be satisfied that the measures (whether physical or not) proposed by a source are effective in precluding public access under the circumstances presented. Thus, under this revised policy, measures may be considered effective, under a given set of circumstances, even if there is not 100 percent certainty that they will prevent public access.[21]

The EPA will apply a rule of reason in evaluating the effectiveness of any measures proposed by a source. In doing so, this evaluation should address relevant factors, such as the nature of the measure used (*e.g.*, physical or non-physical), source location, type and size of source and property to be excluded, surrounding area (including the proximity, nature, and size of the population in the area), and other factors affecting whether members of the general public would readily be able to trespass upon or otherwise have access to the source's property. Air agencies should consider all relevant information provided by the source or other interested parties, or otherwise available to the air agencies, regarding the effectiveness of the measures to prevent public access. For instance, the use of clearly visible, well-spaced "No Trespassing" signs in conjunction with some degree of fencing or other physical and/or non-physical barriers, may potentially be effective to preclude access by the general public in appropriate situations. In other cases, such as in areas accessible to children (*e.g.*, areas adjacent to schools), or where the nature of the property offers an incentive for persons to access or trespass (*e.g.*, a short cut to a destination), it may be necessary to use a different combination of measures to effectively preclude public access.

Related to the use of measures (particularly non-physical measures) to preclude public access is the question of whether such measures should be addressed in enforceable conditions (*e.g.*, PSD permit conditions). Although the draft revised policy did not address this issue, a few commenters submitted comments either supporting or opposing inclusion of such measures as enforceable permit terms. One air agency commented that while a physical barrier such as existing source fencing can be reasonably considered to be fixed and to last for the operational life of the source, a non-physical measure may warrant consideration as a permit term, especially where the measure does not "correspond with the facility's [source's] operational footprint." EPA will consider the need for enforceable permit conditions on a case-by-case basis and other air agencies may similarly exercise discretion in determining whether a permit condition is appropriate to ensure that a source administers the selected measures in a way that maintains continued public health protection. For example, security procedures and maintenance of surveillance records might be considered as enforceable permit conditions to help ensure that a particular measure continues to be carried out in an effective manner. A permit condition may be appropriate if, for example, a

---

[20] "Air agency" refers to a state, local or tribal air permitting agency and may also refer to the EPA, depending on the context.

[21] *See* discussion at fn.17.

PET 781

REC 1147

decision was made to exclude a model receptor at a particular location where, prior to implementation of effective measures to preclude public access, there was an historic practice of allowing public access to the area of concern.

As previously stated, determinations concerning the adequacy of measures to preclude public access should be made on a case-by-case basis after consideration of information in the relevant administrative record. When an air agency, other than the EPA, is responsible for the determination, EPA Regional offices will be available to assist as needed.

IV. CONCLUSION

In setting forth this revised ambient air policy, the EPA is making a limited change to the way it applies the "access" element in the regulatory definition of ambient air, while maintaining the level of public health protection afforded by the original policy. This narrow change is that the EPA will no longer consider a fence or other physical barriers to be the exclusive means by which public access may be effectively precluded for purposes of excluding an area owned or controlled by the source from ambient air under the regulatory definition. Accordingly, the EPA is replacing a concept in the 1980 letter with a broader concept of measures, which may include physical barriers, that are effective in precluding access by the general public. Thus, the EPA's revised ambient air policy, consistent with its discretion available under the regulatory definition of ambient air, is that *the atmosphere over land owned or controlled by the stationary source may be excluded from ambient air where the source employs measures, which may include physical barriers, that are effective in precluding access to the land by the general public.*

This revised policy is intended to be implemented by EPA Regional offices and by those air agencies to which the EPA has delegated its authority to issue federal PSD permits under 40 CFR § 52.21(u). The EPA is also making this policy available as guidance for consideration by air agencies with SIP-approved programs. Depending on the particular regulatory context and wording of the applicable SIP, air agencies implementing a SIP-approved program may be able to use this revised policy. In addition to PSD permitting, the EPA intends, as appropriate, to apply the revised policy to other NAAQS-related assessments and characterizations of air quality.

This revised policy is neither a regulation subject to notice-and-comment rulemaking requirements nor a final agency action. This action does not amend the definition of "ambient air" in EPA regulations at 40 CFR § 50.1(e) and does not create or change any legal requirements on the EPA, on state, local and tribal agencies or on the public. This document does not determine that any particular area or type of area may be excluded from ambient air on the basis of particular measures taken to preclude public access. Determinations concerning the adequacy of such measures can only be made by air agencies on a case-by-case basis after consideration of the relevant administrative record in each case. State and local air agencies are not required to apply this policy and retain their existing discretion to require measures (including fences or physical barriers) that they consider appropriate in each circumstance to establish that the general public does not have access to all or a portion of a source's property.

Appendix

One commenter cited a May 23, 1977, memorandum from Walter C. Barber, Director of the Office of Air Quality Planning and Standards titled, "Applicability of PSD Increments over Company Property." That memorandum addressed the question of whether PSD increments apply over a proposed source's property if the general public is effectively precluded from access to that property. The response to this question has the word "yes" crossed out and "no" written in its place; the response also says "[t]his issue has been addressed with respect to the NAAQS" in an OAQPS Guideline and a 1972 memorandum from the Office of General Counsel. The response goes on to state that PSD increments should be treated the same as the NAAQS in this respect and "[t]herefore, as indicated in the OGC memorandum, the test for determining if public access is effectively precluded requires some kind of physical barrier." The response attaches a September 28, 1972, memorandum from Michael A. James, Attorney, OGC, Air Quality and Radiation Division, to Jack R. Farmer, Chief, Plans Management Branch, Standards Development and Implementation Division that states that, in the context of identifying sites for air monitoring equipment to be located near certain smelters that were the subject of a pending rulemaking, the phrase "to which the general public has access" in the EPA's regulatory definition of "ambient air" was "most reasonably interpreted as meaning property which members of the community at large are not physically barred in some way from entering." The "Discussion" section of the 1972 memorandum quotes 40 CFR § 50.1(e) and expresses the view that the regulatory definition limits the applicability of the NAAQS to the atmosphere outside the facility fenceline "since 'access' is the ability to enter," citing a dictionary definition of "access" as "permission, liberty, or ability to enter." Administrator Reilly referenced this portion of the memorandum in a 1989 decision on the appeal of a PSD permit. *In re Hibbing Taconite*, 2 E.A.D. 838 (Admr. 1989).

The 1972 memorandum further explains that areas to which access has not been restricted by physical means can be trespassed upon and that persons, whether knowing or innocent trespassers, would be exposed to air above the property. The memorandum disagrees with treating the property line, rather than the fenceline within the property, as the boundary for ambient air for two reasons: 1) "access" includes the right or the ability to enter; and 2) a definition of "ambient air" that excepts fenced private property is "probably inconsistent" with section 107 of the CAA, and expanding the exception is "clearly not legally supportable." The memorandum goes on to say that "an argument can be made" that 40 CFR § 50.1(e) is not inconsistent with section 107 of the CAA as to primary NAAQS but that no such argument applies to secondary NAAQS.

While Administrator Reilly subsequently relied on a portion of the 1972 attorney memorandum to support his decision in the *Hibbing Taconite* permit appeal, EPA decisionmakers have not endorsed all the views expressed in the memorandum. First, the 1972 memorandum does not express the official position of the EPA's General Counsel. Instead, it was a response from an EPA line attorney to questions posed by a program office branch chief, and as such, is more appropriately viewed as an internal communication rather than a statement of the EPA's position or views. While the memorandum advised that the existing, duly promulgated regulatory definition of ambient air, unchanged since its issuance, was "probably inconsistent" with section 107 of the CAA, the EPA did not subsequently take any action to revise the definition on this basis. The revised policy is intended to implement, not revise, the regulatory definition. In addition, the 1977 OAQPS memorandum attached to the 1972 memorandum, did not adopt or endorse all of the

discussion by the line attorney. It appears the attorney memorandum was attached merely to show that the issue in the 1977 memorandum (whether PSD increments apply over a proposed source's land) had already been addressed previously in the analogous context of whether NAAQS apply over a proposed source's land. The EPA's ambient air policy was authoritatively stated in the 1980 letter and 1989 adjudication by the EPA's Administrator, and thus the views expressed in the 1977 memoranda and portions of the 1972 memorandum that were not referenced in the 1989 adjudication did not become part of the EPA's ambient air policy.

The revised policy is consistent with the principal view expressed in the 1972 memorandum that the border of the ambient air surrounding a source is not automatically out at the property line, but rather is located where there is an effective measure, whether a physical barrier or not, to preclude public access. The only specific ambient air issue addressed in the 1972 memorandum was whether a property line or fenceline should be used as the border of ambient air, and the memorandum concluded a fenceline was more appropriate because "access" in the regulatory definition meant "the ability to enter" and trespassers could enter the property if there was no physical barrier.

The 1972 memorandum also asserted a policy conclusion that the only type of effective measure to preclude access was a physical barrier, which was essentially a factual conclusion rather than a legal interpretation of the regulatory language. Such a factual conclusion is inherently subject to change over time, as developments occur in the availability and effectiveness of measures to preclude public access to property. Although the incoming questions from the program branch chief refers to signage, the 1972 memorandum did not provide factual information to show that signs or other potential means of precluding access could never be effective to preclude access by the general public.

As explained in the body of this document, the EPA believes the clarification and flexibility provided in the revised policy is reasonable, appropriate, and consistent with the existing regulatory definition of ambient air in 40 CFR § 50.1(e).

SUBJECT: Guidance an Enforceability Requirements for Limiting Potential to Emit through SIP and §112 Rules and General Permits

FROM: Kathie A. Stein, Director
Air Enforcement. Division

TO: Director, Air and, Pesticides and Toxics
Management Division, Regions I and IV
Director, Air and Waste Management Division,
Region II
Director, Air, Radiation and Toxics Division,
Region III
Director, Air and Radiation Division,
Region V
Director, Air, Pesticides and Toxics Division,
Region VI
Director, Air and Toxics Division,
Regions VII, VIII, IX, and X

Attached is a guidance document developed over the past year by the former Stationary Source compliance Division in coordination with the Air Enforcement Division, Office of Air Quality Planning and Standards$ OAR's Office of Policy Analysis and Review, and the Office of General Counsel, as well-as with significant input from several Regions.

A number of permitting authorities have begun discussions with or have submitted programs for review by EPA that would provide alternative mechanisms for limiting potential to emit Several authorities have submitted SIP rules and at least one State has been developing a state general permit approach.; We believe that this guidance is important to assist the EPA Regions as well as States in approving and developing such approaches.

For additional information regarding this guidance, please contact me or Clara Poffenberger of my staff at (202) 564-8709.

Air Branch Chiefs, Regions I -X

Enforceability Requirements for Limiting potential to Emit Through SIP and §112 Rules and General Permits

Introduction

As several EPA guidance describe, there are several mechanisms available for sources to limit potential to emit. EPA guidance have also describe the importance of practical enforceability or the means used to limit the Potential to Emit. This guidance is intended to provide additional guidance on practical enforceability for such limits. We provide references for guidance an practical enforceability for permits and rules in general and provide guidance in this document for application of the same principles to "limitations established by rule or general permit," as described in the guidance document issued January 25, 1995, entitled "Options for Limiting Potential to Emit (PTE) of a Stationary Source under section 112 and Title V of the Clean Air Act (Act)." The description is as follows:

> Limitations established by rules. For less complex plant sites, and for source categories involving relatively few operations that are similar in nature, case-by-case permitting may not be the most administratively efficient approach to establishing federally enforceable restrictions. One approach that has been used is to establish a general rule which creates federally enforceable restrictions at one time for many sources (these rules have been referred to as "prohibitory" or "exclusionary" rules). The concept of exclusionary rules is described in detail in the November 3, 1993 memorandum ["Approaches to Creating Federally Enforceable Emissions Limits," from John S. Seitz]. A specific suggested approach for VOC limits by rule was described in EPA's memorandum dated October 15, 1993 entitled "Guidance for State Rules for Optional Federally Enforceable Emissions Limits Base Upon Volatile Organic Compound (VOC) Use." An example of such an exclusionary rule is a model rule developed for use in California. (The California model rule is attached, along with a discussion of its applicability to other situations - see Attachment 2). Exclusionary rules are included in a State's SIP or 112 program and generally become effective upon approval by the EPA.

The EPA prefers the term "exclusionary rule" in that this phrase is a less ambiguous description of the overall purpose of these rules.

General permits -A concept similar to the exclusionary rule is the establishment Of a general permit for a given source type. A general permit is a single permit that establishes terms and conditions that must be complied with by all sources subject to that permit. The establishment of a general permit could provide for emission limitations in a one-time permitting process, and thus avoid the need to issue separate permits for each source. Although this concept is generally thought of as an element of Title V permit programs there in no reason that a state or local agency could not submit a general permit program as a SIP submittal Aimed at creating synthetic minor sources. Additionally FESOP [Federally Enforceable State Operating Permit usually reffering to Title I State OperatingPermit Programs approved under- the criteria established by EPA in the June 28, 1989 Federal Register notice, 54 FR 27274] programs can include general permits as an element of the FESOP program being approved into the SIP. The advantage of a SIP general permit, when compared to an exclusionary rule, is that upon approval by the EPA of the state's general permit program, a general permit could be written for an additional source type without triggering the need for the formal SIP revision process. (January 25, 1995 Seitz and Van Heuvelen memorandum, page 4.)

SIP or §112 Rules

Source-category standards 'approved in the. SIP. or under 112,if enforceable as a. practical matter, can be used as federally enforceable limits on potential to emit. Such provisions require public participation and EPA review. Once a specific source qualifies under the applicability requirements of the source category rule, additional public participation is not required to make the limits federally enforceable as a matter of legal sufficiency since the rule itself underwent public participation and EPA review. The rule must still be enforceable as practical matter in order to be considered federally enforceable. A source that violates this type of rule limiting potential to emit below major a source thresholds or is later determined not to qualify for coverage under the rule, could be subject to enforcement action for violation of the rule and for constructing or operating without a proper permit (a. part 70, a New Source Review permit, or operating without meeting §112 requirements, or any combination thereof).

General Permits

The title V regulations set out provisions for general permits covering numerous similar sources. The primary purpose of general permits is to provide a permitting alternative where

the normal permitting process would be overly burdensome, such as for area sources under section 112. General permits may be issued to cover any category of numerous similar sources, including major sources, provided that such sources meet certain criteria laid out in 40 CFR part 70. Sources may be issued general permits strictly for the purpose of avoiding classification as major source. in other words, general permits may be used to limit the potential to emit for numerous similar sources. However, general permits must also most both legal and practical federal enforceable requirements.

With respect to legal sufficiency, the operating permit regulations provide that once the general permit has been issued, after opportunity for public participation and, EPA and affected State review, the permitting authority may grant or deny a sources request to be covered by a general permit without further public participation or EPA or affected State review. The action of granting or denying the source's request is not subject to judicial review. A general permit does not carry a permit shield. A source may be subject to enforcement action for operating without a part 70 permit if the source is later determined not to qualify for coverage under the general permit. Sources covered by general permits must comply with all part 70 requirements.

State SIP or 112(l) General Permits

Another mechanism available to limit potential to emit is a general permit program approved into the SIP or under section 112(1), the hazardous air pollutant program authority. This mechanism allows permitting authorities to issue and revise general permits consistent with SIP or 112(1) program requirements without going through the SIP or 112(1) approval process for each general permit or revision of a general permit. The program is also separate from title V, like Title I state operating permits, and issuance and revisions of the permits are to comply with title V procedures.

Once a program is approved, issuing and revising general permits should be significantly less burdensome and time-consuming for State legislative and rulemaking authorities. The EPA review should also be less burdensome and time-consuming. After a program is approved, permitting authorities have the flexibility to submit and issue general permits as needed rather than submitting them all at once as part of a SIP submittal. Given the reduced procedural burden, permitting authorities should be able to issue general permits to small groups or categories or sources rather than attempt to cover broad categories with a generic rule. We anticipate that specific permit requirements or general permits may be readily developed with the assistance of interested industry groups.

The state general permit approach may allow sources to meet the federal the federal enforceability requirements more easily than other approaches. However, to use this approach, states must have a federally enforceable program that provides the state the authority, to issue such permits; to accomplish this, EPA must approve the program into the SIP or pursuant to section. 112(1) of the Clean Air Act.

Enforceability Principles

In 1989, in response to challenges from the Chemical Manufacturers Association and other industry groups, EPA reiterated its position that controls and limitations used to limit a source's Potential to emit must be federally enforceable. See 54 FR 27274 (June 28, 1989). Federally enforceable limits can be established by Clean Air Act programs such as NSPS, NESHAPs, MACTs, and SIP requirements. However, source-specific limits are generally set forth in permits. Generally, to be considered federally enforceable, the permitting program must be approved by EPA into the SIP and include provisions for public participation. "In addition, permit terms and conditions must be practicably enforceable to be considered federally enforceable. EPA provided specific guidance on federally enforceable permit conditions in a June 13, 1989 policy memo "Limiting Potential to Emit in New Source Permitting" from John Seitz and in the June 28, 1989 Federal Register notice (54 FR 27274) Additional guidance Can also be found in United states v. Louisiana Pacific,682 F. Supp 1122 (D. Colo. 1987) 682 F. Supp 1141 (D. Colo.1988), which led to these guidance statements and a number of other memoranda covering practicable enforceability as it relates to rolling averages, short-term averages, and emission caps. See "Use of Long Term Rolling Averages to Limit Potential to Emit," form John. B. Rasnic to David Kee, February 24, 1992; "Limiting Potential to Emit;" from Mamie Miller to George Czerniak, August, 1992; "Policy Determination an Limiting Potential to Emit for Koch Refining Company's Clean Fuels Project", from John B. Rasnic to David Kee, March 13, 1992; and "3M Tape Manufacturing Division Plant, St. Paul, Minnesota" from. John B. Rasnic to David Kee, July 14, 1992.

In 1987, EPA laid out enforceability criteria that SIP rules must meet. see "Review of State Implementation Plans and Revisions for Enforceability and Legal Sufficiency," from Michael Alushin, Alan Eckert, and John Seitz, September 3, 1987 (1997 SIP memo). The criteria include clear statements as to applicability, specificity as to the standard that must be met, explicit statements of the compliance time frames (e.g. hourly, daily, monthly, or 12-month averages, etc.), that the time frame and method of compliance employed must be sufficient to protect the standard involved, record keeping requirements must be specified, and equivalency provisions must meet certain requirements.

Based an these precedents this guidance describes six enforceability criteria which a rule or a general permit must meet to make limits enforceable as a practical matter. In general, practical enforceability for a source-specific permit term means that the provision must specify (1) a technically accurate limitation and the portions of the source subject to the limitation; (2) the time period for the limitation (hourly, daily, monthly, annually); and (3) the method to determine compliance including appropriate monitoring, record keeping and reporting. For rules and general permits that apply to categories of sources, practical enforceability additionally requires that the provision (4) identify the categories of sources that are covered by the rule; (5) where coverage is optional, provide for notice to the permitting authority of the source's election to be covered by the rule; and (6) recognize the enforcement consequences relevant to the rule.

This guidance will address requirements (4) "arid (5) first as they are concepts that are unique to rules and general' permits.

A. Specific Applicability

Rules and general permits designed to limit potential to emit must be specific as to the emission units or sources covered by the rule or permit. In other words, the rule or permit must clearly identify the category(ies) of the sources that qualify for the rule's coverage. The rule must apply to categories of sources that are defined specifically or narrowly enough so that specific limits and compliance monitoring can be identified and achieved by all sources in the categories defined.

A rule or general permit that covers, a homogeneous group of sources should allow standards to be set that limit potential to emit and provide the specific monitoring requirements. (Monitoring is more fully addressed in section D.) The State can allow for generic control efficiencies where technically sound and appropriate, depending on the extent of the application and ability to monitor compliance with resultant emission limits. Similarly, specific and narrow applicability may allow generic material usage or limits on hours of operation to be sufficient. For example, a rule or general permit that applies to fossil fuel fired boilers of a certain size may allow for limits on material usage, such as fuel-type and quantity. A rule or general permit that applies, only to standby diesel generators or emergency generators may allow restrictions on hours of operation to limit potential to emit. The necessary compliance terms (i.e., monitoring or record keeping) associated with any of these limits, such as with hours of operation, can readily be specified in the rule or the general permit itself.

General permits under Title V are assumed to include this

PET 791

REC 1157

enforceability principle because the Part 70 regulations set out specific criteria that states should consider in developing their general permit provisions (See 57 FR 32278). These factors include requirements that

> "categories of sources covered by general permits should be generally homogenous in terms of operations, processes, and emissions. All sources in the category should have essentially similar operations or processes and emit pollutants with similar characteristics."

Another factor stated is "sources should be subject to the same or substantially similar requirements governing operation, emissions, monitoring, reporting, or record keeping." Examples of source categories appropriate for general permits include: degreasers, dry cleaners, small heating systems, sheet fed printers, and VOC storage tanks (see 57 FR 32278).

B. Reporting or Notice to Permitting Authority

The rule or general permit should provide specific reporting requirements as part of the compliance method. Although the compliance method for all sources must include record keeping requirements, the permitting authority may make a determination that reporting requirements for small sources would provide minimal additional compliance assurance. Where ongoing reporting requirements are determined not to be reasonable for a category of sources, the rule or general permit should still provide that the source notify the permitting authority of its coverage by the rule or the permit. In the limited situation where all the sources described in a source category are required to comply with the all of the provisions of a rule or general permit, notice is not needed. However, where there are no reporting requirement's and no opt-in provisions, the permitting authority must provide the public with the names and locations of sources subject to the rule or permit.

For Title V general permits, Part 70 requires sources to submit an application for a general permit which must be approved or disapproved by the permitting authority. For SIP or §112 rules and SIP or §112 general permits, in response to receiving the notice or application, the permitting authority may issue an individual permit, or alternatively, a letter or certification. The permitting authority may also determine initially whether it will issue a response for each individual application or notice, and may initially specify a reasonable time period after which a source that has submitted an application or notice will be deemed to be authorized, to operate under the general permit or SIP or §112 rule.

C. Specific Technically Accurate Limits

The rule or general permit issued pursuant to the SIP or §112 must specify technically accurate limits on the potential to emit. The rule or general permit must clearly specify the limits that apply, and include the specific associated compliance monitoring. (The compliance monitoring requirements are discussed further in the next section.) The standards or limits must be technically specific and accurate to limit potential to emit, identifying any allowed deviations.

The 1987 policy on SIP enforceability states that limitations "must be sufficiently specific so that a source is fairly on notice as to the standard it must meet." For example, "alternative equivalent technique" provisions should not be approved without clarification concerning the time period over which equivalency is measured as wall as whether the equivalency applies on a per source or per line basis or is facility-wide.

Further, for potential to emit limitations, the standards set must be technically sufficient to provide assurance to EPA and the public that they actually represent a limitation on the potential to emit for the category of sources identified. Any presumption for control efficiency must be technically accurate and the rule must provide the specific parameters as enforceable limits to assure that the control efficiency will be met. For example, rules setting presumptive efficiencies for incineration controls applied to a specific or broad category must state the operating temperature limits or range, the air flow, or any other parameters that may affect the efficiency on which the presumptive efficiency is based. Similarly, material usage limits such as fuel limits, as stated above, require specifying the type of fuel and may require specifying other operating parameters.

A rule that allows sources to submit the specific parameters and associated limits to be monitored may not be enforceable because the rule itself does not set specific technical limits. The submission of these voluntarily accepted limits on parameters or monitoring requirements would need to be federally enforceable. Absent a source-specific permit and appropriate review and public participation of the limits, such a rule is not consistent with the EPA's enforceability principles.

D. Specific compliance Monitoring

The rule must specify the methods to determine compliance. Specifically, the rule must state the monitoring requirements, record keeping requirements, reporting requirements, and test methods as appropriate for each potential to emit limitation; and clarity which methods are used for making a direct determination of compliance with the potential to emit limitations.

PET 793

REC 1159

"Monitoring" refers to many different types of data collection, including continuous emission or opacity monitoring, and measurements of various of Parameters of process or control devices (e.g. temperature, pressure drop, fuel usage) and record keeping of parameters that been limited ,such as hours of operation, production levels, or raw material usage. Without a verifiable plantwide, verifiable emission limits must assigned to each unit or group of units subject to the subject to he rule or general permit. Where monitoring cannot be used to determine emissions directly, limits on appropriate operating parameters must be established for the units or source, and must the monitoring must be sufficient to yield data form the relevant time period that is representative of the source's compliance with the standard or limit. Continuous emissions monitoring, especially in the case of smaller sources, is not required.

E. Practicably Enforceable Averaging Times

The averaging time for all limits must be practicably enforceable. In other words, the averaging time period must readily allow for determination of compliance. EPA policy expresses a preference toward short term limits, generally daily but not to exceed one month. However, EPA policy allows for rolling limits not to exceed 12 months or 365 days where the permitting authority finds that the limit provides an assurance that compliance can be readily determined and verified. See June 13, 1989 "Guidance on Limiting Potential to Emit," February 24, 1992 memorandum "Use of Long Term Rolling Averages to Limit Potential to Emit" from John Rasnic to David Kee and March 13 1992 "Policy Determination on Limiting Potential to Emit for Koch Refining Company Clean Fuels Project" from John B. Rasnic to David Kee, stating that determinations to allow an annual rolling average versus a shorter term limit must be made on a case by case basis. Various, factors weigh in favor of allowing a long term rolling average, such as historically unpredictable emissions. Other factors may weigh in favor of shorter term limit, such as the inability to set interim limits during the first year. The permitting agency must make a determination as to what monitoring and averaging period is warranted for the particular source-category in light of how close the allowable emissions would be to the applicability threshold.

F. Clearly Recognized Enforcement

Violations of limits imposed by the rule or general permit that limit potential to emit constitute violations of major source requirements. In other words the source would be violating a "synthetic minor" requirement which may result in the source being treated as a major source under Titles I and V. The 1989 Federal Register Notice provides for separate enforcement

and permitting treatment depending on whether the source subsequently chooses to become a major or remain minor. Thus violations of the rule or general permit or violation of the specific conditions of the rule or general permit subjects the source to potential enforcement under the Clean Air Act and state law. The operating permit rule states that not withstanding the shield provisions of part 70, the source subject to a general permit may be subject to enforcement action for operating without a part 70 permit if the source is later determined not to qualify or the conditions and terms of the general permit. Moreover, violation of any of the conditions of the rule or general permit may result in a different determination of the source's potential to emit and thus may subject the source to major requirements and to enforcement action for failure to comply with major source requirements from the initial determination.

G. Rule Requirements for State General Permit Programs

As discussed above, general permit programs must be submitted to EPA for approval under SIP authority or under section 112(1), or both, depending on its particular pollutant application. SIP and §112(1) approval and rulemaking procedures must be met, including public notice and comment. The specific application of the enforceability principles for establishing State SIP or §112(1) general permit programs require that the rule establishing the program set out these principles as rule requirements. In other words, these principles must be specific rule requirements to be met by each general permit.

The rule establishing the program must require that (1)general permits apply to a specific and narrow category of sources; (2) sources electing coverage under general permits where coverage is not mandatory, provide notice or reporting to the permitting authority; (3) general permits provide specific and technically accurate(verifiable) limits that restrict the potential to emit; (4) general permits contain specific compliance requirements; (5) Limits in general permits are established based on practicably enforceable averaging times; and (6) violations of the permit are considered violations of the state and federal requirements and result in the source being subject to major source requirements.

In addition, since the rule establishing the program does not provide the specific standards to be met by the source, each general permit, but not each application under each general permit, must be issued pursuant to public and EPA notice and comment. The 1989 Federal Register notice covering enforceability of operating permits requires that SIP operating permit programs issue permits pursuant to public and EPA notice and comment. Title V requires that permits, including general permits, be issued subject to EPA objection.

Finally, sources remain liable or compliance with major source requirements if the specific application of a general permit to the source does not limit the source's potential to emit below major source or major modification thresholds. (The limits provided in these mechanisms may actually limit the potential to emit of sources but may not limit the potential to emit for some sources to below the threshold necessary to avoid major source requirements. For example, a general permit for industrial boilers may in fact provide limits that are sufficient to bring a source with only two or three boilers to below the subject thresholds but a source with more than three boilers may have a limited PTE but not limited below the major source threshold.) Also, where the source is required to use another mechanism to limit potential to emit, i.e., a construction permit, the general permit may not be relied upon by the source or the State, to limit potential to emit.

Permits issued pursuant to the approved program, meeting the above requirements, are adequate to provide federally enforceable limits on potential to emit for New Source Review, title V, and §112 programs as long as they are approved pursuant to SIP (section 110) and section 112(1) authorities.

PET 796

REC 1162

13.2.2 Unpaved Roads

13.2.2.1 General

When a vehicle travels an unpaved road, the force of the wheels on the road surface causes pulverization of surface material. Particles are lifted and dropped from the rolling wheels, and the road surface is exposed to strong air currents in turbulent shear with the surface. The turbulent wake behind the vehicle continues to act on the road surface after the vehicle has passed.

The particulate emission factors presented in the previous draft version of this section of AP-42, dated October 2001, implicitly included the emissions from vehicles in the form of exhaust, brake wear, and tire wear as well as resuspended road surface material[25]. EPA included these sources in the emission factor equation for unpaved public roads (equation 1b in this section) since the field testing data used to develop the equation included both the direct emissions from vehicles and emissions from resuspension of road dust.

This version of the unpaved public road emission factor equation only estimates particulate emissions from resuspended road surface material [23, 26]. The particulate emissions from vehicle exhaust, brake wear, and tire wear are now estimated separately using EPA's MOBILE6.2 [24]. This approach eliminates the possibility of double counting emissions. Double counting results when employing the previous version of the emission factor equation in this section and MOBILE6.2 to estimate particulate emissions from vehicle traffic on unpaved public roads. It also incorporates the decrease in exhaust emissions that has occurred since the unpaved public road emission factor equation was developed. The previous version of the unpaved public road emission factor equation includes estimates of emissions from exhaust, brake wear, and tire wear based on emission rates for vehicles in the 1980 calendar year fleet. The amount of PM released from vehicle exhaust has decreased since 1980 due to lower new vehicle emission standards and changes in fuel characteristics.

13.2.2.2 Emissions Calculation And Correction Parameters[1-6]

The quantity of dust emissions from a given segment of unpaved road varies linearly with the volume of traffic. Field investigations also have shown that emissions depend on source parameters that characterize the condition of a particular road and the associated vehicle traffic. Characterization of these source parameters allow for "correction" of emission estimates to specific road and traffic conditions present on public and industrial roadways.

Dust emissions from unpaved roads have been found to vary directly with the fraction of silt (particles smaller than 75 micrometers [μm] in diameter) in the road surface materials.[1] The silt fraction is determined by measuring the proportion of loose dry surface dust that passes a 200-mesh screen, using the ASTM-C-136 method. A summary of this method is contained in Appendix C of AP-42. Table 13.2.2-1 summarizes measured silt values for industrial unpaved roads. Table 13.2.2-2 summarizes measured silt values for public unpaved roads. It should be noted that the ranges of silt content vary over two orders of magnitude. Therefore, the use of data from this table can potentially introduce considerable error. Use of this data is strongly discouraged when it is feasible to obtain locally gathered data.

Since the silt content of a rural dirt road will vary with geographic location, it should be measured for use in projecting emissions. As a conservative approximation, the silt content of the parent soil in the area can be used. Tests, however, show that road silt content is normally lower than in the surrounding parent soil, because the fines are continually removed by the vehicle traffic, leaving a higher percentage of coarse particles.

PET 797
REC 1163

Other variables are important in addition to the silt content of the road surface material. For example, at industrial sites, where haul trucks and other heavy equipment are common, emissions are highly correlated with vehicle weight. On the other hand, there is far less variability in the weights of cars and pickup trucks that commonly travel publicly accessible unpaved roads throughout the United States. For those roads, the moisture content of the road surface material may be more dominant in determining differences in emission levels between, for example a hot, desert environment and a cool, moist location.

The PM-10 and TSP emission factors presented below are the outcomes from stepwise linear regressions of field emission test results of vehicles traveling over unpaved surfaces. Due to a limited amount of information available for PM-2.5, the expression for that particle size range has been scaled against the result for PM-10. Consequently, the quality rating for the PM-2.5 factor is lower than that for the PM-10 expression.

PET 798

REC 1164

Table 13.2.2-1. TYPICAL SILT CONTENT VALUES OF SURFACE MATERIAL ON INDUSTRIAL UNPAVED ROADS[a]

Industry	Road Use Or Surface Material	Plant Sites	No. Of Samples	Silt Content (%)	
				Range	Mean
Copper smelting	Plant road	1	3	16 - 19	17
Iron and steel production	Plant road	19	135	0.2 - 19	6.0
Sand and gravel processing	Plant road	1	3	4.1 - 6.0	4.8
	Material storage area	1	1	-	7.1

PET 799
REC 1165

The following empirical expressions may be used to estimate the quantity in pounds (lb) of size-specific particulate emissions from an unpaved road, per vehicle mile traveled (VMT):

For vehicles traveling on unpaved surfaces at industrial sites, emissions are estimated from the following equation:

$$E = k\,(s/12)^a (W/3)^b \quad (1a)$$

and, for vehicles traveling on publicly accessible roads, dominated by light duty vehicles, emissions may be estimated from the following:

$$E = \frac{k\,(s/12)^a (S/30)^d}{(M/0.5)^c} - C \quad (1b)$$

where k, a, b, c and d are empirical constants (Reference 6) given below and

E = size-specific emission factor (lb/VMT)
s = surface material silt content (%)
W = mean vehicle weight (tons)
M = surface material moisture content (%)
S = mean vehicle speed (mph)
C = emission factor for 1980's vehicle fleet exhaust, brake wear and tire wear.

The source characteristics s, W and M are referred to as correction parameters for adjusting the emission estimates to local conditions. The metric conversion from lb/VMT to grams (g) per vehicle kilometer traveled (VKT) is as follows:

1 lb/VMT = 281.9 g/VKT

The constants for Equations 1a and 1b based on the stated aerodynamic particle sizes are shown in Tables 13.2.2-2 and 13.2.2-4. The PM-2.5 particle size multipliers (k-factors) are taken from Reference 27.

Table 13.2.2-2. CONSTANTS FOR EQUATIONS 1a AND 1b

Constant	Industrial Roads (Equation 1a)			Public Roads (Equation 1b)		
	PM-2.5	PM-10	PM-30*	PM-2.5	PM-10	PM-30*
k (lb/VMT)	0.15	1.5	4.9	0.18	1.8	6.0
a	0.9	0.9	0.7	1	1	1
b	0.45	0.45	0.45	-	-	-
c	-	-	-	0.2	0.2	0.3
d	-	-	-	0.5	0.5	0.3
Quality Rating	B	B	B	B	B	B

*Assumed equivalent to total suspended particulate matter (TSP)
"-" = not used in the emission factor equation

Table 13.2.2-2 also contains the quality ratings for the various size-specific versions of Equation 1a and 1b. The equation retains the assigned quality rating, if applied within the ranges of source conditions, shown in Table 13.2.2-3, that were tested in developing the equation:

Table 13.2.2-3. RANGE OF SOURCE CONDITIONS USED IN DEVELOPING EQUATION 1a AND 1b

Emission Factor	Surface Silt Content, %	Mean Vehicle Weight		Mean Vehicle Speed		Mean No. of Wheels	Surface Moisture Content, %
		Mg	ton	km/hr	mph		
Industrial Roads (Equation 1a)	1.8-25.2	1.8-260	2-290	8-69	5-43	4-17[a]	0.03-13
Public Roads (Equation 1b)	1.8-35	1.4-2.7	1.5-3	16-88	10-55	4-4.8	0.03-13

[a] See discussion in text.

As noted earlier, the models presented as Equations 1a and 1b were developed from tests of traffic on unpaved surfaces. Unpaved roads have a hard, generally nonporous surface that usually dries quickly after a rainfall or watering, because of traffic-enhanced natural evaporation. (Factors influencing how fast a road dries are discussed in Section 13.2.2.3, below.) The quality ratings given above pertain to the mid-range of the measured source conditions for the equation. A higher mean vehicle weight and a higher than normal traffic rate may be justified when performing a worst-case analysis of emissions from unpaved roads.

The emission factors for the exhaust, brake wear and tire wear of a 1980's vehicle fleet (*C*) was obtained from EPA's MOBILE6.2 model [23]. The emission factor also varies with aerodynamic size range

PET 801
REC 1167

as shown in Table 13.2.2-4

Table 13.2.2-4. EMISSION FACTOR FOR 1980'S VEHICLE FLEET EXHAUST, BRAKE WEAR AND TIRE WEAR

Particle Size Range[a]	*C*, Emission Factor for Exhaust, Brake Wear and Tire Wear[b] lb/VMT
$PM_{2.5}$	0.00036
PM_{10}	0.00047
PM_{30}[c]	0.00047

[a] Refers to airborne particulate matter (PM-x) with an aerodynamic diameter equal to or less than x micrometers.
[b] Units shown are pounds per vehicle mile traveled (lb/VMT).
[c] PM-30 is sometimes termed "suspendable particulate" (SP) and is often used as a surrogate for TSP.

It is important to note that the vehicle-related source conditions refer to the average weight, speed, and number of wheels for all vehicles traveling the road. For example, if 98 percent of traffic on the road are 2-ton cars and trucks while the remaining 2 percent consists of 20-ton trucks, then the mean weight is 2.4 tons. More specifically, Equations 1a and 1b are *not* intended to be used to calculate a separate emission factor for each vehicle class within a mix of traffic on a given unpaved road. That is, in the example, one should *not* determine one factor for the 2-ton vehicles and a second factor for the 20-ton trucks. Instead, only one emission factor should be calculated that represents the "fleet" average of 2.4 tons for all vehicles traveling the road.

Moreover, to retain the quality ratings when addressing a group of unpaved roads, it is necessary that reliable correction parameter values be determined for the road in question. The field and laboratory procedures for determining road surface silt and moisture contents are given in AP-42 Appendices C.1 and C.2. Vehicle-related parameters should be developed by recording visual observations of traffic. In some cases, vehicle parameters for industrial unpaved roads can be determined by reviewing maintenance records or other information sources at the facility.

In the event that site-specific values for correction parameters cannot be obtained, then default values may be used.In the absence of site-specific silt content information, an appropriate mean value from Table 13.2.2-1 may be used as a default value, but the quality rating of the equation is reduced by two letters. Because of significant differences found between different types of road surfaces and between different areas of the country, use of the default moisture content value of 0.5 percent in Equation 1b is discouraged. The quality rating should be downgraded two letters when the default moisture content value is used. (It is assumed that readers addressing industrial roads have access to the information needed to develop average vehicle information in Equation 1a for their facility.)

The effect of routine watering to control emissions from unpaved roads is discussed below in Section 13.2.2.3, “Controls”. However, all roads are subject to some natural mitigation because of rainfall and other precipitation. The Equation 1a and 1b emission factors can be extrapolated to annual

average uncontrolled conditions (but including natural mitigation) under the simplifying assumption that annual average emissions are inversely proportional to the number of days with measurable (more than 0.254 mm [0.01 inch]) precipitation:

$$E_{ext} = E\ [(365 - P)/365] \quad (2)$$

where:

E_{ext} = annual size-specific emission factor extrapolated for natural mitigation, lb/VMT

E = emission factor from Equation 1a or 1b

P = number of days in a year with at least 0.254 mm (0.01 in) of precipitation (see below)

Figure 13.2.2-1 gives the geographical distribution for the mean annual number of "wet" days for the United States.

Equation 2 provides an estimate that accounts for precipitation on an annual average basis for the purpose of inventorying emissions. It should be noted that Equation 2 does not account for differences in the temporal distributions of the rain events, the quantity of rain during any event, or the potential for the rain to evaporate from the road surface. In the event that a finer temporal and spatial resolution is desired for inventories of public unpaved roads, estimates can be based on a more complex set of assumptions. These assumptions include:

1. The moisture content of the road surface material is increased in proportion to the quantity of water added;
2. The moisture content of the road surface material is reduced in proportion to the Class A pan evaporation rate;
3. The moisture content of the road surface material is reduced in proportion to the traffic volume; and
4. The moisture content of the road surface material varies between the extremes observed in the area. The CHIEF Web site (http://www.epa.gov/ttn/chief/ap42/ch13/related/c13s02-2.html) has a file which contains a spreadsheet program for calculating emission factors which are temporally and spatially resolved. Information required for use of the spreadsheet program includes monthly Class A pan evaporation values, hourly meteorological data for precipitation, humidity and snow cover, vehicle traffic information, and road surface material information.

It is emphasized that the simple assumption underlying Equation 2 and the more complex set of assumptions underlying the use of the procedure which produces a finer temporal and spatial resolution have not been verified in any rigorous manner. For this reason, the quality ratings for either approach should be downgraded one letter from the rating that would be applied to Equation 1.

13.2.2.3 Controls[18-22]

A wide variety of options exist to control emissions from unpaved roads. Options fall into the following three groupings:

1. Vehicle restrictions that limit the speed, weight or number of vehicles on the road;

PET 803

REC 1169

2. Surface improvement, by measures such as (a) paving or (b) adding gravel or slag to a dirt road; and
3. Surface treatment, such as watering or treatment with chemical dust suppressants.

Available control options span broad ranges in terms of cost, efficiency, and applicability. For example, traffic controls provide moderate emission reductions (often at little cost) but are difficult to enforce. Although paving is highly effective, its high initial cost is often prohibitive. Furthermore, paving is not feasible for industrial roads subject to very heavy vehicles and/or spillage of material in transport. Watering and chemical suppressants, on the other hand, are potentially applicable to most industrial roads at moderate to low costs. However, these require frequent reapplication to maintain an acceptable level of control. Chemical suppressants are generally more cost-effective than water but not in cases of temporary roads (which are common at mines, landfills, and construction sites). In summary, then, one needs to consider not only the type and volume of traffic on the road but also how long the road will be in service when developing control plans.

Vehicle restrictions. These measures seek to limit the amount and type of traffic present on the road or to lower the mean vehicle speed. For example, many industrial plants have restricted employees from driving on plant property and have instead instituted bussing programs. This eliminates emissions due to employees traveling to/from their worksites. Although the heavier average vehicle weight of the busses increases the base emission factor, the decrease in vehicle-miles-traveled results in a lower overall emission rate.

PET 804
REC 1170

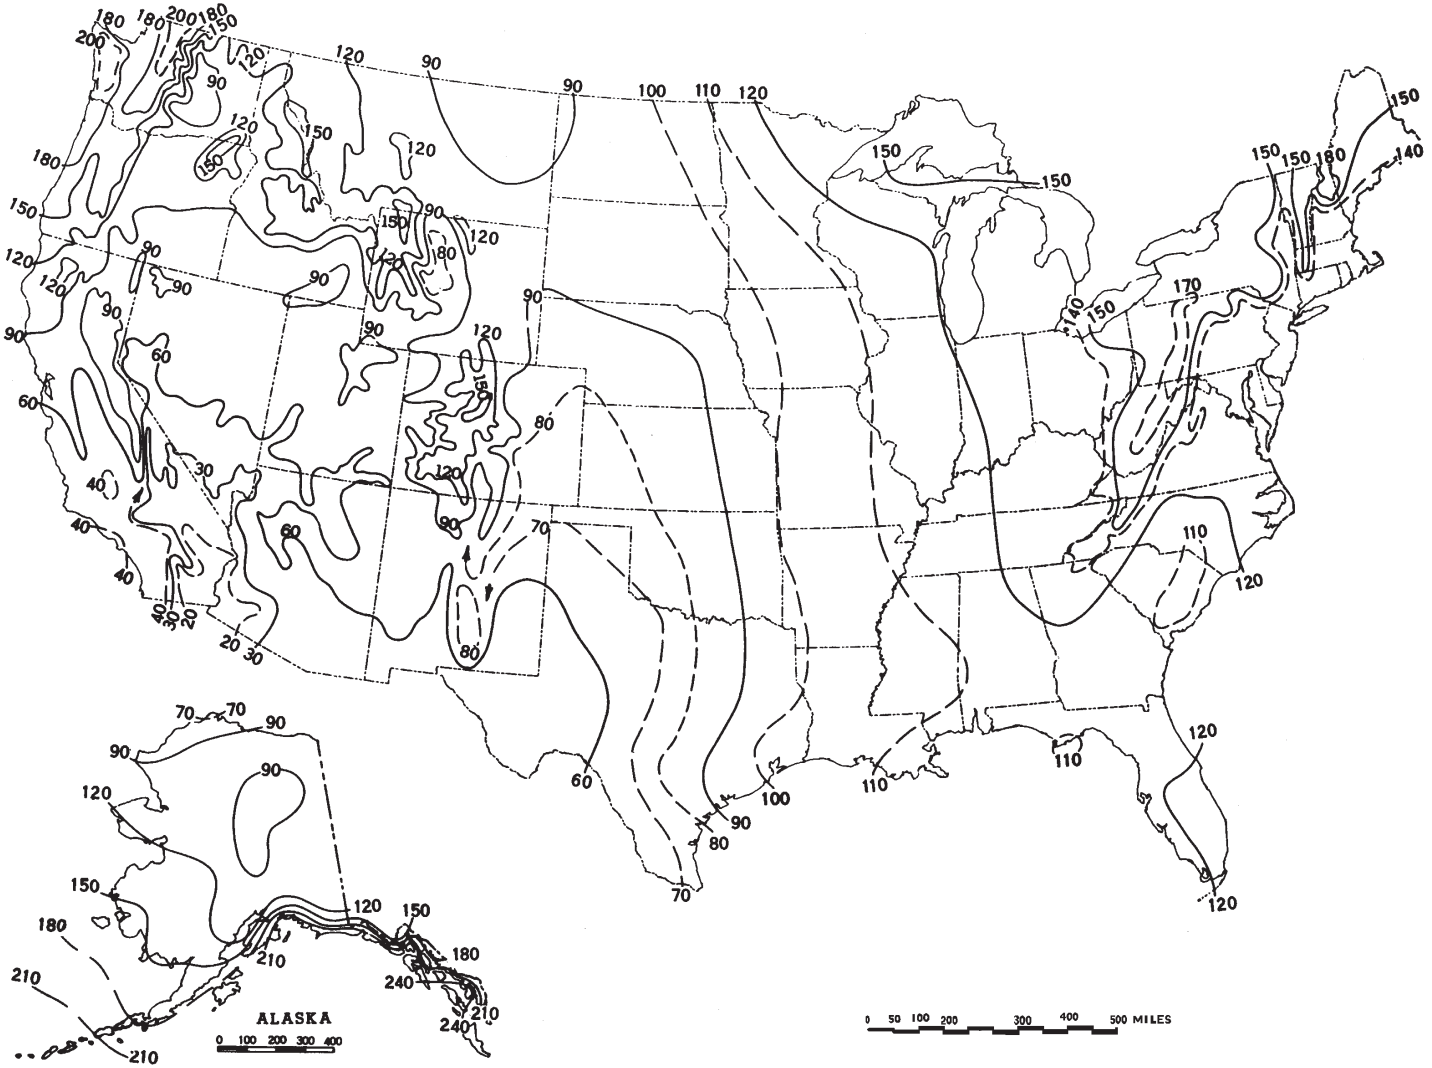

Figure 13.2.2-1. Mean number of days with 0.01 inch or more of precipitation in United States.

Surface improvements. Control options in this category alter the road surface. As opposed to the "surface treatments" discussed below, improvements are relatively "permanent" and do not require periodic retreatment.

The most obvious surface improvement is paving an unpaved road. This option is quite expensive and is probably most applicable to relatively short stretches of unpaved road with at least several hundred vehicle passes per day. Furthermore, if the newly paved road is located near unpaved areas or is used to transport material, it is essential that the control plan address routine cleaning of the newly paved road surface.

The control efficiencies achievable by paving can be estimated by comparing emission factors for unpaved and paved road conditions. The predictive emission factor equation for paved roads, given in Section 13.2.1, requires estimation of the silt loading on the traveled portion of the paved surface, which in turn depends on whether the pavement is periodically cleaned. Unless curbing is to be installed, the effects of vehicle excursion onto unpaved shoulders (berms) also must be taken into account in estimating the control efficiency of paving.

Other improvement methods cover the road surface with another material that has a lower silt content. Examples include placing gravel or slag on a dirt road. Control efficiency can be estimated by comparing the emission factors obtained using the silt contents before and after improvement. The silt content of the road surface should be determined after 3 to 6 months rather than immediately following placement. Control plans should address regular maintenance practices, such as grading, to retain larger aggregate on the traveled portion of the road.

Surface treatments refer to control options which require periodic reapplication. Treatments fall into the two main categories of (a) "wet suppression" (i. e., watering, possibly with surfactants or other additives), which keeps the road surface wet to control emissions and (b) "chemical stabilization/ treatment", which attempts to change the physical characteristics of the surface. The necessary reapplication frequency varies from several minutes for plain water under summertime conditions to several weeks or months for chemical dust suppressants.

Watering increases the moisture content, which conglomerates particles and reduces their likelihood to become suspended when vehicles pass over the surface. The control efficiency depends on how fast the road dries after water is added. This in turn depends on (a) the amount (per unit road surface area) of water added during each application; (b) the period of time between applications; (c) the weight, speed and number of vehicles traveling over the watered road during the period between applications; and (d) meteorological conditions (temperature, wind speed, cloud cover, etc.) that affect evaporation during the period.

Figure 13.2.2-2 presents a simple bilinear relationship between the instantaneous control efficiency due to watering and the resulting increase in surface moisture. The moisture ratio "M" (i.e., the x-axis in Figure 13.2.2-2) is found by dividing the surface moisture content of the watered road by the surface moisture content of the uncontrolled road. As the watered road surface dries, both the ratio M and the predicted instantaneous control efficiency (i.e., the y-axis in the figure) decrease. The figure shows that between the uncontrolled moisture content and a value twice as large, a small increase in moisture content results in a large increase in control efficiency. Beyond that, control efficiency grows slowly with increased moisture content.

Given the complicated nature of how the road dries, characterization of emissions from watered roadways is best done by collecting road surface material samples at various times between water truck passes. (Appendices C.1 and C.2 present the sampling and analysis procedures.) The moisture content measured can then be associated with a control efficiency by use of Figure 13.2.2-2. Samples that reflect average conditions during the watering cycle can take the form of either a series of samples between water applications or a single sample at the midpoint. It is essential that samples be collected during periods with active traffic on the road. Finally, because of different evaporation rates, it is recommended that samples be collected at various times during the year. If only one set of samples is to be collected, these must be collected during hot, summertime conditions.

When developing watering control plans for roads that do not yet exist, it is strongly recommended that the moisture cycle be established by sampling similar roads in the same geographic area. If the moisture cycle cannot be established by similar roads using established watering control plans, the more complex methodology used to estimate the mitigation of rainfall and other precipitation can be used to estimate the control provided by routine watering. An estimate of the maximum daytime Class A pan evaporation (based upon daily evaporation data published in the monthly Climatological Data for the state by the National Climatic Data Center) should be used to insure that adequate watering capability is available during periods of highest evaporation. The hourly precipitation values in the spreadsheet should be replaced with the equivalent inches of precipitation (where the equivalent of 1 inch of precipitation is provided by an application of 5.6 gallons of water per square yard of road). Information on the long term average annual evaporation and on the percentage that occurs between May and October was published in the Climatic Atlas (Reference 16). Figure 13.2.2-3 presents the geographical distribution for "Class A pan evaporation" throughout the United States. Figure 13.2.2-4 presents the geographical distribution of the percentage of this evaporation that occurs between May and October. The U. S. Weather Bureau Class A evaporation pan is a cylindrical metal container with a depth of 10 inches and a diameter of 48 inches. Periodic measurements are made of the changes of the water level.

The above methodology should be used only for prospective analyses and for designing watering programs for existing roadways. The quality rating of an emission factor for a watered road that is based on this methodology should be downgraded two letters. Periodic road surface samples should be collected and analyzed to verify the efficiency of the watering program.

As opposed to watering, chemical dust suppressants have much less frequent reapplication requirements. These materials suppress emissions by changing the physical characteristics of the existing road surface material. Many chemical unpaved road dust suppressants form a hardened surface that binds particles together. After several applications, a treated road often resembles a paved road except that the surface is not uniformly flat. Because the improved surface results in more grinding of small particles, the silt content of loose material on a highly controlled surface may be substantially higher than when the surface was uncontrolled. For this reason, the models presented as Equations 1a and 1b cannot be used to estimate emissions from chemically stabilized roads. Should the road be allowed to return to an

PET 807
REC 1173

uncontrolled state with no visible signs of large-scale cementing of material, the Equation 1a and 1b emission factors could then be used to obtain conservatively high emission estimates.

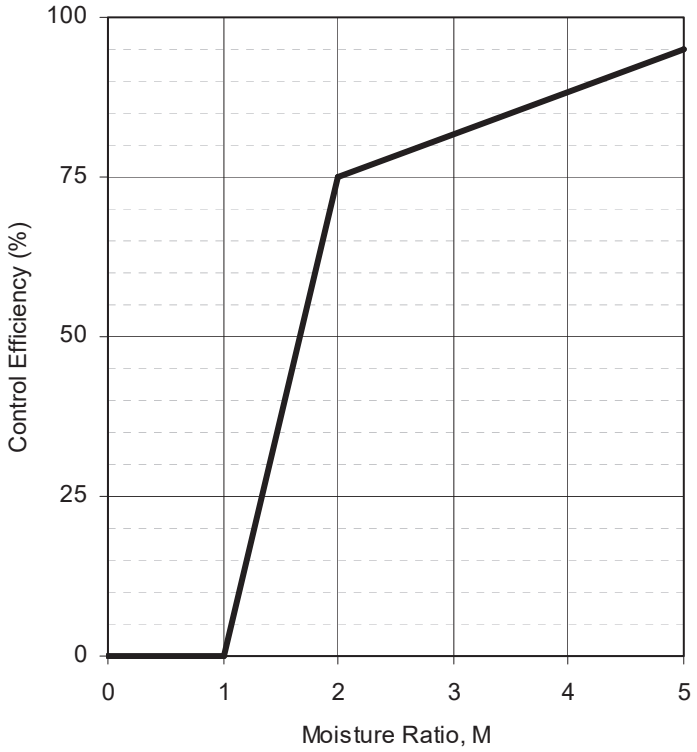

Figure 13.2.2-2. Watering control effectiveness for unpaved travel surfaces

The control effectiveness of chemical dust suppressants appears to depend on (a) the dilution rate used in the mixture; (b) the application rate (volume of solution per unit road surface area); (c) the time between applications; (d) the size, speed and amount of traffic during the period between applications; and (e) meteorological conditions (rainfall, freeze/thaw cycles, etc.) during the period. Other factors that affect the performance of dust suppressants include other traffic characteristics (e. g., cornering, track-on from unpaved areas) and road characteristics (e. g., bearing strength, grade). The variabilities in the above factors and differences between individual dust control products make the control efficiencies of chemical dust suppressants difficult to estimate. Past field testing of emissions from controlled unpaved roads has shown that chemical dust suppressants provide a PM-10 control efficiency of about 80 percent when applied at regular intervals of 2 weeks to 1 month.

PET 809
REC 1175

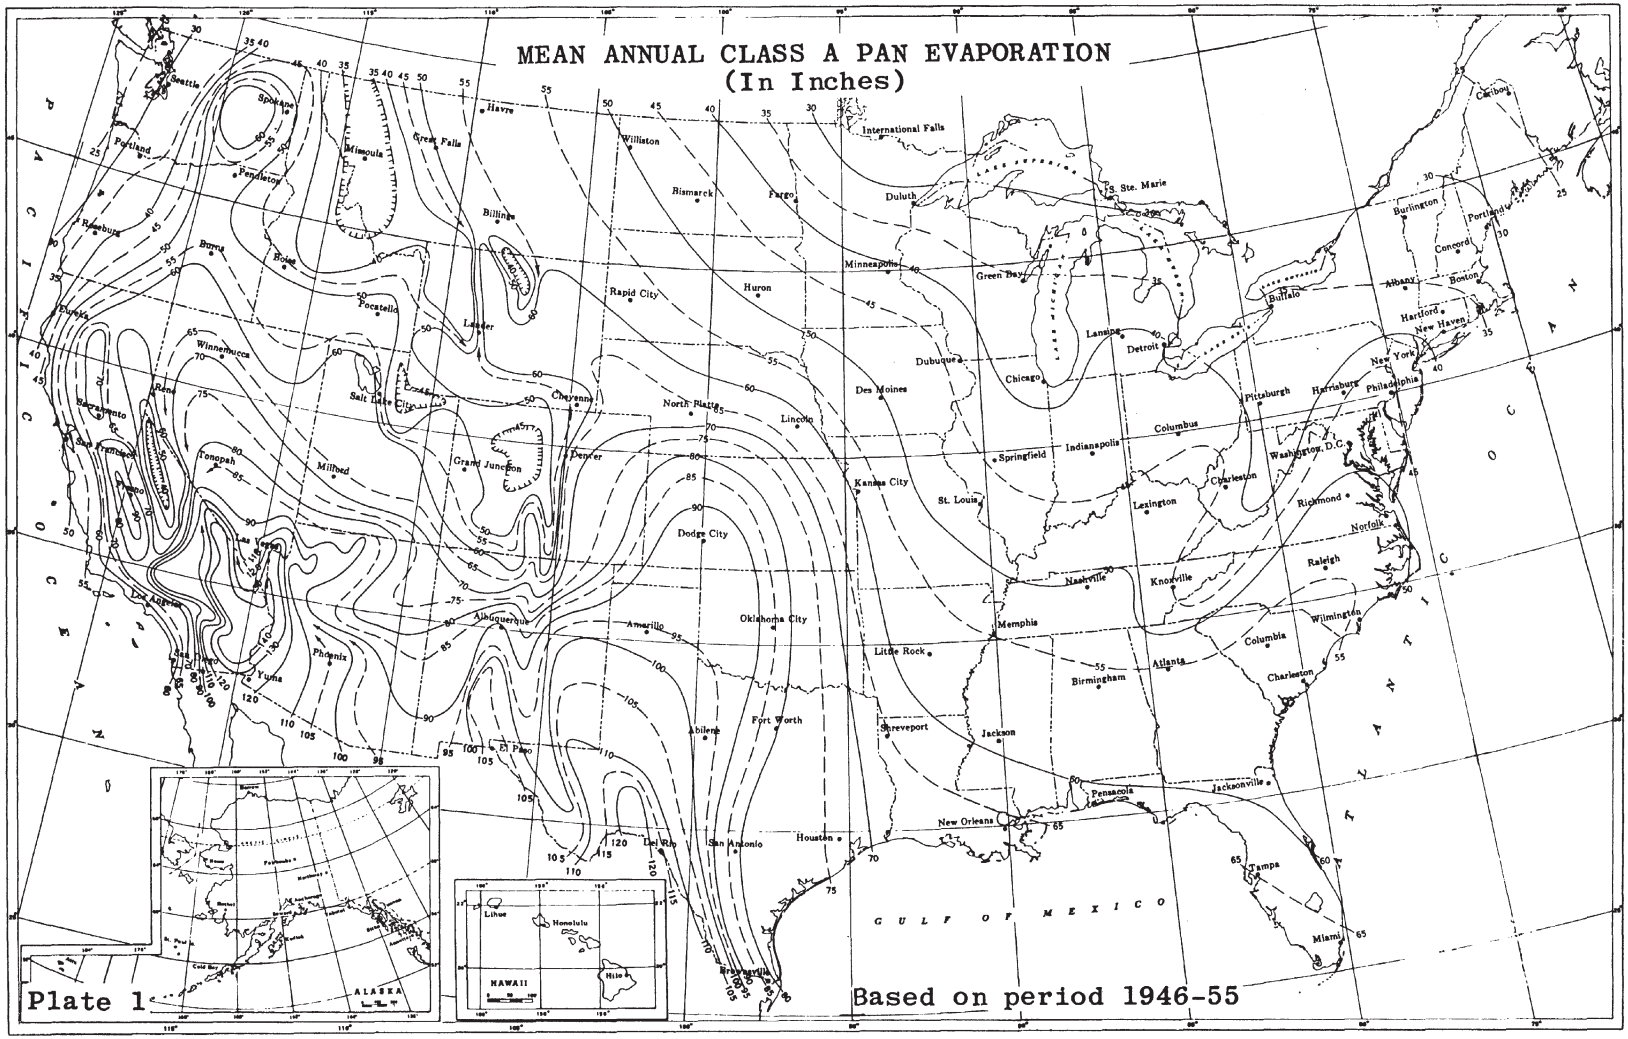

Figure 13.2.2-3. Annual evaporation data.

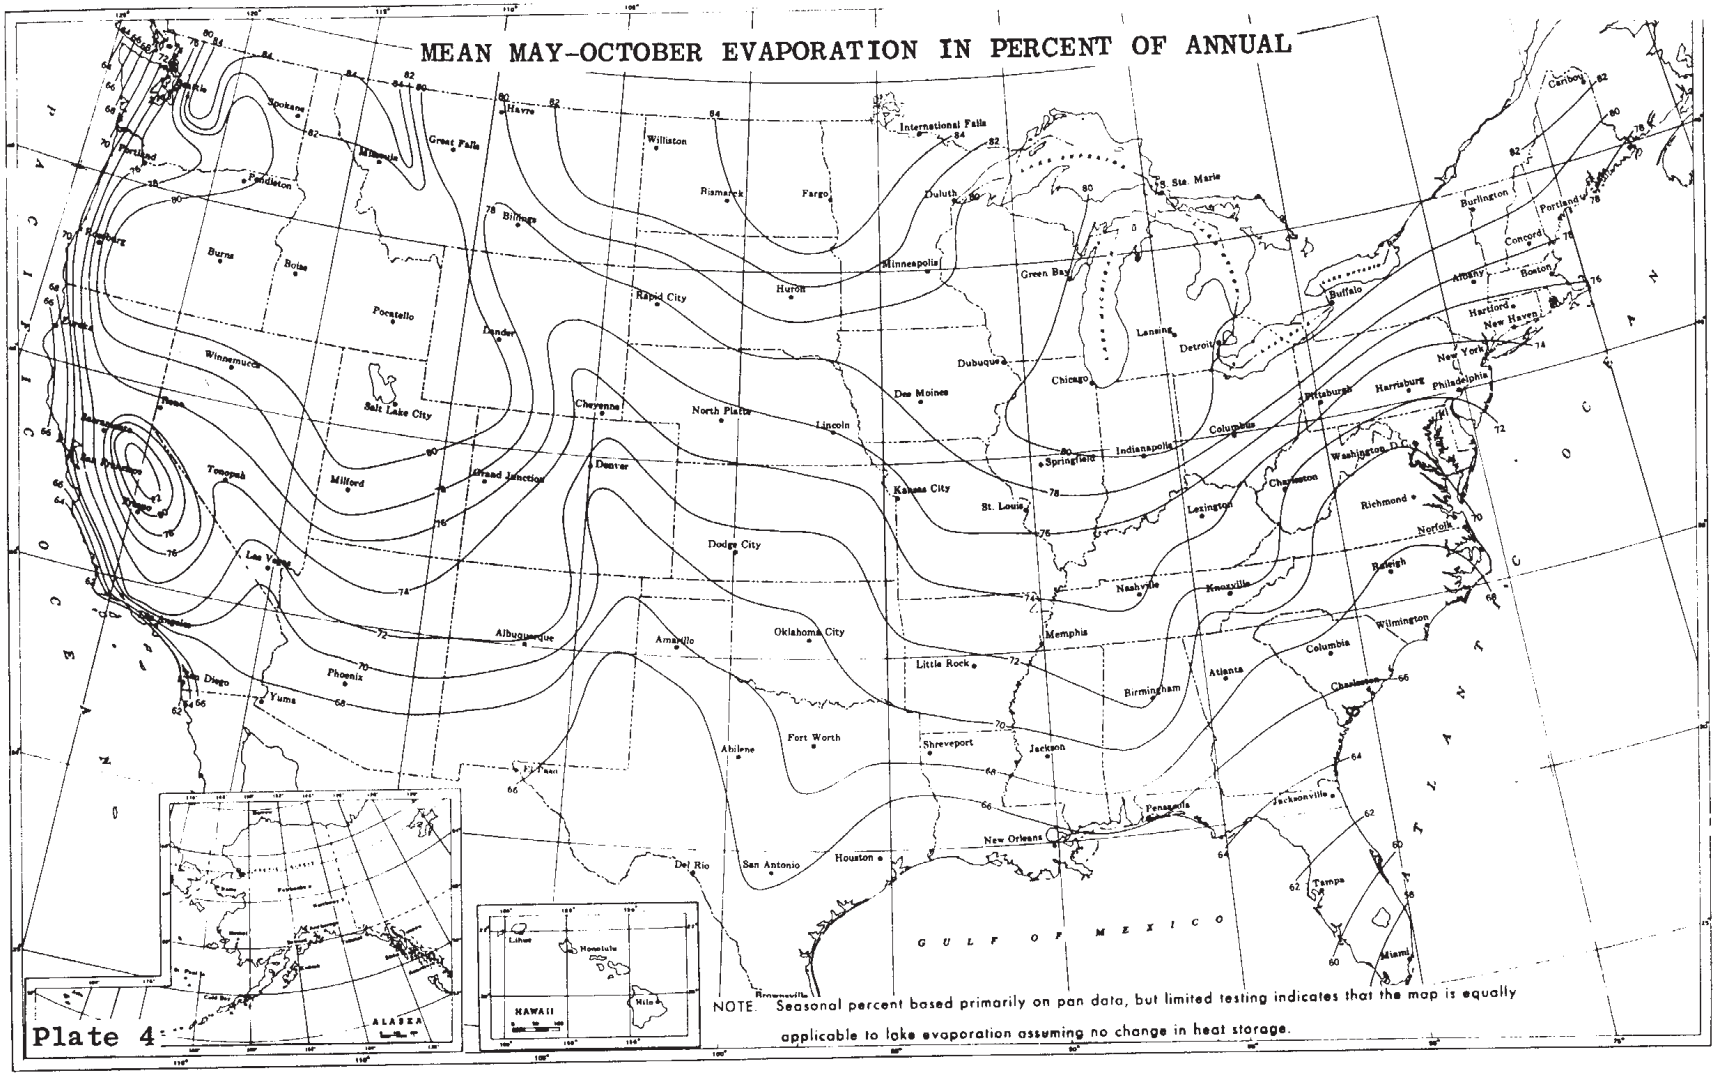

Figure 13.2.2-4. Geographical distribution of the percentage of evaporation occurring between May and October.

Petroleum resin products historically have been the dust suppressants (besides water) most widely used on industrial unpaved roads. Figure 13.2.2-5 presents a method to estimate average control efficiencies associated with petroleum resins applied to unpaved roads.[20] Several items should be noted:

1. The term "ground inventory" represents the total volume (per unit area) of petroleum resin concentrate (*not solution*) applied since the start of the dust control season.

2. Because petroleum resin products must be periodically reapplied to unpaved roads, the use of a time-averaged control efficiency value is appropriate. Figure 13.2.2-5 presents control efficiency values averaged over two common application intervals, 2 weeks and 1 month. Other application intervals will require interpolation.

3. Note that zero efficiency is assigned until the ground inventory reaches 0.05 gallon per square yard (gal/yd^2). Requiring a minimum ground inventory ensures that one must apply a reasonable amount of chemical dust suppressant to a road before claiming credit for emission control. Recall that the ground inventory refers to the amount of petroleum resin concentrate rather than the total solution.

As an example of the application of Figure 13.2.2-5, suppose that Equation 1a was used to estimate an emission factor of 7.1 lb/VMT for PM-10 from a particular road. Also, suppose that, starting on May 1, the road is treated with 0.221 gal/yd^2 of a solution (1 part petroleum resin to 5 parts water) on the first of each month through September. Then, the average controlled emission factors, shown in Table 13.2.2-5, are found.

Table 13.2-2-5. EXAMPLE OF AVERAGE CONTROLLED EMISSION FACTORS FOR SPECIFIC CONDITIONS

Period	Ground Inventory, gal/yd^2	Average Control Efficiency, %[a]	Average Controlled Emission Factor, lb/VMT
May	0.037	0	7.1
June	0.073	62	2.7
July	0.11	68	2.3
August	0.15	74	1.8
September	0.18	80	1.4

[a] From Figure 13.2.2-5, ≤10 µm. Zero efficiency assigned if ground inventory is less than 0.05 gal/yd^2. 1 lb/VMT = 281.9 g/VKT. 1 gal/yd^2 = 4.531 L/m^2.

Besides petroleum resins, other newer dust suppressants have also been successful in controlling emissions from unpaved roads. Specific test results for those chemicals, as well as for petroleum resins and watering, are provided in References 18 through 21.

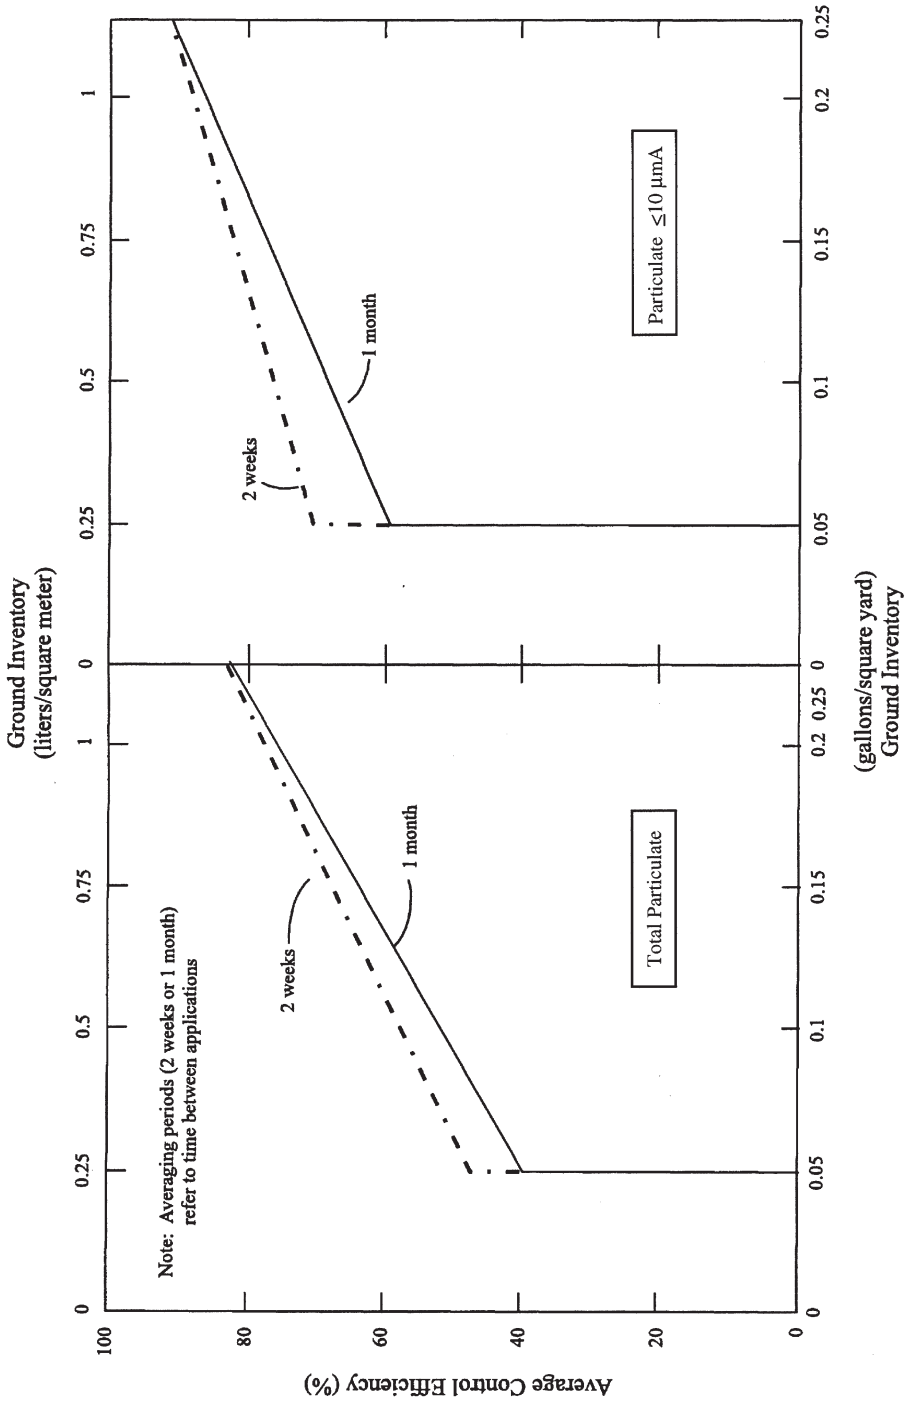

Figure 13.2.2-5. Average control efficiencies over common application intervals.

REC 1179

13.2.2.4 Updates Since The Fifth Edition

The Fifth Edition was released in January 1995. Revisions to this section since that date are summarized below. For further detail, consult the background report for this section (Reference 6).

October 1998 (Supplement E)– This was a major revision of this section. Significant changes to the text and the emission factor equations were made.

October 2001 – Separate emission factors for unpaved surfaces at industrial sites and publicly accessible roads were introduced. Figure 13.2.2-2 was included to provide control effectiveness estimates for watered roads.

December 2003 – The public road emission factor equation (equation 1b) was adjusted to remove the component of particulate emissions from exhaust, brake wear, and tire wear. The parameter C in the new equation varies with aerodynamic size range of the particulate matter. Table 13.2.2-4 was added to present the new coefficients.

January 2006 – The PM-2.5 particle size multipliers (i.e., factors) in Table 13.2.2-2 were modified and the quality ratings were upgraded from C to B based on the wind tunnel studies of a variety of dust emitting surface materials.

ARSENIC MODELING ADDENDUM REVIEW, IDENTIFIED QUESTIONS, AND CONCERNS (as per Kevin Schilling)

1.0 Deficiencies of the Existing TAPs Analyses

1.1 NESHAP-Addressed Sources Incorrectly Identified

The latest TAPs Section 210 analyses DEQ received (prior to the special arsenic analysis) incorrectly excluded some carcinogenic TAP emissions from the inventory, screening emission level (EL) analyses, and modeling analysis using the provision that such emissions were addressed by a NESHAP. This included arsenic and a host of other carcinogenic TAPs. Arsenic is the controlling TAP, as it was confidently estimated that if the arsenic TAP increment could be met, then the increment for other TAPs could be easily met.

1.2 Ideas for Path Forward

DEQ modelers brainstormed ideas for refining the arsenic analyses, including:

1. Refining arsenic emissions from road dust by committing to use road base material having a lower arsenic concentration.
2. Looking at the life of the mine and making adjustments to account for a life-time (70-year) risk. DEQ would need legal opinion as to whether this meets requirements of Section 210.
3. Demonstrating that T-RACT is used for arsenic emission sources.
4. Account for operational scenarios at different stages of the mine life. For example, during years 3-5 maximum emissions might be 200 lbs/year from Source X and 50 lbs/year from Source Y, but in years 6-10 emissions might be 50 lbs/year from Source X and 200 lbs/year from Source Y. Without scenarios, we would be allowing 200 lbs/year from Source X and 200 lbs/year from source Y, thereby overestimating emissions by 150 lbs/year for each year. The challenge with this approach is that the permit would need to make the change in annual allowable emissions from specific sources reasonably enforceable.

The modelers' general idea would be that a revised Section 210 analysis would be done using some of the above refinements, while still only looking at Non-NESHAP sources. There would also be utility in Air Sciences performing a risk-based arsenic analysis considering all emission sources, since this is what the public is most concerned with.

PET 817

REC 1183

1.3 Discussion with Air Sciences

After identification of improper exclusion of TAP sources in Section 210 analyses, DEQ internal discussions on a path forward occurred on June 8. On July 9, I sent out a 1-page analysis approach that could be used for TAP compliance. This was an internal document only. This approach included: 1) identify sources that must be modeled and exclude those not applicable; 2) refine TAP emissions, perhaps using less conservative emission-affecting parameters (different road base, seasonality, additional operational scenarios); 3) refine dispersion-affecting parameters in the model, including deposition; 4) demonstrate T-RACT is implemented; 5) account for an exposure period of less than 70 years; 6) explore the idea of using a longer averaging period for emission and throughput limits in the permit; 7) evaluate use of a more refined model such as CALPUFF; 8) propose ambient sampling to demonstrate unacceptable levels are not generated.

A 1-hour meeting was held between Mike Simon, Kevin Schilling, Dale Kerner (Perpetua), and Kevin Lewis (Air Sciences) to discuss the issues and potential paths forward. The above mentioned ideas were brought up and seemed to be consistent with what Air Sciences was thinking.

Kevin Lewis contacted me on June 17th to discuss some issues/questions on the analyses they were performing. I was on vacation (he called my personal cell) during this week but indicated in an email reply that time could be made to discuss issues. I also indicated that Pao Baylon was available to discuss methods/data for the refined arsenic analysis. Kevin Lewis tried to contact me again on June 18th (I was still on vacation) about a brief discussion in the afternoon; however, I indicated the afternoon wouldn't work but an evening call could. Kevin Lewis then stated that he would contact me after I returned from vacation. Additional discussions did not occur and the arsenic analysis was submitted on July 8, 2021

2.0 Air Science's Special Arsenic Analysis Submittal

What DEQ received on July 8, 2021, was a complete rework for the arsenic emission inventory and an impact analysis considering all arsenic sources, T-RACT, source-by-source variable emissions by year in the life of the mine, adjustment of averaging periods to 16 years (life of mine) and 70 years (receptor lifetime exposure assumed for AACCs), and revised arsenic emissions from roadways. The operations were based on the SGP Refined Proposed Action – ModPRO2. Air Sciences stated that ModPRO2 is the basis of a Supplemental Draft EIS, currently in preparation by the Forest Service, and it is based on improvements and refinements with a smaller footprint of the mine.

The analysis modeled each of the 16 years of the mine life separately, with varying emissions of sources during each year. With over 400 sources in the model, this results in about 6,700 variables to evaluate (this is somewhat of an overstatement because some sources are modeled as a group of sources, such as road segments).

There were no analyses addressing the identified problems with the Section 210 analyses in the previous submittal, and this special analysis only addresses arsenic. In the introduction, Air Sciences says the submitted arsenic analysis address the public comment request that all TAP emission sources be modeled for a Section 161 analysis.

Year-by-year modeled impacts presented in the special arsenic analyses varied from 0.00017 $\mu g/m^3$ to 0.00208 $\mu g/m^3$, with a 16-year average impact of 0.00068 $\mu g/m^3$. This compares to the AACC of 0.00023 $\mu g/m^3$. However, the T-RACT AACC is 0.0023 $\mu g/m^3$. Also the maximum impact when averaged over a 70-year period is only 0.00015 $\mu g/m^3$. This modeled impact is limited to a small area northeast of the site, near the facility boundary. Within a few thousand meters, impacts drop to below 0.00005 $\mu g/m^3$.

3.0 Legal Question of whether a Different Section 161 Analysis can be used in Place of Section 210 Requirements

Idaho Air Rules Section 203.03 outlines TAP permit requirements for new stationary sources. The rule states:

"*Using the methods provided in Section 210, the emissions of toxic air pollutants from the stationary source or modification would not injure or unreasonably affect human or animal life or vegetation as required by Section 161. Compliance with all applicable toxic air pollutant carcinogenic increments and toxic air pollutant non-carcinogenic increments will also demonstrate preconstruction compliance with Section 161 with regards to the pollutants listed in Sections 585 and 586*."

The question is whether this section locks DEQ into requiring methods in Section 210. This is certainly how DEQ has used this section in the past, but I don't believe we have grappled with idea of using something other than Section 210. This is something our Attorney General should assist us in.

Section 210, may further lock DEQ into specific methods, as it states: "*In accordance with Subsection 203.03, the applicant shall demonstrate preconstruction compliance with Section*

PET 819

REC 1185

161 to the satisfaction of the Department. The accuracy, completeness, execution and results of the demonstration are all subject to review and approval by the Department."

Modeling methods are addressed in Section 210.03. In general it states the applicant may use methods provided in 202.02 to estimate ambient concentrations. Section 202.02 effectively links methods to 40 CFR 51, Appendix W (Guideline on Air Quality Models). Among other things, Appendix W requires modeled rates to be those under PTE or as limited by an enforceable permit condition. DEQ has consistently required TAPs modeling to be in accordance with Section 202.02.

How modeling results are handled is described in Idaho Air Rules Section 210.08, where it states: "*Compare the source's or modification's controlled ambient concentration at the point of compliance for the toxic air pollutant to the applicable acceptable ambient concentration listed in Sections 585 or 586.*" Note that in Section 586, the rules state that "*The AACC in this section are annual averages." The definition of Toxic Air Pollutant Carcinogenic Increments is defined in Section 005.125 as, "Those ambient air quality increments based on the probability of developing excess cancers over a seventy (70) year lifetime exposure to one (1) microgram per cubic meter (1 ug/m^3) of a given carcinogen and expressed in terms of a screening emission level or an acceptable ambient concentration for a carcinogenic toxic air pollutant. They are listed in Section 586.*" The AACCs are based on an acceptable risk of 1-in-1,000,000

4.0 DEQ Review of Arsenic Analysis

4.1 Level of Review

DEQ has not been able to provide a thorough review of submitted information. Although general methods (terrain, meteorological data, most source parameters, etc) have not changed, what was submitted is a substantial reworking of emissions and operational scenarios. Also, because of the workload, substantial review of this submitted analysis was not able to begin until around August 1.

The special arsenic analysis is largely based on emission estimates and operational schedules provided in ModPRO2, which has not been thoroughly reviewed by DEQ at this point. ModPRO2 is largely different from what was submitted in the permit application. It is my opinion that ModPRO2 and the submitted arsenic analysis should be thoroughly reviewed by the DEQ permit writer, as the majority of the revised information is emission rates of year-by-year operational scenarios. The permit writer should also review the T-RACT claims and the

permit writer will need to draft permit conditions to make the assumptions in the analyses reasonably enforceable.

4.2 Differences from Previous Arsenic Analyses

It's difficult to determine whether the submitted analysis is a supplemental analysis or a correction to previous deficiencies, or both. In general, it appears to mainly address the public request for a facility-wide Section 161 type assessment.

The previous TAP analyses did not use operational scenarios, but the PM_{10} and $PM_{2.5}$ analyses used limited operational scenarios, maintaining maximum annual allowable throughput rates. This special arsenic analysis provides year-by-year operational scenarios with each modeled source having different emission rates for each different year. It appears to me that this new analysis is not consistent with the draft permit at this point.

As an example, the current DEQ Statement of Basis lists facility-wide arsenic emissions at 2.4 ton/year, but ModPRO2 suggests arsenic emissions of only 0.217 ton/year (as averaged over the 16 year life of the mine).

4.3 Review Remaining to be Performed

At a minimum, the following of portions of the submitted arsenic analysis are still in need of review:

1. T-RACT documentation and justification, assuring that T-RACT requirements outlined in Section 210 are met.
2. Further review of year-by-year operational levels of various sources.
3. Thorough review of ModPRO2 documentation.
4. Draft questions on the special arsenic analysis and submit to Air Sciences.

5.0 Path Forward

5.1 Overall Thoughts/Concerns

I would have preferred that Air Science perform two separate arsenic analyses. One analysis would be a refined Section 210 analysis, looking only at applicable sources (excluding sources addressed by a NESHAP) but refining by scenarios and by long-term average exposure (70 year or the 16 year life of the mine). The other analysis would be along the lines of what we have

PET 821

REC 1187

now and would address the public's concern about the need to look at all arsenic sources for a comprehensive risk analysis.

For non-arsenic TAPs, a revised analysis should be submitted that addresses the deficiencies identified previously. Alternatively, DEQ could perform our own modeling or make an argument that arsenic is the worst-case TAP and correction of the improperly performed analyses could not result in an exceedance of a TAP increment.

Regardless of which path we take on what the submitted arsenic analysis can be used for, it still needs to be reviewed by the permit writer, who is most familiar with described operations and resulting emissions. The submitted analysis is actually more of an emission inventory revision and refinement than a modeling refinement.

If we move forward with the submitted special arsenic analysis satisfying TAP requirements for permit issuance, the permit writer must draft revised limits to reasonably address the year-to-year variability of operations, throughput, and emissions. As it currently stands, if they operate as allowed in the permit, they will not meet the arsenic AACC; but if they operate as claimed in ModPRO2 then impacts should be fine. Also, there is so much year-to-year and source-to-source variability in emission rates and source-specific throughput that making such parameters enforceable would require an exceptionally complex permit.

5.2 To-Do List

The following must be answered/addressed:

1. Can requirements outlined in Section 210 be disregarded for a Section 161 analysis?
2. Can a 70 year average concentration be used for comparison to AACCs rather than a single year average for Section 210 analyses?
3. For carcinogenic TAPs other than arsenic, we still only have Section 210 analyses that improperly excluded emission sources as being addressed by NESHAPS. Although we highly suspect those other TAPs will not be an issue, we don't have an analysis that shows this.
4. Decide whether we would like Air Sciences to perform a refined Section 220 analysis that excludes NESHAP sources but has less year-to-year variability of parameters to make permit-writing easier.
5. Determine how we handle the new special arsenic analysis. As currently submitted, it is a complete rework of the arsenic inventory. On other

PET 822

REC 1188

projects, we may have asked applicants to withdraw and resubmit, or, at a minimum, would require another public comment period after making the changes.

6. Finish review of the submitted analyses (if applicable), then generate questions for clarification and requests for additional information.
7. Revision of the modeling memo, the Statement of Basis, and the proposed permit.

==========

Additional Thoughts/Concerns

Appendix W Requirement

Idaho Air Rules, Section 202.02 states, "All estimates of ambient concentrations shall be based on the applicable air quality models, data bases, and other requirements specified in 40 CFR 51, Appendix W (Guideline on Air Quality Models). Appendix W, as federal rule, only discusses permitting from the perspective of PSD. It is assumed from Idaho Air Rules that we are to apply Appendix W guidance to minor source modeling to the extent that it can be.

Appendix W Section 8.2.2.c (Source Data Requirements) states that "the new or modifying stationary point source shall be modeled with "allowable" emissions in the regulatory dispersion modeling." Table 8-2 of Appendix W further states that the operating level of the proposed source must be at "design capacity or federally enforceable permit condition." This effectively requires DEQ modeling to use allowable emissions, and allowable emissions are not the same as estimated maximum emissions. Since 202.02 applies for all permitting, it would also apply to a Section 161 analysis as well.

Annual Risk Assessment Report

From Idaho Air Rules and Appendix W, the operational rates used to calculate emissions in either a Section 220 or 161 analysis must be maximum allowable as established by design capacity or by enforceable permit condition. This presents a substantial challenge for the case where emissions from a source vary with each year of mine operation, with some increasing and some decreasing with any particular year.

What is important for TAP compliance is the long-term emissions. Therefore, even restrictions on annual emissions and operations is not critical to compliance with AACCs, especially if we're

under Section 161 rather than 210. Therefore, we can establish something like a 10-year rolling for sources with variable operational rates. We would still need some compliance check at a more frequent interval, such as annually. Perhaps during the first 3 years, the operational rates could not exceed the long term average plus a multiple of the standard deviation.

An alternative approach would be to require an annual look at risk resulting from the previous year's actual operations. This would then be added to all previous years' risks to generate a cumulative risk to that point. The cumulative risk would have to remain below the level identified as acceptable.

Potential Problem with Section 161 Type Analysis

Because Section 161 does not have regulatory sideboards, it is open to considerable criticism on whatever methods and data we use. This would include the carcinogenic risk factors (we really should use the most recent risk factors in a Section 161 analysis). Also, for a real risk assessment we should look at all carcinogenic compounds and multiple paths, but I do believe we can scale back from that approach. Note that 161 reads, "*Any contaminant which is by its nature toxic to human or animal life or vegetation shall not be emitted in such quantities or concentrations as to alone, or in combination with other contaminants, injure or unreasonably affect human or animal life or vegetation.*"

If we're doing a true Section 161 analysis, we should have a toxicologist and/or risk assessment individual reviewing the approach. An alternate idea is that we are modifying Section 210 by accounting for all arsenic sources, but adjusting operational rates to something closer to actuals.

Submitted Arsenic Analysis vs PTC Application

The submitted operational plan in the special arsenic analysis is completely different than what was submitted in the PTC application. Effectively it is a different permitting approach, based on activity variation with time rather than different scenarios by location. It will take time to understand what is going on with ModPRO2 and how that might be made into enforceable permit conditions. Note that there were even some sources in the PTC application that were not modeled in the arsenic analysis (and they would have had arsenic emissions).

DEQ Position on the Arsenic Modeling Addendum To the Perpetua Resources Stibnite Gold Project Permit to Construct Application

(by Kevin Schilling, Stationary Source Air Modeling Supervisor)

1.0 Introduction

DEQ received an *Arsenic Modeling Addendum* from Air Science following discussions of concerns with existing Section 210 TAP analyses to support the Perpetua Resources Stibnite Gold Project (SGP) Permit to Construct application. This paper summarizes the process to this point, briefly describes the addendum, points out challenges working with the addendum within the context of existing sections of the application, and outlines potential paths forward.

2.0 Review of Permitting Project to this Point

2.1 First Two Comment Periods

In response to comments from the first public comment period and DEQ's further evaluation of TAP source applicability to Section 210 (and the exemption of NESHAP sources from analyses), a revised TAP emission inventory and air impact modeling analysis was performed. Results of these revisions and a new proposed Statement of Basis and draft permit were then put out for a second public comment period and public informational meeting.

Additional concerns of arsenic emissions and proper exclusion of NESHAP sources arose after the second public comment period in March 2021. In general, the issue was that certain TAP sources were excluded from the TAP increment compliance demonstration that should have been included. Of most importance was fugitive carcinogenic emissions from vehicle traffic on mining roads and other fugitive emission sources. Arsenic was the TAP driving the analyses.

2.2 Path Leading to Arsenic Modeling Addendum

Air Sciences (Perpetua's consultant) and Perpetua met with DEQ on June 17, 2021, to discuss potential options to achieve acceptable modeled impacts. Some of these "brainstorming ideas" discussed included: 1) demonstrate that T-RACT is used for arsenic sources, thereby increasing acceptable impacts by a factor of 10; 2) refine arsenic emission estimates for sources, and

especially for road dust fugitive emission sources; 3) adjust averaging periods of modeled TAP impacts to reflect a longer period, as Acceptable Ambient Concentrations of Carcinogens are based on a 70-year exposure and the life of the mine is only 16 years; 4) perhaps propose permit operation/production limits based on multiple years (such as a 5-year rolling average); 5) define operational levels closer to what is actually anticipated. Ambient monitoring was mentioned as a means to increase the level of confidence if compliance is still not confidently demonstrated.

2.3 Arsenic Modeling Addendum Contents

On July 8, 2021, Air Sciences submitted an *Arsenic Modeling Addendum* for DEQ review. The addendum states the purpose is to address a public comment request that analyses be provided to assure compliance with Idaho Air Rules Section 161 regarding total project-wide arsenic emissions. The addendum also states that it "provides additional information requested by IDEQ to support its determination that the HAP/TAP emissions from the SGP comply with applicable regulations."

The addendum is based on operations as described in the SGP Refined Proposed Action – ModPRO2, which is the basis of a Supplemental Draft EIS currently in preparation by the Forest Service. ModPRO2 accounts for project improvements and refinements, with a smaller footprint of the mine.

The mine operational model used for the *Arsenic Modeling Addendum* is vastly different than that used in the original application. The original permit application provides a description of maximum operations of numerous emission sources that may occur at the facility, with an air quality assessment of emissions from those operations. ModPRO2 does not use this approach, but alternatively provides a best estimate of actual operations over the life of the mine. For example, the current DEQ Statement of Basis lists facility-wide arsenic emissions at 2.4 ton/year, but ModPRO2 lists emissions at 0.22 ton/year (as averaged over the 16 year life of the mine).

3.0 Why DEQ cannot Move Forward with Permit Issuance at this Point

DEQ is at the point in the permitting process where finishing touches are typically put on a permit or, at the most, slight adjustments are made to analyses or supporting data. Instead, with the concern over Section 210 analyses for arsenic we have an *Arsenic Modeling Addendum*

that, when combined with the existing application, looks like the confused mess of a "dog's breakfast."

First, how is the *Arsenic Modeling Addendum* to be used? Is it to replace the Section 210 analyses in the existing application (which DEQ asserts is incorrect), is it to supplement those analyses, or is it to merely respond to public concern about facility-wide arsenic impacts. Secondly, the addendum uses a substantially different approach from what is described in the application, Statement of Basis, and the draft PTC. Operational rates used for the inventory supporting the addendum lack substantiation and are radically different than those presented in other sections of the application. We're left wondering what should be disregarded in the application because of conflicting statements in the addendum. At this point, how does DEQ handle issues and concerns we may have on methods and data used in the addendum? How will permit limits be crafted to make claims in the addendum legally and practically enforceable, even to a minimally acceptable level? How does DEQ establish a timeline for permitting milestones at this point?

3.1 DEQ Permitting Process

Idaho Air Rules are very clear on the permit issuance process. As stated in Section 209, within 30 days after application submittal DEQ must determine whether the application is complete or "whether more information must be submitted . . ." Then, within 60 days DEQ must either approve or deny the permit. Once the application is complete, then the permitting decision is made based on that information submitted. These deadlines form a critical component of DEQ's performance measures designed to assure timely permitting.

Submission of new information, data, and analyses after the application has been declared complete constitutes an "out of scope" change, and a new permit application must be submitted. This is done for two important reasons: 1) the opportunity for public comment is based on the scope, data, and analyses provided in the original application; 2) entertaining substantial changes during the permit drafting phase requires substantial reworking by DEQ permitting staff, and keeping staff priorities on reworking a project is not fair to other permit applications recently submitted that may be complete. DEQ does periodically accept complementary information or minor corrections/clarifications after the completeness determination, as those do not substantially alter the underlying technical and regulatory basis of permit issuance. However, DEQ typically requires application withdraw and resubmittal for substantial changes that affect the emission inventory and especially when such changes require remodeling of air impacts.

3.3 Incomplete or Inadequate TAPs Compliance Demonstration

DEQ determined, after the March 2021 comment period, that TAP analyses used to demonstrate compliance with Idaho Air Rules Section 210 had again incorrectly excluded some TAP sources. It was assumed the *Arsenic Modeling Addendum* would address this issue. The addendum attempts to address arsenic, but does not provide any analyses of other TAPs for either modeling applicability or results from impact modeling.

3.4 Substantial change in Regulatory Approach

The *Arsenic Modeling Addendum* is a complete change in the regulatory approach used to demonstrate compliance with toxics. It abandons the Section 210 approach used in the application for an arsenic Section 161/210 hybrid analysis. The methods used in this unique analysis should be thoroughly vetted by DEQ well before a permit application is submitted. A month before permit issuance is not the time for developing a creative permitting approach with new emission inventory approaches, new modeling analyses, and challenges for crafting enforceable permit provisions/limits.

3.5 Inconsistency between NAAQS Inventory and Inventory used for Addendum

Emission inventories are estimated using emission source identification (including location and number of like sources), emission factors, emission control measures, operational levels, and operational schedules. Typically and most simply, permitting is done using maximum applicable factors, minimum control measures, and maximum operational levels and schedules. This makes for a relatively simple permit where claimed emissions and operations are easily made into verifiable permit conditions and minimal monitoring can assure compliance with the permit and, therefore, the underlying assumptions used in analyses.

The originally submitted application and previous revisions largely used maximum rates, with use of some operational scenarios where compliance with NAAQS was challenging by assuming maximum rates of all sources. The *Arsenic Modeling Addendum* uses an inventory that mostly uses the established emission factors and emission control measures; however, it accounts for temporally and spatially varying operational levels and schedules such that emissions are vastly less than those listed in other parts of the application. The addendum accounts for different operations and operational rates for each year of mine operation. Not only is there a question on whether the operational levels and schedules in the addendum can be translated into reasonably enforceable permit conditions/limits, but it is uncertain how other portions of the application and draft permit may be affected.

4.0 Potential Path Forward

Considering what was presented in the *Arsenic Modeling Addendum*, which was based on planned actual operations as described in ModPRO2 (used in the latest version of the draft EIS), it seems highly likely that the Stibnite Gold Project is permittable, provided aggressive emission controls are implemented. The challenge is finding a path that results in compliance with permitting rules/regulations, provides needed operational flexibility, and results in a permit that is not unnecessarily burdensome for monitoring and recordkeeping.

4.1 Technical Path for either Section 210 or Section 161 Analyses

Refinements for TAP analyses may include the following (arranged somewhat in order of priority):

1. Demonstrate that T-RACT is used for TAP emission sources, thereby allowing impacts at 10 times the AACC. Some discussion may be needed with DEQ to determine what is necessary for such a demonstration.
2. Refine estimates of road base arsenic content and resulting fugitive emissions from vehicle traffic. The DEQ permit writer would need to verify such revisions.
3. Agree to take a permit limit on life of the mine (based either on total years at a given operational rate or total mine-life production).
4. Adjust modeling results to obtain a long-term average concentration, accounting for the life of the mine and the 70-year exposure period used for assessing life-time cancer risk. For example, total impact = (1 year impact)(16 year life of mine)/(70 years of exposure).
5. Explore the option of some sources having permit limits based on a multi-year average, such as rolling 5-year average production rates from a certain area at the mine, etc.
6. Explore options for operational rates and schedules that vary with time, provided those can be made into enforceable permit limits.

Where confidence of compliance with TAP increments may be decreased for any number of reasons, or where the effectiveness of operational monitoring is questionable to assure compliance, ambient monitoring can provide additional confidence of compliance to allow permit issuance.

4.2 Organized, Consistent, Accurate Application

Whether DEQ requires withdraw of the existing permit application and resubmission of a revised application or allows continuation under the current project, DEQ requests an updated

PET 829

REC 1195

and revised application document. The application must be accurate and consistent across regulatory evaluations, emission inventory assessment, and modeling of impacts.

Whichever path is chosen, considerable DEQ time and resources will be necessary to review new regulatory analyses, verify emission calculations, review modeling analyses, draft appropriate permit limits, revise the Statement of Basis, revise the draft permit, and go back through the public comment period.

Attorneys for Respondent

BEFORE THE BOARD OF ENVIRONMENTAL QUALITY
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047	
NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON Petitioners, v. IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent, and PERPETUA RESOURCES IDAHO, INC. Intervenor.	CASE DOCKET NO. 0101-22-01 **RESPONSE TO PETITIONERS' FIRST DISCOVERY REQUESTS AND REQUESTS FOR PRODUCTION OF DOCUMENTS**

TO: Petitioners Nez Perce Tribe, Idaho Conservation League, and Save the South Fork Salmon and its attorney of record:

Respondent, the Idaho Department of Environmental Quality, after making a diligent search of its records, hereby responds to the Petitioners' discovery requests. The Respondent also hereby objects to Instruction number 7 as being unduly burdensome in this case. Nine responsive documents were withheld because they fall within the ambit of the Attorney-client Privilege.

INSTRUCTIONS

1. Unless otherwise indicated, these Interrogatories and Requests for Production refer to Air Quality Permit to Construct P-2019-0047.

2. In responding to this Discovery Request, base your responses on all information available to you, not merely information within your own personal knowledge; please include information in the possession of your attorneys, experts, employees, agents, representatives, members, and consultants, whether past or present.

3. If documents supporting a Request for Production have already been provided via the Project File, sent by IDEQ to the parties on or about October 22, 2022, there is no need to reproduce that information here. Instead, the Respondent may refer to the relevant document in the Project File by file name, including reference to relevant page(s) and/or section(s), if appropriate.

4. Whether for privilege or other reasons, if you do not provide a complete response to any Interrogatory or Request for Production, state with respect to such Interrogatory or Request for Production that a complete response is not provided and state the reason for the incomplete response.

5. If you contend that any information response to any of the following Interrogatories or Requests for Production is privileged, in whole or in part, or should otherwise

not be disclosed, or otherwise object to any part of the discovery request, you should identify with particularly each piece of information for which you claim a privilege or to which you object, state the grounds for exclusion or reasons for your objection, and describe the information withheld or objected to in terms of its subject matter, the time at which it was acquired or communicated, the parties who possessed and/or exchanged such information, and other information as may be reasonably needed by Petitioners to understand the basis of your objection to disclosure.

6. These Interrogatories and Requests for Production are deemed continuing in nature, and your answers are to be supplemented as additional information and knowledge become available to you.

7. Produce all documents in searchable PDF format with Bates numbers, with the exception of Microsoft Excel based files. These types of files are requested to be produced in their original Excel format. Provide input and output files for modeling simulations in format that can be opened with standard public-domain software, or provide the necessary software that

allows for proprietary format or other non-standard format files to be opened, viewed, and for the subject data to be comprehended by a human viewer.

RELATED INTERROGATORIES & REQUESTS FOR PRODUCTION

INTERROGATORY NO. 1: Identify and describe all air emissions inventory calculations conducted by IDEQ, or conducted by anyone else and which IDEQ is aware of, related to development of the PTC for which the results were not presented in the Statement of Basis, including by describing the results of the other emissions inventory calculations and by describing the inputs, data set(s), and/or assumptions used in the other emissions inventory calculations which differ from those for which the results are presented in the Statement of Basis.

RESPONSE: DEQ is unaware of any air emissions inventory calculations related to the

development of the PTC for which the results were not presented in the Statement of Basis.

REQUEST FOR PRODUCTION NO. 1: Provide all Documents that support or relate to your answer to Interrogatory No. 1.

RESPONSE: No responsive documents found.

INTERROGATORY NO. 2: Identify and describe all air dispersion modeling simulations conducted by IDEQ, or conducted by anyone else and which IDEQ is aware of, related to development of the PTC for which the results were not presented in the Statement of Basis, including by describing results of the modeling simulations and by describing the inputs, data set(s), and/or assumptions used in the modeling simulations which differ from those for which the results are presented in the Statement of Basis.

RESPONSE: Please see document titled "readme," which is found within the folder marked "Modeling Files for Interrogatory No. 2."

REQUEST FOR PRODUCTION NO. 2: Provide all Documents that support or relate to your answer to Interrogatory No. 2.

RESPONSE: Please see documents submitted herewith.

ADDITIONAL REQUESTS FOR PRODUCTION

INSTRUCTION FOR REQUESTS FOR PRODUCTION NOS. 3–6: "Communications" for Interrogatories Nos. 3 through 6 means all communications, including but not limited to all letters, emails, calls, voicemails, text messages, meetings, meeting notes, reports, status updates, memos to file, and all Documents included with such Communications, and includes those generated prior and up to the date of the issuance of the PTC as well as after the date of the issuance of the PTC and up to the present day.

REQUEST FOR PRODUCTION NO. 3: Provide all internal IDEQ communications

related to the development and issuance of the PTC

RESPONSE: Please see documents submitted herewith.

REQUEST FOR PRODUCTION NO. 4: Provide all Communications, both internal and external, related to or between IDEQ and EPA regarding the development and issuance of the PTC.

RESPONSE: Please see documents submitted herewith.

REQUEST FOR PRODUCTION NO. 5: Provide all Communications, both internal and external, related to or between IDEQ and Midas Gold, Perpetua Resources, or any of their consultants, experts, or contractors regarding development and issuance of the PTC.

RESPONSE: Please see documents submitted herewith.

REQUEST FOR PRODUCTION NO. 6: Provide all Communications, both internal and external, related to or between IDEQ and any other person, agency (local, state, or federal), or entity regarding the development and issuance of the PTC.

RESPONSE: Please see documents submitted herewith.

REQUEST FOR PRODUCTION NO. 7: Provide all guidance, policies, memos to file, or other Documents supporting use of a 70-year "lifetime" average for arsenic emissions in comparison to the AACC for the PTC.

RESPONSE: No responsive documents found.

REQUEST FOR PRODUCTION NO. 8: Provide all air permits issued by IDEQ, other than the PTC, that applied a 70-year "lifetime" average for any carcinogenic TAP in comparison to the associated AACC, including the statements of basis.

RESPONSE: No responsive documents found.

REQUEST FOR PRODUCTION NO. 9: Provide all guidance, policies, memos to file, or

other Documents related to defining an ambient air boundary.

RESPONSE: Please see documents submitted herewith.

REQUEST FOR PRODUCTION NO. 10: Provide all air permits issued by IDEQ, other than the PTC, for which the general public had regular, conditional access to any location within the facility's ambient air boundary, including the statements of basis.

RESPONSE: No responsive documents found.

REQUEST FOR PRODUCTION NO. 11: To the extent not previously disclosed in the Project File or in response to any of the above, provide all Documents stored in the project folder in IDEQ's electronic records management system for Project 62288.

RESPONSE: No responsive documents found.

REQUEST FOR PRODUCTION NO. 12: To the extent not previously disclosed in the Project File or in response to any of the above, provide all Documents stored under the facility folder for Midas Gold and/or Perpetua Resources (or any similar variation) in IDEQ's electronic records management system.

RESPONSE: Please see "Facility-Wide Classification Form P-2019.0047"

II. The Hearing Officer Must Grant Summary Judgment in Favor of DEQ Because DEQ Crafted the PTC Requirements to Control Dust Based on its Expertise, Following A Careful Investigation and Deliberate Decision-Making Process. ..... **Error! Bookmark not defined.**

A. Petitioners fail to demonstrate that any of the alleged errors in the PTC regarding dust emissions affect a substantial right. ..... **Error! Bookmark not defined.**

B. The Petitioners fail to demonstrate DEQ abused its discretion by requiring Perpetua to detail specific traffic-related parameters in the Fugitive Dust Control Plan rather than the PTC. ..... **Error! Bookmark not defined.**

C. The Petitioners fail to demonstrate DEQ abused its discretion by requiring Perpetua to achieve a 93.3% dust control efficiency. ..... **Error! Bookmark not defined.**

D. Petitioners fail to show that DEQ erred by requiring operating procedures to be detailed in an enforceable Operations and Maintenance Manual. ..... **Error! Bookmark not defined.**

E. Using precipitation data from EPA's AP-42 was not arbitrary or capricious. .....**Error! Bookmark not defined.**

III. The Hearing Officer Must Grant Summary Judgment in Favor of DEQ as it Relates to Arsenic from Various Sources. ..... **Error! Bookmark not defined.**

A. Petitioners fail to demonstrate that any of the alleged errors in the PTC regarding arsenic emissions affect a substantial right..... **Error! Bookmark not defined.**

B. DEQ's T-RACT analysis complies with the Air Rules.. **Error! Bookmark not defined.**

C. DEQ properly used its discretion and expertise to average arsenic emissions over the projected duration of the mine..... **Error! Bookmark not defined.**

D. Petitioners fail to demonstrate DEQ's decision to exclude the Stibnite Road Access Route from the ambient air boundary is arbitrary and capricious. ..... **Error! Bookmark not defined.**

IV. The Hearing Officer Must Grant Summary Judgment in Favor of DEQ Because Petitioners Have Failed to Show that DEQ's Customary Use of Operating Plans is Arbitrary and Capricious. ..... **Error! Bookmark not defined.**

Conclusion ..... **Error! Bookmark not defined.**

COMES NOW, Respondent, the Idaho Department of Environmental Quality ("DEQ"), by and through the Office of the Attorney General, and hereby submits this Response to Petitioners' Joint Motion for Summary Judgment and a brief in support of its Cross Motion for Summary Judgment.

SUMMARY

DEQ's Air Quality Program issues between sixty to eighty permits to construct ("PTCs") annually. ("Decl. of Mike Simon," p. 9). Typically, DEQ holds one public comment period, if it is requested, and issues a PTC within approximately 150 days of the application submission. ("Decl. of Tiffany Floyd," p. 3). Perpetua Resources submitted an application for a permit to construct for its Stibnite Mine Project on August 20, 2019. Id. DEQ expended extraordinary efforts to evaluate the application, consider public comments, and engage in highly technical decision-making to arrive at a legally and environmentally sound permit. See, id. DEQ engaged in three extended public comment periods and two public informational meetings and issued the PTC in June 2022, *nearly three years after submission of the application*. Id. at 4.

Petitioners, Nez Perce Tribe, Idaho Conservation League ("ICL"), and Save the South Fork Salmon ("SSFS"), filed a petition to contest DEQ's issuance of PTC to Perpetua Resources for its Stibnite Mine Project. The PTC in question covers a range of potential air emissions from anticipated mining activities, but Petitioners limit their challenge to the permitted dust emissions. Perpetua intervened in the action and filed a motion to dismiss the petition, which DEQ joined. The resultant "Order on Motion to Dismiss" categorized Petitioners' claims into four general issues: PM_{10} from haul trucks/road, (2) Arsenic from various sources, and (3) Ambient air boundary, and (4) Ambient air monitoring. Subsequently, Petitioners filed their "First Amended Petition to Initiate

Contested Case" on December 6, 2022 (hereinafter, "Amended Petition"). In the following response, DEQ addresses Petitioners' assignments of error as those allegations were categorized in the "Order on Motion to Dismiss" issued November 15, 2022. Before considering the merits of the case, however, DEQ will address the dispositive issue of standing because while all Petitioners claim the dust emissions will cause them injury, none explain how.

THE HEARING OFFICER MUST GRANT SUMMARY JUDGMENT IN FAVOR OF DEQ BECAUSE PETITIONERS LACK STANDING

Summary judgment must be granted when there is no genuine dispute as to any material fact and the movant is entitled to judgment as a matter of law. I.R.C.P. 56(a). The moving party bears the "initial burden of establishing the absence of a genuine issue of material fact." Venable v. Internet Auto Rent & Sales, Inc., 156 Idaho 574, 581, 329 P.3d 356, 363 (2014). "Once the moving party establishes the absence of a genuine issue, the burden shifts to the nonmoving party to show that a genuine issue of material fact on the challenged element of the claim does exist." MFG Fin., Inc. v. Vigos, 163 Idaho 252, 255, 409 P.3d 832, 835 (2018) (citation omitted). In other words, while a court must construe the record in the light most favorable to the party opposing the motion, the nonmoving party "may not rest upon mere allegations in the pleadings, but must set forth by affidavit specific facts showing there is a genuine issue for trial." Gagnon v. W. Bldg. Maint., Inc., 155 Idaho 112, 114, 306 P.3d 197, 199 (2013) (citation omitted).

The Idaho Environmental Protection and Health Act entitles "[a]ny person aggrieved by an action or inaction of the department" to a fair hearing. I.C. § 39-107(5). Pursuant to DEQ's regulations, an "aggrieved person" is a person or entity with legal standing. IDAPA 58.01.23.005.01. Whether a petitioner has standing is a fundamental issue that must be addressed before a tribunal can consider the merits of a petitioner's claim. See, Valencia v. Saint Alphonsus Med. Ctr. - Nampa, Inc., 167 Idaho 397, 401–02, 470 P.3d 1206, 1210–11 (2020) quoting State v. Philip Morris, Inc., 158 Idaho 874, 881, 354 P.3d 187, 194 (2015).

> The doctrine of standing focuses on the party seeking relief and not on the issues the party wishes to have adjudicated. In order to satisfy the requirement of standing, the petitioners must allege or demonstrate an injury in fact and a substantial likelihood that the judicial relief requested will prevent or redress the claimed injury . . . The petitioners must establish a peculiar or personal injury that is different than that suffered by any other member of the public.

Noh v. Cenarrusa, 137 Idaho 798, 800, 53 P.3d 1217, 1219 (2002) (quotations and citations omitted). See also, In the Matter of Section 401 Water Quality Certification for Relicensing of the C.J. Strike Hydroelectric Facility, Docket No. 0102-01-06, Order (November 4, 2002). A petitioner bears the burden of "showing [a] distinct palpable injury and fairly traceable causal connection between the claimed injury and the challenged conduct." Valencia v. Saint Alphonsus Med. Ctr. - Nampa, Inc., 167 Idaho 397, 401–02, 470 P.3d 1206, 1210–11 (2020) (quoting Haight v. Idaho Dep't of Transp., 163 Idaho 383, 392, 414 P.3d 205, 214 (2018)). An "aggrieved" person's injury must be "immediate, not merely some remote, possible consequence, or mere possibility arising from some unknown and future contingency." Application of Fernan Lake Vill., 80 Idaho 412, 415, 331 P.2d 278, 279 (1958) (citation omitted). Finally, the petitioner must demonstrate "a substantial likelihood the judicial relief requested will prevent or redress the claimed injury." Valencia,167 Idaho at 402, 470 P.3d at 1211 (2020).

I. The Hearing Officer must grant the DEQ's motion for summary judgment because Petitioners have failed to show that they will suffer personal injuries that are causally connected to the alleged errors in the PTC or that the claimed harm can be prevented by the requested relief.

A. *Petitioners do not have standing because they fail to allege—and prove—personal injuries particular to themselves and distinct from the general public.*

To have standing, a litigant must demonstrate they will suffer an injury which is "distinct and palpable and not be one suffered alike by all citizens in the jurisdiction." Selkirk-Priest Basin Ass'n, Inc. v. State ex rel. Batt, 128 Idaho 831, 833–34, 919 P.2d 1032, 1034–35 (1996) (citing Miles v. Idaho Power Co., 116 Idaho 635, 641, 778 P.2d 757, 763 (1989)). In Selkirk, a non-profit

organization called the Selkirk-Priest Basin Association ("SPBA") challenged the Land Board's decision to sell timber from state endowment lands. 128 Idaho at 832, 919 P.2d at 1033 (1996). The SPBA claimed its members worked in and used the affected area for aesthetic and recreational enjoyment, which would be diminished by the timber sale. In its analysis of the issue, the Idaho Supreme Court compared SPBA's claim of injury to that of an outfitter in Boundary Backpackers v. Boundary Cnty., 128 Idaho 371, 375, 913 P.2d 1141, 1145 (1996). In Boundary Backpackers, a county ordinance was challenged by three non-profit organizations and eighteen individuals. Id. The Court found that all the plaintiffs lacked standing except for one commercial guide who would suffer a significant pecuniary injury if the county ordinance were left intact because it could result in the loss of the open, natural spaces from which he derived a living. 128 Idaho at 375, 913 P.2d at 1145 (1996). The Selkirk Court distinguished the outfitter's personal injury in Boundary Backpackers from SPBA's aesthetic or recreational injury because the affidavits submitted by SPBA's members failed to "establish a peculiar or personal injury that is different than that suffered by any other member of the public." Id. 128 Idaho at 834, 919 P.2d at 1035. The Court characterized SPBA's alleged injury as, "at best a generalized grievance," and therefore affirmed the district court's order granting summary judgment on the issue of standing. Id. In Idaho, generalized grievances must be remedied through the political process, not litigation. Troutner v. Kempthorne, 142 Idaho 389, 392, 128 P.3d 926, 929 (2006) citing Gallagher v. State, 141 Idaho 665, 115 P.3d 756 (2005).

Like the plaintiffs in Selkirk, Petitioners fail to demonstrate they will suffer personal injuries, distinct from the public. The Nez Perce tribe claims it will "suffer physical, cultural, spiritual, and economic injury caused by excessive air pollutants resulting from DEQ's issuance of the PTC."[1] ("First Amended Petition" p. 5.) However, the Nez Perce Tribe fails to explain how the permitted

[1] It is unclear whether "excessive air pollutants" means *any* dust emissions from mining activity or only those dust emissions that are in excess of what Petitioners claim could be allowed by law.

dust emissions will cause them harm that is not just a "generalized grievance" shared by all. In particular, the Nez Perce Tribe fails to provide any concrete basis demonstrating that any one particular, alleged shortcoming in the PTC will cause a distinct "physical, cultural, spiritual, and economic injury." Moreover, there is absolutely no evidence in the record to support such a claim.

Likewise, ICL claims it has standing because its members visit the mining site and nearby areas for "professional, recreational, aesthetic, and other purposes." ("First Amended Petition" p. 6.) The decisions in Selkirk and Boundary Backpackers require an "aggrieved party" to allege more than general recreational and aesthetic injuries. Furthermore, ICL makes no effort to detail what "professional" or "other" uses its members make of the mining site and "nearby areas."[2] Again, ICL fails to connect the PTC to any particular injury and fails to adduce any evidence in support of its claims. Save the South Fork Salmon makes similar claims to the other two Petitioners, alleging generic and generally applicable environmental harms without specifically averring how the PTC creates those injuries. Like the other Petitioners, SSFS makes no effort to detail an immediate, personal injury and has provided no evidence in support of its claims.

The Petitioners in this case are like others that have come before the Board of Environmental Quality and failed to articulate a personal injury from a final agency action. In Simmons Sanitation, for example, the petitioner-citizen challenged DEQ's approval of a solid waste landfill on the grounds that the landfill could pollute a nearby creek and because the application was legally deficient. (Docket No. 0106-05-01, "Preliminary Order" 9/23/2005).[3] The Hearing Officer found, *sua sponte*, that the petitioner failed to demonstrate how the deficiencies of the permit analysis or

[2] It is unclear from the Petition what constitutes a "nearby area;" there is no claim, or evidence in the record, that permitted dust emissions will escape from the mine site and damage off-site natural resources.
[3] Available at https://www.deq.idaho.gov/public-information/laws-guidance-and-orders/petitions-for-review-and-precedential-orders/ (last accessed 5/4/23).

pollution of the creek would impact him personally, so he lacked standing to challenge the landfill permit. ("Preliminary Order," p. 9).

Petitioners fail to aver specific, personal injuries, and have also failed to supply any evidence supporting their generalized grievances. Therefore, there are no facts to dispute. The Hearing Officer should find Petitioners have not demonstrated they are "aggrieved persons" and therefore lack standing under Idaho law to challenge the PTC.

B. *Petitioners do not have standing because they fail to demonstrate how their alleged injuries are caused by the alleged errors in the PTC.*

In addition to showing a concrete, palpable injury, a petitioner must show "a sufficient causal connection between the injury and the conduct complained of . . .." State v. Philip Morris, Inc., 158 Idaho 874, 881, 354 P.3d 187, 194 (2015) (citation and quotation marks omitted). The failure to clearly delineate a causal connection is a common issue among unsuccessful litigants coming before the Board of Environmental Quality. For example, in Rebound v. Idaho Dep't of Health and Welfare, Docket No. 0101-99-07, the petitioner trade union organization challenged DEQ's modification to a power plant permit, which authorized the facility to operate a gas turbine for auxiliary power. ("Order Affirming Decision of the Hearing Officer," 2/28/2000).[4] The Board reviewed affidavits from the organization's members to determine whether the organization had standing to challenge the permit modification. (Id. at 3). One of the petitioner's members claimed the modified permit would result in air pollution that would impair the local air quality, and in turn, the enjoyment and value of his property. (Id. at 5). Another member claimed the power plant's emissions during the winter would impair air quality to the point that he would be prohibited from using his wood burning stove and be forced to heat his home with more expensive options. (Id.) The Board found, however, that neither affidavit demonstrated a causal link between increased emissions allowed under the challenged

[4] Available at https://www2.deq.idaho.gov/admin/LEIA/api/document/download/5548 (last accessed 5/4/23).

permit and a diminishment in the use and enjoyment of property, or increased heating expenses. (Id.) Like the alleged injuries in this case, the allegations in Rebound were too speculative and unsupported by specific facts to demonstrate a "fairly traceable link" to the challenged conduct.

In another contested case before the Board, a citizen-petitioner challenged DEQ's decision to issue two separate Tier I air permits for the Potlach lumber processing complex on the grounds that two permits would be more difficult to enforce than one and that hindered enforcement would result in unsafe levels of toxic air pollutants. Solomon v. Idaho Dep't of Environmental Quality, Docket No. 0101-03-01 ("Order," p. 6).[5] The citizen, who was a member of ICL, complained he could view and smell the facilities' air emissions from his home and on his visits to Lewiston. ("Order," p. 5.) The Board found that the petitioner failed to connect his alleged injury to the challenged agency action because there was simply no evidence that issuing two permits instead of one would expose the petitioner to unpermitted levels of air pollution. (Id. at 6). Neither the citizen-petitioner, nor ICL, had standing to challenge DEQ's permits. (Id. at 8).

The present case also bears a close resemblance to Rickards v. Idaho Dep't of Health and Welfare, in which the petitioner challenged an air permit issued to the Department of Energy for the Idaho National Engineering Laboratory on the grounds that the permit would allow for excessive radionuclide emissions. (Docket No. 0101-92-12). The petitioner claimed that the excessive radionuclide emissions could adversely affect him because he regularly used the highway near the laboratory and lived in the vicinity. ("Hearing Officer's Findings of Fact, Conclusions of Law, and Proposed Decision and Order on Motions for Summary Judgment," 12/21/1992).[6] The Board adopted the Hearing Officer's finding that the petitioner's claimed injury was "too speculative," and

[5] Available at https://www2.deq.idaho.gov/admin/LEIA/api/document/download/5554 (last accessed 5/4/23).
[6] Available at https://www2.deq.idaho.gov/admin/LEIA/api/document/download/5532 (last accessed 5/4/23)

that he failed to establish a causal connection between the claimed harm and the alleged deficiencies in DEQ's permit analysis. (Id. at 11.)[7]

Like the petitioners in the aforementioned cases, the Nez Perce Tribe, ICL and SSFS all fail to clearly articulate a traceable causal connection between the challenged conduct and their alleged injuries. For example, Petitioners argue DEQ inaccurately determined that the dust mitigation provisions in the PTC will successfully prevent a violation of the PM_{10} NAAQS. ("First Amended Petition," p. 13.) However, they neglect to explain how a hypothetical violation of the NAAQS for PM_{10} causes one of their alleged injuries. Moreover, the language employed in the First Amended Petition belies the speculative nature of the Petitioners' apprehensions: "Changing these variables . . . *could* cause a violation of the NAAQS" (id. at 15); "[a] lesser control efficiency . . . *could* exceed the NAAQS" (id. at 16); "DEQ's failure to use the most representative data . . . *increases the risk* of miscalculation . . .." (Id. at 17) (Emphasis added).

The problem for Petitioners is threefold: (1) they fail to connect a violation of the PM_{10} NAAQS to one of their amorphous injuries; (2) even if they were to demonstrate a causal connection between a PM_{10} NAAQS violation and an injury, they have not shown that there is a substantial likelihood that the PTC will result in such a NAAQS violation, and (3) they have provided no evidence in support of their allegations. In fact, their briefing seems to admit DEQ's modeling analysis was correct, but that in certain hypothetical situations, too much dust *could* be emitted. The Petitioners' arguments regarding dust-borne arsenic ("First Amended Petition," pp. 17- 22) are similarly deficient. Overall, Petitioners' allegations are speculative, hypothetical, and bear no connection to any specific provision in the PTC. Most importantly, even if Petitioners had sufficiently alleged causal connections to their alleged injuries, they have failed to supply any evidence in support. The Hearing Officer must find that Petitioners do not have standing in this case

[7] The "Order" is available at https://www2.deq.idaho.gov/admin/LEIA/api/document/download/5530 (as of 5/4/23).

as a matter of law because they have failed to demonstrate a causal link between the challenged conduct and their alleged injuries.

C. *Petitioners do not have standing because they fail to show that the relief they seek will prevent their alleged injuries*.

The Petitioners are required to demonstrate a "substantial likelihood" that the relief they request will prevent or redress their claimed injuries. Noh v. Cenarrusa, 137 Idaho 798, 800, 53 P.3d 1217, 1219 (2002). But while the requested relief is highly specific, Petitioners fail to show that if the relief were granted, their injuries would be prevented. As discussed above, the injuries alleged are general and vague and bear no connection to the PTC. For example, Petitioners fail to demonstrate that should the relief be provided, they would only then be able to recreate or enjoy any one specific water body, physical location, or potential use. This is true of each allegation in the First Amended Petition. For this third reason, the Hearing Officer should find that Petitioners lack standing to challenge the PTC for Perpetua's Stibnite Mine Project.

THE HEARING OFFICER SHOULD GRANT SUMMARY JUDGMENT IN FAVOR OF DEQ BECAUSE THE PTC ANALYSIS WAS A LAWFUL EXPRESSION OF DEQ'S DISCRETION AND A DIRECT RESULT OF ITS DILIGENT INVESTIGATION AND EXPERTISE

I. Standard of Review

In Idaho, state agencies are afforded great deference in choosing the manner in which they carry out their administrative duties. The Idaho Legislature requires Idaho courts to uphold agency actions except in very narrow circumstances, in which an aggrieved party proves the action (a) violates statutory or constitutional provisions; (b) exceeds the agency's statutory authority; (c) is made upon unlawful procedure; (d) is not supported by substantial evidence in the record; or (e) is arbitrary, capricious, or an abuse of discretion. I.C. § 67–5279(3). The challenging party must prove the agency erred in a manner specified in Idaho Code § 67–5279(3), and that a substantial right of

that party has been prejudiced. Peck v. State, Dep't of Transp., 153 Idaho 37, 42, 278 P.3d 439, 444 (Ct. App. 2012) citing I.C. § 67–5279(4).

The Idaho Supreme Court recognizes that agencies are "clothed with power to construe [the law] as a necessary precedent to administrative action" J.R. Simplot Co. v. Idaho State Tax Comm'n, 120 Idaho 849, 854, 820 P.2d 1206, 1211 (1991) and has "long followed the rule that the construction given to a statute by the executive and administrative officers of the State is entitled to great weight and will be followed by the courts unless there are cogent reasons for holding otherwise." Id. (citation omitted). "A strong presumption of validity favors an agency's actions." Chisholm v. Idaho Dep't of Water Res., 142 Idaho 159, 162, 125 P.3d 515, 518 (2005) citing Young Elec. Sign Co. v. State ex rel. Winder, 135 Idaho 804, 807, 25 P.3d 117, 120 (2001). And an "agency's factual determinations are binding on the reviewing court, even where there is conflicting evidence before the agency, so long as the determinations are supported by substantial and competent evidence in the record." Peck v. State, Dep't of Transp., 153 Idaho 37, 42, 278 P.3d 439, 444 (Ct. App. 2012) (citations omitted).

Summary judgment must be granted when there is no genuine dispute as to any material fact and the movant is entitled to judgment as a matter of law. I.R.C.P. 56(a). DEQ is entitled to judgment as a matter of law unless Petitioners prove, by a preponderance of the evidence, (1) the truth of their claims of error, (2) that the alleged errors fall within those enumerated in I.C. § 67–5279(3), and (3) that the alleged errors affect their substantial rights. I.C. § 67–5279(4); IDAPA 58.01.23.062 ("Unless otherwise provided by statute, the petitioner has the burden of proving by a preponderance of the evidence, the allegations in the petition.")

II. The Hearing Officer Should Grant Summary Judgment in Favor of DEQ Because DEQ Crafted the PTC Requirements to Control Dust Based on its Expertise, Following A Careful Investigation and Deliberate Decision-Making Process.[8]

A. *Petitioners fail to demonstrate that any of the alleged errors in the PTC regarding dust emissions affect a substantial right.*

[8] Claims 1-5 in the "Order on Motion to Dismiss" 11/15/22, p. 8.

Idaho law requires agency decisions be upheld absent a showing of one of the errors enumerated in I.C. § 67–5279(3) and proof that the error affects the challenging party's substantial rights. Noble v. Kootenai Cnty. ex rel. Kootenai Cnty. Bd. of Comm'rs, 148 Idaho 937, 943, 231 P.3d 1034, 1040 (2010) (appellant failed to show Board's denial of his application to build subdivision prejudiced his right to develop his property); I.C. § 67–5279(4) (An "agency action shall be affirmed unless substantial rights of the appellant have been prejudiced.")

Here, the Petitioners have failed to allege—let alone prove—that any of the alleged errors in DEQ's analysis of particle emissions affects their substantial rights. In fact, there is no evidence in the record that can support a finding that any alleged error impacts the Petitioners at all. This is a dispositive issue that entitles DEQ to judgment as a matter of law.

B. *The Petitioners fail to demonstrate DEQ abused its discretion by requiring Perpetua to detail specific traffic-related parameters in the Fugitive Dust Control Plan rather than the PTC.*

An agency does not abuse its discretion when it "(1) correctly perceives the issue as one of discretion; (2) acts within the outer boundaries of its discretion; (3) acts consistently with the legal standards applicable to the specific choices available to it; and (4) reaches its decision by the exercise of reason." Chambers v. Idaho Bd. of Pharmacy & Agency, 170 Idaho 701, 705, 516 P.3d 571, 575 (2022) citing Lunneborg v. My Fun Life, 163 Idaho 856, 863, 421 P.3d 187, 194 (2018).

The Petitioners fail to explain—let alone prove—how DEQ abused its discretion by requiring Perpetua to detail traffic-related parameters for the haul roads in the Fugitive Dust Control Plan ("FDCP"). Instead, Petitioners argue that the lack of specific haul road permit conditions undermines DEQ's conclusion that the project will comply with allowable emissions. (Pet. Br. p. 25). This argument does not provide the Hearing Officer with grounds to remand the PTC. Moreover, it is a customary practice for DEQ to require permit applicants to develop detailed operational plans after

a permit to construct is issued. ("Decl. of Mike Simon," p. 7). As Petitioners point out, DEQ is aware of which traffic-related parameters are "critical" to ensure Perpetua does not exceed modeled emissions, and DEQ will be able to enforce those requirements because they are incorporated into the PTC. DEQ has experience enforcing provision contained with fugitive dust control plans (id.) and there is no evidence in the record to support the contention that DEQ will allow Perpetua to operate with an inadequate and unenforceable FDCP.

C. *Petitioners fail to demonstrate DEQ abused its discretion by requiring Perpetua to achieve a 93.3% dust control efficiency.*[9]

An agency does not abuse its discretion when it "(1) correctly perceives the issue as one of discretion; (2) acts within the outer boundaries of its discretion; (3) acts consistently with the legal standards applicable to the specific choices available to it; and (4) reaches its decision by the exercise of reason." Chambers, 170 Idaho at 705, 516 P.3d at 575 (2022).

In this case, Petitioners argue the permit conditions restricting fugitive dust are insufficient. (Pet. Br. p. 23, "Perpetua's operations would cause a violation of the PM_{10} NAAQS and arsenic AACC, even while fully complying with the Permit."). According to Petitioners, the fugitive dust permit conditions are faulty for three reasons: (1) Petitioners are not convinced that a combination of water spray and chemical dust suppressants will achieve a 93.3% dust control efficiency, (2) even if the 93.3% is achievable, the permit conditions inadequately specify the procedures for applying water and chemical dust suppressants, (3) the specific procedures, which will be contained in the FDCP, will not be subject to public comment—only DEQ approval. These arguments concede DEQ had the discretion to make different choices, yet the Petitioners neglect to argue exactly how DEQ supposedly abused its discretion in making those choices.

[9] The "Order on Motion to Dismiss" 11/15/22 (p. 10) retained Claim No. 2 ("Assumption of 93.3% Emissions Control") because it seemed possible that Petitioners could show DEQ abused its discretion by declining to include additional and unspecified permit conditions to help ensure a 93.3% control efficiency; however, Petitioners have not argued—or demonstrated—that DEQ abused its discretion.

Moreover, the Petitioners' argument is illogical: Petitioners argue that requiring Perpetua to develop and maintain a plan to "ensure compliance with fugitive dust requirements" (Permit Condition 2.5) "in no way assures that Perpetua will both develop and follow" the plan. (Pet. Br. p. 21). This begs the question: what evidence do Petitioners have that adding more specific provisions to the permit—rather than the FDCP—will ensure that Perpetua controls its dust emissions? Furthermore, Petitioners' briefing and references to DEQ's analysis make it abundantly clear that DEQ knows that to be successful, the FDCP must contain specific provisions about haul road conditions and maintenance. Finally, Petitioners have failed to provide any evidence that a public comment period would improve the FDCP or compliance therewith. Overall, the record supports the conclusion that DEQ is aware of the operational variables that can impact Perpetua's compliance with NAAQS, and there is no evidence that DEQ will approve a FDCP that lacks the necessary controls.

In fact, DEQ carefully and conscientiously studied this complex issue to ensure air standards were met. (See, PET 558-59 "Response to Comments" *and* "Declaration of Kevin Schilling," pp. 15-16 and "Declaration of Mike Simon," pp. 5-6). Requiring Perpetua to achieve a 93% control efficiency was soundly within DEQ's discretion and supported by objective data that was reasonably relied upon.

D. Petitioners fail to show that DEQ erred by requiring operating procedures to be detailed in an enforceable Operations and Maintenance Manual.[10]

Petitioners argue that DEQ erred by requiring Perpetua to develop monitoring and recordkeeping procedures for haul road activities in the Operation and Maintenance Manual ("O&M"). However, this allegation appears to fall within the scope of Claim 3 or Claim 4, as discussed in the "Order on Motion to Dismiss" (pp. 11-14), and those claims were dismissed.

[10] Petitioners do not argue that use of the "O&M" plan is arbitrary or capricious or any other actionable error under I.C. § 67–5279(3).

E. *Using precipitation data from EPA's AP-42 was not arbitrary or capricious*.[11]

Perpetua's environmental consultants provided DEQ with precipitation data gathered at the mine site that showed 155 days of measurable precipitation per year. ("Decl. of Kevin Schilling," p. 13). DEQ declined to use those data because they were gathered over too short a timeframe to be reasonably relied upon to reflect climatic variability. Id. AP-42, however, is a compilation of emissions factors that EPA has published since the 1970s and is sufficiently detailed to support reasonably accurate emissions estimates. Id. The Taylor Ranch station is over forty kilometers away from the mine site, which undermines its utility for this project. Id. Moreover, the data from that station was essentially the same as provided by AP-42. Id. It was well within DEQ's discretion to use the AP-42 for its precipitation data, and Petitioners have offered no argument, or evidence, showing otherwise.

III. The Hearing Officer Should Grant Summary Judgment in Favor of DEQ as it Relates to Arsenic from Various Sources.[12]

A. *Petitioners fail to demonstrate that any of the alleged errors in the PTC regarding arsenic emissions affect a substantial right*.

Idaho law requires agency decisions be upheld absent a showing of one of the errors enumerated in I.C. § 67–5279(3) and proof that the error affects the challenging party's substantial rights. Noble, 148 Idaho 937, 231 P.3d 1034 (2010); I.C. § 67–5279(4).

Again, the Petitioners have failed to allege—let alone prove—that any of the alleged errors in DEQ's PTC analysis of arsenic emissions affect their substantial rights. There is no evidence in the record that can support a finding that any alleged error impacts the Petitioners at all.

B. *DEQ's T-RACT analysis complies with the Air Rules*

An agency decision is considered arbitrary or capricious only if made if it is made "without

[11] Again, Petitioners do not actually argue that this alleged error was arbitrary or capricious, only that it "undermines" DEQ's estimates of road emissions.
[12] Claims 6-10 in the "Order on Motion to Dismiss."

a rational basis, or in disregard of the facts and circumstances, or without adequate determining principles." Rouwenhorst v. Gem Cnty., 168 Idaho 657, 662, 485 P.3d 153, 158 (2021) (citation omitted). When an aggrieved party challenges an agency's interpretation of a rule or statute, the reviewing court employs a four-pronged test to determine the appropriate level of deference to the agency interpretation. Duncan v. State Bd. of Acct., 149 Idaho 1, 3, 232 P.3d 322, 324 (2010). The court must determine whether: (1) the agency is responsible for administration of the rule in issue; (2) the agency's construction is reasonable; (3) the language of the rule does not expressly treat the matter at issue; and (4) any of the rationales underlying the rule of agency deference are present. Id. citing Preston v. Idaho State Tax Comm'n, 131 Idaho 502, 960 P.2d 185 (1998).

Here, Petitioners argue DEQ acted arbitrarily and capriciously by failing to consider the economic costs and environmental impacts of Perpetua's plan to control arsenic-containing dust from the haul roads. (Pet. Br. p. 32). To support this contention, Petitioners argue that DEQ's approval of Perpetua's arsenic control plan violated DEQ's Air Rules 210.14.a-b because "DEQ *must* consider" effectiveness, economic costs, operational feasibility and unmitigated environmental impacts of the proposed control. Id. (Emphasis added). This is an inaccurate representation of the Air Rule, which does not use mandatory language but rather grants DEQ wide-ranging discretion in its consideration of available control technologies for toxic air pollutants, as discussed below.

Several provisions in the TAPs rules grant DEQ ample discretion to determine whether a control technology is appropriate for a particular project. First, a permit applicant is required to "demonstrate preconstruction compliance with Section 161 *to the satisfaction of the Department*." IDAPA 58.01.01.210 (emphasis added). This means that the applicant's proposal must satisfy DEQ that the relevant toxic air pollutant emissions will not "injure or unreasonably affect human or animal life or vegetation." IDAPA 58.01.01.161. Whether DEQ is satisfied is a matter of discretion. Second, DEQ has the discretion to determine whether a control technology is "reasonably available" based

on technological and economic feasibility. IDAPA 58.01.01.210. If DEQ decides a "control technology is not feasible, the emission standard may be based on the application of a design, equipment, work practice or operational requirement, or combination thereof." Id.

The Petitioners' entire argument that DEQ's T-RACT decision was arbitrary and capricious appears to hinge on the contention that the Air Rules require DEQ to consider—to an unknown extent and in unknown detail—environmental impacts, economic costs, and operational feasibility of proposed control technologies. This blanket argument incorrectly interprets the plain language of the rule, which allows DEQ to determine T-RACT on a "case-by-case basis." Id. at 210.14. These rules are meant to guide the permit applicant to submit the correct information to DEQ—not dictate DEQ's analysis of the information. If the rule were meant to require DEQ to consider environmental impacts and economic costs of proposed control technology (again, to an unspecified degree) then the rule would employ mandatory language that would render the analysis patently non-discretionary. Compare Section 214.a, where the applicant "must" submit information to DEQ and Section 210.14.c, in which technological feasibility "will" be determined based on various factors.

Idaho appellate courts have interpreted the plain language of statutes to determine whether a government function was non-discretionary. In Coeur D'Alene Tribe v. Denney, 161 Idaho 508, 521, 387 P.3d 761, 774 (2015), for instance, the Idaho Supreme Court held that the Secretary of State had a non-discretionary duty to certify a bill as law because the plain language of the statute said the "certificate *must* be signed by the Secretary of State and deposited with the laws in his office." citing I.C. § 67–505 (emphasis added). See also, State v. Thiel, 158 Idaho 103, 107, 343 P.3d 1110, 1114 (2015) (statutory language created ministerial, non-discretionary function for court to perform); Oppenheimer Indus., Inc. v. Johnson Cattle Co., 112 Idaho 423, 425, 732 P.2d 661, 663 (1986) (state brand inspector had no discretion to accept "fresh" brand as proof of cattle ownership when statute said fresh brands "shall not" be accepted); Saviers v. Richey, 96 Idaho 413, 415, 529 P.2d 1285,

1287 (1974) (ordinance terms requiring interpretation allowed city officials to use their discretion).

Furthermore, Petitioners' argument runs contrary to DEQ's interpretation of the rule. The Hearing Officer should defer to the agency's interpretation because DEQ is the responsible agency for administration of this rule and its construction is reasonable. As stated by Stationary Source Bureau Chief Mike Simon, DEQ approaches its T-RACT analysis in five steps:

1. Identify all available control options.
2. Eliminate technically infeasible options.
3. Rank Remaining Control Technologies.
4. Consider the energy, environmental and economic impacts.
5. Select the most effective control not eliminated in step 4.

("Decl. of Mike Simon," pp. 11-12). Perpetua proposed two controls for dust generated on the haul roads: paving, and a combination of water and chemical dust suppressants. Id. at 13. Paving was judged to be technologically infeasible due to the process and operating procedures of the mine. Id. That left chemical dust suppressants as the remaining option and obvious choice. Chemical dust suppressants are commonly used in the industry, and DEQ found no associated environmental impacts so long as manufacturer's instructions are followed. Id. Therefore, DEQ did not approve the use of chemical dust suppressants "without a rational basis, or in disregard of the facts and circumstances, or without adequate determining principles." Rouwenhorst, 168 Idaho 657, at 485 P.3d at 158 (2021). DEQ used its discretion and experience to approve a plan for controlling arsenic-laden dust with a proven technology in accordance with its traditional interpretation of Idaho's T-RACT rules.

C. *DEQ properly used its discretion and expertise to average arsenic emissions over the projected duration of the mine.*[13]

Petitioners argue that DEQ acted arbitrarily and capriciously when it "broke from its established practice" and employed multi-year averaging of arsenic dust emissions, which will create

[13] Claim No. 9 in the "Order on Motion to Dismiss."

"a real risk to public health." (Pet. Br. pp. 36-7). In other words, Petitioners accuse DEQ of acting without a rational basis or in disregard of the facts and circumstances before them, or without adequate determining principles. This accusation is false. DEQ developed its approach based on the facts and circumstances of the proposed project, employing a comparable adjustment factor used for other short-term projects.

DEQ's approach to modeling TAP compliance employed the Short-Term Source Factor rule (Section 210.15) by analogue. ("Decl. of Kevin Schilling," pp. 11-12). "This section allows an impact of 10 times the AACC for projects having an operational lifetime of no greater than five years. DEQ simply used this general approach to develop a project-specific adjustment factor for the SGP, using the 16-year maximum life of the project." Id. DEQ's calculations were as conservative as reasonably possible: the equation for calculating lifetime exposure risk to arsenic utilized the *highest* annual concentration from *fourteen* different models and repeated it over sixteen years, the lifetime of the mine. The annual arsenic emissions were based on 135,000 tons of per day, every day, for sixteen years. ("Statement of Basis, TAPs Addendum Modeling Review Attachment" PET 344). This total ore production is *over fifty percent greater* than the actual potential mine production. Id. Using worst-case scenarios, or overestimating expected emissions, is a common modeling strategy that ensures actual emissions do not exceed applicable air standards. (See, "Decl. of Kevin Schilling.")

Petitioners, on the other hand, offer absolutely no evidence that multi-year averaging presents a public health risk. There is no evidence that the general public will be exposed to any of the dust created at the isolated mine site, and the record is devoid of the data necessary to substantiate Petitioners' medical claim. For these reasons, DEQ is entitled to summary judgment on this issue.

D. *Petitioners fail to demonstrate DEQ's decision to exclude the Stibnite Road Access Route from the ambient air boundary is arbitrary and capricious*.[14]

[14] Claims 11, 12, and 13 in the "Order on Motion to Dismiss."

An agency decision is considered arbitrary or capricious only if made if it is made "without a rational basis, or in disregard of the facts and circumstances, or without adequate determining principles." Rouwenhorst v. Gem Cnty., 168 Idaho 657, 662, 485 P.3d 153, 158 (2021) (citation omitted).

Here, the Petitioners argue that DEQ's decision to allow Perpetua's registered guests to travel the Route means the air along the Route must be classified as "ambient air," as that term is defined at 40 CFR § 50.19(c) and IDAPA 58.01.01.006.10.[15] More specifically, the Petitioners argue that DEQ's decision to differentiate between Perpetua's registered guests and the "general public" was arbitrary and capricious. (Pet. Br. p. 18).[16] To support this proposition, Petitioners argue that DEQ violated its own written guidance and rule defining ambient air. In this way, the Petitioners are challenging DEQ's interpretation of its own rule defining a term of art. DEQ's interpretation is due substantial deference.

Petitioners also miscite EPA's 2019 "Revised Policy on Exclusions from 'Ambient Air,'" which does not require state agencies to apply the policy because they "retain the discretion to determine whether the steps taken by a source will be adequate to preclude public access." PET 773. The Petitioners misunderstand the scenario EPA warned "would expand the exclusion beyond reason," because that scenario involves two separate private properties, the first being the location of a stationary source, and the other being downwind. Under these specific circumstances, it would be unreasonable to exclude the guests of the downwind property from the "ambient air" just because they are located on private property not open to the general public. This scenario is also explained

[15] It is unclear from the Petitioners' argument exactly how far from the Route the "ambient air" boundary should extend from either side of the road.

[16] This appears to be a different argument than previously litigated; the Hearing Officer's "Order on Motion to Dismiss" 11/15/22 declined to dismiss Claim 11 on the grounds that Petitioners could possibly provide evidence that Perpetua does not have legal authority to exclude the "general public," and no such showing has been made.

in DEQ's guidelines: "employees of other facilities are considered to be general public for the facility in question." PET 744. More relevant to the current circumstances is that EPA's policy specifically excludes "business invitees" from the definition of "general public." PET 776.

DEQ's decision to differentiate between the "general public" and Perpetua's guests was not arbitrary, capricious, or an abuse of discretion, and DEQ's interpretation of the definition of "ambient air" merits considerable deference because (1) DEQ is responsible for administration of this rule in issue, (2) its construction is reasonable, and (3) the language of the rule does not expressly treat the matter at issue. See, Preston, 131 Idaho 502, 960 P.2d 185 (1998). DEQ excluded the Route from ambient air because Perpetua represented that it had legal authority to prohibit access by the "general public" and the practical ability to do so. ("Decl. of Mike Simon," p. 5 and "Decl. of Kevin Schilling pp. 4-8). The "general public" will be precluded from accessing the Route on a routine basis, and access for all guests will be carefully managed. The Route will not be, as Petitioners contend, a "public access road." Permit Condition 2.7 requires a combination of security escort vehicles, manned guardhouses, locked gates, barriers, warning signs, and registration of all guests to the mine site. These conditions are more than sufficient to notify a reasonable person that his presence is not permitted and therefore punishable under I.C. § 18-7008 for criminal trespass and actionable under I.C. § 6-202 for civil trespass. The DEQ guidance Petitioners cite regarding "right-of-way easements" or "common service roads" is inapplicable in these circumstances. PET 744. The "general public" retains no "right" to traverse the mine site, and access to guests will be strictly managed pursuant to Permit Condition 2.7 and the AMP.

E. *The Hearing Officer Should Grant Summary Judgment in Favor of DEQ Because Petitioners Have Failed to Show that DEQ's Customary Use of Operating Plans is Arbitrary and Capricious*.[17]

[17] This claim was introduced in Petitioners' "First Amended Petition to Initiate Contested Case" filed 12/6/22 following issuance of the "Order on Motion to Dismiss" 11/15/22.

Petitioners claim DEQ violated the Air Rule and acted arbitrarily and capriciously when it "rushed forward and issued Perpetua what is essentially a *partial, incomplete PTC*" so that it can subsequently review Perpetua's plans "outside the normal PTC process." (Pet. Br. p. 29). Again, Petitioners question DEQ's interpretation of its own rules and challenge a tried-and-tested permitting process that has governed Idaho's regulated community for years. The only aspect of the Stibnite PTC that falls "outside the normal PTC process" was the extraordinary and unprecedented three-year collaboration that preceded it.

Incorporating post-construction operational plans is common practice. According to Mike Simon, DEQ's Stationary Source Bureau Chief for the past nineteen years, DEQ commonly requires "certain plans, such as an O&M manual or FDCP to be prepared by the permittee post permit issuance." ("Decl. of Mike Simon" p. 10). The process "allows the permittee to prepare a specific plan or manual based on the actual equipment purchased and installed, the manufacturer's instructions and recommendations, as well as the operational characteristics of the facility after construction is completed." Id. This process also increases administrative efficiency because if specific conditions for a plan, such as the FDCP, "were instead listed in as permit conditions, any small change to the plan would trigger an administrative permit revision process." Id. at 7. DEQ can, and has, enforced the specific conditions contained in post-construction plans. Id. DEQ's practice of requiring and enforcing post-construction operational plans demonstrates that the requirements in this case are neither arbitrary nor capricious. DEQ takes very seriously its mission to protect public health and the environment, and it has a proven track record of doing just that.

CONCLUSION

The Hearing Officer should deny Petitioners' Motion for Summary Judgment. The Petitioners have failed to prove that they have standing to challenge the Stibnite PTC. Furthermore, the Petitioners have failed to prove that DEQ committed any errors in its thorough and diligent PTC

analysis that subject the permit to remand. Instead, the Hearing Officer should grant summary judgment in favor of DEQ because the Petitioners lack standing to challenge the PTC and because DEQ's analysis of dust and arsenic emissions comply with applicable statutes and conform with its customary permitting practice.

Dated: May 12, 2023, FOR RESPONDENT:

Attorneys for Respondent

BEFORE THE OFFICE OF ADMINISTRATIVE HEARINGS
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047 NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON Petitioners, v. IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent, and PERPETUA RESOURCES IDAHO, INC., Intervenor.	Agency Case No. 0101-22-01 OAH Case No. 23-245-01 DECLARATION OF KEVIN SCHILLING

I, Kevin Schilling, hereby declare under penalty of perjury pursuant to the law of the State of Idaho that the following is true and correct:

My name is Kevin Schilling. I am currently the Stationary Source Air Modeling Supervisor for the Stationary Source Bureau at the State Air Quality Division Program Office of the Idaho Department of Environmental Quality (DEQ) in Boise. I have held this general position since September of 2004, although the position was transferred from the Monitoring, Modeling, and Emissions Inventory (MMEI) section to the Stationary Source section in August 2017.

I received a Bachelor of Science (BS) degree in Environmental Science, with a minor in chemistry, from Washington State University in 1986. I attended graduate school after graduation and was employed by Washington State University as a research assistant at the Laboratory for Atmospheric Research. I received a Master of Science (MS) degree in Environmental Engineering (specializing in atmospheric chemistry, meteorology, air pollution monitoring, and atmospheric pollutant dispersion) from Washington State University in 1988.

I initially began employment with DEQ (at that time the Division of Environmental Quality) in spring of 1989 and then left the agency in 1990 to work as an environmental consultant at Morrison Knudsen, a civil engineering and construction company. I worked within the environmental services group at Morrison Knudsen, providing air quality science and engineering services on a wide range of projects. Specific services included air permitting, pollutant emissions estimation, atmospheric dispersion modeling, air pollution monitoring, and industrial hygiene functions. I returned to DEQ in December of 2001, working in the Technical Services Division where I primarily reviewed air modeling analyses submitted as part of air permit applications. In 2004, I transferred to the Air Quality Program Office as the Stationary Source Air Modeling Coordinator. My basic duties are to coordinate and oversee the review of air impact modeling analyses submitted to DEQ as part of air quality permit applications. To do this, I must have a strong understanding of *Idaho Air Rules*, DEQ policy, and DEQ guidance materials as well as EPA rules, policy, and guidance (much of which formed the basis of Idaho's rules, policy, and guidance). Outside of drawing on my regulatory

knowledge obtained through extensive experience in air quality permit modeling in Idaho (having reviewed hundreds of impact modeling analyses), I frequently consult air quality permit modelers in other states, EPA air permit modelers, and EPA rules, policy, and guidance materials. My duties also involve proposing changes to guidance and analytical procedures used to demonstrate compliance with air quality standards.

Presently, two staff positions, both Air Quality Dispersion Modeling Analysts, report directly to me. Darrin Mehr fills one of those positions and the other has recently been vacated by Dr. Pao Baylon who left DEQ to work with a private environmental consulting company. Dr. Baylon was the Air Quality Dispersion Modeling Analyst who reviewed most of the Perpetua Resources Idaho, Inc. (PRI) Stibnite Gold Project (SGP) air impact analyses.

My role in the permitting of the SGP has been both supervisory and technical/policy review and evaluation. As mentioned above, Dr. Baylon was the lead in the review and verification of impact analyses and the generation of supplemental analyses used to boost DEQ's confidence that the SGP would not cause or contribute to violation of air quality standards or increments. Where air impact modeling methods used by PRI in the application were atypical or of questionable appropriateness, Dr. Baylon discussed the approach, data, and analyses with me. Prior to permit issuance, Dr. Baylon, DEQ Permit Writer Kelli Wetzel, Permitting Supervisor Darrin Pampaian, and Stationary Source Bureau Chief Mike Simon discussed the various aspects of the SGP, including proposed operations, emission calculations, and various monitoring and recordkeeping requirements. This was done to provide a comprehensive assessment of DEQ's confidence of NAAQS and TAP compliance in a weight-of-evidence type approach. At the conclusion, I was highly confident that operation of the SGP, as described in the application and as required by the DEQ Permit to Construct (PTC), will not cause or contribute to a violation of a National Ambient Air Quality Standard (NAAQS) or exceed an applicable Toxic Air Pollutant (TAP) increment.

DEQ's Decision to Exclude the Stibnite Access Route from Ambient Air

Facilities exclude all or a portion of their sites from access by the general public for either: 1) security reasons, preventing theft or damage to the property or equipment present; or 2) protection of non-employees from hazards that may be present at the site, dictating either special instruction to appropriately protect those in the area from the hazard or the exclusion of certain individuals determined to be too sensitive to those hazards. Once a facility is reasonably secure to prevent unauthorized access, it is the facility's discretion who they allow or do not allow to access their site.

Handling of the Stibnite Road Access Route in the New Source Review ambient air impact analyses presents the unique situation where those seeking access to the facility wish to do so only for the purpose of passing through to a different destination. As such, the issues it presents were not anticipated during the development of DEQ guidance nor even EPA guidance. Therefore, certain specific details of DEQ guidance and even EPA guidance cannot be relied on to provide adequate resolution to the claim. For example, the DEQ *Air Modeling Guideline* (*Guideline for Performing Air Quality Impact Analysis*. Stationary Source Program. Air Quality Division. State of Idaho Department of Environmental Quality. July, 2021) states, "For the purpose of defining ambient air, the 'general public' is considered anyone not directly associated with the facility." Obviously, those wishing to access the site for the purpose of more efficiently accessing another destination are not directly associated with the facility; however, an elementary school class taking a tour of the mine site are not directly associated with the facility either, but they are unquestionably excluded from consideration as the *general public*. Alternatively, if the facility operates a visitor center with unrestricted/uncontrolled access, those visitors would be considered as the *general public*.

It is important to note that the Stibnite Road Access Route is excluded from ambient air

consideration for carcinogenic TAPs, even if the road were a public roadway. *Idaho Air Rules* Section 210.03 states that "if the toxic air pollutant is listed in Section 586 (carcinogenic TAPs), the receptor site is not considered to be at a point of public access if the receptor site is located on or within a road, highway or other transportation corridor transecting the facility." This provision accounts for the negligible long-term exposure opportunities for such roadways. Therefore, Argument I is only applicable to criteria pollutants such as PM_{10} and $PM_{2.5}$.

Early in the permitting process, the permit applicant (Midas Gold at that time) engaged with DEQ on the issue. Midas Gold explained that maintaining efficient historical access to recreational areas was very valuable to a group of people who visit the area, and Midas Gold wanted to explore options for allowing this to the greatest extent possible. However, if the roadway were treated similarly to ambient air areas outside of a facility boundary, it would be exceedingly difficult to demonstrate compliance with applicable ambient air quality standards. There were two primary options for addressing the Stibnite Road Access Route in an air impact analysis:

1) Analyze the road as ambient air, with unrestricted access for the *general public* (understanding that the permittee would need to close access during certain mining activities deemed as unsafe). The close proximity of the road to certain emission points would require a more refined and less conservative impact analysis. However, because the pollutant exposure potential on the roadway is limited by the short time anyone would be traveling on the road, DEQ's required level of NAAQS compliance confidence for permit issuance is less than for other ambient air areas where there is a higher potential for longer term exposure (long-term in the context of the averaging period of the standard considered – 24 hours for the 24-hour PM_{10} and $PM_{2.5}$ NAAQS and annual for the annual $PM_{2.5}$ NAAQS).
2) Exclude the road from ambient air, providing procedures on how access to the facility will be controlled to prevent access by the *general public*. To accomplish this, the permittee must

first assert that they have sole control of access to the area with the legal right to refuse access to anyone at any time and for any reason. Secondly, the permittee must practically manage access. Key to this is that those accessing the area clearly understand they are leaving a public area (and the protections that affords) and entering an industrial facility where their safety is the responsibility of the facility.

It was anticipated that NAAQS compliance could be demonstrated using either option. Option 1 was used in the air impact analyses presented in the draft Environmental Impact Statement (EIS). NAAQS compliance was more easily demonstrated in the EIS because emissions in the EIS could be based on best estimates of mining operations and associated emission-affecting parameters. Impact analyses supporting the state-issued PTC must be based on maximum allowable operations as allowed by enforceable permit conditions. PTC conditions could be drafted to support further refinement of emission calculations to confidently demonstrate NAAQS compliance along the Stibnite Road Access Route, but this would require considerable analytical scenarios and an extensive number of permit conditions to make such scenarios enforceable. After consideration, Option 2, excluding the Stibnite Road Access Route from *general public* access and from ambient air, was selected as the preferred approach for permitting.

The first requirement for excluding an area from ambient air is that the permittee has the legal right to preclude access by the *general public*. Perpetua has asserted that they have sole and complete control of access to the Stibnite Road Access Route, including complete closure of the roadway to anyone except mining employees at any time for any reason. For this to hold, PRI must not be legally required to provide access to the *general public* by any contract or agreement, and PRI must be able to deny access to anyone at any time. This is explained in Section 3.3.10 of DEQ *Modeling Review Memorandum* (*Demonstration of Compliance with IDAPA 58.01.01.203.02 (NAAQS) and 203.03 (TAPs) as it relates to air quality impact analyses*. Memorandum from Pao Baylon, Modeling

Review Analyst, Air Program, DEQ, through Kevin Schilling, Modeling Supervisor, to Kelli Wetzel, Permit Writer. January 6, 2022).

In addition to the legal ability to preclude access, the permittee must have the practical ability to preclude access by the *general public* and then demonstrate that practical measures will be implemented during facility operations. To answer this, it was first necessary to evaluate what excludes someone from consideration as the *general public*. All employees of the mine and contractors having official business with the mine can obviously be excluded from consideration as the *general public*. Alternatively, if a facility operated a retail business with unrestricted access, those areas of unrestricted access would be considered as ambient air. Permittees may also periodically provide tours of their facilities. These tourists can only be excluded from consideration as the *general public* if their access is carefully managed. Ordinarily, DEQ-issued permits do not include requirements pertaining to access management for those not employed by the facility. Access management is left to the facility; however, simply opening the facility gate to allow anyone to walk through would not serve to reasonably preclude access by the *general public*. We considered the following as requirements for exclusion from consideration as the *general public*:

1) Those requesting access must be informed that they are leaving a public area and entering (if access is granted) an area exclusively controlled by the facility.
2) The evaluation of who is granted access to the facility must be made on an individual basis.

Beyond the above listed requirements, it is not DEQ's responsibility or authority to evaluate reasons a facility may grant access to or through their site. What is important is that those accessing the facility clearly understand that they are no longer in a public area and no longer afforded any protections associated with that (such as NAAQS). Permit condition 2.7 outlines this and requires PRI to develop an *Access Management Plan* (AMP) to establish finer details of how site access will be managed. The third bullet of condition 2.7 addresses the access for the purpose of passing through

the facility, stating, "Only registered guests of the facility will be allowed to access to or through the facility. Those seeking to be a guest for the sole purpose of passing through the facility to another destination shall be provided a registration sheet that explains Perpetua's requirements for accessing the site and identifies potential hazards of the site."

DEQ consulted with EPA during the permitting process to discuss excluding the Stibnite Road Access Route from consideration as ambient air. EPA Region 10 Meteorologist and Regional Modeling Contact, Dr. Jay McAlpine, responded to an email I had sent to him on March 23, 2020, regarding the road. He stated, "My understanding is the road is likely exempt from ambient air protections because it is fully under the control and surveillance of the source and unsupervised public access is precluded. It seems like a slam dunk, based on my understanding of EPA's revised ambient air policy." An accurate copy of this email is attached hereto, as Exhibit A.

DEQ's TAP Compliance Methodology

The regulatory air permitting process has been established to primarily regulate well-defined, consistent pollutant-emitting processes. An example is a manufacturing process occurring inside a factory where the same processes occur year-after-year to create a product, with market fluctuation as the main variable. Emissions occur from well-defined points that are consistent through time. A major challenge in assessing pollutant exposures for mining activities, in the context of establishing allowable emissions in an air permit for a mining operation, is the dynamic nature of emissions and types of emission-generating activities. A mining operation involves numerous operational phases, each with different emission generating activities and a different magnitude of emission quantities, occurring at different locations at the site and at differing times. Even the distinction between *construction* and *operation* for mining activities becomes very fuzzy, as new areas are continually developed, utilized, and then decommissioned. It is challenging to develop a workable permit that addresses all mining phases and is supported by air impact analyses that account for these dynamic

activities in a conservative manner while still allowing for reasonable operational flexibility, which is critical for continually changing mining operations. The typical permitting approach is to use worst-case assumptions and data in a limited number of analyses that will confidently show that allowable operations, as described and limited in the permit and permit-required plans and procedures, cannot result in impacts that exceed applicable standards. When this approach is applied to mining operations, results of the impact modeling tend to greatly overstate actual impacts that will occur or even could occur.

The initial PRI PTC application assessed arsenic impacts in a straightforward application of Idaho's TAP permitting rules in Section 210 of *Idaho Air Rules*. This involved the following for carcinogenic TAPs:

1. Calculation of maximum allowable annual-averaged emissions from applicable sources, excluding sources that are considered exempt from consideration by *Idaho Air Rules* Section 210.20 (Sources covered by or addressed by 40 CFR Part 60, 61, or 63).
2. Modeling of maximum allowable annual emissions, using the single year of meteorological data collected onsite, to evaluate the annual impact at ambient air locations.
3. From the air dispersion modeling results (annual concentrations predicted at more than 9,500 specific points surrounding the mine), the maximum impact was identified and compared to the AACC provided in *Idaho Air Rules* Section 586.
4. Compliance with Section 210 is demonstrated if the maximum ambient air impact is less than the AACC.

The number of TAP-applicable arsenic emission sources for the SGP was expanded late in the permit application review process, after it was determined that some sources had been incorrectly excluded from analysis as per *Idaho Air Rules* Section 210. The incorrect exclusion was confirmed by the DEQ Permit Writer, the DEQ Permitting Supervisor, and the DEQ Stationary Source Bureau

Chief after considering comments received during a public comment period. Without completely reworking the complex and still very conservative approach used to assess carcinogenic TAP impacts, compliance could not be demonstrated using the typical approach outlined above. I then undertook the task of evaluating whether a more refined approach could be used to demonstrate compliance with TAP rules of Section 210.

A first step in refinement of impacts or adjustment of allowable impacts was to assure that reasonably available control technologies were used for all sources of arsenic. This level of control is referred to as T-RACT and its use in the evaluation of carcinogenic TAPs is described in Idaho *Air Rules Section* 210.12. If T-RACT is used to control emissions from sources, then the allowable impact is ten times that of the AACCs, corresponding to a lifetime cancer risk of 1 in 100,000. The AACC conservatively represents a long-term exposure (70 years) that would result in a 1 in 1,000,000 cancer risk. The DEQ Permit Writer is responsible for review and approval of T-RACT.

Consideration of T-RACT in the analyses still resulted in modeled arsenic impacts exceeding a value of 10 times the AACC. Faced with this problem, there were effectively two options: 1) revision of the emission calculation and modeling methods, using those that would be less conservative (less of a tendency to overestimate emission quantities that could occur) and perhaps more complicated; or 2) refine the exposure calculation to better account for the dynamic nature of emission-generating activities and the limited project lifetime. Before undertaking an extensive revision of the conservative emission calculation approach used in the emission inventory and the air impact model, DEQ evaluated whether certain refinements in exposure calculations would be consistent with requirements of *Idaho Air Rules* and specifically with *Idaho Air Rules* Section 210 for carcinogenic TAPs.

A worst-case conservative but simplistic approach used for the SGP did not show compliance with the arsenic AACC, or even the AACC multiplied by a factor of ten to reflect the allowable

impact when using T-RACT. DEQ then reviewed the basis for the AACCs to further evaluate refinement of exposure calculations to provide a more representative comparison to the AACC. AACCs were established in *Idaho Air Rules* to protect against a project-caused lifetime excess cancer risk of more than 1-in-1,000,000, or 1-in-100,000 where T-RACT is used to control emissions from sources. Prior to a regulatory clean up in 2022, *Idaho Air Rules* Section 006.125 defined *Toxic Air Pollutant Carcinogenic Increments (AACCs)* as, "Those ambient air quality increments based on the probability of developing excess cancers over a seventy (70) year lifetime exposure to one (1) microgram per cubic meter (1 $\mu g/m^3$) of a given carcinogen and expressed in terms of a screening emission level or an acceptable ambient concentration for a carcinogenic toxic air Pollutant. They are listed in Section 586." Although a lifetime risk is the benchmark, DEQ listed annual averages for the AACCs in *Idaho Air Rules* because that timeframe 1) is long enough to establish a good representation of long-term impacts for most sources requiring a permit, 2) is short enough to provide compliance assurance early in the life of the industrial operation, and 3) is convenient for compliance monitoring and reporting, providing a practically enforceable limit on operations. Use of an annual limit is not key to attaining a limit on the lifetime cancer risk; and, since a lifetime risk is the benchmark, use of annual averaged emissions to show compliance with the AACC on an annual basis could be unnecessarily restrictive where processes vary considerably year-to-year and have a project lifetime substantially shorter than 70 years, such as mining processes.

PRI indicated that the SGP will have a 16-year maximum project lifetime. To calculate a project-based arsenic concentration representative of the project, appropriate for comparison to the AACC (based on a 70-year exposure), the modeled impact was adjusted by the factor 16/70.

TAPs rules in *Idaho Air Rules* Section 210 have already established means to allow an adjustment for short-term projects. Section 210.15 provides for a *Short-Term Source Factor*. This section allows an impact of 10 times the AACC for projects having an operational lifetime of no

greater than five years. DEQ simply used this general approach to develop a project-specific adjustment factor for the SGP, using the 16-year maximum life of the project.

As an atmospheric scientist, my approach for the refined calculation of exposure was based on what I believe to be the regulatory intent of the TAP rules. I am uniquely positioned to comment on this because I participated in the development of these rules during the 1990s. I worked as an environmental consultant for Morrison Knudsen, and I was working with DEQ on the development of the TAP rules through the Idaho Association of Commerce and Industry (IACI). However, since I am not an expert in environmental law, I felt it was critical that my approach for the SGP be thoroughly reviewed by my management and the Idaho Attorney General's office. Although I did not receive any written review of the approach, I was assured by my management that the Deputy Attorney General reviewed it and found it to be consistent with the rules.

Finally, DEQ specified a 5-year averaging period for calculating emissions from allowable operations to evaluate TAP compliance. This was done to better allow for the large year-to-year variability in emission-generating activities and operational rates. This is appropriate since the benchmark is a lifetime risk rather than an annual risk. A 5-year averaging-period still affords a reasonable window for periodic compliance assessment through monitoring and recordkeeping.

DEQ's Use of Precipitation Data for Calculating Annual $PM_{2.5}$ Emissions from Haul Roads

The DEQ stationary source air modeling group is not directly responsible for review and approval of particulate emission calculations, including those for fugitive emissions from haul roads; however, when these emissions are a primary driver in modeled impacts, we periodically provide feedback to the permit writer on the appropriateness, variability, and uncertainty of emission factors and inputs to emission calculation equations. Fugitive particulate emissions from vehicle traffic on unpaved roads were calculated for the SGP using methods provided in EPA's AP42, Section 13.2.2. For annual emissions only, this section provides for a control factor that is a function of precipitation

(number of days in a year with precipitation greater than 0.01 inches). To aid in this calculation, AP42 also provides a map of the United States with contours of days with precipitation greater than 0.01 inches. This map, based on climatological data, was used to select the 120-day number representing conditions at the SGP location. Although the map's resolution is somewhat coarse, it is not "generic" as suggested in the Petitioners' Opening Brief. The resolution provided by the AP42 map is adequate to provide reasonably accurate emission estimation, well within the general uncertainty of the factor and other inputs such as silt content, vehicle weight, and control efficiencies of various measures that can be taken to reduce emissions.

It was suggested in the Petitioners' Opening Brief that climatological data from Taylor Ranch station should have been used in the emission calculation equation rather than the AP42 map. This station is over 40 kilometers from the SGP site, making it questionably more representative than the AP42 map. Furthermore, the Taylor Ranch data indicated there was an average of 113 days each year with precipitation over 0.01 inches, effectively matching the 120-day value obtained from the AP42 map. One year of precipitation data were also collected at the SGP site along with other meteorological parameters used in the air dispersion modeling. Since the onsite data were only collected for one year, it is questionable whether it can be considered more representative than the AP42 map for typical conditions because of the year-to-year variability (for example, variability in precipitation caused by El Nino and La Nina climate pattens). Finally, review of onsite precipitation data for 2014 indicates there were 155 days with precipitation equal to or greater than 0.01 inches, well above the 120 days obtained from the AP42 map. Use of these data would have lowered emission estimates for annual $PM_{2.5}$ fugitive emissions from vehicle traffic on SGP haul roads.

I acknowledge the large uncertainty and potential variability in calculated particulate emissions from vehicle traffic on mine-site haul roads relative to other stack emissions that are more easily quantified. The criteria bar for permit issuance is not to assure that emissions and impacts

were estimated using the most accurate means possible. The bar is evaluating whether impact analyses (including emission estimates), using the methods and data presented in the application and any supplemental DEQ analyses, demonstrate compliance with applicable NAAQS and TAP increments to the satisfaction of DEQ. DEQ satisfaction is then considered to be met when the review analyst has a high level of confidence that standards will not be exceeded. The compliance confidence level is evaluated in a weight-of-evidence type approach considering all aspects of the analyses, including but not necessarily limited to the following: magnitude and extent of estimated impacts; uncertainty in methods and data used; variability in emission generating activities and emission-affecting parameters; conservatism in operational scenarios used; effectiveness of monitoring methods to verify data and emission control; potential for impacts to sensitive receptors. Lead DEQ modeling review analyst Dr. Pao Baylon and I, after review of the analyses conducted and submitted in support of the permit application, were highly confident that implementation of the SGP as described in the application and the DEQ *Modeling Review Memorandum* and as limited by the issued permit and subsequent permit-required plans and procedures, will not cause or contribute to a violation of any applicable NAAQS or TAP increment.

Ambient Air Monitoring

Recently, I was made aware of an EPA guideline on ambient air monitoring in permitting actions (*Ambient Monitoring Guidelines for Prevention of Significant Deterioration (PSD)*. U.S. Environmental Protection Agency. Office of Air Quality Planning and Standards. Monitoring and Analysis Division. Research Triangle Park, NC. EPA 450/4-87-007. May 1987); however, this guideline was not specifically used during review of the SGP permitting process. As quoted from the guideline, postconstruction ambient air monitoring may be required in the following situations:

a. *NAAQS are threatened – The postconstruction air quality is projected to be so close to the NAAQS that monitoring is needed to certify attainment or to trigger SIP related actions if nonattainment results.*

b. *Source impact is uncertain or unknown – Factors such as complex terrain, fugitive emissions, and other uncertainties in source or emission characteristics result in significant uncertainties about the projected impact of the source or modification. Postconstruction data is justified as a permit condition on the basis that model refinement is necessary to assess the impact of future sources of a similar type and configuration.*

Although I did not specifically use the monitoring guideline to evaluate whether to recommend ambient air monitoring, the general procedure outlined by the guidance was used. A key consideration in the guideline is that ambient air monitoring is not required for a set of specific triggering conditions. Regarding postconstruction ambient air monitoring, the guideline states, "The PSD regulations include authority to require postconstruction monitoring. In general, EPA may require postconstruction monitoring from large sources or sources whose impacts will threaten standards or PSD increments. The permit granting authority will make this decision on a case-by-case basis."

The DEQ *Modeling Review Memorandum* describes the submitted impact analyses, DEQ's review of those, and DEQ's supplemental analyses. The impact analyses were performed using meteorological data collected onsite, unlike most minor source permitting projects where meteorological data are obtained from the closest existing meteorological station. However, PRI's consultant, Air Sciences, Inc. (Air Sciences), proposed to use a meteorological processing approach for permitting (referred to as the NON-BULKRN method) differing from what was used in analyses supporting the EIS (referred to as the BULKRN method). Both methods are considered acceptable by EPA modeling guidance, although the BULKRN method is more refined and uses the full extent

of meteorological parameters monitored at the site. I was somewhat uncomfortable with this approach as it generally went against recommendations from the EPA Region X Air Dispersion Modeler, Jay McAlpine, to use more refined methods where data needed for those methods had been collected. DEQ then requested Air Sciences to perform supplemental analyses with the BULKRN-processed data to provide further insight into the effect of meteorological data processing methods on modeled impacts. The analyses using the NON-BULKRN-processed data were considered as the primary compliance demonstration.

Maximum modeled PM_{10} 24-hour impacts, using the NON-BULKRN data, were at 75 percent of the NAAQS when combined with monitored background levels. Analyses using the BULKRN-processed meteorological data showed maximum impacts at 106 percent of the standard. With a modeled exceedance shown when using the supplemental analysis, DEQ was not highly confident of NAAQS compliance at this point. Further analysis was performed to evaluate the potential for exceeding the NAAQS.

DEQ further investigated the modeled exceedances shown when using the BULKRN-processed meteorological data. There were only five receptors (of 9,500 receptors modeled) that showed an exceedance of the 24-hour standard when assessing one year of hourly meteorological data. At the worst-case impact location, the standard was only exceeded by about 6 percent. The modeled exceedances were limited to an area northeast of the facility, and the frequency of days exceeding the 24-hour standard was less than 4 days out of 365 days in the year modeled.

Modeled high 24-hour PM_{10} impacts were found to be caused by the operational scenario of West End Pit activities, with onsite traffic on haul roads accounting for the majority of impacts that approach or exceed NAAQS. Next, we investigated those days where the model indicated an exceedance of the standard. All days when the 24-hour PM_{10} NAAQS was exceeded occurred during late December through mid-January. Not only is the potential for fugitive emissions less because of

higher precipitation and greater moisture levels during this period, especially on roadways, but background PM_{10} concentrations tend to be much lower (which was not accounted for in the analyses).

We also evaluated predicted impacts for operational rates closer to what would be expected. The 24-hour NAAQS compliance modeling used emissions associated with a production rate of 180,000 ton/day of development rock. This would correspond to 65,700,000 ton/year, which is considerably more than the expected peak rate of 42,692,000 ton/year (116,964 ton/day). DEQ then evaluated impacts for a rate of 120,000 ton/day, keeping other model variables constant. Results were at 148.5 $\mu g/m^3$, slightly below the 150 $\mu g/m^3$ NAAQS for the maximum impacting operational scenario and using the BULKRN-processed meteorological data.

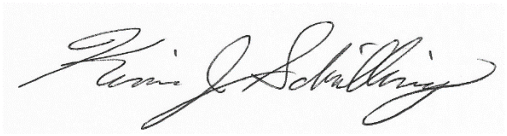
Finally, we evaluated the importance of achieving a 93 percent control efficiency for fugitive emissions from haul road traffic. An analysis was performed using a 90 percent control efficiency for haul road traffic emissions along with a more typical mining production rate of 120,000 ton/day. Compliance with the 24-hour PM_{10} NAAQS was demonstrated for the case when NON_BULKRN-processed meteorological data were used. When BULKRN-processed data were used, NAAQS exceedances were still modeled at five receptors. These results prompted the modeling group to recommend "that the permit require aggressive implementation of measures to achieve above 93% control efficiency for fugitive particulate emissions from roadways."

Late in the review process, PRI determined that the West End Development Rock Storage Facility will not be constructed, thereby eliminating the modeling operational scenario W5. Scenario W5 was the scenario where modeled exceedances of the 24-hour PM_{10} NAAQS were shown when using the BULKRN-processed meteorological data. When Scenario W5 is removed, the highest impacting operational scenario is W3, which represents the transport of development rock from the West End Pit to the Hanger Flats Development Rock Storage Facility. Maximum impacts still

slightly exceed the NAAQS when using a single value background concentration value, but are well below NAAQS when seasonal backgrounds are used (82% of the NAAQS at 123.5 $\mu g/m^3$).

The uncertainty in emission estimation methods greatly affects the NAAQS compliance certainty of the air impact analyses, as impacts are directly proportional to emission quantities. Modeled 24-hour PM_{10} impacts are heavily affected by particulate emissions from traffic on haul roads. The base emission factor, before accounting for any emission control measures, is a function of the silt content of the road surface. The submitted application used a silt content of 4.0 percent. This was the calculated median silt content of core samples of material collected onsite. The detailed review of emission calculation methods is primarily the responsibility of the permit writer, and the modeling group was not aware of the non-conservative silt content number used in the emission calculation until later in the review process. After learning that the median silt content was used for calculating emissions used to demonstrate compliance with the 24-hour PM_{10} NAAQS, I expressed my belief that NAAQS compliance could not be assured at a sufficiently high confidence level for haul road emissions representative of median conditions, even though there are other areas of the analyses that are very conservative. The options at this point were: 1) recalculate PM_{10} emissions from haul roads using a more conservative statistic for road silt than the median value, then revise the air impact modeling analyses; 2) require post construction ambient air monitoring to increase the assurance of NAAQS compliance; 3) use the 4.0 percent silt value as a maximum allowable value in the permit, requiring periodic monitoring of the road silt content during mining operations; and/or 4) develop other means by which lower levels of fugitive emissions from vehicle traffic could be attained and assured through monitoring (monitoring other than ambient air monitoring).

Requiring ambient air monitoring for the SGP was discussed within the Air Division, including stationary source staff, ambient monitoring staff, and State Implementation Plan (SIP) staff. From the perspective of air permit modeling verification, I believe the requirement of PM_{10}



ambient air monitoring to assure NAAQS compliance is of limited value for the SGP because of the following:

- Monitored values showing compliance with the NAAQS only demonstrates compliance for that point in space and time. While a monitored exceedance likely indicates a failure to adequately control emissions (unless the exceedance may be caused by elevated background concentrations), compliance doesn't assure compliance at other ambient air locations.
- Selecting a single monitoring location to represent worst-case impacts is nearly impossible. In general, atmospheric dispersion models perform reasonably well at predicting the magnitude of maximum impacts (provided the inputs of emissions and emission release parameters is reasonably accurate); however, they perform poorly at predicting the location of maximum impacts in most cases. The accuracy of predicted locations of maximum impacts is even worse for analyses involving complex terrain, complex meteorological conditions, and emission sources involving atypical release characteristics (fugitive emissions from vehicle traffic, blasting operations, ore handling, etc.). Monitoring results that show compliance with NAAQS may portray a false confidence of NAAQS compliance on a facility-wide scale.
- No sensitive receptors have been identified near the facility. Sensitive receptors are locations where there is likely to be a concentration of the *general public* present. These include private residences, schools, hospitals, care centers, retail stores, parks, and resorts. DEQ believes the confidence of NAAQS compliance must be higher at these locations than at locations where there is a lower probability of public exposure. Ambient air monitoring at these locations can provide the additional assurance that air pollutant impacts from a neighboring industry will not violate standards and impact the health of the *general public* at sensitive receptor locations.

After internal discussions, Option 3 was selected, changing the 4.0 percent silt content limit from the median value to a maximum value. If the required sampling and testing of road material indicates a maximum silt content above 4.0 percent, it will be a permit violation. The permittee must then work with DEQ to develop a way to further reduce emissions, adjust operations, and/or revise impact analyses to enable NAAQS compliance to be demonstrated. This would likely require a permit modification.

Exhibit A

From: McAlpine, Jerrold
To: Kevin Schilling
Subject: RE: Excluding roadways from consideration as ambient air.
Date: Friday, March 27, 2020 10:29:28 AM
Attachments: image001.png

Kevin,

I apologize, I missed this email earlier this week. My understanding is the road is likely exempt from ambient air protections because it is fully under the control and surveillance of the source and unsupervised public access is precluded. It seems like a slam dunk, based on my understanding of EPA's revised ambient air policy. This is my opinion based on interpretation of the policy, though … I cannot provide an approval.

If Idaho concludes the decision still falls with a 'gray area,' a formal request to the EPA can be provided and I can assist with getting the request to the ambient air review team (a part of the headquarters OAQPS air policy group).

Feel free to give me a call if you have questions or with to discuss more,
Jay

Subject: Excluding roadways from consideration as ambient air.

Hi Jay,

I hope things are going as smoothly as possible with you these days.

What are your thoughts on excluding a roadway that bisects a permitted facility from consideration as ambient air? During a NACCA call discussion on the recent changes in ambient air policy, there seemed to be some flexibility in how roadways could be considered. The case I'm most interested in involves a roadway that the permittee can legally control access, and access through the facility would not be a necessity for people (not needed to access homes, work, essential resources, etc - it would be used primarily to access a

recreational area). My thoughts were that the area could be excluded from ambient air by considering those using the roadway as guests of the industry. This would be accomplished by: 1) vehicles using the road would be escorted by the company through the area; 2) people wishing to use the road would be informed that they are considered as a guest of the facility while traveling through the area; 3) vehicles using the road would not be allowed to stop; 4) the facility would restrict use of the road during periods when high-emitting activities were performed that would likely cause high impacts to the roadway.

Thank you for any thoughts, suggestions, etc.

Best Regards,

Kevin

Attorneys for Respondent

BEFORE THE OFFICE OF ADMINISTRATIVE HEARINGS
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047 NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON Petitioners, v. IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent, and PERPETUA RESOURCES IDAHO, INC., Intervenor.	Agency Case No. 0101-22-01 OAH Case No. 23-245-01 DECLARATION OF MIKE SIMON

I, Mike Simon, hereby declare under penalty of perjury pursuant to the law of the State of Idaho that the following is true and correct:

My name is Mike Simon. I am currently the Stationary Source Bureau Chief within the Air Division of the State of Idaho Department of Environmental Quality (DEQ). I have held this position since 2004. I have over 30 years of air quality experience conducting air quality analyses, writing air quality permits, processing air quality enforcement cases and managing air quality programs. I received a Bachelor of Science (BS) degree in Electrical Engineering from the University of Idaho in 1993. Prior to my work at DEQ, I served in the US Air Force from 1986 to 1990 as a meteorological and navigational aids maintenance technician. My primary responsibilities included installation, operation, calibration, and maintenance of monitoring equipment that provided weather and navigational data for flight operations. Specific weather equipment experience is with temperature and dewpoint systems, wind speed and direction systems, transmissometers, cloud height sensing equipment, and weather radar systems.

During my tenure at the DEQ, I have held positions as an air quality permit writer, operating permit supervisor, enforcement supervisor, permits and enforcement manager and bureau chief. My primary role as Bureau Chief is in staffing, budgeting, and ensuring state-wide consistency in the permitting and compliance decision making process for the regulated community. The Stationary Source Bureau has three sections: modeling, permitting and compliance assurance. The modeling section is composed of two modeling analysts and a supervisor. The primary function of the modeling section is in the review and approval of air impact modeling analysis from applicants seeking air quality permits. The permitting section

is composed of seven permit engineers, one permit writer and a permit engineering manager. The permit engineers are assigned air quality permit applications by the permit supervisor and develop the permit and statement of basis based on technical reviews of emissions inventory estimates, review of applicable state and federal rules, guidance, and policy, and public comment. The permit program issues well over 100 permitting actions a year (these include Permits to Construct for new and modified sources, Tier I Operating Permits, General Permits, Permit by Rule, and exemptions) for a wide variety of industrial sources across the state of Idaho. The compliance assurance section has two compliance analysts and a compliance supervisor. The primary function of this section is to provide policy and guidance oversight for the inspection process, provide compliance assistance, and to process enforcement cases for apparent violations on air permits, rules, and regulations, from the regulated community. Each section supervisor reports directly to me.

On August 20, 2019, Perpetua Resources Idaho, Inc. (PRI), formally Midas Gold Idaho, Inc., submitted an air quality Permit to Construct (PTC) application for the proposed construction and operation of the Stibnite Gold Project (SGP). The SGP is an open-pit mining, ore preparation, and gold extraction facility proposed in Valley County, Idaho. The application triggered the minor new source review permitting requirements. During the nearly three years of processing PRI's PTC application, the application was determined incomplete three times; two public informational meetings were conducted, and three public comment periods with extensions were held.

My role in permitting the SGP has been in the supervision of staff, providing technical and policy review oversight for bureau staff and supervisors and in ensuring the

administrative process for issuing permits was followed. The DEQ staff involved in the PTC development for the SGP included permit supervisor Darrin Pampaian, permit writers Morrie Lewis and Kelli Wetzel, modeling supervisor Kevin Schilling, and permit modelers Tom Swain and Dr. Pao Baylon. DEQ staff spent a considerable amount of time on this application as compared to most all other permitting actions in recent history. For example, a typical PTC is processed in 100 days with no public comment period and 150 days with a comment period. The DEQ staff time included many discussions with PRI's technical team on almost a weekly basis to obtain clarifications or receive additional information. This was done to provide a comprehensive assessment of all sources of emissions and develop an enforceable permit that ensures pre-construction compliance with applicable air quality standards and to address public comment. I am confident that the proposed operation of the SGP as required by the final PTC will not cause or contribute to a violation of any National Ambient Air Quality Standard (NAAQS) or exceed an applicable Toxic Air Pollutant (TAP) increment.

DEQ's Decision to exclude the Stibnite Access Route from Ambient Air

PRI (then Midas Gold) proposed in their PTC application to exclude the Stibnite Access Road from ambient air by asserting their complete and sole authority to control access to or through the facility, granting or excluding access at their direction to anyone requesting to visit the site or pass through the site. PRI explained their intention to explore ways to maintain certain access of the Stibnite Access Road to area recreationalists while excluding the road from the ambient air analysis. This presented a unique situation for DEQ to establish requirements in a PTC that to my knowledge has never been done before.

DEQ's modeling staff were satisfied that PRI had the legal authority to preclude

public access. DEQ modeling staff also evaluated EPA guidance on Ambient Air and outlined requirements the permit needed to address to manage access to the facility. This decision is documented in Section 3.3.10 of the January 6, 2022, Modeling Memorandum from Dr. Pao Baylon. [PET 256] The permit staff developed the Access Management Plan (AMP) in the PTC which requires PRI to identify all measures employed to discourage public access at the mining facility, including any and all access roads. These measures include, but are not limited to, posting warning signs, using personnel to establish security patrols and escorts, creating barriers, providing locked gates, manned guardhouses, as well as developing registration requirements and safety information for those seeking to pass through the facility. Perpetua is required to identify and describe all of these procedures in the AMP and submit for DEQ approval 30 days prior to startup. Once the AMP is approved by DEQ, it becomes incorporated by reference into the PTC and is enforceable. DEQ uses its authority to develop this permit condition in accordance with IDAPA 58.01.01.211.01 for reasonable conditions. DEQ asserts the AMP is sufficient, reasonable, and appropriate to establish requirements for excluding or restricting access to the site and which supports the NAAQS air impact analysis for the entire facility.

Chemical Dust Suppressant Control for Unpaved Roads

PRI's consultant, Air Sciences, Inc., provided information in their application from their research of AP-42: Compilation of Air Emission Factors, Section 13.2.2, emission factors for unpaved roads (EPA 2006). According to AP-42, test studies on various unpaved industrial roads where chemical dust suppressants were applied documented a range from 90 to 99 percent dust control efficiency for PM_{10}. Based on this data, PRI proposed to use a 90%

dust control efficiency for PM_{10} when utilizing chemical dust suppressants on unpaved roads. DEQ permit staff recognized that the control efficiency of a chemical dust suppressant decreases with time, the number of vehicle passes, road maintenance, and weather conditions. In order to ensure the high efficiency of PM_{10} fugitive dust control on unpaved haul roads is maintained on a daily and annual basis, DEQ developed several permit conditions. These permit conditions include the development and approval of a Fugitive Dust Control Plan (PTC condition 2.6), requiring monitoring records every 12 hours for methods used to control fugitives at the facility (PTC condition 2.2), requiring daily inspections of all sources of fugitive emissions at the facility (PTC condition 2.4), and requiring haul road traffic to comply with a 10% visible emissions opacity limit, on an instantaneous basis, on haul road traffic (PTC condition 2.5). This haul road opacity requirement is the most stringent ever imposed by DEQ for haul road fugitive dust. In addition, the daily inspection of fugitive emissions requirement is more stringent than other permits DEQ has issued which require inspections on a less frequent basis, i.e., weekly, monthly, or quarterly.

DEQ requires comprehensive Fugitive Dust Control Plan

In developing the FDCP, permit staff evaluated the key parameters that influence the dust control efficiency using chemical dust suppressants. These are mixture rate, application rate, time between applications, amount of traffic, and meteorological conditions. The PTC requires PRI to address these key parameters in the FDCP which is reviewed and approved by DEQ prior to facility startup. Developing a dust control plan post permit issuance allows the permittee to develop cost-effective dust control program designed for their specific operation. For example, the permittee can identify the specific chemical dust suppressant

manufacture, safety data sheet, instructions, and incorporate site specific procedures for their personnel to follow in the FDCP. If the specific conditions for a FDCP were instead listed in as permit conditions, any small change to the plan would trigger an administrative permit revision process that is not efficient to administer. It is a common practice for FDCP's to be developed and updated by the facility and submitted to DEQ for review and approval. These Dust Plans are incorporated by reference in permits and are enforceable. DEQ has issued many permits requiring fugitive dust control plans, these include mining operations such as Jervois Mining USA Limited – Idaho Cobalt Operations, Cyprus Thompson Creek Mining Company, and Itafos Conda LLC - Rasmussen Ridge Mine. Fugitive dust control plans are found in other industries as well, such as sand and gravel plants, concrete batch plants, and asphalt plants. These fugitive dust control plans are also enforceable, and DEQ has conducted an enforcement action on a facility for failure to comply with a fugitive dust plan.

In addition to unpaved haul roads, the PTC regulates all other sources of fugitive dust at the facility including drilling, blasting, excavating, crushing, rock dumps, ore handling and processing equipment, and storage piles. The FDCP must address the reasonable control of emissions from all fugitive emission sources on a facility-wide basis. The permit also includes a requirement that PRI conduct daily inspections of all fugitive sources on a facility-wide basis. If fugitive emissions are not being reasonably controlled, or not meeting prescribed requirements in the permit, PRI must take corrective action as expeditiously as practicable.

The permit specifies all the minimum requirements the FDCP must include. For example, the plan must address the posting of haul road speed limits, identifying the

frequency and application rates of water and/or chemical dust suppressants, installation of wind barriers and fences, and the training of certain personnel. PRI must also conduct an annual evaluation of the FDCP for its effectiveness. The PRI permit requires a more comprehensive and detailed FDCP than in any other minor source permit DEQ has issued.

Haul Road Fugitive Dust Factors

In addition to using the chemical dust suppressant, controlled PM_{10} emission calculations for unpaved haul roads also incorporate the control efficiency for water. For annual dust control from water, AP-42 accounts for this in an equation that uses annual precipitation data. When using the 120 days of precipitation obtained from AP-42 section 13.2.2, the precipitation term accounts for natural mitigation in calculating the annual unpaved road emissions. Staff reviewed and approved this methodology. The daily unpaved road emission calculations use an applied water control efficiency of 33%. This value was supported by permit staff based on an evaluation of figure 13.2.2-2 of AP-42 for water control effectiveness on unpaved roads.

The haul road PM_{10} emissions were calculated using equations from AP-42 Section, 13.2.2. This calculation approach is very commonly used for unpaved haul roads in permit applications. This haul road equation utilizes three key variables: percent (%) silt content of the roadway, mean vehicle weight, and annual precipitation data. These variables influence the results in pounds emitted per vehicle mile travelled. DEQ determined that of the three variables, silt content needed specific enforceable permit conditions. The silt content relied upon for the haul road emission calculations was limited in the permit to 4% (PTC condition 3.13). The silt sampling procedures to demonstrate compliance with the silt limit were

developed as part of the Haul Road Capping Plan (PTC condition 3.13).

In reviewing the mean vehicle weight variable used in calculating haul road emissions, PRI proposed the use of 20 large Cat 789D mining trucks and 12 smaller CAT 740B dump trucks. PRI stated that the ratio of large to small trucks would be 20:12. Mean vehicle weight used in the calculation for haul road emissions include the total mean vehicle weight from fully loaded trucks. Rather than developing a methodology in the permit to measure and determine average vehicle weight each day, DEQ developed a haul road usage limit of 180,000 tons of ore and development rock per day (PTC condition 3.5). This limit accounts for the average loaded vehicle weight of all trucks as well as the average round-trip distance traveled as presented in the application. The monitoring methodology required to measure daily ore and development rock hauling is addressed in the required Operations and Maintenance Manual (PTC condition 2.20).

DEQ's requirement to develop Manuals and Plans in the PTC process

The permit requires PRI to develop and submit for DEQ approval 30 days prior to startup a Fugitive Dust Control Plan (FDCP), Operations and Maintenance (O&M) Manual, Access Management Plan (AMP) and a Haul Road Capping Plan (HRCP). The permit details the minimum and substantive requirements that PRI must consider and evaluate when preparing each Plan and Manual. DEQ contends the requirement to review and approve each Plan and Manual after the permit is issued and prior to facility startup is sufficient, reasonable, and appropriate to ensure compliance with applicable requirements. These approved plans and manuals are incorporated by reference in the permit and all elements are enforceable as part of the permit. The permit program issues between 60 and 80 PTCs

annually for a wide variety of industrial sources in Idaho. It is common for the permit program to require certain plans, such as an O&M manual or FDCP to be prepared by the permittee post permit issuance. This allows the permittee to prepare a specific plan or manual based on the actual equipment purchased and installed, the manufacturer's instructions and recommendations, as well as the operational characteristics of the facility after construction is completed. DEQ uses its authority to require a permittee to develop and submit for DEQ approval Plans and Manuals in accordance with IDAPA 58.01.01.211.01 as reasonable permit conditions.

DEQ's Decision not to include a PM_{10} Ambient Air Monitor

DEQ did consider the option of requiring a PM_{10} ambient air monitor in the PRI PTC. In considering this option, staff reviewed DEQ's history of decisions requiring ambient air monitors in permits. Where DEQ did require an ambient monitor in a permit, the facility had already been in operation for many years and there was a recent modeled NAAQS (National Ambient Air Quality) violation. In these cases, DEQ negotiated with the facility to site and operate an ambient air monitor and develop a corrective action plan for the facility. This allowed the facility to monitor air quality while it made process changes and modified its permit to demonstrate a return to NAAQS compliance. Once the changes were implemented or approved, the facility would then demonstrate NAAQS compliance through modeling analysis. The monitor was eventually removed from their respective permits. In these few situations, DEQ never had an ambient air monitored violation.

In all cases where DEQ processed a PTC application for a new or modified facility, DEQ required the applicant to demonstrate NAAQS pre-construction compliance using

DEQ's approved modeling procedures as outlined in the "State of Idaho Guideline for Performing Air Quality Impact Analysis." DEQ will not issue a final PTC if the applicant has not demonstrated pre-construction NAAQS compliance to the satisfaction of the Department.

DEQ also considered the location of the proposed PRI facility, the proximity of nearby residences and the implementation costs of requiring an ambient monitor. Given all of these factors, DEQ ultimately decided not to require an ambient air monitor in the permit. DEQ did reach out to PRI prior to final PTC issuance to see if they would voluntarily install an ambient monitor but declined at that time.

DEQ's T-RACT Analysis

T-RACT is an emission standard based on the lowest emission of toxic air pollutants that a particular source is capable of meeting by the application of a control technology that is reasonably available, as determined by DEQ, considering technological and economic feasibility. T-RACT is an allowable analysis to demonstrate preconstruction compliance for toxic air pollutants in accordance with IDAPA 58.01.01.210.12. PRI submitted a T-RACT application to demonstrate compliance for arsenic as well as other TAPs.

Idaho's T-RACT rules were developed to follow the general principles of the major new source review requirements to determine Best Available Control Technology (BACT). The process for selecting BACT in a major new source review application generally follows a five-step approach, often referred to as a top-down approach, and is determined on a case-by-case basis by the state authority. These steps include:

1. Identify all available control options.

2. Eliminate technically infeasible options.
3. Rank Remaining Control Technologies.
4. Consider the energy, environmental and economic impacts.
5. Select the most effective control not eliminated in step 4.

Idaho's T-RACT requirements generally mirror the BACT approach and requires an applicant to identify all available control options. Once all control options are identified, those options that are demonstrated to be technically infeasible can be removed from the list. The remaining control options would be ranked by control effectiveness, typically the highest percentage of pollutant removed is first. Selection of the final control option is then determined when considering environmental, energy and economic impacts.

PRI proposed a T-RACT analysis for both drilling rigs and haul roads. In reviewing the T-RACT analysis for the drill rig component, PRI identified three possible control technologies:

1. Best Management Practices
2. Wet Drilling with water injection
3. Dry Drilling with dust collectors

Wet Drilling was eliminated as technically infeasible due to several issues identified by PRI. Staff agreed with PRI's assessment and the remaining control options were Dry drilling with dust collection and Best Management Practices. PRI selected the top control technology as dry drilling with dust collection. Permit staff approved this option. The permit addresses the dust collector in the Operations and Maintenance Manuel requirements (PTC condition 2.20)

In reviewing the T-RACT analysis for haul roads, PRI identified the following possible control options:

1. Paving roads
2. Application of chemical dust suppressants and water

Paving haul roads was determined to be technically infeasible by PRI and permit staff because paving is not feasible for mining roads utilizing very heavy trucks which would exceed the design limitations of paving. Application of chemical dust suppressants and water is an effective dust control method which is a common control technology for unpaved haul roads. Magnesium chloride and water combinations are widely used and effective dust suppressant by state, county, and industrial unpaved roadways. DEQ is not aware of any negative environmental impacts as long as the operators apply the dust suppressant according to manufacturer's recommendations. DEQ has adequately included the requirements for chemical dust suppressants in the FDCP previously discussed.

PRI also proposed capping the haul roads with low arsenic quartzite as an additional work practice standard in addition to the T-RACT application of dust suppressants. The implementation of haul road capping of low arsenic material is specifically listed in the permit (PTC condition 3.13). The permit requires a Haul Road Capping Plan (HRCP) be developed and submitted to DEQ for approved (PTC condition 3.13) which will contain the sampling plan procedures for arsenic concentration. This will be used to ensure the median arsenic concentration of the development rock applied to haul roads does not exceed 90 ppm.

Attorneys for Respondent

BEFORE THE BOARD OF ENVIRONMENTAL QUALITY
STATE OF IDAHO

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047	CASE DOCKET NO. 0101-22-01
NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON Petitioners, v. IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent, and PERPETUA RESOURCES IDAHO, INC. Intervenor.	**DECLARATION OF TIFFANY FLOYD IN SUPPORT OF RESPONDENT'S CROSS MOTION FOR SUMMARY JUDGMENT**

I, Tiffany Floyd, hereby declare under penalty of perjury and pursuant to the law of the State of Idaho that the following is true and correct:

1. My name is Tiffany Floyd, and I am employed by the State of Idaho, Department of Environmental Quality ("the Department") as the Air Quality Division Administrator ("Air Administrator").

2. I have been working for the Department as the Air Administrator for 11 years.

3. I have worked for DEQ for nearly 24 years and have had the opportunity to work collaboratively with many agencies, businesses, and organizations both by being in Department regional offices and the 11 years in my current role.

4. I have a Bachelor of Science degree in engineering, specializing in civil engineering, from Idaho State University.

5. As the Air Administrator, I directly supervise four staff, and indirectly supervise thirty-two staff. The Air Quality Division has three bureaus: stationary source, planning, and data management.

6. One main responsibility within the Air Quality Division is to issue air pollution permits. The stationary source bureau is responsible for permitting, modeling, and compliance of air pollution sources. This bureau, comprised of sixteen staff members, works diligently to ensure businesses comply with federal and state air permitting rules. The permits issued provide for the greatest required level of protection of air quality.

7. The Department obtains delegated authority annually from the Environmental Protection Agency ("EPA") to implement the Clean Air Act in Idaho, which includes the authority to issue permits. The Department has had delegated authority for decades, and EPA approves our Clean Air Act program year after year.

8. In writing permits, staff use federal and state regulations as well as internal guiding practices outlined in standard operating procedures. Permit writers also use a peer review process wherein other permit writers review each other's permitting decisions to ensure permit conditions are appropriate for the type of source, are enforceable and comply with requirements, and lastly are documented in the Statement of Basis supporting the permit. These practices provide a structure that reinforces regulatory compliance while accounting for a broad range of stakeholder perspectives. With these mechanisms in place, and the expertise of these staff, I trust their decision making.

9. When the Department receives a permit application for a Permit to Construct, the Department strives to issue the permit within 150 days, which includes time for a public comment period. There is typically only one public comment period. The Department only holds a public hearing if one is specifically requested.

10. On August 20, 2019, Perpetua submitted its application to the Department for a Permit to Construct for the Stibnite gold mine site.

11. Upon review, the Department found more information was needed to support the permit application. After three incompleteness determinations and one addendum, Perpetua eventually provided the additional information the Department was seeking, and the Department began permit development.

12. It soon became apparent to the Department that this project was going to be one of the larger permitting actions by the Air Quality Division and was going to require greater involvement of the public, the Nez Perce Tribe, non-governmental organizations, EPA, and other federal agencies. To that end, over the next three years, the Department's permitting and modeling staff spent additional time providing opportunities for public involvement. In addition, permitting and modeling staff spent considerable time deliberating adherence to state and federal

requirements. The development of this permit took more than seven times the standard amount of time it takes to develop a permit to construct.

13. The Department held three extended public comment periods after three draft permits were prepared.

14. The Department held two public informational meetings to discuss the permit.

15. Staff crafted permit conditions in response to public comments received and the meetings from the many organizations mentioned above.

16. Additionally, the Department held frequent meetings with Perpetua and their consultant, sometimes monthly and eventually weekly, to ensure stakeholder concerns were vetted and addressed to reasonable satisfaction.

17. A final permit was eventually issued on June 17, 2022, almost three years after Perpetua submitted its permit application.

18. This effort was an unusual one, as most permitting projects don't often proceed this way with several informational meetings and extended public comment periods. This effort took almost three years, much longer than the typical 150-day timeframe for permit issuance.

19. The Air Quality Division prides itself on issuing permits in a timely manner. The Department does not often take years to complete permit projects because we are sensitive to the needs of balancing economic growth, support of business, and protection of the environment.

20. The Department took additional time than is typical in issuing this permit, time necessary to ensure the permit was reasonable and protective. It was a thoroughly vetted effort which followed guiding permitting principles and met state and federal requirements.

Tiffany Floyd

IN THE MATTER OF AIR QUALITY PERMIT TO CONSTRUCT P-2019.0047 _____ NEZ PERCE TRIBE, IDAHO CONSERVATION LEAGUE, and SAVE THE SOUTH FORK SALMON, Petitioners, v. IDAHO DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent, and PERPETUA RESOURCES IDAHO, INC., Intervenor-Respondent.	Case Docket No. 0101-22-01 **INTERVENOR-RESPONDENT'S MOTION FOR SUMMARY JUDGMENT**

COMES NOW Intervenor-Respondent Perpetua Resources Idaho, Inc. ("Perpetua"), by and through its counsel of record Stoel Rives LLP, moves the Board to enter summary judgment pursuant IDAPA 58.01.23, Idaho Rule of Civil Procedure 56, and the January 19, 2023 Scheduling Order in this matter. Perpetua is entitled to judgment as a matter of law on all of

Petitioners' claims for relief alleged in the Amended Petition to Initiate Contested Case: Air Quality Permit to Construct P-2019.0047 (June 17, 2022), filed December 6, 2022.

This motion is supported by Perpetua's accompanying Memorandum in Support of Motion for Summary Judgment and the Declaration of W. Christopher Pooser, as well as the documents and pleadings on file in this matter. For the reasons stated in Perpetua's accompanying memorandum, the Board should grant Perpetua summary judgment and dismiss the Petitioners' Amended Petition.

MEMORANDUM IN SUPPORT OF INTERVENOR-RESPONDENT'S MOTION FOR SUMMARY JUDGMENT AND IN OPPOSITION TO PETITIONERS' MOTION FOR SUMMARY JUDGMENT

TABLE OF CONTENTS

TABLE OF AUTHORITIES iii

KEY TO TERMS AND ABBREVIATIONS VI

INTRODUCTION 1

DEQ'S PERMIT RECORD AND EVIDENCE RELIED ON 2

STATEMENT OF UNDISPUTED FACTS 2

I. The Project, the permit history, and Petitioners' contested case. 2

II. PM_{10} emissions from the Project were conservatively estimated by DEQ. 4

III. The Stibnite Access Route. 6

IV. DEQ adopted long-established and well recognized control measures to control arsenic emissions from the Project. 6

V. DEQ analyzed arsenic emissions and determined that they would not exceed the lifetime risk limit established by the Idaho Air Rules. 7

STANDARD OF REVIEW 9

I. The Board must decide, as a matter of law, whether DEQ's action was arbitrary and capricious, an abuse of discretion, or contrary to law. 9

II. The Board may defer to DEQ's technical expertise and special skill. 11

ARGUMENT 13

I. Petitioners have failed to demonstrate, as is their burden, that they are persons "aggrieved" by an action or inaction of DEQ. 13

II. DEQ did not violate the CAA or part 51 regulations. 14

III. DEQ followed EPA guidance and exercised its discretion in excluding the Stibnite Access Route from the Project's ambient air (Claims 11 and 12). 16

A. EPA guidance on ambient air and agency discretion. 17

B. DEQ reasonably exercised its discretion in determining that the Stibnite Access Route is exempt from the Project's ambient air. 19

IV. DEQ did not act arbitrary and capricious or violate the Idaho Air Rules in determining that fugitive dust emissions from the Project's roads will met the PM_{10} NAAQS and arsenic AACC. 22

A. DEQ reasonably determined that 93.3% control efficiency for fugitive dust from haul roads was attainable and enforceable (Claims 2 and 8). 22

1. Petitioners have not shown that DEQ's use of the 93.3% control efficiency was unsupported or unreasonable. 22

2. Petitioners have not shown that the Final Permit lacks enforceable conditions to ensure 93.3% control efficiency

when DEQ imposed daily monitoring and other substantive conditions. 23

B. Petitioners have not shown that DEQ is required to impose conditions restricting vehicle miles traveled and truck weights when DEQ imposed surrogate production limits and other requirements (Claims 1 and 8). 27

C. Petitioners have not shown that DEQ's use of 120 days of precipitation data to estimate fugitive dust emissions was counter to DEQ guidance or arbitrary and capricious (Claims 5 and 8). 30

D. Petitioners have not shown that the Final Permit's production limits are unenforceable when DEQ imposed monitoring and recordkeeping requirements to determine compliance (Claims 4 and 8). 32

V. The Final Permit requires Perpetua to develop work plans for DEQ approval and does not violate the CAA or the Idaho Air Rules (Claim 3). 34

A. The CAA and the Idaho Air Rules do not require work plans to be submitted with applications or circulated for public comment. 35

B. Petitioners' legal authority from the Clean Water Act is distinguishable and inapplicable to DEQ's preconstruction permitting process. 37

VI. DEQ did not violate the law by issuing a Final Permit that omitted ambient air monitoring (Claim 13). 38

VII. Because chemical dust suppressant and water are already established as reasonably available control technologies, DEQ was not required to conduct an technological or economic feasibility analysis (Claims 6 and 7). 41

VIII. DEQ reasonably exercised its discretion in evaluating the health risks from arsenic (Claim 9). 45

INTRODUCTION

After nearly three years of repeated opinions and critiques, the Nez Perce Tribe, Idaho Conservation League, and Save the South Fork Salmon ("Petitioners") filed this contested case. Petitioners challenge the Idaho Department of Environmental Quality ("DEQ") Permit to Construct No. 2019.0047 (the "Final Permit") issued to Perpetua Resources Idaho, Inc. ("Perpetua")[1] for the Stibnite Gold Project (the "Project"). The Final Permit authorizes construction of a minor stationary source in a remote Idaho landscape that is designated in attainment with the National Ambient Air Quality Standards ("NAAQS"). Petitioners present the same opinions and critiques in this contested case that were previously presented to, and were addressed by, DEQ during the permitting process.

Ultimately, Petitioners reject DEQ's decision making and justifications for the conclusions reached in the Final Permit and ask that the Board of Environmental Quality ("Board") substitute their opinions and preferences for DEQ's substantive work and discretion. The Idaho Administrative Procedure Act ("APA") leaves agencies with the ability to judge how to interpret data and deal with scientific uncertainty and to decide which scientific and technical analyses to accept or reject. DEQ is delegated responsibility to make such determinations in air quality preconstruction permitting. After repeated attempts during the permitting process to substitute their preferences for DEQ's, Petitioners now ask the Board to second-guess the experience, expertise, scientific analyses, expert judgments, and reasoned conclusions of DEQ.

Respectfully, DEQ is better suited, and legally authorized, to make policy decisions based on scientific uncertainty. Petitioners' Amended Petition must be dismissed because DEQ's decisions were not arbitrary and capricious, an abuse of discretion, or contrary to law. Perpetua

[1] In the permit record, Perpetua is referred to as "PRI."

asks that the Board deny Petitioners' motion for summary judgment and instead grant Perpetua's motion for summary judgment as a matter of law.

DEQ'S PERMIT RECORD AND EVIDENCE RELIED ON

In opposition to Petitioner's motion for summary judgment and in support of its own motion for summary judgment, Perpetua relies on documents from DEQ's permit file supporting the Final Permit. Those documents include the exhibits submitted by Petitioners (cited as "PET [bates #]") and Perpetua (cited as "PRI [bates #]"). In addition, Perpetua cites to the Declarations of Kevin Schilling ("Schilling Decl.") and Mike Simon ("Simon Decl."), submitted by DEQ.

STATEMENT OF UNDISPUTED FACTS

I. The Project, the permit history, and Petitioners' contested case.

Perpetua designed the Project to develop gold and antimony resources from a previously mined landscape. PET 49, 51. The Project is located in central Idaho, approximately 10 miles east of the small community of Yellow Pine, Valley County, Idaho. PET 49. Perpetua has three distinct purposes for the Project: (1) to responsibly produce precious metals, as well as critical minerals necessary for the country's energy transformation; (2) to remediate and restore the legacy Stibnite mine site that was abandoned in 2012 by the federal government after decades of mining; and (3) to maintain a strong partnership with the local community.

In August 2019, Perpetua applied to DEQ for a permit to construct for a new source review minor source. PET 52. DEQ's review of Perpetua's application was thorough and comprehensive. Over the next three years, DEQ supplemented the application with additional information from Perpetua before determining the application complete, offered three extended comment opportunities to solicit public feedback and held two public informational meetings. PET 52-54, 93. Petitioners fully participated and repeatedly criticized DEQ's evaluations and proposed controls of particulate matter ("PM") and toxic air pollutant ("TAP") emissions. *See*

PET 549-634. Petitioners also engaged frequently and directly with DEQ staff and technical permit reviewers throughout the permitting process requesting information, analysis, and explanation of DEQ's ongoing work. *See*, *e.g.*, PRI 807-811, 812-816, 817, 970-974.

In response to Petitioners' formal comments during the three extended public comment periods, DEQ requested, and Perpetua provided, additional information such as updated hazardous air pollutant ("HAP") and TAP emission inventories and modeling analyses. *See* PET 52-54. With that information, DEQ conducted additional modeling evaluations of PM emissions, additional analyses of TAP emissions, and enhanced the enforceable permit requirements. *See* PET 53-54. All in all, DEQ asked Perpetua to supplement the application with additional information four times, prepared three draft permits (dated July 14, 2020, February 8, 2021, and December 9, 2021), and provided robust responses to Petitioners' public comments. This multi-year, comprehensive process culminated in the issuance of the Final Permit on June 17, 2022. *See* Amended Petition ¶¶ 23-26; PET 52-54.

Now Petitioners ask the Board to set aside and remand the Final Permit on the grounds that DEQ's issuance of the permit failed to comply with and violates the federal Clean Air Act ("CAA"), 42 U.S.C. § 7401, *et seq*., and Idaho rules, regulations, and guidance for permitting. In their Amended Petition, Petitioners repeat the same critiques pressed during the public review periods, seek more review and work by DEQ, and allege that DEQ's actions and the Final Permit are flawed. Notwithstanding their active participation, Petitioners are dissatisfied with the Final Permit issued by DEQ and urge the Board to substitute their suggestions for DEQ's reasoned decision making. While the Petitioners' Motion for Summary Judgment expresses differences of opinion and desired outcomes, the Petitioners fail to state facts or identify law sufficient to support allegations that DEQ failed to comply with or violated applicable law.

II. PM_{10} emissions from the Project were conservatively estimated by DEQ.

In accordance with Idaho law, DEQ implements air quality permitting through rules promulgated by the Board (the "Idaho Air Rules"). IDAPA 58.01.01. The Idaho Air Rules establish requirements for applicants and DEQ that govern the issuance of permits to construct for new and modified emissions sources. IDAPA 58.01.01.200-227. Under Section 203 of the rules, no permit to construct can be issued unless the applicant demonstrates "to the satisfaction of the Department" that the proposed project "would not cause or contribute to a violation of any ambient air quality standard" (or NAAQS) and that emissions of a TAP "would not injure or unreasonably affect human or animal life or vegetation." IDAPA 58.01.01.203.03.

PM_{10} emissions from the Project represent the largest pollutant emissions for this minor source. Emissions from stationary sources and fugitive sources of PM_{10} were estimated in the permit application materials. As DEQ recognized, air emission impact analyses for mining operations "typically involve considerable uncertainty and variability" in both emission-affecting parameters and dispersion-affecting parameters. PET 578-579. DEQ mitigated the uncertainties and variabilities with a conservative approach (i.e., overstating impacts) and analyzed the proposed emissions and modeling to fulfill the requirements of Section 203. PET 551-553, 561-562; *see generally* Schilling Decl.

There are four general steps for determinations based on modeling assessments.

Step 1: Calculate estimated air emissions from all appropriate sources of air pollution. This step typically utilizes the maximum capacity of each source of emissions, an emission factor that represents the best available information to estimate emissions, and an emission control efficiency if an emission control device or practice is used to reduce emissions. EPA's AP-42, *Compilation of Air Pollutant Emissions Factors*, is a commonly used reference for

emission factor information for air pollution sources, such as unpaved roads.[2] Acceptable emissions estimation methods vary and often require site-specific parameters.

Step 2: Characterize each air pollution source. Each emission source must be characterized by its initial air dispersion type (e.g., point, volume, or area) and initial air dispersion parameters (e.g., initial exhaust temperature and velocity, length, width, and height of the emitting source), and source location.

Step 3: Use the EPA approved air dispersion model to predict the downwind impacts of the emissions from all sources. The model inputs include the emissions from each source estimated in Step 1, the source characterizations from Step 2, the local terrain and meteorological conditions, and other model inputs.

Step 4: Run the model. The final step is running the model for all pollutants and the appropriate averaging periods to inform DEQ's determinations. In the case of PRI's permit, DEQ ran the model for many emissions scenarios to reflect the dynamic operational plan involved in mining activity.

DEQ issues a permit to construct when it is satisfied that the proposed emissions will not cause or contribute to a violation of a NAAQS and the TAP emissions would not injure or unreasonably harm human health, animal health, or vegetation. *See* IDAPA 58.01.01.203. The permitting record before DEQ, including the Final Permit, the Statement of Basis, and the Response to Comments, details the agency's analysis and decision making. As detailed below, that record shows that DEQ satisfied the requirement to produce and issue the Final Permit in conformity with the Idaho Air Rules.

[2] U.S. EPA, Technical Air Pollution Rules, AP-42 (Aug. 2021), http://www.epa.gov/ttn/chief/ap42/index.html#toc.

III. The Stibnite Access Route.

Because DEQ must be satisfied that a project's proposed emissions conform to the NAAQS, the boundary of the project's "ambient air" is important. Both EPA and the Idaho Air Rules define "ambient air" as "that portion of the atmosphere, external to buildings, to which the general public has access." 40 C.F.R. § 50(e); IDAPA 58.01.01.006.10. EPA's longstanding guidance provides that the ambient air boundary depends on the source's control of the area and the measures it takes to preclude the general public's access to the land. *See* PRI 1; PET 772.

The Stibnite Access Route refers to a road that will pass through the Project. PET 49. Public comments from local residents indicated a significant interest in access through the Project. PET 529. Individuals in the Johnson Creek and Yellow Pine areas who use Stibnite Road to access Thunder Mountain Road and points beyond were particularly concerned about access changes that would lengthen travel time. *Id*. In response to those concerns and at the direction of the U.S. Forest Service, Perpetua's predecessor, Midas Gold, evaluated numerous access options through and around the Project. *Id*. The Stibnite Access Route was identified as a route that would safely address local interests. *Id*.; *see also* PET 310.

Early in the permitting process, Midas Gold engaged with DEQ on the Stibnite Access Route because of the importance of establishing the ambient air boundary for the Project. *See* Schilling Decl. at 5. DEQ contacted EPA, who indicated that the Stibnite Access Route would be exempt from the Project's ambient air because it is fully under the control and surveillance of Perpetua and unsupervised public access would be precluded. PRI 10-11, 156-157.

IV. DEQ adopted long-established and well recognized control measures to control arsenic emissions from the Project.

Following the second public comment period and in response to Petitioners' comments, Perpetua modeled carcinogenic TAPs emissions using an emission inventory that included toxic

air pollutant reasonably available control technology ("T-RACT") controls, as authorized by Section 210 of the Idaho Air Rules. *See* PRI 604; IDAPA 58.01.01.007.12 (defining T-RACT). The Idaho Air Rules require that, when an applicant proposes to use T-RACT to demonstrate preconstruction compliance, that the applicant selects, and DEQ approves, control measures that are T-RACT. IDAPA 58.01.01.210.14. For a control measure to be approved as T-RACT, it must be reasonably available considering the technological and economic feasibility. *Id.*

Perpetua proposed, and DEQ approved, the following well recognized control measures as T-RACT:

- Installing and operating dust collection systems on drilling rigs;
- Capping the haul roads that are outside of the pits and development rock storage facilities with clean development rock; and
- Use of chemical dust suppressant with frequent watering on roads.

PET 70; PRI 604, 616. Perpetua considered, but rejected, paving the haul roads as technologically infeasible because the haul trucks exceeded the operational weight limit of paved roads. PRI 615, 617. Prior to being adopted as T-RACT, the use of chemical suppressants and watering had been included as conditions in the draft permit. PRI 620.

V. DEQ analyzed arsenic emissions and determined that they would not exceed the lifetime risk limit established by the Idaho Air Rules.

Under IDAPA 58.01.01.203, no permit to construct can be issued unless the applicant demonstrates "to the satisfaction of the Department" that the proposed emissions of a TAP "would not injure or unreasonably affect human or animal life or vegetation." Following the second public comment period, DEQ and Perpetua reevaluated TAP emissions in response to concerns expressed by Petitioners. PET 331. DEQ determined that a refined analysis of TAP

emissions, particularly arsenic, was needed to demonstrate preconstruction compliance with the Idaho Air Rules. *Id.*

On October 5, 2021, Perpetua submitted the *Stibnite Gold Project (SGP) Permit to Construct Application TAP Addendum* (the "TAP Addendum"). PET 331. The TAP Addendum reassessed source applicability to TAP permitting requirements, refined TAPs regulatory methods to demonstrate compliance with applicable TAP increments, revised and refined operations and operational parameters affecting TAP emissions, and refined TAP air impact analyses. *See id.* Specifically, the TAP Addendum evaluated arsenic emissions after considering the above-described T-RACT controls and operational adjustments. PET 333. The refined TAP analysis included many layers of conservative assumptions, including continual operation of the worst-case operational scenario; operation at maximum allowable rates for the entire averaging period; and no reduction in wintertime emissions from fugitive sources, thus discounting the emission suppression effects of increased moisture. *Id.*

Once the modeled carcinogenic TAP concentrations were obtained they were adjusted to account for the short, 16-year, life of the Project operations. PET 344; PRI 607. This was accomplished by multiplying the highest annual concentrations from the modeling scenarios by 16 years and then dividing by 70 years. PET 344; PRI 607. Multiplying the highest annual concentration of arsenic by 16 years allowed DEQ to determine the maximum concentration of arsenic an offsite receptor would be exposed to during the 16 year operational period. Dividing this maximum concentration by 70 years allowed DEQ to evaluate the lifetime health risk from that maximum exposure. PET 344; PRI 607.

DEQ and Perpetua determined that the maximum lifetime exposure concentration of arsenic would be 0.00095 $\mu g/m^3$, which is 41.3% of the lifetime exposure limit reflected as the acceptable ambient concentration for a carcinogen ("AACC") in Section 586. PET 348.

STANDARD OF REVIEW

I. The Board must decide, as a matter of law, whether DEQ's action was arbitrary and capricious, an abuse of discretion, or contrary to law.

The following discussion presents the Board with the appropriate standard of review in this contested case proceeding. Existing precedential orders lack clarity on the appropriate standard for the Board's review of a DEQ action that is based on a complete underlying record, developed over time and through the agency's routine work in the permit to construct review process. Both parties agree that it is the Board's role to conduct a review of the permitting record before DEQ and decide if DEQ acted lawfully under the Idaho Air Rules to issue the Final Permit. *See* Opening Br. at 13.

Under the Board's contested case rules, Petitioners have "the burden of proving by a preponderous of the evidence, the allegations in the petition." IDAPA 58.01.23.062. The rules also authorize the Board, or the hearing officer as its designee, to consider motions for summary judgment, governed by the Idaho Rules of Civil Procedure ("I.R.C.P."). IDAPA 58.01.23.162.02, .410; Idaho Code § 39-107(5). Thus the standards under I.R.C.P. 56 are appliable here. Based on Rule 56(a), the Board "must grant summary judgment if the movant shows that there is no genuine dispute as to any material fact and the movant is entitled to judgment as a matter of law." A moving party must support its assertion by citing particular materials in the record or by showing the "materials cited do not establish the … presence of a genuine dispute, or that an adverse party cannot produce admissible evidence to support the fact[s]." I.R.C.P. 56(c)(1)(B).

Here Petitioners challenge DEQ's action in issuing the Final Permit under the APA standard for judicial review for adjudicative agency actions. *See* Opening Br. at 13 (citing Idaho Code § 67-5279(3)). Under that standard, an agency action may only be overturned if it is (a) in violation of constitutional or statutory provisions, (b) in excess of statutory authority, (c) made on unlawful procedure, (d) not supported by substantial evidence, or (e) is arbitrary, capricious, or an abuse of discretion.[3] Idaho Code § 67-5279(3). The agency action must be upheld unless substantial rights of the petitioner have been prejudiced. Idaho Code § 67-5279(4).

There are additional principles regarding the APA standard worth addressing. The party challenging the agency decision must demonstrate that the agency erred in a manner specified in Section 67-5279. *Wheeler v. Idaho Dep't of Health & Welfare*, 147 Idaho 257, 260, 207 P.3d 988, 991 (2009). Thus, by relying on the APA standard, Petitioners invite a review process. Under Idaho law, it is DEQ's role to resolve factual issues in determining whether and under what conditions to issue a permit to construct, supported by the permitting record before it. *See* Idaho Code § 39-115. It follows that the Board's function is to decide whether, as a matter of law, DEQ's issuance of the Permit violated the law, was arbitrary and capricious, or was an abuse of discretion.

That means Petitioners present no true disputes of material fact—and indeed their opening brief identifies none—only question the legal conclusions drawn from the Final Permit's issuance. The Board's review is limited to determining whether DEQ acted as Petitioners allege. A violation of law speaks for itself. An "arbitrary and capricious decision occurs where the decision was reached in an unreasonable manner or based on clearly erroneous findings." *Floyd*

[3] Petitioners do not allege that DEQ's issuance of the Permit exceeded its statutory authority. *See* Opening Br. at 1, 14-37.

v. Bd. of Ada Cnty. Comm'rs, 164 Idaho 659, 668, 434 P.3d 1265, 1274 (2019). "Clearly erroneous applies where factual findings are not supported by substantial and competent evidence." *Id*. "An abuse of discretion standard examines whether the [agency] acted within the boundaries of its discretionary decision and applicable legal standards, and reached a decision by exercising reason." *Id*.

II. The Board may defer to DEQ's technical expertise and special skill.

In addition to those standards, the APA speaks to the deference the Board may afford DEQ in reaching a decision in a contested case: "[t]he agency's experience, technical competence, and specialized knowledge may be utilized in the evaluation of the evidence." Idaho Code § 67-5251(5); IDAPA 04.11.01.600.[4] Also the Board may take official notice of "generally recognized technical or scientific facts within the agency's specialized knowledge." Idaho Code § 67-5251(4)(b); IDAPA 04.11.01.602. Thus Idaho law explicitly recognizes that "the agency's repeated exposure to a specialized subject matter is a source of specialized knowledge that is useful in evaluating evidence." Michael S. Gilmore & Dale D. Goble, *The Idaho Administrative Procedure Act: A Primer for the Practitioner*, 30 Idaho L. Rev. 273, 319 (1994).

It follows that the Board, and the Hearing Officer as its designee, may give due consideration and deference to the technical expertise and special skill of DEQ. The deference the Board may give DEQ is illustrated by the deference courts give agencies, when reviewing an agency action.

First, Idaho courts defer to agency interpretations of law. *J.R. Simplot Co. v. Idaho State Tax Comm'n*, 120 Idaho 849, 862-63, 820 P.2d 1206, 1219-20 (1991); *see also Ranchers Cattlemen Action Legal Fund United Stockgrowers of Am. v. U.S. Dep't of Agric.*, 415 F.3d

[4] The Board's contested case rules incorporate the Idaho Rules of Administrative Procedure of the Attorney General, Sections 600 to 606. *See* IDAPA 58.01.23.003.13.

1078, 1093 (9th Cir. 2005) ("Regulations are presumed to be valid, and therefore review is deferential to the agency."). When an agency is entrusted with administering a statute, the courts may defer to the agency's interpretation of a statute or rule if the interpretation is reasonable and not contrary to its express language. *See Simplot*, 120 Idaho at 862, 820 P.2d at 1219.

Generally, the Idaho Supreme Court finds agency interpretations of statutes and rules are "reasonable unless the agency relied on erroneous facts or law in its determination." *Duncan v. State Bd. of Accountancy*, 149 Idaho 1, 4, 232 P.3d 322, 325 (2010) (citing cases). Stated differently, an agency's interpretation of a rule or statute is unreasonable when it "is so obscure and doubtful that it is entitled to no weight or consideration." *Simplot*, 120 Idaho at 862, 820 P.2d at 1219 (citation omitted).

Second, the reviewing courts defer to the agency when reviewing a scientific determination in its particular field of expertise. *See* Idaho Code § 67-5251(5); IDAPA 04.11.01.600; *see also Simplot*, 120 Idaho at 859, 820 P.2d at 1216 ("[T]he expertise of an agency is often useful in technical areas of the law where the risk of failing to understand all of the implications of a decision are great."); *Grindstone Butte Mut. Canal Co. v. Idaho Pub. Utils. Comm'n*, 102 Idaho 175, 182, 627 P.2d 804, 811 (1981) (noting that the Court will temper its review with deference to the expertise of the Idaho Public Utilities Commission when considering testimony that is technical in nature).

Indeed, when a court is reviewing a scientific determination, rather than a simple finding of fact, "a reviewing court must generally be at its most deferential," considering that the agency is making predictions, within its area of special expertise. *See Balt. Gas & Elec. Co. v. Nat. Res. Def. Council, Inc*., 462 U.S. 87, 103 (1983); *see also Appalachian Power Co. v. EPA*, 135 F.3d 791, 802 (D.C. Cir. 1998) (noting that deference is traditionally given to an agency when

reviewing a scientific analysis within its area of expertise). In other words, a scientific determination or analysis is not a finding of fact. Rather the agency is making a decision within its area of special expertise.

ARGUMENT

Applying those standards to this case, summary judgment is appropriate and is warranted in favor of DEQ and Perpetua as a matter of law. Petitioners appeal the issuance of the Final Permit based on alleged errors in the preconstruction permitting process. That process requires DEQ to reach decisions through the exercise of discretion and through its scientific and technical expertise. Summary judgment on contested cases has been found appropriate where the action being challenged involved a discretionary decision reached by the exercise of DEQ's special skill and expertise. *See, e.g*., *In re: Permit Applicant Garnet Energy LLC (Permit No. 0027-00081)*, Dkt. No. 0101-01-10, Order Granting Motion for Summary Judgment (Feb. 22, 2002).

For the Board's and the hearing officer's convenience, in the headings that follow, Perpetua identifies the "Claim" numbers as set out in the hearing officer's Order on Motion to Dismiss. *See* Order at 8-9, 25-26 (Nov. 15, 2022).[5]

I. Petitioners have failed to demonstrate, as is their burden, that they are persons "aggrieved" by an action or inaction of DEQ.

Perpetua joins in DEQ's argument that none of the Petitioners have demonstrated legal standing. Only persons "aggrieved by an action or inaction of the department" may initiate a contested case. *See* Idaho Code § 39-107(5). The Board's contested case rules explain that an "aggrieved person" is "[a]ny person or entity with legal standing to challenge an action or inaction of the Department." IDAPA 58.01.23.005.01. Legal standing, whether for a person or an

[5] Note that Claim 10, related to the impacts of future permitting actions on arsenic emissions, was dismissed and not revived in the Amended Petition.

organization, requires a showing of a real and actual injury in fact and a substantial likelihood that the claimed relief will prevent the claimed injury. *See Solomon v. Idaho Department of Environmental Quality*, Docket No. 0101-03-01, Order at 4-5 (Dec. 17, 2003).

At summary judgment, a plaintiff can no longer rest on mere allegations of standing but must set forth by affidavit or other evidence specific facts to demonstrate their legal standing. *Camp Easton Forever, Inc. v. Inland Nw. Council BSA*, 156 Idaho 893, 898, 332 P.3d 805, 810 (2014). Petitioners have not provided any evidence to show a real and actual injury, much less an injury that is causally connected to the challenged DEQ action and that will be redressed by a favorable decision. That failure alone requires the dismissal of the Petition. *See*, *e.g.*, *Solomon*, Order at 5-8; *Thatcher v. Idaho Department of Environmental Quality*, Docket No. 0105-19-01, Amended Order at 4-6 (Sept. 24, 2019).

II. DEQ did not violate the CAA or part 51 regulations.

At the start, the Board must reject Petitioners' allegations that DEQ's issuance of the Final Permit violates the CAA and 40 C.F.R. part 51. *See* Opening Br. at 18 (addressing the Project's "ambient air"), 28-30 (addressing "future plans"). Petitioners misconstrue the framework of federal and state obligations under the CAA. They cannot challenge a state agency action, such as issuance of a permit, for failure to comply with the statute.

The CAA creates a partnership between the federal government and the states to prevent and control air pollution. *Cal. Dump Truck Owners Ass'n v. Nichols*, 784 F.3d 500, 502 (9th Cir. 2015); *see also Michigan v. EPA*, 268 F.3d 1075, 1083 (D.C. Cir. 2001) (explaining that the CAA is "an experiment in cooperative federalism"). While EPA retains certain powers of supervision and enforcement, states hold "primary responsibility for assuring air quality" through the development of a state implementation plan ("SIP"). 42 U.S.C. § 7407(a). A SIP specifies

"the manner in which [NAAQS] will be achieved and maintained within each air quality control region in such State." *Id*.

The CAA and the part 51 regulations delineate the required contents of SIPs. *See* 42 U.S.C. § 7410(a). As one federal court amply explained, the federal provisions describe "the general *types* of emissions standards and limitations that a SIP must contain"—they establish "requirements for *SIPs*, not *sources*." *NRDC v. S. Coast Air Quality Mgmt. Dist.*, 694 F. Supp. 2d 1092, 1105, 1111 (C.D. Cal. 2010) (emphases in original) (addressing the CAA's scheme with respect to SIP requirements for non-attainment areas), *aff'd*, 651 F.3d 1066 (9th Cir. 2011). EPA must approve a SIP so long as it satisfies those requirements. *See* 42 U.S.C. § 7410(k)(3); *Train v. Nat. Res. Def. Council, Inc.*, 421 U.S. 60, 79-80 (1975).

This distinction between SIPs and sources is important here. EPA "is plainly charged by the Act with the responsibility for setting the [NAAQS]. Just as plainly, however, it is relegated by the Act to a secondary role in the process of determining and enforcing the specific, source-by-source emission limitations." *Train*, 421 U.S. at 79. Thus, EPA has "no authority to question the wisdom of a State's choices of emission limitations." *Id*. "[S]o long as the ultimate effect of a State's choice of emission limitations is compliance with the [NAAQS], the State is at liberty to adopt whatever mix of emission limitations it deems best suited to its particular situation." *Id*.; *see also Union Elec. Co. v. EPA*, 427 U.S. 246, 269 (1976) ("Congress plainly left with the States, so long as the national standards were met, the power to determine which sources would be burdened by regulation and to what extent.").

Choosing a mix of emission limitations is what DEQ did in the Final Permit. EPA approved Idaho's SIP, including DEQ's specific preconstruction rules for new source review

permits. IDAPA 58.01.01.200-223.[6] EPA approval is subject only to the condition that the SIP satisfy the general requirements applicable to implementation plans. *Train,* 421 U.S. at 80. It follows that DEQ achieved compliance with the CAA and the part 51 regulations. And because the federal provisions do not themselves establish enforceable emissions limitations, Petitioners cannot challenge DEQ's compliance with SIP requirements.[7] Given DEQ's primary responsibility to determine the Permit's emission limitations, the only question before the Board with respect to each of Petitioners' contested case claims is this: *did DEQ act lawfully under the Idaho Air Rules in issuing the Final Permit?*

III. DEQ followed EPA guidance and exercised its discretion in excluding the Stibnite Access Route from the Project's ambient air (Claims 11 and 12).

Petitioners assert that DEQ's decision to exclude the Stibnite Access Route from ambient air protections is unlawful and "cannot be squared with the CAA, the Idaho Air Rules, and EPA's national ambient air policy." Opening Br. at 14-15. As explained above, DEQ did not violate the CAA. It simply exercised its authority under the Idaho Air Rules, and Petitioners cannot now challenge DEQ's compliance with the CAA's SIP requirements. As for the Idaho Air Rules and EPA guidance, Petitioners simply disagree with DEQ's analysis and its exercise of discretion and take a view of ambient air that is far narrower than what EPA guidance allows.

[6] Idaho's SIP was originally approved in 1972, *see* 37 Fed. Reg. 10,842 (May 31, 1972), and has been amended since. EPA's approved Idaho Air Rules can be found at https://www.epa.gov/sips-id/epa-approved-regulations-idaho-sip#IDAPA580101.

[7] Moreover, Petitioners cannot challenge DEQ's compliance with the CAA and part 51 regulations because the Board lacks jurisdiction over such a claim. *See Cal. Dump Truck Owners Ass'n*, 784 F.3d at 502 (recognizing that the CAA vests federal circuit courts of appeals with exclusive jurisdiction over challenges to a SIP); *see also* Idaho Code § 39-107(11) (assigning the Board powers, which do not include deciding challenges to the Idaho SIP).

A. EPA guidance on ambient air and agency discretion.

The term "ambient air" is not defined in the CAA. EPA filled this gap by defining "ambient air" as "that portion of the atmosphere, external to buildings, *to which the general public has access*." 40 C.F.R. § 50.1(e) (emphasis added). Idaho similarly defines "ambient air" as "that portion of the atmosphere, external to buildings, to which the general public has access." IDAPA 58.01.01.006.05. EPA has long recognized that an applicant need not demonstrate the impact of a source's emissions on air within areas to which public access is restricted. *See* PRI 1; PET 772; *see also* PRI 465.

Thus, EPA has consistently exempted "the atmosphere over land [1] owned or controlled by the source and [2] to which the public access is precluded by a fence or other physical barriers" from "ambient air." PET 772. In 2019, EPA broadened the "fence or other physical barriers" element and recognized that physical boundaries are not the only way in which to preclude public access. PET 780. Specifically, EPA recognized that other measures (such as video surveillance, monitoring, clear signage, and routine security patrols) may be effective in deterring or precluding access to the land by the general public. *Id*. EPA gives the example that clearly visible "No Trespassing" signs in conjunction with some degree of fencing or other physical and/or non-physical barriers may be effective to preclude access by the general public in appropriate situations. PET 781.

Also important, EPA recognizes a source's "ambient air" is reviewed based on the individual, case-by-case basis after consideration of information in the relevant administrative record. PET 781-782. As EPA explains in the 2019 guidance:

> The EPA will apply a rule of reason in evaluating the effectiveness of any measure proposed by a source … this evaluation should address relevant factors, such as the nature of the measure used (e.g., physical or non-physical), source location, type and size of source and property to be excluded, surrounding area (including the proximity, nature, and size of the population in

> the area), and other factors affecting whether members of the general public would readily be able to trespass upon or otherwise have access to the source's properties.

PET 781. Air agencies "should consider all relevant information provided by the source or other interested parties, or otherwise available regarding the effectiveness of the measures to prevent public access." *Id*. Thus air agencies exercise discretion in determining whether a permit condition is appropriate to ensure that the source administers selected measures in a manner that maintains continued public health protection. *Id*.

That exercise of discretion has been recognized by the courts. *See REDOIL v. U.S. EPA*, 716 F.3d 1155, 1165 (9th Cir. 2013). In *REDOIL*, the Ninth Circuit denied a petition to review two air permits that authorized exploratory drilling operations by a drillship and support vessels. *Id*. at 1157-58. The petitioners challenged EPA's grant of a 500-meter radius ambient air exemption, which was contingent on the Coast Guard's establishment of an effective safety zone precluding public access to the area. *Id.* at 1164.

According to the Ninth Circuit, "[t]he relevant inquiry is whether the EPA's grant of the ambient air exemption to Shell is *plainly erroneous or inconsistent with its regulatory definition of ambient air*." *Id.* at 1165 (emphasis added). The Ninth Circuit also noted that when EPA first issued its guidance on ambient air, it did not have the occasion to consider how it would apply the exemption to an overwater situation. *Id.* Accordingly, that the agency "'requires some leeway'" in determining how to apply the ambient air rule and guidance to the situation at hand "is just common sense." *Id.* (citation omitted). The Ninth Circuit held that EPA's grant of an ambient air exemption conditioned on a safety zone was a permissible interpretation of the ambient air regulation and guidance. *Id.*

B. DEQ reasonably exercised its discretion in determining that the Stibnite Access Route is exempt from the Project's ambient air.

Following *REDOIL*, the relevant question here is whether DEQ's grant of an ambient air exemption to the Stibnite Access Route is plainly erroneous or inconsistent with its regulatory definition of ambient air. *Id.* at 1165. During the public comment period, Petitioners objected to DEQ's exclusion of the Stibnite Access Route from the ambient air boundary. PET 590-592. Petitioners repeat the same objections here. *See* Opening Br. at 14-18. As evidenced by the permit record, DEQ conducted a thorough review of this issue. In deciding that the air above the Stibnite Access Route is not ambient air, DEQ reached a reasonable determination consistent with the definition of ambient air and EPA's guidance.

From the beginning, both DEQ and Perpetua recognized that establishing the ambient air boundary was crucial to permitting the Project. *See* Schilling Decl. at 8. Given the importance of the issue, in 2018, DEQ contacted EPA Region 10, who gave this guidance via email: "If the public access road is only accessible to public traveling in automobiles under the escort, supervision, and monitoring of Midas personnel (they mentioned a pilot car as a possibility), and there are no stopping points with public access along the road, then the road is not ambient air." PRI 10. Then, in 2020, EPA Region 10 reiterated that the Stibnite Access Route would be exempt "because it is fully under the control and surveillance of the source and unsupervised public access is precluded. It seems like a slam dunk, based on my understanding of EPA's revised ambient air policy." PRI 156; Schilling Decl. at 8.

During the permitting process, Perpetua identified the following measures to preclude public access: Perpetua would (1) employ physical barriers at points of potential access, including the current Stibnite Road point of entry and proposed site access via the Burntlog Route, with locked gates and appropriate adjacent barriers such as fencing, boulders, or other

boundaries, in addition to natural features that serve as barriers or impediments to access; (2) post signs warning the public against entry into the site; (3) implement routine patrolling and surveillance for unauthorized individuals; and (4) only allow registered guests to access to or through the facility, including requiring all persons to receive a registration sheet that explains Perpetua's requirements for accessing the site and identifies potential hazards of the site. PET 310-311, PET 569-570; *see also* PRI 467-469.

DEQ analyzed the ambient air boundary issue using EPA's guidance. *See* PET 310-311, 569-570, 592. With respect to the first element (control), DEQ was satisfied with Perpetua's representation that it has sole and complete control of access to the Stibnite Access Route, including complete closure when necessary. PET 310-311, 570. As to the second element (measures precluding public access), DEQ evaluated how Perpetua would restrict access and prohibit the public from freely accessing the Stibnite Access Route. PET 310-311, 570. DEQ considered that Perpetua would preclude access to the Stibnite Access Route to the general public by posting signs warning the public against entry into the site and establishing manned access gates at points prior to the ambient air boundary. PET 310, 570. DEQ was satisfied that all persons seeking access will be required to register at the access gate and be instructed on procedures and any potential hazards of areas they may encounter while using the Stibnite Access Route. PET 311, 570.

Nevertheless, Petitioners liken the Stibnite Access Route to a right-of-way easement or common service road and argue that individuals traveling the Route are the general public. Opening Br. at 17. They also contend that the Final Permit does not preclude access to the general public. *Id*. at 16. But unlike a right-of-way or common service road, members of the general public will not be permitted to freely access the Stibnite Access Route. PET 10

(Condition 2.7); *see also* PET 310-311, 569-570. In Condition 2.7, DEQ conditioned the Final Permit on the establishment of an Access Management Plan ("AMP") prohibiting the general public from freely accessing the Stibnite Access Route. PET 10.

Condition 2.7 was updated based on public comment to state: "Only registered guests of the facility will be allowed to access to or through the facility. Those seeking to be a guest for the sole purpose of passing through the facility to another destination shall be provided a registration sheet that explains Perpetua's requirements for accessing the stie and identified potential hazards of the site." *Id*. Those that seek access must be required to register at the access gate and will be informed that they are proceeding as guests of Perpetua rather than members of the general public. *Id*. Perpetua must also install locked gates and barriers for the two primary access points, plus posted warning signs, require registration by users seeking access, and more. *Id*. Also the measures specified in the AMP will be incorporated by reference into the Final Permit and will be enforceable permit conditions. *Id.*

DEQ's decision not to exclude the Stibnite Access Route from the ambient air demonstration is no different than EPA's grant of an air boundary exemption in *REDOIL*. As in that case, DEQ dealt with a novel situation and conditioned its decision on an effective safety zone and procedures to restrict public access. *See* 716 F.3d at 1165. Accordingly, based on the situation here, DEQ made a well-reasoned and permissible interpretation of the Idaho Air Rules and EPA guidance. Schilling Decl. at 6-7. Just as the Ninth Circuit upheld EPA's decision in *REDOIL*, the Board should uphold DEQ's determination on the Project's ambient air boundary.

IV. DEQ did not act arbitrary and capricious or violate the Idaho Air Rules in determining that fugitive dust emissions from the Project's roads will met the PM_{10} NAAQS and arsenic AACC.

A. DEQ reasonably determined that 93.3% control efficiency for fugitive dust from haul roads was attainable and enforceable (Claims 2 and 8).

DEQ's evaluation to satisfy the requirements of Section 203 included estimates of fugitive dust emissions from the Project's haul roads, including a dust control efficiency of 93.3%. *See* PET 18 (Condition 3.2), 551. Conditions in the Final Permit ensure that control efficiency will be maintained through a combination of chemical dust suppressants (e.g., magnesium chloride or calcium chloride) and frequent watering, among other permit conditions. *Id*. Petitioners contend it is "highly questionable whether 93.3% fugitive dust control is realistically attainable" and that the Permit lacks enforceable conditions to ensure the control efficiency will be met. Opening Br. at 19-23. DEQ found otherwise, and Petitioners have not shown that DEQ's conclusion was unreasonable.

1. Petitioners have not shown that DEQ's use of the 93.3% control efficiency was unsupported or unreasonable.

The 93.3% control efficiency is based on a combination of dust suppressant chemical application (90% or higher) and watering (33% and higher) to increase road surface moisture.[8] *See* PET 143. Petitioners believe 80% is a more realistic control efficiency for chemical dust suppressants under AP-42 Section 13.2.2, Unpaved Roads (2006).[9] Opening Br. at 20 (citing PET 809). AP-42, however, does not provide a reference for that value or the chemical type. *See* PET 809. That led Perpetua to examine all the studies referenced in Section 13.2.2 pertaining to chemical dust suppressants. PRI 2-7, 498. The referenced test reports actually show a 90% to

[8] 93.3% control = (1-90%) * (1-33%).

[9] Petitioners do not contest DEQ's conservative use of a 33% control efficiency for watering. According to AP-42, watering that increases the surface moisture by 1% reduces fugitive dust by 75% to 95%. PET 808 (Figure 13.2.2-2); *see also* PET 548.

99% control efficiency for chemical dust suppressant alone and 98% for magnesium chloride in particular. PET 546.

Perpetua and DEQ also reviewed EPA's RACT/BACT/LAER Clearinghouse ("RBLC") database and identified 10 projects using chemical dust suppressant (with and without watering) using 90% to 98% control efficiency. PET 546-547. While Petitioners sought to discredit most of the 10 projects as unrepresentative in public comments, DEQ found the RBLC database provided additional support "that a control efficiency of 90% is achievable by treating unpaved roads with chemical suppressant in various states with similar operations." PET 557-559.

Petitioners also speculate that "the application of water *may* dissolve the bond between the chemical suppressant and road particles, thus decreasing the control efficiency—not increasing it." Opening Br. at 20 (emphasis added). They provide no support for that claim. Even so, Petitioners do not challenge that chemical and water dust suppressants are used in combination in practice. PET 557, 558. Nor, as DEQ noted, did Petitioners demonstrate that their assumptions "were more accurate or appropriate than data provided by" Perpetua and accepted by DEQ. PET 620.

In the end, DEQ reasonably supported its finding that the 93.3% control efficiency for chemical dust suppression and watering was both achievable and conservative, and Petitioners have not shown that conclusion was unreasonable based on the permit record.

2. Petitioners have not shown that the Final Permit lacks enforceable conditions to ensure 93.3% control efficiency when DEQ imposed daily monitoring and other substantive conditions.

Also without merit is Petitioners' contention that the Permit lacks enforceable conditions to ensure the 93.3% control efficiency will be met. Opening Br. at 20-23. Petitioners argue that DEQ should have included conditions on the type, quantity, application rate, and frequency of dust suppressants. *Id*. But they cite to no legal authority that DEQ was required to include those

conditions and instead rely on AP-42 Section 13.2.2 and the various factors that bear on the effectiveness of chemical dust suppressants. *Id*. at 20-21. Further, DEQ developed permit conditions to ensure the 93.3% control efficiency is maintained on a daily and annual basis, and Petitioners have not shown those conditions are unreasonable or unenforceable.

According to EPA guidance, for source-specific permit provisions to be practically enforceable, they must specify: (1) a technically accurate limitation and the portions of the source subject to the limitation; (2) the time period for the limitation (hourly, daily, monthly, annually); and (3) the method to determine compliance including appropriate monitoring, recordkeeping and reporting. PET 791. DEQ ensured those enforceability criteria were met with respect to the 93.3% control efficiency. Not only did DEQ include that level of control in the Final Permit and find it achievable (as just explained), it found that the Final Permit required the proper application of dust suppressant chemicals and watering as verified through daily visible emission monitoring and recordkeeping. PET 551, 555, 557, 568, 571.

DEQ's conclusion is well supported and reasonable. Condition 2.2 requires Perpetua to monitor the frequency and methods used to control fugitive dust at least once every 12 hours and maintain those records. PET 8. Condition 2.4 requires daily facility-wide inspections of hauling activities to ensure the expected control efficiency is achieved. *Id*. Condition 2.5 mandates that fugitive dust control measures be applied to haul roads "on a frequency such that visible emissions from vehicle traffic on a haul road do not exceed 10% opacity." PET 9. And if emissions exceed that level, Perpetua must take immediate corrective action until fugitive dust control is achieved. *Id*. The daily inspection and haul road opacity requirements are more stringent than in other permits that DEQ has issued. Simon Decl. at 6.

Moreover, the FDCP must be submitted to DEQ for approval 30 days prior to startup, and once approved, will be incorporated into the Permit and enforceable. PET 9-10 (Conditions 2.6 and 2.8). The FDCP itself ensures compliance with fugitive dust requirements. Condition 2.6 establishes minimum and substantive requirements for the FDCP, including:

- posting and limiting the maximum speed of haul trucks;
- applying water or suitable dust suppressant chemicals to haul roads during the dry season and at other times as necessary to control fugitive dust;
- prior to onset of winter conditions, maintenance of the roads and any preventative dust suppression activities before the roads are frozen;
- developing specific criteria to determine what frequency and type (water and/or chemical) of dust suppressant and appropriate suppressant application rates;
- applying chemical dust suppressants consistent with manufacturer's instructions and recommendations;
- providing training to all relevant employees and conducting visible emissions evaluations by certified employees who are visible emission observers; and
- at least once each year, evaluating FDCP requirements to identify additional requirements and evaluating the effectiveness of practices.

PET 9-10. Thus, DEQ did not give "vague direction" to consider type, quantity, and rates of dust suppressants later in its FDCP. *See* Opening Br. at 21. As DEQ explained in response to Petitioners' criticisms, the Final Permit requires Perpetua to apply dust suppressants in proper amounts and proper frequencies as local conditions dictate and also requires daily inspections to ensure the 93.3% control efficiency is met. PET 551, 555, 557, 568, 571. Ultimately the Final

Permit "requires a more comprehensive and detailed FDCP than in any other minor source permit DEQ has issued." Simon Decl. at 8.

DEQ also recognized the challenge of achieving fugitive dust controls at the 93.3% control efficiency. PET 90. Petitioners try to use DEQ's acknowledgment against it, *see* Opening Br. at 21-23, but it illustrates that DEQ's choices were deliberate, rational, and reasonable. The Permit mandates the "conscientious efforts, vigilant inspection and monitoring, and a comprehensive FDCP" necessary to achieve the 93.3% control efficiency. *See* PET 8-10 (Conditions 2.1 – 2.8). For instance, DEQ reasoned that frequent inspections "once every 12 hours ensures that both daytime and nighttime operations will be observed, to confirm that sufficient fugitive dust control measures are applied as assumed in demonstrations of compliance with NAAQS on a 24-hour basis." PET 358. DEQ also considered the Final Permit's surrogate production limits (discussed below) and that a 93.3% level of control could be met and likely exceeded during wintertime conditions, when modeling showed possible violations of the PM_{10} NAAQS. PET 558-559, 629-630.

DEQ's imposition of minimum and substantive requirements in the Final Permit and through the FCDP was not unreasonable. It understood how uncommon and impractical it would be to establish specific numeric limits to control efficiency variables advocated by Petitioners. Instead, the Final Permit, among other conditions, requires that chemical suppressants be applied in accordance with the manufacturer's instructions and recommendations and that the control effectiveness of the combination of dust suppressant chemicals and watering be verified daily. Petitioners have not satisfied their burden to show that the many permit conditions imposed by DEQ will not achieve the expected control efficiency.

B. Petitioners have not shown that DEQ is required to impose conditions restricting vehicle miles traveled and truck weights when DEQ imposed surrogate production limits and other requirements (Claims 1 and 8).

Under AP-42 Section 13.2.2, the emission estimation method for unpaved road dust emissions relies on a variety of site-specific parameters. *See* PET 797-803. Some of the parameters include the silt content of the road, the vehicle miles traveled, and the average weight of the haul truck fleet. PET 797-798, 800. Petitioners claim that DEQ should have developed Permit conditions based on parameters for miles traveled and truck weight, and because DEQ did not, its determination of compliance with the PM_{10} NAAQS and the arsenic AACC is flawed. Opening Br. at 23-25. Petitioners and EPA made similar claims during the public comment period, which DEQ rejected. *See* PET 556, 572-573.

Petitioners have not shown, and cannot show, that DEQ erred in a manner specified under Idaho Code § 67-5279(3) or that their substantial rights have been prejudiced. In the Statement of Basis, DEQ noted this about Perpetua's application:

> it was recognized that accurate determination of site-specific parameters characterizing road conditions and vehicle traffic was critical to estimating particulate matter emissions and ambient air impacts. PRI provided site-specific information to support parameters such as silt content, mean vehicle weight, and dust suppressant control efficiencies, and provided an analysis evaluating the conservatism of the resulting emission factor (AP-42).

PET 62. In excerpting that passage, Petitioners mischaracterize it. *See* Opening Br. at 23-24. They claim that because vehicle miles traveled and truck weights were "critical" to estimating fugitive dust emissions, the Permit must include limits on vehicles miles traveled and truck weights as enforceable conditions. *Id*.

Petitioners, however, cite no legal authority to support such a claim. Nor do they show how the absence of enforceable conditions for vehicle miles traveled and truck weights means

that DEQ lacked a reasonable basis to conclude the Project will comply with the PM_{10} NAAQS and the arsenic AACC. Under the Idaho Air Rules, DEQ has the discretion to impose "any reasonable conditions upon an approval." IDAPA 58.01.01.211.01; *see also* IDAPA 58.01.01.651 ("All reasonable precautions must be taken to prevent particulate matter from becoming airborne."). Here DEQ imposed many reasonable and enforceable conditions to control fugitive dust emissions from the haul roads and explained why it chose those conditions.

Petitioners largely ignore those conditions and why they were imposed. DEQ explained that emissions limits and parameters associated with estimating emissions (like vehicle miles traveled and truck weight) are not commonly included in permits for fugitive sources and are documented in the Statement of Basis and application materials. PET 557, 574. Instead, DEQ uses production limits and monitoring and recordkeeping requirements, which it did here. PET 557, 574. In particular, in Condition 3.5, DEQ established daily hauling and excavation limits of 180,000 tons/day and 135,000 tons/day on a five-year rolling basis (which is more restrictive than the 180,000 tons/day limit). PET 19; *see also* PET 573. It did so because daily production limits directly limit "hauling operations and associated emissions" and "serve as surrogate emissions limits for PM, PM_{10}, $PM_{2.5}$, HAP and TAP from fugitive sources." PET 356, 557, 574; *see also* Simon Decl. at 9.

DEQ also recognized the importance of the silt content parameter in estimating fugitive dust emissions and ensuring compliance with the PM_{10} NAAQS. PET 552. In response to Petitioners' and EPA's comments, DEQ imposed Condition 3.13, which requires Perpetua to cap haul roads with material having a maximum of 4% silt content and to develop the HRCP to ensure that limit is met. PET 19-20, 552, 572. Further, as noted above, DEQ imposed Conditions 2.1 to 2.8, which require fugitive dust emission limits (to ensure that visible emissions do not

exceed 10% opacity) and control requirements (such as the application of water and chemical dust suppressants to haul roads). PET 8-10, 90.

Equally important are the monitoring and recordkeeping requirements DEQ imposed. As DEQ explained, "[s]uch monitoring includes the monitoring of maximum road silt content [and] monitoring of production levels to verify estimated vehicle miles traveled (VMT) used in fugitive road dust emission calculations." PET 562. Indeed, Condition 3.13 requires sampling and monitoring of the maximum road silt content, and Condition 3.16 requires daily, monthly, and yearly hauling and excavating monitoring. PET 20. And, again, Condition 2.6 requires Perpetua to develop and maintain the FDCP to ensure compliance with Conditions 2.1 to 2.5. PET 9-10. The FCDP must include precautions to minimize fugitive dust emissions, such as maximum speed limits, monitoring and maintenance of haul roads, and frequency of chemical dust suppressant and watering. *Id*.

Finally, Petitioners ignore the conservative assumptions that overestimated fugitive dust emissions from the haul roads and modeled maximum PM_{10} impacts. EPA's method for estimating haul road fugitive dust emissions predicts higher emissions for more miles traveled and a heavier vehicle weight. *See* PET 798. Thus, DEQ also justified its choice of conditions because the emissions were "[c]alculated at maximum daily processing rates" and "would tend to be conservatively estimated." PET 65. That is true. At the 180,000 tons/day production limit (or 65,700,00 tons/year), DEQ modeled all hauling scenarios to capture the maximum case hauling distance of 16,415 miles per day (or approximately 500,000 miles per month). *Id*.

But the Project's peak production rate is actually 116,964 tons/day (or 42,692,000 tons/year), *id*., and the peak hauling mileage is approximately 116,700 miles per month, far less than modeled, PET 356. The average vehicle weight of the haul trucks (183 tons) was also

overestimated compared to the actual vehicle weight (180 tons) during peak production. *Compare* PET 142 *with* PRI 891. And where the conservatism of some emissions calculated was questioned, "DEQ required enhanced monitoring and record-keeping," such as Conditions 3.13 and 3.16. PET 562.

In sum, the entire premise of Petitioners' challenge is wrong – there is no legal requirement for DEQ to include vehicle miles traveled and truck weights as enforceable permit conditions to control fugitive dust emissions from the haul roads. Petitioners also ignore the actual conditions DEQ chose to impose and its justification for establishing surrogate production limits and enhanced monitoring and recordkeeping requirements. Petitioners may disagree with DEQ's choices, but they have not shown that DEQ lacked a reasonable basis for such conditions or that it was unreasonable to conclude that Perpetua's operations could cause a violation of the PM_{10} NAAQS or exceed the arsenic AACC.

C. Petitioners have not shown that DEQ's use of 120 days of precipitation data to estimate fugitive dust emissions was counter to DEQ guidance or arbitrary and capricious (Claims 5 and 8).

Another parameter AP-42 uses for estimating fugitive dust emissions from unpaved roads is the number of days of precipitation (rain and snow) with at least 0.01 inches at the site. PET 802-803. Because precipitation acts like "watering" to increase moisture on the surface, EPA recognizes that "all roads are subject to some natural mitigation because of rainfall and other precipitation." PET 802. EPA's emission estimation method predicts lower dust emissions for sites with higher precipitation and conversely higher dust emissions for sites with lower precipitation. *See* PET 802-803.

In AP-42, EPA also provides the mean annual number of "wet" days for the United States. *See* PET 803, 805. For the Project site, the number is 120 wet days per year. *See* PET 805. DEQ used the default 120 day per year value to calculate fugitive dust emissions from the

access road. *See* PET 146. According to Petitioners, DEQ should have used more representative local meteorological data.[10] Opening Br. at 25. Petitioners contend that DEQ's air modeling guidance prefers local data and thus the failure to use local data was arbitrary, counter to DEQ guidance, and "undermines DEQ's estimates of Project road emissions, and DEQ's determinations that the project will not cause or contribute to a violation of the PM_{10} NAAQS and arsenic AACC." *Id*. at 25-26.

Petitioners are wrong. One reason is that Petitioners confuse the calculation of fugitive dust emissions, on one hand, with the modeling of fugitive dust impacts, on the other. Precipitation data only affects fugitive dust emission calculations, not modeling. PRI 975. Thus contrary to Petitioners' contention, DEQ air modeling guidance does not directly apply to or affect its calculation of fugitive dust emissions from the access road. DEQ's use of the default 120 day per year value was consistent with AP-42 and not arbitrary. *See* PET 802-803, 805.

Even so, Petitioners are also wrong because they assume the use of local precipitation data would have resulted in higher fugitive dust emissions. But that is not true. Site-specific meteorological data from the Project collected in 2014 shows 168 days per year of precipitation, far more than EPA's default 120 wet days per year. PRI 12. Again, using more days of precipitation would result in lower estimates of fugitive dust emissions. Using the 120 days per year value is conservative, overestimated emissions, and ultimately resulted in more conservative PM_{10} NAAQS and arsenic AACC determinations. DEQ's use of 120 days per year precipitation value did not underestimate emissions or undermine DEQ's evaluation of the PM_{10} NAAQS and arsenic AACC.

[10] DEQ also used the 120 days per year precipitation value for calculating fugitive dust emissions from the haul roads. *See* PET 142-144. Petitioners do not challenge the use of the 120 day value for those calculations. *See* Opening Br. at 25 (citing PET 146).

D. Petitioners have not shown that the Final Permit's production limits are unenforceable when DEQ imposed monitoring and recordkeeping requirements to determine compliance (Claims 4 and 8).

Petitioners' final challenge to DEQ's assessment and regulation of fugitive dust emissions concerns Condition 3.5's hauling and excavation limits (180,000 tons/day and 135,000 tons/day on a five-year rolling basis) and associated monitoring and recordkeeping requirements. Petitioners contend that the Permit lacks developed and enforceable monitoring requirements to ensure the production limits are met and because compliance is not ensured, that DEQ lacked a reasonable basis to find the PM_{10} NAAQS and the TAPs AACCs will be met. Opening Br. at 26-28. DEQ considered and correctly rejected those criticisms. *See* PET 562-563, 566-567, 569.

As detailed earlier, practical enforceability means that source-specific permit provisions specify a technically accurate limitation, the time period for the limitation, and the method to determine compliance. PET 791. DEQ ensured those enforceability criteria were met with respect to Condition 3.5's production limits. Condition 3.5 includes accurate daily and annual production limits, based on both an annual and a rolling basis. PET 19. As DEQ noted, the Permit's monitoring and recordkeeping requirements establish a daily and monthly schedule for monitoring compliance with the production limits using devices and methodologies identified in the O&M Manual. PET 563-564. These details must be incorporated in the O&M Manual within 30 days of startup. *Id*.

All that is true, and Petitioners are simply wrong that Condition 3.5's production limits are not enforceable. The production limits are made enforceable by numerous monitoring and recordkeeping requirements, starting with Condition 3.16. Condition 3.16 requires that: "Each day, the permittee shall monitor and record the amount of ore and DR [development rock] transported on haul trucks (T/day)." PET 20. Each month, Perpetua must monitor and record the amounts transported in tons per month and per year to determine compliance with the 180,000

tons/day and 135,000 tons/day on a five-year rolling basis production limits. *Id*. Those records must be retained for a period of at least five years. PET 40 (Condition 7.10).

Condition 3.16 also requires that "[t]he devices and methodologies used to measure weights shall be identified in the O&M Manual." PET 20. Condition 2.20 mandates that the O&M Manual establish a regular schedule for operation, inspection, maintenance, and repair of devices that ensure compliance. PET 12-14. Not only that, in response to Petitioners' comments, DEQ required the O&M Manual be submitted for review and approval 30 days prior to startup, and any changes to the manual must likewise be reviewed and approved.[11] PET 14 (Condition 2.21); PET 566-567. Once approved, the requirements of the O&M will be incorporated into the Permit and "shall be enforceable permit conditions." PET 12 (Condition 2.20).

Thus the details on devices and measurement methodologies will be incorporated into the O&M Manual when available, but no later than 30 days prior to startup and then into the Permit as enforceable conditions. DEQ's compliance method is both reasonable and correct. It is common to include such information in an O&M Manual because, prior to construction and startup, the device and measurement methodology are often unknown and have yet to be selected. *See* PET 567 (observing that "certain operating parameters will not be determined or available until after control equipment has been installed"); Simon Decl. at 10. This is why Condition 2.21 does not require the O&M Manual to be submitted to DEQ for approval until 30 days before startup. *See id*.

EPA's own regulations illustrate this necessary flexibility and the monitoring and recordkeeping requirements necessary (and conversely those that are not necessary) to make

[11] Prior to this change, the draft Permit required Perpetua to submit the O&M Manual 60 days after startup. *See* PET 379, 380 (draft Conditions 2.19 and 2.20).

limitations enforceable. Take, for example, EPA's gold mining NESHAP (40 C.F.R. pt. 63, subpt. EEEEEEE), which is incorporated by reference in Condition 2.22. PET 14. Subpart EEEEEEE requires precious metal concentrate be measured and recorded daily. *See* 40 C.F.R. § 63.11646(a)(9), (11). It also requires the specific measurement equipment and procedures be documented and available for review by the permitting agency. *See* 40 C.F.R. § 63.11646(a)(10); 40 C.F.R. § 63.11648(f).

The minimum monitoring and recordkeeping requirements under subpart EEEEEEE are no different than the minimum requirements DEQ imposed in Condition 3.16 and Conditions 2.20, 2.21, and 7.10. Both require the permittee to document monitoring devices and the procedures used to measure compliance and to make that documentation available for agency review. Yet DEQ went further than EPA to provide the monitoring and recordkeeping framework for the enforceable limitations. The Final Permit requires approval and enforceability of the procedures in Conditions 2.21 and 2.20.

It follows that Petitioners have not shown that the Permit lacks enforceable monitoring requirements to ensure compliance with the production limits. The obligation to have a device and compliance methodology is enforceable at permit issuance. Further, the specific device and method become enforceable through incorporation into the Permit prior to operation. DEQ's basis for concluding the Project will comply with the PM_{10} NAAQS and the arsenic AACC deals was rational and reasonable.

V. The Final Permit requires Perpetua to develop work plans for DEQ approval and does not violate the CAA or the Idaho Air Rules (Claim 3).

Petitioners' allegation that DEQ's reliance on the FDCP, HRCP, AMP, and O&M Manual violates the CAA and Idaho Air Rules is legally untenable. Pursuant to DEQ's discretion, the Final Permit required Perpetua to develop work practice plans, include specific

provisions in the plans, and submit them to DEQ for approval at least 30 days prior to startup. PET 9-10 (Condition 2.6 (FDCP) and Condition 2.7 (AMP)), 12-14 (Condition 2.20 (O&M Manual)), 19-20 (Condition 3.13 (HRCP)). DEQ did not violate the CAA or Idaho Air Rules.

A. The CAA and the Idaho Air Rules do not require work plans to be submitted with applications or circulated for public comment.

The CAA and part 51 regulations require that SIPs provide for an opportunity for public comment on "information submitted by owners and operators [and] [t]he public information must include the agency's analysis of the effect of construction or modification on ambient air quality, including the agency's proposed approval or disapproval." 40 C.F.R. § 51.161. As noted already, the CAA and the part 51 regulations establish requirements for SIPs, not sources. And since EPA approved the Idaho SIP, the only relevant question is whether DEQ complied with the Idaho Air Rules.

The Idaho Air Rules do not require that source work plans be developed at all, let alone that they be prepared before construction commences or be available for public comment before a permit to construct can be issued. *See* IDAPA 58.01.01.211.01. Section 202 of the Idaho Air Rules specifies the requirements for a permit to construct application and identifies information required to be included in the application. IDAPA 58.01.01.202.01. Requisite information for new sources includes information related to the design of the source, nature and amount of emissions, the manner in which the source will be operated and controlled, and a schedule for construction. *Id.* DEQ may request any additional information necessary to make determinations under the Idaho Air Rules. IDAPA 58.01.01.202.03.

DEQ must provide an opportunity for public comment on its "proposed action, together with the information submitted by the applicant and the Department's analysis of the information." IDAPA 58.01.01.209.01.c.i. As such, Petitioners' argument that Perpetua's

application is "incomplete" or that these plans must be made available for public comment are legally incorrect. *See* Opening Br. at 29. Following the Idaho Air Rules, DEQ's review of Perpetua's application included four requests for additional information to supplement the application, three extended public comment opportunities to solicit feedback from the public and other stakeholders, two informational meetings requested by the public, and three iterations of draft permits. PET 52-53, 93.

During the public comment period, Petitioners submitted comments that raised concerns with the submission and review process of the FDCP, HRCP, AMP, and O&M Manual. PET 566-567. DEQ responded and explained that the permit specifies minimum and substantive requirements for the plans. *Id*. In addition, while these plans are not required to be submitted at all, DEQ will exercise oversight, review and approve the work plans, and publish the final plans on its website. *Id*. Perpetua shall submit the plans to DEQ for approval at least 30 days prior to startup. PET 10 (Condition 2.8), 14 (Condition 2.21), and 20 (Condition 3.13); *see also* PET 566. Furthermore, elements of the plans, including recordkeeping and reporting requirements, will be incorporated and enforceable through the Final Permit. PET 10 (Condition 2.8), 14 (Condition 2.21), and 20 (Condition 3.13); *see also* PET 566.

How DEQ addressed the work plans in the Final Permit is consistent with DEQ's practice and reasonable. *See* Simon Decl. at 10. It allows the permittee to prepare a specific plan or manual based on information that is not available at the permit to construct phase, such as the actual equipment purchased and operational characteristics of the facility. *Id*. Petitioners disagree with the approach executed by DEQ, but dislike is not the legal standard. DEQ exercised reasonable discretion in developing the permit conditions related to the work plans. DEQ's approach did not violate the CAA governing SIPs, nor the Idaho Air Rules governing sources.

B. Petitioners' legal authority from the Clean Water Act is distinguishable and inapplicable to DEQ's preconstruction permitting process.

Petitioners fail to cite any case law to support their position that public review is required for work plans under the CAA or Idaho Air Rules for permits to construct. This is not an oversight. The relevant CAA jurisprudence affords broad discretion to states to develop permit conditions. *See supra*, *Train*, 421 U.S. at 79. As demonstrated above, to issue the Final Permit lawfully, these plans need not be included with applications or published for public comment and review as part of the preconstruction review process.

Petitioners cite two Clean Water Act cases to support their position on the work plans. In the first case, *Waterkeeper Alliance, Inc. v. U.S. EPA*, the plaintiff sought review of the National Pollution Discharge Elimination System Permit Regulation and Effluent Limitation Guidelines and Standards for Concentrated Animal Feeding Operations (the "CAFO Rule"). 399 F.3d 486, 492 (2d Cir. 2005). The plaintiff argued that the permitting scheme established by the CAFO Rule violated the Clean Water Act's public participation requirements because it did not require nutrient management plans, which constitute effluent limitations, to be made available to the public. *Id.* at 503. Under the Clean Water Act, effluent limitations are specifically identified in the list of items that public participation should be provided for. 33 U.S.C. § 1251. As such, the Second Circuit held the CAFO Rule "violates the plain dictates of 33 U.S.C. § 1251(e)." *Waterkeeper Alliance*, 399 F.3d at 504.

Similarly, in *Environmental Defense Center, Inc. v. EPA,* the Ninth Circuit held that Notices of Intent ("NOI") are functional equivalents to permits under the Clean Water Act's general permit option, and EPA's failure to require review of NOIs available to the public contravened the express requirements of the Clean Water Act. *Env't. Def. Ctr., Inc. v. EPA*, 344 F.3d 832, 858 (9th Cir. 2003).

Both *Waterkeeper Alliance* and *Environmental Defense Center* rested their holdings on express requirements under the Clean Water Act for public review of specific materials. The decisions are clearly distinguishable from Perpetua's work plans, which are not required by any express provision of Idaho Air Rules (nor the CAA) to be included in the application, the Final Permit, or any part of the public comment process. The Board should accordingly not give any weight to Petitioners' cases because they are factually and legally distinguishable and have no analogy to the facts in the present case. Instead, the Idaho Air Rules support DEQ.

VI. DEQ did not violate the law by issuing a Final Permit that omitted ambient air monitoring (Claim 13).

Petitioners contend that "DEQ must require ambient air monitoring" and repeat their public comments urging DEQ to impose this obligation. *See* Opening Br. at 31-32. Petitioners' claim reflects another preference and opinion for a condition that DEQ did not include in the Final Permit. Applying the standard for review, DEQ's thorough review and justification for its decision complied with its obligations under the Idaho Air Rules.

To begin, Petitioners do not identify any Idaho Air Rule violated by DEQ's issuance of a Final Permit omitting ambient air monitoring. IDAPA 58.01.01.211.01.d states that DEQ "may impose any reasonable conditions upon an approval," including conditions requiring "[i]nstrumentation for ambient monitoring to determine the effect [of] emissions from the stationary source or facility." But the rule does not require it. Thus we are left with Petitioners' different opinion. Applying the standard for review, DEQ's thorough review and justification for its decisions complied with its obligations under the law.

Like all of the assertions raised in this contested case, Petitioners' ambient air monitoring demand was presented to DEQ many times in the permitting process. In the Response to

Comments, DEQ found that ambient air monitoring was not necessary to ensure NAAQS compliance. Among the many reasons why:

- "Although there are identified uncertainties in the analyses predicting air pollutant emissions and atmospheric dispersion of such emissions, DEQ is reasonably confident that impacts to ambient air will be below applicable standards. Furthermore, ambient monitoring would only be required where such monitoring would serve to protect a potentially exposed public residing in the area of impact. The areas where maximum potential impacts from the SGP are highest are remote, located far from areas where the general public live and reside. There are no public residences, public businesses, schools, hospitals, or other areas where members of the general public would be expected on a continual basis." PET 559.
- "DEQ is requiring extensive fugitive dust control measures in the permit and has reviewed or conducted modeling analyses that demonstrates compliance with NAAQS at a satisfactory level of confidence for permit issuance. Therefore, DEQ is not requiring any ambient air monitoring in the permit." PET 560.
- "The issued permit includes limits on operational levels and key parameters such as (but not limited to) ore excavation and hauling rates, silt content of roadway material, application of dust suppressant measures, etc. These limits represent values associated with maximum or upper-level emissions for the time interval consistent with the averaging period of the standard. The permit also includes monitoring and recordkeeping requirements to ensure compliance with permit limits and ultimately ensure compliance with NAAQS and TAP increments at a satisfactory level of confidence to support permit issuance." PET 561.

- "DEQ does not typically require ambient air pollutant monitoring for permit issuance, especially at facilities with emissions below major source thresholds. Ambient monitoring is not considered unless DEQ lacks a satisfactory confidence of NAAQS or TAP increment compliance (as specified by Idaho Air Rules Section 203.02 and 203.03) without such monitoring. [Listing conditions normally required to justify post-construction ambient air monitoring]. The SGP does not meet the above criteria to justify the requirement of ambient air monitoring. It has been indicated that PRI did not use convincingly conservative data and assumptions for some emission calculations. Where the conservatism of such data was in question, DEQ required enhanced monitoring and recordkeeping of such parameters. Such monitoring includes the monitoring of maximum road silt content, monitoring of production levels to verify estimated vehicle miles traveled (VMT) used in fugitive road dust emission calculations, and monitoring of the median arsenic content of road base material to help justify fugitive road dust arsenic emissions used in TAP analyses. Finally, there are no sensitive receptors identified near the ambient boundary of the facility, where elevated impacts of pollutants would be expected." PET 562.
- "As discussed previously in DEQ's response to Comment 6, the issued permit includes limits on operational levels and key parameters such as (but not limited to) ore excavation and hauling rates, silt content of roadway material, application of dust suppressant measures, etc. These limits represent values associated with maximum or upper-level emissions for the time interval consistent with the averaging period of the standard. The permit also includes monitoring and recordkeeping requirements to assure compliance with permit limits and ultimately assure compliance with NAAQS and TAP increments at

a satisfactory level of confidence to support permit issuance. Even though DEQ is not proposing a monitoring network, it should be noted that any violation of the permit would be processed in accordance with DEQ's enforcement procedures manual." PET 565. Further justification for the approach reflected in the Final Permit is stated in the Statement of Basis. *See* PET 325.

In the end, DEQ "may impose any reasonable conditions," including ambient monitoring, but it is not required to. IDAPA 58.01.01.211.01.d. In DEQ's analysis and judgment, there was no reason to impose ambient air monitoring in the Final Permit. The Idaho Air Rules do not require ambient air monitoring and omitting such conditions from the Final Permit did not violate an applicable law governing DEQ's review. In response to repeated suggestions, DEQ considered the idea and with reasoned analyses rejected it, consistent with applicable practice, deliberate criteria, and DEQ's judgment. Petitioners have not satisfied their burden to show the decision was unlawful, arbitrary, or capricious**.**

VII. Because chemical dust suppressant and water are already established as reasonably available control technologies, DEQ was not required to conduct an technological or economic feasibility analysis (Claims 6 and 7).

As discussed, Perpetua selected, and DEQ approved, haul road capping and the use of chemical dust suppressant with frequent watering to control arsenic emissions from the Project's haul roads. PET 70, PET 544-548. The use of chemical dust suppressant and watering were explicitly required by conditions in the initial draft permit, and by the Idaho Air Rules, to control fugitive dust and TAP emissions. PRI 620; IDAPA 58.01.01.651. Despite the requirement that Perpetua adopt these control measures, Petitioners now contend that DEQ should have conducted additional analyses to determine what every environmental regulatory agency in the country already knows—that these measures are reasonably available control technologies. *See* Opening Br. at 32.

The Idaho Air Rules allow an applicant to "use T-RACT to demonstrate preconstruction compliance for toxic air pollutants listed in Section 586." IDAPA 58.01.01.210.12.a. T-RACT is defined as

> An emission standard based on the lowest emission of toxic air pollutants that a particular source is capable of meeting by the application of control technology *that is reasonably available, as determined by the Department*, *considering technological and economic feasibility*.

IDAPA 58.01.01.210 (emphasis added). For a control measure to be determined to be "reasonably available," it must be both technologically feasible and economically feasible. IDAPA 58.01.01.007.12; IDAPA 58.01.01.210.14.c.-d.

Here, the control measures proposed as, and determined to be, T-RACT were selected based on a search of EPA's RBLC to identify available control technologies. PET 70. The RBLC contains over 6,000 air pollution prevention and control determinations that identify appropriate technologies to control emissions from stationary sources.[12] DEQ approved dry drilling with dust collectors, chemical dust suppressant with frequent watering on roads, and haul road capping as T-RACT for arsenic emissions. *Id*. The use of chemical dust suppressants and watering are required to be used by facilities to prevent the generation of fugitive dust. IDAPA 58.01.01.650, 651.02.

These measures are well recognized by both DEQ and EPA as reasonably available control technologies. In 1992, EPA published a technical document describing best available control measures for unpaved roads, which analyzed and recommended the use of chemical

[12] U.S. EPA, Clean Air Technology Center, User's Manual for the RACT/BACT/LAER Clearinghouse (RBLC) Web (Nov. 2006), https://www.epa.gov/sites/production/files/2020-07/documents/rblcusr1-openaccessible.pdf.

suppressants and water.[13] The RBLC contains at least 28 determinations for using chemical dust suppressant to control dust emissions from unpaved roads.[14] These determinations were created by an agency review process that examined the technological feasibility, economic impact, environmental impact, and energy impact of dust suppressant use on unpaved roads. Finally, between 2010 and today, DEQ has issued at least seven permits to construct, in addition to Perpetua's, that require the use of chemical dust suppressant to control fugitive dust from unpaved roads.[15]

Petitioners only take issue with approval of the use of chemical dust suppressant with frequent watering. *See* Opening Br. at 33. Notably, Petitioners do not suggest that this control measure is not "reasonably available."[16] Instead, Petitioners claim that DEQ failed to thoroughly analyze the operational feasibility, economic costs, and environmental impacts of these control measures. *Id*. at 32-33.

Petitioners myopically focus on Section 210.12.c and .d, which set forth the factors DEQ is to consider when determining whether a control technology is reasonably available. Under Section 210.12, the operational feasibility and environmental impacts of a control technology are to be considered when determining whether a control technology is technologically feasible. IDAPA 58.01.01.210.12.c. The economic costs are considered when determining whether the

[15] Permit No. P-2010.0111 (effective Oct. 20, 2010), Permit No. P-2009.0135 (effective Jan. 6, 2011), P-2013.0014 (effective May 28, 2014), Permit No. P-2012.0012 (effective Dec. 18, 2014), Permit No. P-2016.0025 (effective Sept. 12, 2016), Permit No. P-2013.0046 (effective Jan. 12, 2018), Permit No. P-2013.0051 (effective Mar. 8, 2018).

[16] Petitioners recognize that chemical dust suppressant and watering are well established control measures for fugitive dust from haul roads. Amended Pet. ¶ 38 (citing AP-42 Ch. 13.2.2).

control technology is economically feasible. IDAPA 58.01.01.210.12.d.[17] Nothing in Section 210.12 requires DEQ to reevaluate the technological and economic feasibility of established control measures. Section 210.14.b states that DEQ "shall review the information submitted by the applicant and determine whether the applicant has proposed T-RACT." It does not say that DEQ shall reevaluate the technological and economic feasibility of a proposed control technology, especially one required by the Idaho Air Rules, each time that control technology is proposed. Instead, the factors listed in Section 210.12.b. and c. are to be used by DEQ if it determines in its discretion, that a technological and economic feasibility analysis is required.

As discussed above, chemical dust suppressant and watering are required by the Idaho Air Rules and have long been recognized by both the EPA and DEQ as technologically feasible and reasonably available control technologies. No additional analysis was required for DEQ to rationally determine that, consistent with the Idaho Air Rules, the use of chemical dust suppressants and watering are technologically feasible and reasonably available control technologies.

Petitioners' reliance on *Sierra Club v. U.S. EPA,* 972 F.3d 290 (3d Cir. 2020), is misplaced. *See* Opening Br. at 33. In *Sierra Club*, the Third Circuit was considering whether EPA erred in approving Pennsylvania's SIP, and standards that governed emissions from coal-burning power plants. 972 F.3d at 300. This case only involved a challenge to a SIP under the CAA. It did not involve a challenge to an individual permit. Despite stating that the determination of whether a control measure as RACT required an economic and technological

[17] Typically, these factors are used to evaluate whether a more effective control technology an applicant describes as not reasonably available is actually technologically and economically feasible for the particular application.

feasibility analysis, *id.* at 295, the court never suggested that once RACT was adopted in the SIP it would have to be reevaluated on a facility-by-facility basis.

Petitioners also argue that DEQ was required to conduct an economic analysis to support Perpetua's determination that paving was not a reasonably available control technology. Opening Br. at 34. Not so. As previously explained, for a control technology to be reasonably available, it must be both technologically feasible *and* economically feasible. IDAPA 58.01.01.007.12. Perpetua determined, and DEQ agreed, that paving is not technologically feasible, because the loaded weight of haul trucks would exceed the capacity of paved roads and the haul roads are relocated frequently as mining progresses. PET 547. Therefore no determination needed to be made as to its economic feasibility.

The Air Rules vest DEQ with discretion to determine whether a control measure is T-RACT. Nothing in Section 210.14 requires DEQ to reevaluate a long-established control measure each time that measure is proposed as T-RACT.

VIII. DEQ reasonably exercised its discretion in evaluating the health risks from arsenic (Claim 9).

Petitioners allege that nothing in the Idaho Air Rules allows DEQ to conduct the refined TAPs analysis for demonstrating preconstruction compliance with the Idaho Air Rules.[18] Petitioners fixate on the TAP Carcinogenic Increments in Section 586, while ignoring the rest of Sections 203 and 210. The Idaho Air Rules vest DEQ with discretion to determine the method by which the applicant demonstrates preconstruction compliance for TAPs. *See* IDAPA 58.01.01.203.03, .210. In this case, DEQ rationally exercised its discretion to determine that the

[18] Despite three pages of briefing dedicated to this claim, Petitioners never state their legal theory entitling them to relief. *See* Opening Br. at 34-37. The heading of Section VI suggests that Petitioners believe that DEQ's TAPs analysis violated the Idaho Air Rules, but this is never explained in the body of the brief, nor in the Amended Petition.

arsenic emissions from the Project would not injure or unreasonably affect human or animal life or vegetation, as required by IDAPA 58.01.01.161.

Rule 161 provides that:

> Any contaminant that is by its nature toxic to human or animal life or vegetation must not be emitted in such quantities or concentrations as to alone, or in combination with other contaminants, injure or unreasonably affect human or animal life or vegetation.

Under Rule 203.03, the applicant must show "*to the satisfaction of the Department*" that:

> using the methods provided in Section 210, the emissions of toxic air pollutants from the stationary source or modification would not injure or unreasonably affect human or animal life or vegetation as required by Section 161. Compliance with all applicable toxic air pollutant carcinogenic increments and toxic air pollutant non-carcinogenic increments demonstrates preconstruction compliance with Section 161 with regards to the pollutants listed in Sections 585 and 586.

(Emphasis added.)

Under Section 210.04,

> The applicant *may* use any of the Department approved standard methods described in Subsections 210.05 through 210.08, and may use any applicable specialized method described in Subsections 210.09 through 210.12 to demonstrate preconstruction compliance for each identified toxic air pollutant.

(Emphasis added).

When demonstrating compliance using T-RACT under Section 210.12, as Perpetua did here, DEQ is directed to compare the source's

> approved T-RACT ambient concentration at the point of compliance for the toxic air pollutant to the amount of toxic air pollutant that would contribute an ambient air cancer risk probability of less than one to one hundred thousand (1:100,000) (which amount is equivalent to ten (10) times the applicable acceptable ambient concentration listed in Section 586).

IDAPA 58.01.01.210.12.b.

Section 210.12 gives DEQ discretion to determine the method by which an applicant demonstrates preconstruction compliance for carcinogenic TAPs. Petitioners focus only on the AACC under Section 586, instead of the language of Section 210.12. Under Section 210.12, DEQ is to determine whether ambient concentrations of a carcinogenic TAP create an unacceptable cancer risk, not whether the maximum annual TAP concentration is below the AACC.

Arsenic is a carcinogen, and the concerns for health impacts from arsenic exposure are from a long-term exposure basis. *See* PET 332. To reflect the long-term health impacts, the carcinogenic increments reflected in Section 586 are based on a 70-year lifetime exposure. *See* IDAPA 58.01.01.006.125; PET 597. While the AACC are stated in annual averages, these values were developed to be protective where a facility emits at the level reflected in the AACC over the entire 70-year exposure period. *See* PET 597; IDAPA 58.01.01.006.125. In other words, when adjusted for T-RACT, the concentration established by the AACC assumes that if 100,000 people spend a lifetime (24 hours per day, every day, for 70 years) at the maximum receptor point, one person "may" develop cancer.

Here, the Project will operate, and potentially generate arsenic emissions, for only 16 years. PET 332. Thus, there will be no arsenic generating activity at the Project after year 16. To account for the actual operational period, DEQ determined whether arsenic emissions would contribute less than a one in one hundred thousand cancer risk over a 70-year exposure period, as required by Section 210.12. PET 069, PET 353. Conservatively, DEQ took the highest annual modeled concentration of arsenic and assumed that that concentration would be repeated for each year of operations, 16 years. PET 344. DEQ then averaged this exposure across 70 years, which

is the lifetime exposure required to be evaluated by the Air Rules. PET 344, 597. DEQ then compared the lifetime arsenic exposure from the Project, on an annual basis, to the AACC for arsenic, as provided in Section 586, and determined that the maximum lifetime exposure would be approximately 41% of the AACC. PET 348. By conducting this analysis, DEQ normalized the arsenic emissions from the Project to accurately reflect lifetime exposure risk reflected in the AACC.

Petitioners argue that the Idaho Air Rules only allow DEQ to consider whether the annual maximum concentration of arsenic in any year will exceed the AACC listed in Section 586. Petitioners focus on the AACCs without discussing Section 210.12. As explained, the AACCs are based on and assume a full 70-year exposure to the pollutant concentration reflected in the AACC. Section 210.12 does not require DEQ to find that the maximum annual concentration in any year will not exceed the AACC. Instead, DEQ must determine whether the emissions from the Project would contribute an ambient air cancer risk probability of less than one to one hundred thousand. IDAPA 58.01.01.210.12. That is exactly what DEQ did here. It evaluated the maximum modeled arsenic emissions from the Project during the operational period and then evaluated whether that would exceed the AACC over 70 years, demonstrating that the cancer risk was less than one in one hundred thousand. PET 348.

Petitioners attempt to rely on two internal DEQ memoranda to call into question the approach taken by Perpetua and DEQ. Opening Br. at 35-36. Petitioners suggest that these memoranda call into question the approach DEQ ultimately determined was appropriate to evaluate TAPs compliance for the Project. *Id.* These memoranda appear to have been written shortly after Perpetua submitted its TAP Addendum and before DEQ had thoroughly reviewed the Addendum and the modeling underlying the Addendum. *See* PET 817-824, 825-830. These

memoranda demonstrate that DEQ conducted a thorough and searching review of Perpetua's TAP Addendum, modeling, and proposed T-RACT control measures. Later correspondence from DEQ to Ian von Lindern further confirms that DEQ conducted a thorough review of Perpetua's TAP Addendum, modeling, and control measures and assured itself that Perpetua had demonstrated preconstruction compliance for arsenic emissions. PRI 807-811.

DEQ's thorough review of Perpetua's potential arsenic emissions is also confirmed by DEQ's repeated requests for additional information related to TAPs emissions from the Project. *See* PET 53-54; PRI 586. At DEQ's request, Perpetua prepared a TAP Addendum that analyzed TAP emissions using T-RACT controls, production limits,[19] and emission inventory refinements. PRI 604. Also, at DEQ's request, Perpetua conducted an arsenic modeling analysis comparing the worst-case modeling analysis, used to determine preconstruction compliance, and an assessment of the actual arsenic concentrations expected from the actual mining operations. PRI 609. The arsenic emissions produced from the actual operating analysis are only 19% of the worst-case scenario. PRI 610.

Petitioners' reliance on EPA's comments to the U.S. Forest Service fares no better. *See* Opening Br. at 37 (citing PET 667). EPA's comments are irrelevant in determining whether DEQ correctly interpreted the Idaho Air Rules and acted within its discretion. First, the CAA covers implementation only of federal standards promulgated under the CAA for hazardous air pollutants and does not require states to develop or implement ambient air concentrations for state identified toxic air pollutants. *See* PET 274. EPA has no authority nor ability to determine

[19] DEQ set the life-of-mine hauling and excavating limit at 788.4 million tons of ore and development rock. Whether this amount is mined in 16-years, the life of the mine, or 70 years, the lifetime exposure period, the total arsenic emissions will be the same, they would just be spread out over more time. Thus, the total arsenic exposure to public receptors will be the same irrespective of how long the mine is in operation.

whether DEQ appropriately interpreted the Idaho Air Rules. Second, EPA did not comment on DEQ's TAPs analysis in its comments to DEQ. Irrespective of what EPA told the Forest Service, if it believed that DEQ's TAPs analysis was somehow deficient, EPA should have addressed this issue with DEQ. Finally, nothing in EPA's comments to the Forest Service suggest that DEQ failed to comply with the Idaho Air Rules.

As described in the Statement of Basis, the TAP Addendum Modeling Review Attachment, and the TAP Addendum, DEQ used a conservative approach to evaluate arsenic emissions that ensured public health and the environment would be adequately protected. This approach is entirely consistent with the Idaho Air Rules and well within DEQ's discretion. Petitioners have not demonstrated that DEQ acted contrary to the Idaho Air Rules or abused its discretion, and their claim should be dismissed.

CONCLUSION

The Board should deny Petitioners' motion for summary judgment and instead grant Perpetua's motion for summary judgment as a matter of law.

DATED: May 12, 2023.

DEC 19 1980

Honorable Jennings Randolph
Chairman, Committee on Environment
and Public Works
United States Senate
Washington, D.C. 20510

Dear Mr. Chairman:

Thank you for your letter of October 23, 1980 expressing your continued interest in the Agency's definition of "ambient air." During the time Since David Hawkins, my Assistant Administrator of Air, Noise, and Radiation, met with you last February, the definition has been extensively reviewed and debated.

After reviewing the issues and alternatives, I have determined that no change from the existing policy is necessary. We are retaining the policy that the exemption from ambient air is available only for the atmosphere over land owned or controlled by the source and to which public access is precluded by a fence or other physical barriers. EPA will continue to review individual situations on a case-by-case basis to ensure that the public is adequately protected and that there is no attempt by sources to circumvent the requirement of Section 123 of the Clean Air Act.

I hope that this has been responsive to your needs,

Sincerely yours,

/s/ Douglas M. Costle

TECHNICAL MEMORANDUM

UNPAVED ROAD DUST CONTROL EFFICIENCY FROM CHEMICAL SUPPRESSANTS

PREPARED FOR: Dale Kerner, Midas Gold Idaho, Inc.

PREPARED BY: Kevin Lewis, Air Sciences Inc.

PROJECT NO.: 335-1-1

DATE: January 12, 2018

This memorandum summarizes the review conducted by Air Sciences Inc. (Air Sciences) of AP-42, Section 13.2.2, Unpaved Roads (EPA 2006), with regard to the level of dust control afforded by the application of chemical dust suppressants to unpaved industrial roads. The review includes an examination of all the test studies referenced in Section 13.2.2 that include data pertaining to chemical dust suppressants.

The review concludes that the Section 13.2.2 test studies support the use of a 90 percent or greater control efficiency in estimating dust generation from unpaved roads where chemical dust suppressants will be applied. A summary of the Section 13.2.2 test studies is provided in Table 1. As shown by this table, the dust control efficiency from chemical dust suppressants ranges from 82 to 97 percent (average of 91 percent) for total suspended particulate (TSP), and 90 to 99 percent (average of 94 percent) for PM_{10}.

Several of the Section 13.2.2 test studies reported that the control efficiency of chemical dust suppressant application decreases with time, the number of vehicle passes, road maintenance, and/or weather conditions. Therefore, a Fugitive Dust Control Plan (FDCP) is recommended to maintain a dust control efficiency of 90 percent or greater from the periodic application of chemical dust suppressants.

PRI00000002

REC 1342

Table 1. Control Efficiencies from Chemical Dust Suppressant Application to Unpaved Roads

Study	TSP Control Efficiency	PM_{10} Control Efficiency	Comments
MRI and RTI 2005	87%	90%	The performance of a dust suppressant product on unpaved roads was evaluated over a one-year period based on tests conducted by Research Triangle Institute International (RTII) and the Midwest Research Institute (MRI). The report was verified by the Environmental Protection Agency's (EPA's) Environmental Technology Verification Program. The control efficiencies provided here are from the Maricopa County (MC) location test.[1]
CARB 2000	ND[2]	92%	A dust suppressant product composed of petroleum resins, water, emulsifiers, surfactants, and vacuum residuum was evaluated by the California Air Resources Board (CARB). The evaluation was based on tests conducted by MRI at 11, 12, 26, and 28 days after the second application of the dust suppressant on an unpaved road. The initial control efficiency was 99 percent, which dropped to 85 percent after 28 days and 7,000 vehicle passes (average of 92 percent).
DRI 1996	ND	99%	The petroleum emulsion and polymer mixture chemical dust suppressants studied by the Desert Research Institute (DRI) showed a control efficiency of 99 percent four to ten days after application on unpaved roads/shoulders.
		94%	The polymer emulsions chemical dust suppressants studied by DRI showed a control efficiency of 94 percent four to ten days after application on unpaved roads/shoulders.

[1] See Table 3, page iv of the verification statement (MRI and RTII 2005) for the MC location test results. The Fort Leonard Wood (FLW) location test results in this table (MRI and RTII 2005) were biased low by rain events.

[2] ND = No Data

Table 1. Control Efficiencies from Chemical Dust Suppressant Application to Unpaved Roads

Study	TSP Control Efficiency	PM_{10} Control Efficiency	Comments
		92%	The non-hazardous crude-oil-containing materials (NHCOCM) chemical dust suppressants studied by DRI showed a control efficiency of 92 percent eight months after application on unpaved roads/shoulders.[3]
EPA 1987	90%	93%	The calcium chloride ($CaCl_2$) chemical dust suppressants studied by MRI showed an average control efficiency of 90 percent for TSP and 93 percent for PM_{10} on unpaved roads across the two sites tested. The study reported that without chemical reapplication, the control efficiency would decrease over time.
	85%	90%	The petroleum resins, an emulsified asphalt, and an acrylic adhesive chemical dust suppressants studied by MRI showed an average control efficiency of 85 percent for TSP and 90 percent for PM_{10} on unpaved roads across the two sites tested. The study reported that without chemical reapplication, the control efficiency decreased over time.
MRI 1983a	94%	97%	This MRI study measured the long-term control effectiveness of petroleum resin application on unpaved roads. The control efficiencies shown here represent the test data after reapplication. The control efficiency after initial application was lower. The study reported that without chemical reapplication, the control efficiency decreased over time and with vehicle passes.
	82%	93%	This MRI study measured the long-term control effectiveness of emulsified asphalt application on unpaved roads. The study reported that without chemical reapplication, the control efficiency decreased over time and with vehicle passes.

[3] The fourth chemical studied was a biocatalyst product. This chemical was shown to be "ineffective in reducing PM_{10} emissions" (DRI 1996). Test results for this product showed a negative control efficiency after initial product application (for one of the six tests) and a negative control efficiency three to eleven months after product application (for all tests averaged) (DRI 1996).

PRI00000004

REC 1344

Table 1. Control Efficiencies from Chemical Dust Suppressant Application to Unpaved Roads

Study	TSP Control Efficiency	PM_{10} Control Efficiency	Comments
MRI 1983b	96% – 97%	95%	Control efficiencies for this MRI study were measured after the application of petroleum resins on unpaved roads. The study reported that without chemical reapplication, the control efficiency would decrease over time and with vehicle passes.
PEDCo and MRI 1981	95%	95%	This study by PEDCo Environmental, Inc. (PEDCo) and MRI indicated that 95 percent control efficiency was attained after three months following the application of $CaCl_2$ and subsequent watering on an unpaved access road.
EPA 1979	97%	ND	For this EPA report, initial control efficiency after application of petroleum resins on unpaved roads was 97 percent for TSP, which decreased with vehicle passes.
MRI 1979	88%	ND	Three tests of the application of lignin sulfate on unpaved roads showed TSP control efficiencies of 83 percent, 89 percent, and 91 percent (average of 88 percent).
Average	**91%**	**94%**	Average of all studies.

EPA AP-42, Section 13.2.2

The most commonly used resource in the United States for estimating uncontrolled particulate emissions from unpaved industrial roads is AP-42, Section 13.2.2, Unpaved Roads (EPA 2006). This document provides an equation (Equation 1a) for calculating uncontrolled particulate emissions (all size fractions) from unpaved industrial roads, such as haul roads at a mine site, based on site-specific conditions. This document also provides some general, but limited, information on control efficiency values, which can be applied to the uncontrolled particulate emissions equation to estimate the reduction in particulate emissions when utilizing chemical dust suppressants or water to manage road dust. For chemical dust suppressants, Section 13.2.2 provides the following general information:

1. "The control effectiveness of chemical dust suppressants appears to depend on (a) the dilution rate used in the mixture; (b) the application rate (volume of solution per unit road surface area); (c) the time between applications; (d) the size, speed and amount of

traffic during the period between applications; and (e) meteorological conditions (rainfall, freeze/thaw cycles, etc.) during the period. Other factors that affect the performance of dust suppressants include other traffic characteristics (e. g., cornering, track-on from unpaved areas) and road characteristics (e. g., bearing strength, grade). The variabilities in the above factors and differences between individual dust control products make the control efficiencies of chemical dust suppressants difficult to estimate. Past field testing of emissions from controlled unpaved roads has shown that chemical dust suppressants provide a PM-10 control efficiency of ***about*** *[Emphasis added]* 80 percent when applied at regular intervals of 2 weeks to 1 month" (EPA 2006).

2. Figure 13.2.2-5 shows maximum control efficiencies for total particulate and PM_{10} of 81 percent and 90 percent, respectively, from the application of petroleum resins (EPA 2006).

With regard to Item 1 above, in which EPA states a control efficiency of "about 80 percent," EPA does not provide a reference for this value or the chemical type. Nonetheless, the test studies referenced in Section 13.2.2[4] demonstrate that control efficiencies of greater than 90 percent are achievable.

With regard to Item 2 above, the document referenced for Figure 13.2.2-5 is the 1987 report prepared by MRI for the EPA (EPA 1987). As shown in Table 1 for EPA 1987, the control efficiencies provided in this study are 85 to 90 percent for TSP and 90 to 93 percent for PM_{10}. It appears that Figure 13.2.2-5 generally depicts a conservative graphical representation of the underlining empirical data.

In summary, the limited general information on control efficiency provided in Section 13.2.2 appears to be an overly conservative low approximation of the control effectiveness afforded by chemical dust suppressant application. An examination of the Section 13.2.2 test studies summarized in Table 1 shows that the control efficiency range for chemical dust suppressants is 82 to 97 percent (average of 91 percent) for TSP, and 90 to 99 percent (average of 94 percent) for PM_{10}.

Third-Party Expert Review

Greg Muleski of SACI LLC has reviewed Air Sciences' analysis of chemical dust suppressant control efficiency. Mr. Muleski's review concluded the following:

[4] The Section 13.2.2 test studies are summarized in Table 1.

PRI00000006

REC 1346

> *I agree with the assertion that "... studies support a 90 percent or greater control efficiency for chemical dust suppressants."* (SACI 2015)[5]

Mr. Muleski has conducted over a 1,000 fugitive dust tests during his years at MRIGlobal. He conducted the field programs in the early 1980s through the early 2000s to characterize controlled and uncontrolled particulate emissions from unpaved industrial roads, which were used by EPA to develop AP-42, Section 13.2.2.

Recommendation

Based on the AP-42, Section 13.2.2 test studies described above, Air Sciences recommends the following approach for estimating particulate emissions from unpaved industrial roads that are controlled by the periodic application of chemical dust suppressants in accordance with a site-specific FDCP:

1. Use AP-42, Section 13.2.2, Equation 1a to estimate uncontrolled particulate emissions.

2. Use a control factor of 90 to 95 percent to estimate controlled particulate emissions from the application of chemical dust suppressants.

3. The application of water to supplement chemical dust suppressants will provide additional dust control. Although this memorandum does not provide a numerical value for the increased control level, using a control factor of 90 to 95 percent for the periodic application of both water and chemical dust suppressants is conservative (i.e., potentially overestimating dust emissions).

Subject: RE: Ambient Air question

Kevin, a quick update … I am continuing the investigation and hope to hear back from OAQPS soon:

I have not heard back from OAQPS yet, but have had brief discussion with Dave Bray here at R10. This is our understanding so far, but we need to confirm these points with OAQPS: If public access occurs at any time at a location, then it is considered ambient air all the time. Therefore, ambient air receptors must be modeled all hours of the year – the modeler cannot turn off receptors in periods when public access is not allowed.

Regarding State minor programs though, I assume the Federal definition of ambient air applies to all approved SIP minor air permitting programs also, but may be wrong. I'll discuss this element with Dave (cc'd).

Note, I have more specific questions regarding the Midas Stibnite project included in my request to OAQPS. Region 10 believes the following applies, but we need to confirm these with the policy division:

a. If the public access road is only accessible to public traveling in automobiles under the escort, supervision, and monitoring of Midas personnel (they mentioned a pilot car as a possibility), and there are no stopping points with public access along the road, then the road is not ambient air.
b. If the public is not under the supervision and monitoring of Midas while accessing the road then the road is ambient air. Also, if the road is not entirely fenced or access precluded by another method, then the entire unfenced/un-precluded Midas property may possibly be considered ambient air.

Thank you,
Jay

Thank you very much Jay. I know my question mainly regards minor source permitting, but I really don't see why there should be a difference between minor source permitting and PSD in this instance - there are no differences in applicable rules or definitions in the rules.

Subject: Ambient Air question

Good afternoon Jay,

I have another question I would appreciate your thoughts on. I am somewhat unsure of some fine points on how to treat ambient air with regard to areas that only have infrequent periods of public access. In the past, for minor source permitting, DEQ would allow applicants to exclude time periods during which public access was precluded. In other words, if public access was only allowed during the day, then we would exclude night-time hours from the analyses. Is this practice acceptable? Are there any examples where this has been addressed? Also, if this practice isn't acceptable for PSD applications, do you see EPA having an issue with Idaho using it for minor source permitting? Would a better approach be to consider the access as controlled site visitation (not ambient air at all) rather than public access?

Thank you,

Kevin Schilling

Subject: RE: Excluding roadways from consideration as ambient air.

Kevin,

I apologize, I missed this email earlier this week. My understanding is the road is likely exempt from ambient air protections because it is fully under the control and surveillance of the source and unsupervised public access is precluded. It seems like a slam dunk, based on my understanding of EPA's revised ambient air policy. This is my opinion based on interpretation of the policy, though … I cannot provide an approval.

If Idaho concludes the decision still falls with a 'gray area,' a formal request to the EPA can be provided and I can assist with getting the request to the ambient air review team (a part of the headquarters OAQPS air policy group).

Feel free to give me a call if you have questions or with to discuss more,
Jay

Subject: Excluding roadways from consideration as ambient air.

Hi Jay,

I hope things are going as smoothly as possible with you these days.

What are your thoughts on excluding a roadway that bisects a permitted facility from consideration as ambient air? During a NACCA call discussion on the recent changes in ambient air policy, there seemed to be some flexibility in how roadways could be considered. The case I'm most interested in involves a roadway that the permittee can legally control access, and access through the facility would not be a necessity for people (not needed to access homes, work, essential resources, etc - it would be used primarily to access a recreational area). My thoughts were that the area could be excluded from ambient air by considering those using the roadway as guests of the industry. This would be accomplished by: 1) vehicles using the road would be escorted by the company through the area; 2) people wishing to use the road would be informed that they are considered as a guest of the facility while traveling through the area; 3) vehicles using the road would not be allowed to stop; 4) the facility would restrict use of the road during periods when high-emitting activities were performed that would likely cause high impacts to the roadway.

Thank you for any thoughts, suggestions, etc.

Best Regards,

Kevin

Subject: RE: SGP - ambient air determination?

Piper,

In New Source Review (NSR) permitting, the permit application must demonstrate that emissions from the project do not cause a NAAQS violation to areas considered as "Ambient Air." Idaho Air Rules Section 006 defines ambient air as "that portion of the atmosphere, external to buildings, to which the general public has access." Public roadways with unrestricted access that bisect industrial facilities have typically been considered as ambient air for all NAAQS, including long-term averaging period NAAQS. Although most of these areas are technically considered as ambient air, DEQ's primary concern for attaining a high confidence of NAAQS compliance is for areas outside of the site perimeter boundary. This is because the potential for ongoing exposure is considerably less on roadways bisecting facilities.

If a roadway is part of the land owned or leased by the permitted facility, then the exclusion from ambient air is more straight forward. Where the permittee has legal authority to control access, the governing question becomes who is considered as "general public." For example, guests of a facility are not considered as the "general public." The roadway bisecting the Stibnite Gold Project mine site is under the control of Midas Gold Idaho, Inc. (Midas) and is not a public roadway.

Midas has proposed allowing controlled roadway access through the Stibnite Gold Project site while still excluding the roadway from consideration as ambient air. The following will be considered/implemented to exclude the roadway from ambient air:

1) Midas has complete control over access to the roadway.
2) Access to the roadway through the site will be actively controlled using a manned gate.
3) Those requesting to travel through the area are considered as invitees of Midas rather than members of the general public.
4) DEQ will require Midas to prepare a Roadway Access Control Plan that will outline procedures to control access through the site on the roadway, assuring that those entering are considered facility guests rather than members of the general public. The Roadway Access Control Plan will be submitted to DEQ for comment and approval.

The final details of how public access through the site will be addressed is still in development and will be specified in the issued Permit to Construct and the Roadway Access Control Plan.

Please contact me if you have any questions regarding this ambient air consideration,

Best Regards,

Kevin

Subject: SGP - ambient air determination?

Hi Aaron – wondering if DEQ had finalized a call on whether the State would consider public traffic through active operational areas, as contemplated in DEIS Alternatives 2 and 4, to subject the mine site to NAAQS? If the call is public access within the mine site would not constitute ambient air, would that be unconditioned? Or would an exemption from NAAQS be dependent on any particular management of such public use (e.g. private vehicles being escorted through, etc.)? If DEQ has made any such determination, is there documentation that you could share? Thanks!

52	PCSP2	Portable Crushing and Screening Plant 2 (2 crushers (primary and secondary), 2 screens (primary and secondary), and 5 conveyor transfers)	Water Sprays/Moisture Carry-Over	2,000 ton/day, Aggregate
53	LSBM	Limestone Ball Mill	Baghouse (BH3)	1,130 ton/day, Limestone
54	LK	Parallel Flow Regenerative (PFR) Shaft Lime Kiln	Baghouse (BH4)	169 ton/day, 52,377 ton/yr, Lime
55	LCR	Lime Mill Crushing and associated transfers In and Out	Baghouse (BH5)	169 ton/day, 52,377 ton/yr, Lime
56	LSL	Pebble Lime Silo Loading via Bucket Elevator	Bin Vent Filter	169 ton/day, 52,377 ton/yr, Lime
57	LSU	Pebble Lime Silo discharge to Lime Slaker	Wet Scrubber (WS3)	169 ton/day, 52,377 ton/yr, Lime

* Types of controls used may include water sprays, enclosures, hoods, curtains, shrouds, movable and telescoping chutes, central duct collection systems, and the like.

Emissions Unit - General **Form EU0**
Revision 4
08/28/08

Please see instructions on page 2 before filling out the form.

IDENTIFICATION

1. Company Name:	2. Facility Name:	3. Facility ID No:
Midas Gold Idaho, Inc.	Stibnite Gold Project	
4. Brief Project Description:	Conventional open-pit mining and ore preparation and gold extraction processes.	

EMISSIONS UNIT (PROCESS) IDENTIFICATION & DESCRIPTION

5.	Emissions Unit (EU) Name:	LOADER TRANSFER OF ORE TO GRIZZLY
6.	EU ID Number:	OC1
7.	EU Type:	☒ New Source ☐ Unpermitted Existing Source ☐ Modification to a Permitted Source -- Previous Permit #: Date Issued:
8.	Manufacturer:	TBD
9.	Model:	TBD
10..	Maximum Capacity:	25,000 TON/DAY
11.	Date of Construction:	TBD
12.	Date of Modification (if any):	N/A
13.	Is this a Controlled Emission Unit?	☐ No ☒ Yes If Yes, complete the following section. If No, go to line 22.

EMISSIONS CONTROL EQUIPMENT

14. Control Equipment Name and ID:	Water Sprays		
15. Date of Installation:	TBD	16. Date of Modification (if any):	N/A
17. Manufacturer and Model Number:	TBD		
18. ID(s) of Emission Unit Controlled:	OC1		
19. Is operating schedule different than emission units(s) involved?	☐ Yes ☒ No		
20. Does the manufacturer guarantee the control efficiency of the control equipment?	☐ Yes ☒ No (If Yes, attach and label manufacturer guarantee)		

	Pollutant Controlled					
	PM	PM10	SO_2	NOx	VOC	CO
Control Efficiency	In EF	In EF				

21. If manufacturer's data is not available, attach a separate sheet of paper to provide the control equipment design specifications and performance data to support the above mentioned control efficiency. Control efficiency included in emission factors, AP42, Tab. 11.19.2-2, conveyor transfer, controlled

EMISSION UNIT OPERATING SCHEDULE (hours/day, hours/year, or other)

22.	Actual Operation:	8,760 HR/YR
23.	Maximum Operation:	8,760 HR/YR

REQUESTED LIMITS

24.	Are you requesting any permit limits?	☒ Yes ☐ No (If Yes, indicate all that apply below)
	☐ Operation Hour Limit(s):	
	☒ Production Limit(s):	25,000 TON/DAY, ORE
	☐ Material Usage Limit(s):	
	☐ Limits Based on Stack Testing:	Please attach all relevant stack testing summary reports
	☐ Other:	
25.	Rationale for Requesting the Limit(s):	ORE PROCESSING DESIGN RATE

Revision 4
08/28/08

Please see instructions on page 2 before filling out the form.

IDENTIFICATION

1. Company Name:	2. Facility Name:	3. Facility ID No:
Midas Gold Idaho, Inc.	Stibnite Gold Project	

4. Brief Project Description:	Conventional open-pit mining and ore preparation and gold extraction processes.

EMISSIONS UNIT (PROCESS) IDENTIFICATION & DESCRIPTION

5.	Emissions Unit (EU) Name:	SAG MILL FEED CONVEYOR TRANSFER TO SAG MILL
6.	EU ID Number:	OC11
7.	EU Type:	☒ New Source ☐ Unpermitted Existing Source ☐ Modification to a Permitted Source -- Previous Permit #: Date Issued:
8.	Manufacturer:	TBD
9.	Model:	TBD
10..	Maximum Capacity:	27,600 TON/DAY
11.	Date of Construction:	TBD
12.	Date of Modification (if any):	N/A
13.	Is this a Controlled Emission Unit?	☐ No ☒ Yes If Yes, complete the following section. If No, go to line 22.

EMISSIONS CONTROL EQUIPMENT

14. Control Equipment Name and ID:	ENCLOSURE		
15. Date of Installation:	TBD	16. Date of Modification (if any):	N/A
17. Manufacturer and Model Number:	TBD		
18. ID(s) of Emission Unit Controlled:	OC11		
19. Is operating schedule different than emission units(s) involved?	☐ Yes ☒ No		
20. Does the manufacturer guarantee the control efficiency of the control equipment?	☐ Yes ☒ No (If Yes, attach and label manufacturer guarantee)		

	Pollutant Controlled					
	PM	PM10	SO_2	NOx	VOC	CO
Control Efficiency	80%	80%				

21. If manufacturer's data is not available, attach a separate sheet of paper to provide the control equipment design specifications and performance data to support the above mentioned control efficiency. Control efficiency based on AP42, Chapter 13.2.4, reduction in EF due to wind speed

EMISSION UNIT OPERATING SCHEDULE (hours/day, hours/year, or other)

22.	Actual Operation:	8,760 HR/YR
23.	Maximum Operation:	8,760 HR/YR

REQUESTED LIMITS

24.	Are you requesting any permit limits?	☒ Yes ☐ No (If Yes, indicate all that apply below)
	☐ Operation Hour Limit(s):	
	☒ Production Limit(s):	27,600 TON/DAY, ORE
	☐ Material Usage Limit(s):	
	☐ Limits Based on Stack Testing:	Please attach all relevant stack testing summary reports

13.	Is this a Controlled Emission Unit?	☒ No ☐ Yes If Yes, complete the following section. If No, go to line 22.

EMISSIONS CONTROL EQUIPMENT

14. Control Equipment Name and ID:			
15. Date of Installation:		16. Date of Modification (if any):	
17. Manufacturer and Model Number:			
18. ID(s) of Emission Unit Controlled:			
19. Is operating schedule different than emission units(s) involved?	☐ Yes ☐ No		
20. Does the manufacturer guarantee the control efficiency of the control equipment?	☐ Yes ☐ No (If Yes, attach and label manufacturer guarantee)		

	Pollutant Controlled					
	PM	PM10	SO_2	NOx	VOC	CO
Control Efficiency						

21. If manufacturer's data is not available, attach a separate sheet of paper to provide the control equipment design specifications and performance data to support the above mentioned control efficiency.

EMISSION UNIT OPERATING SCHEDULE (hours/day, hours/year, or other)

22.	Actual Operation:	8,760 HR/YR
23.	Maximum Operation:	8,760 HR/YR

REQUESTED LIMITS

24.	Are you requesting any permit limits?	☒ Yes ☐ No (If Yes, indicate all that apply below)
	☐ Operation Hour Limit(s):	
	☒ Production Limit(s):	17,500 TON/YR, LIME
	☐ Material Usage Limit(s):	
	☐ Limits Based on Stack Testing:	Please attach all relevant stack testing summary reports
	☐ Other:	
25.	Rationale for Requesting the Limit(s):	BASED ON ORE PROCESSING DESIGN RATE

Emissions Unit - General **Form EU0**
Revision 4
08/28/08

Please see instructions on page 2 before filling out the form.

IDENTIFICATION

1. Company Name:	2. Facility Name:	3. Facility ID No:
Midas Gold Idaho, Inc.	Stibnite Gold Project	

4. Brief Project Description:	Conventional open-pit mining and ore preparation and gold extraction processes.

EMISSIONS UNIT (PROCESS) IDENTIFICATION & DESCRIPTION

5.	Emissions Unit (EU) Name:	PRILL SILOS LOADING (2 X 100 TON)
6.	EU ID Number:	PSL
7.	EU Type:	☒ New Source ☐ Unpermitted Existing Source ☐ Modification to a Permitted Source -- Previous Permit #: Date Issued:
8.	Manufacturer:	TBD
9.	Model:	TBD
10..	Maximum Capacity:	100 TON/HR, EACH
11.	Date of Construction:	TBD
12.	Date of Modification (if any):	N/A
13.	Is this a Controlled Emission Unit?	☒ No ☐ Yes If Yes, complete the following section. If No, go to line 22.

EMISSIONS CONTROL EQUIPMENT

14. Control Equipment Name and ID:			
15. Date of Installation:		16. Date of Modification (if any):	
17. Manufacturer and Model Number:			
18. ID(s) of Emission Unit Controlled:			
19. Is operating schedule different than emission units(s) involved?	☐ Yes ☐ No		
20. Does the manufacturer guarantee the control efficiency of the control equipment?	☐ Yes ☐ No (If Yes, attach and label manufacturer guarantee)		

	Pollutant Controlled					
	PM	PM10	SO_2	NOx	VOC	CO
Control Efficiency						

21. If manufacturer's data is not available, attach a separate sheet of paper to provide the control equipment design specifications and performance data to support the above mentioned control efficiency.

EMISSION UNIT OPERATING SCHEDULE (hours/day, hours/year, or other)

22.	Actual Operation:	8,760 HR/YR
23.	Maximum Operation:	8,760 HR/YR

REQUESTED LIMITS

24.	Are you requesting any permit limits?	☒ Yes ☐ No (If Yes, indicate all that apply below)
	☐ Operation Hour Limit(s):	
	☒ Production Limit(s):	7,300 TON/YR, TOTAL, PRILL
	☐ Material Usage Limit(s):	
	☐ Limits Based on Stack Testing:	Please attach all relevant stack testing summary reports
	☐ Other:	
25.	Rationale for Requesting the Limit(s):	BASED ON ORE MINING DESIGN RATE

Please see instructions on page 2 before filling out the form.

IDENTIFICATION

1. Company Name:	2. Facility Name:	3. Facility ID No:
Midas Gold Idaho, Inc.	Stibnite Gold Project	
4. Brief Project Description:	Conventional open-pit mining and ore preparation and gold extraction processes.	

EMISSIONS UNIT (PROCESS) IDENTIFICATION & DESCRIPTION

5.	Emissions Unit (EU) Name:	MINE SITE DIESEL TANK #3
6.	EU ID Number:	TD3
7.	EU Type:	☒ New Source ☐ Unpermitted Existing Source ☐ Modification to a Permitted Source -- Previous Permit #: Date Issued:
8.	Manufacturer:	TBD
9.	Model:	TBD
10..	Maximum Capacity:	25,000 GALLONS
11.	Date of Construction:	TBD
12.	Date of Modification (if any):	N/A
13.	Is this a Controlled Emission Unit?	☒ No ☐ Yes If Yes, complete the following section. If No, go to line 22.

EMISSIONS CONTROL EQUIPMENT

14. Control Equipment Name and ID:			
15. Date of Installation:		16. Date of Modification (if any):	
17. Manufacturer and Model Number:			
18. ID(s) of Emission Unit Controlled:			
19. Is operating schedule different than emission units(s) involved?	☐ Yes ☐ No		
20. Does the manufacturer guarantee the control efficiency of the control equipment?	☐ Yes ☐ No (If Yes, attach and label manufacturer guarantee)		

	Pollutant Controlled					
	PM	PM10	SO_2	NOx	VOC	CO
Control Efficiency						

21. If manufacturer's data is not available, attach a separate sheet of paper to provide the control equipment design specifications and performance data to support the above mentioned control efficiency.

EMISSION UNIT OPERATING SCHEDULE (hours/day, hours/year, or other)

22.	Actual Operation:	8,760 HR/YR
23.	Maximum Operation:	8,760 HR/YR

REQUESTED LIMITS

24.	Are you requesting any permit limits?	☒ Yes ☐ No (If Yes, indicate all that apply below)
	☐ Operation Hour Limit(s):	
	☐ Production Limit(s):	
	☒ Material Usage Limit(s):	725,000 GAL/YR, DIESEL
	☐ Limits Based on Stack Testing:	Please attach all relevant stack testing summary reports

1.4 Form EU1 – Emission Units Industrial IC Engine Information (4 forms)

Table 2 provides a list of the industrial internal combustion (IC) emission units. The actual manufacturer and model are to be determined. IC engine exhaust stack parameters used for the ambient impact assessment are provided on the forms. Emissions data for each unit can be found in the detailed emission inventory in the "Stibnite Gold Project Air Quality Modeling Report," Attachment A of this application. Supporting documentation can be found on the digital media provided with this application.

Table 2. Industrial IC Engines

Form #	Source ID	Description	Power Rating	Ignition Type	Fuel	Assumed Displacement
1	EDG1	Camp Emergency Generator (Mfr. Yr. >2007; diesel)	1,000 kW	Compression	Diesel	<10 liters/cylinder
2	EDG2	Plant Emergency Generator #1 (Mfr. Yr. >2007; diesel)	1,000 kW	Compression	Diesel	<10 liters/cylinder
3	EDG3	Plant Emergency Generator #2 (Mfr. Yr. >2007; diesel)	1,000 kW	Compression	Diesel	<10 liters/cylinder
4	EDFP	Mill Fire Pump (Mfr. Yr. >2009; diesel)	200 kW	Compression	Diesel	<10 liters/cylinder

Revision 9
10/23/13

Please see instructions on page 2 before filling out the form.

IDENTIFICATION

1. Company Name	2. Facility Name:
Midas Gold Idaho, Inc.	Stibnite Gold Project

3. Brief Project Description:	Conventional open-pit mining and onsite ore preparation and gold extraction processes. This form is for: Source ID: EDG1, Camp Emergency Generator (1,000 kW)

IC ENGINE DESCRIPTION AND SPECIFICATIONS

4. Type of unit:

- ☒ New unit ☐ Unpermitted existing unit ☐ Modification to an existing permitted unit? Permit number: _____
- ☐ Full-time operation (non-emergency standby use)?
- ☒ Emergency standby use only (operation limited to 100 hrs/yr for maintenance and testing and emergency use only)?
- ☐ Emergency fire pump use only?
- ☐ Stationary test cell/stand operation only (as defined in NSPS Subpart ZZZZ)?
- ☐ National security operation only (as defined in NSPS Subpart ZZZZ)?
- ☐ Institutional emergency standby IC engine (as defined in NSPS Subpart ZZZZ)?

IC ENGINE SPECIFICATIONS

Questions 5 through 15 apply to **all IC engines**.

5. IC Engine Manufacturer: TBD 6. Model: TBD 7. Date manufactured: After 2007 8. Model year: After 2007
9. Date of installation (if an existing IC engine): TBD 10. IC Engine cylinder displacement: < 10 liters per cylinder
11. Maximum rated horsepower (per the data plate/manufacturer specifications): 1,341 bhp
12. EPA Certification: Tier certification number TBD or ☐ None/not tier certified
13. Ignition type: ☐ Spark ☒ Compression
14. Fuel combusted in the IC engine? ☒ Distillate fuel oil ☐ Natural gas/LNG ☐ LPG/propane
    If distillate fuel oil (#1, #2, or a mixture) is used, what is the maximum sulfur content? ☒ 15 ppm (0.0015% by weight) ☐ 500 ppm (0.05% by weight)
15. IC engine exhaust stack parameters: Diameter 18 inches Height 7 feet Temperature 1,100 ºF Flow rate 10,328 acfm

IC ENGINE EMISSIONS PARAMETERS

Questions 16 through 27 apply to **full-time** non-Tier certified IC engines or Tier certified IC engines manufactured prior to July 11, 2005. If you are proposing a Tier certified IC engine manufactured on and after July 11, 2005 or an emergency standby IC engine do not answer questions 17 through 27.

16. Testing schedule (for emergency standby IC engines only): 24 hrs/day _____ hrs/mon _____ hrs/qtr 100 hrs/yr
17. Maximum daily operation: _____ hrs/day 18. Maximum annual operation: _____ hrs/yr **Note:** These operational limits will be placed in the permit.
19. Will CO emissions be limited to a specific ppmvd (i.e. 49 or 23 ppmvd)? ☐ Yes ☐ No 20. What will the CO emissions limit be? _____ ppmvd
21. Will CO emissions be reduced by 70% or more? ☐ Yes ☐ No
22. Will a CEMS (Continuous Emissions Monitoring System) be used to measure pollutants in the IC engine exhaust stream? ☐ Yes ☐ No
23. Will a CPMS (Continuous Parameters Monitoring System) be used to measure parameters of the IC engine exhaust stream? ☐ Yes ☐ No
24. Will the IC engine be equipped with an oxidation catalyst? ☐ Yes ☐ No
25. If applicable, will the oxidation catalyst be equipped with a temperature measurement system to ensure it is operating properly? ☐ Yes ☐ No
26. Will the IC engine be equipped with a diesel particulate filter? ☐ Yes ☐ No
27. If applicable, will the diesel particulate filter be equipped with a backpressure monitor that notifies the owner or operator when the high backpressure limit of the engine is approached? ☐ Yes ☐ No

1.5 Form EU2– Emissions Units Nonmetallic Mineral Processing Plant

This form requests information about equipment at a nonmetallic mineral processing plant, as defined in 40 CFR 60.671, that **generates fugitive emissions only**. Table 3 provides a list of the Stibnite Gold Project nonmetallic mineral processing plant fugitive emission sources.

In addition to form EU2, forms EU0 and BCE have been provided for the Limestone Ball Mill and associated baghouse (BH3) as part of this application.

Emissions data for each unit can be found in the detailed emission inventory in the "Stibnite Gold Project Air Quality Modeling Report," Attachment A of this application. Supporting documentation can be found on the digital media provided with this application.

Table 3. Nonmetallic Mineral Processing Plant Emission Units – Fugitive Emissions Only

Source ID	Description	Source Type	Control
LS1	Limestone transfer to Primary Crusher Hopper	Conveyor	None
LS2	Primary Crushing and Associated Transfers In and Out	Crusher	None

Emissions Units - Nonmetallic Mineral Processing Plant **Form EU2**
Revision 5
08/28/08

Please see instructions on page 3 before filling out the form.

This form requests information about equipment at a nonmetallic mineral processing plant, as defined in 40 CFR 60.671, that generates fugitive emissions only.

In addition, Form EU0 and appropriate control equipment forms should be used for each stack emission point from the same plant.

IDENTIFICATION		
1. Company Name:	2. Facility Name:	3. Facility ID No:
Midas Gold Idaho, Inc.	Stibnite Gold Project	
4. Brief Project Description:	Open-pit mining and onsite onsite ore preparation and gold extraction processes.	

EQUIPMENT (EMISSION UNIT) DESCRIPTION AND SPECIFICATIONS					
5. Equipment Description	6. Construction Date	7. Serial Number	8. Equipment ID Number (company's)	9. Rated Capacity	10. Emission Control Type
Transfer to Primary Crusher Hopper	TBD	TBD	LS1	1,130 ton/day	None
Primary Crusher	TBD	TBD	LS2	1,130 ton/day	None
Primary Screen	TBD	TBD	LS3	1,130 ton/day	None
Secondary Crusher	TBD	TBD	LS4	1,130 ton/day	None
Secondary Screen	TBD	TBD	LS5	1,130 ton/day	None
Transfer to Ball Mill Feed Bin	TBD	TBD	LS6	1,130 ton/day	None
Transfer to Ball Mill Feed Conveyor	TBD	TBD	LS7	1,130 ton/day	None
Ball Mill Feed transfer to Ball Mill	TBD	TBD	LS8	1,130 ton/day	None
Transfer to Kiln Feed Bin	TBD	TBD	LS9	267 ton/day	None
Transfer to Lime Kiln Feed Conveyor	TBD	TBD	LS10	267 ton/day	None
Fines Screen	TBD	TBD	LS11	267 ton/day	None
Kiln Feed transfer to PFR Shaft Lime Kiln	TBD	TBD	LS12	267 ton/day	None

OPERATING SCHEDULE (hours/day, or hours/week, or months/year, or other)					
11 Actual Operation	TBD				
12. Maximum Operation	24 hr/day, 8,760 hr/yr				

1.6 Form EU5 – Emissions Units Industrial Boiler Information (15 forms)

Table 4 provides a list of the industrial boiler emission units. The actual manufacturer and model are to be determined. Exhaust stack parameters used for the ambient impact assessment are provided on the forms. Emissions data for each unit can be found in the detailed emission inventory in the "Stibnite Gold Project Air Quality Modeling Report," Attachment A of this application. Supporting documentation can be found on the digital media provided with this application.

Table 4. Industrial Boiler Emission Units

Form #	Source ID	Description	MMBtu/hr	Fuel
1	Sb1	Sb Dryer	2.72	Propane
2	ACB	POX Boiler	17	Propane
3	CKB	Carbon Regeneration Kiln	2.255	Propane
4	PV	Propane Vaporizer	0.1	Propane
5	HS	Strip Circuit Solution Heater	5	Propane
6	H1M	Mine Air Heater #1	4	Propane
7	H2M	Mine Air Heater #2	4	Propane
8	HM	Mill HVAC Heaters	4 x 1.0	Propane
9	HAC	Autoclave HVAC Heater	0.25	Propane
10	HR	Refinery HVAC Heater	0.25	Propane
11	HA	Admin HVAC Heater	0.25	Propane
12	HMO	Mine Ops. HVAC Heaters	2 x 0.25	Propane
13	HTS	Truck Shop HVAC Heaters	2 x 1.0	Propane
14	HW	Warehouse HVAC Heaters	3 x 1.0	Propane
15	LKC	PFR Shaft Lime Kiln Combustion	22.0	Propane

1.7 Form CA – Carbon Adsorber (4 forms)

Table 5 provides a list of all emission units controlled by a carbon adsorber. The actual carbon adsorber information is to be determined along with operational parameters. Emissions data for each unit can be found in the detailed emission inventory in the "Stibnite Gold Project Air Quality Modeling Report," Attachment A of this application. Supporting documentation can be found on the digital media provided with this application.

Table 5. Sources Controlled by a Carbon Adsorber

Form #	Source ID	Description	Control
1	CKD	Carbon Regeneration Kiln (Drum)	Carbon Filter (CA1)
2	EW	Electrowinning Cells & Pregnant Solution Tank	Carbon Filter (CA2)
3	MR	Mercury Retort	Carbon Filter (CA3)
4	MF	Induction Melting Furnace	Carbon Filter (CA4)

Carbon Adsorber - **Form CA**
Revision 2
08/28/08

Please see instructions on page 3 before filling out the form.

IDENTIFICATION

1. Company Name:	Midas Gold Idaho, Inc.	2. Facility Name:	Stibnite Gold Project	3. Facility ID No.:	
4. Brief Project Description:	Conventional open-pit mining and ore preparation and gold extraction processes.				

CARBON ADSORBER INFORMATION

Equipment Description

5. Manufacturer:	TBD	6. Model Number:	TBD	7. Make:	TBD

8. Type	☐ Fixed regenerative beds ☐ Disposable/rechargeable canisters ☐ Traveling bed adsorbers/rotary concentrators ☐ Fluidized adsorbers	Number of beds: TBD Capacity of each bed: TBD pounds of adsorbent
9. Adsorbent Material	☒ Granulated activated carbon ☐ Zeolite, molecular sieve ☐ Synthetic adsorbent Trade name: ☐ Other:	Adsorbent capacity: TBD (pound of vapor/pound of carbon)
10. Dimensions	Adsorbent vessel diameter: TBD feet	Depth of carbon in bed: TBD feet

Waste Gas Stream Characteristics

11. Brief Description of Process	Carbon loaded with gold from the ore leaching process is stripped with a caustic solution. The stripped carbon must be periodically regenerated in the carbon regeneration kiln. The exhaust from the kiln drum passes through a carbon adsorption bed, where any mercury is adsorbed onto activated carbon before being emitted, through a stack, into the atmosphere. This form is for the Carbon Regeneration Kiln (drum), Carbon Filter CA1

12. Waste Gas Stream	Material: Mercury Check box if material is a hazardous air pollutant (HAP) ☒ ☐ ☐ ☐	**Flow rate scfm** **(standard conditions are 68 degrees F and 14.7 psia)** Minimum: TBD Average: Maximum: Average concentration ppmv:
	Are reactive organics present? (e.g., ketone, aldehydes) ☐ Yes ☒ No	Relative humidity: % Cycle time for adsorption: hour(s) Lower explosive limit of mixture: ppmv or % volume
	Is the adsorbent material regenerated on-site? ☐ Yes ☒ No Regeneration rate: lb/min	On-site regeneration by: ☐ Steam ☐ Air ☐ Inert gas ☐ Process gas Other: Cycle time for regeneration: hour(s)
13. Regeneration	N/A	
14. Instrumentation Data	Exhaust temperature will be measured at the carbon adsorber inlet per 63.11647(g).	
15. Operating Schedule	Normal: 24 hours/day 7 days/week 52 weeks/year Maximum: 24 hours/day 7 days/week 52 weeks/year

Equipment Description

5. Manufacturer:	TBD	6. Model Number:	TBD	7. Make:	TBD

8. Type	☐ Fixed regenerative beds ☐ Disposable/rechargeable canisters ☐ Traveling bed adsorbers/rotary concentrators ☐ Fluidized adsorbers	Number of beds: TBD Capacity of each bed: TBD pounds of adsorbent
9. Adsorbent Material	☒ Granulated activated carbon ☐ Zeolite, molecular sieve ☐ Synthetic adsorbent Trade name: ☐ Other:	Adsorbent capacity: TBD (pound of vapor/pound of carbon)
10. Dimensions	Adsorbent vessel diameter: TBD feet	Depth of carbon in bed: TBD feet

Waste Gas Stream Characteristics

11. Brief Description of Process	Carbon loaded with gold from the ore leaching process is stripped with a caustic solution. This gold-bearing solution is then sent to the electrowinning (EW) plating process. The EW cells remove the gold from the solution by plating it onto cathodes consisting of stainless-steel plates with steel wool. The EW cells exhaust passes through a carbon adsorption column, where any remaining vapor mercury is adsorbed onto activated carbon before being emitted, through a stack, into the atmosphere. This form is for the Electrowinning Cells & Pregnant Solution Tank, Carbon Filter CA2

10. Dimensions	Adsorbent vessel diameter: TBD feet	Depth of carbon in bed: TBD feet

Waste Gas Stream Characteristics

11. Brief Description of Process	The gold concentrate is loaded into the retort, where it is heated under vacuum to drive off the mercury. The retort exhaust passes through a shell and tube condenser to cool the exhaust and condense the vapor mercury into a liquid, which is collected by the mercury trap. The exhaust passes through a carbon adsorption column, where any remaining vapor mercury is adsorbed onto sulfur-impregnated activated carbon before being emitted, through a stack, into the atmosphere. This form is for the Mercury Retort, Carbon Filter CA3

10. Dimensions	Adsorbent vessel diameter: TBD feet	Depth of carbon in bed: TBD feet

Waste Gas Stream Characteristics

11. Brief Description of Process	After retorting, the gold concentrate is transferred to the electric induction melting furnace. Only retorted concentrate may be melted in the furnace. The exhaust passes through a carbon adsorption column, where any remaining vapor mercury is adsorbed onto activated carbon before being emitted, through a stack, into the atmosphere. This form is for the Induction Melting Furnace, Carbon Filter CA4.

1.8 Form BCE – Baghouses Control Equipment (14 forms)

Table 6 provides a list of all controls provided on a baghouse control form. This list includes both the baghouse controls and the bin vent filters located on silos for loading emissions. The noted references, along with the particulate matter emission concentrations can be found in the detailed emission inventory in the "Stibnite Gold Project Air Quality Modeling Report," Attachment A of this application. Supporting documentation can be found on the digital media provided with this application.

Table 6. Sources Controlled by a Baghouse

Form #	Source ID	Description	Control
1	Sb2	Sb Bagging	Baghouse (BH1)
2	MF	Induction Melting Furnace	Baghouse (BH2)
3	LSBM	Limestone Ball Mill	Baghouse (BH3)
4	LK	Parallel Flow Regenerative (PFR) Shaft Lime Kiln	Baghouse (BH4)

BAGHOUSE INFORMATION

4. Baghouse Manufacturer: TBD	5. Baghouse Model: TBD	6. Baghouse Equipment ID: BH1

7 (a). Baghouse particulate matter emission concentration. **Note: Provide information in 7(a)-(c) or answer question #8 below.**	0.017 gr/dscf	*Manufacturers typically provide guarantees in grains per dry standard cubic foot (gr/dscf). Provide a copy of the guarantee, or other documentation, with the application along with a description of the types of bags that must be used to achieve the emission concentration.* ***Emission concentrations less than 0.01 gr/dscf will receive additional scrutiny by DEQ and a source test of the baghouse may be required.*** *If a guarantee is not provided then you must document how you obtained the emission concentration. Without documentation the application is not complete.*
7 (b). Percentage PM_{10} Or Provide PM_{10} Emission Concentration	100 % _____ gr/dscf	*What percentage of the PM concentration listed in question #7(a) is PM_{10}. You must provide documentation as to how the percentage was determined (i.e per the baghouse manufacturer). Without documentation the application is not complete.*
7 (c). Baghouse flow rate	800 dscfm	*Provide the baghouse flow rate in dry standard cubic feet per minute. Actual cubic feet per minute may be given in lieu of dscfm* ***if it is documented*** *that moisture content is insignificant. You must provide documentation as to how this flow rate was determined (i.e. per the exhaust fan manufacturer, combustion evaluation, etc.). Without documentation the application is not complete.*
8. Baghouse particulate matter control efficiency. **Note: Not needed if section #7 is completed.**	_____ % PM control _____ % PM_{10} control	*Applicant's providing the control efficiency of the baghouse must provide control efficiency for both PM and PM_{10}. Provide a copy of the control efficiency documentation with the application. Documentation must include a description of the types of bags that must be used to achieve the control efficiency. Without documentation the application is not complete.*
9. Is the baghouse equipped with a bag leak detector?	☐ Yes ☒ No	*If a bag leak detector is installed provide documentation on the leak detector, including; how the leak detector functions and what level of the output signal indicates that a bag is leaking. Without documentation the application is not complete.*

7 (a). Baghouse particulate matter emission concentration. **Note: Provide information in 7(a)-(c) or answer question #8 below.**	0.01 gr/dscf	*Manufacturers typically provide guarantees in grains per dry standard cubic foot (gr/dscf). Provide a copy of the guarantee, or other documentation, with the application along with a description of the types of bags that must be used to achieve the emission concentration.* ***Emission concentrations less than 0.01 gr/dscf will receive additional scrutiny by DEQ and a source test of the baghouse may be required.*** *If a guarantee is not provided then you must document how you obtained the emission concentration. Without documentation the application is not complete.*
7 (b). Percentage PM_{10} Or Provide PM_{10} Emission Concentration	_____ % 0.003 gr/dscf	*What percentage of the PM concentration listed in question #7(a) is PM_{10}. You must provide documentation as to how the percentage was determined (i.e per the baghouse manufacturer). Without documentation the application is not complete.*
7 (c). Baghouse flow rate	1400 dscfm	*Provide the baghouse flow rate in dry standard cubic feet per minute. Actual cubic feet per minute may be given in lieu of dscfm* ***if it is documented*** *that moisture content is insignificant. You must provide documentation as to how this flow rate was determined (i.e. per the exhaust fan manufacturer, combustion evaluation, etc.). Without documentation the application is not complete.*
8. Baghouse particulate matter control efficiency. **Note: Not needed if section #7 is completed.**	_____ % PM control _____ % PM_{10} control	*Applicant's providing the control efficiency of the baghouse must provide control efficiency for both PM and PM_{10}. Provide a copy of the control efficiency documentation with the application. Documentation must include a description of the types of bags that must be used to achieve the control efficiency. Without documentation the application is not complete.*
9. Is the baghouse equipped with a bag leak detector?	☐ Yes ☒ No	*If a bag leak detector is installed provide documentation on the leak detector, including; how the leak detector functions and what level of the output signal indicates that a bag is leaking. Without documentation the application is not complete.*

1.9 Form SCE – Scrubbers Control Equipment (3 forms)

Table 7 provides a list of all emission units controlled by a wet scrubber. The actual scrubber types are to be determined along with operational parameters. Emissions data for each unit can be found in the detailed emission inventory found in the "Stibnite Gold Project Air Quality Modeling Report" found in Attachment A of this application. Supporting documentation can be found on the digital media provided with this application.

1.10 Forms EI – Emissions Inventory

The IDEQ facility wide potential to emit emission inventory tables for new source review (NSR) regulated pollutants (Table 8), hazardous air pollutants (HAP) (Table 9), and toxic air pollutants (TAP) (Table 10 and Table 11) are provided here. In addition, the ambient impact assessment emission inventory table is provided (Table 12).

The detailed emission inventory and full ambient impact assessment can be found in the "Stibnite Gold Project Air Quality Modeling Report," Attachment A of this application. Supporting documentation for the emission inventory can be found on the digital media provided with this application.

1.11 PP – Plot Plan

A scaled plot plan of the entire facility can be found here. Figure 1 shows the SGP mining operations with the haul roads and operations boundary. Figure 2 shows the SGP processing and refining area, Figure 3 shows the administration, warehouse and storage area, and Figure 4 shows the worker housing facility. Figures 2, 3 and 4 show the buildings and emission points with identification numbers. The building heights can be found on the Modeling Information – Buildings and Structures Form MI4. The location of the gasoline and diesel tanks is to be determined so these emission points are excluded from the figures.

1.13 Form FRA – Federal Regulation Applicability

Table 13 provides a list of federal regulations determined to be applicable to the Midas Gold – SGP. A detailed regulatory review has been provided for each regulation, with the exception of NESHAP, Subpart ZZZZ.[1] Additional details on the regulatory analysis can be found in Section 4.0 of this application.

Table 13. Applicable Federal Regulations

Regulation	Description
NSPS, Subpart LL 40 CFR §60.380	Standards of Performance for Metallic Mineral Processing Plants
NSPS, Subpart OOO 40 CFR §60.670	Standards of Performance for Nonmetallic Mineral Processing Plants
NSPS, Subpart IIII 40 CFR §60.4200	Standards of Performance for Stationary Compression Ignition Internal Combustion Engines
NESHAP, Subpart ZZZZ 40 CFR §63.6580	National Emissions Standards for Hazardous Air Pollutants for Stationary Reciprocating Internal Combustion Engines
NESHAP, Subpart CCCCCC 40 CFR §63.11110	National Emission Standards for Hazardous Air Pollutants for Source Category: Gasoline Dispensing Facilities
NESHAP, Subpart EEEEEEE 40 CFR §63.11640	National Emission Standards for Hazardous Air Pollutants: Gold Mine Ore Processing and Production Area Source Category

[1] As discussed in Section 4.0 of this application, for the proposed sources, compliance with NESHAP, Subpart ZZZZ is accomplished by complying with the requirements of NSPS, Subpart IIII. No further requirements under NESHAP apply.

In each box in the table below, CTRL+click on the blue underlined text for instructions and information.

IDENTIFICATION	
1. Company Name:	2. Facility Name:
Midas Gold Idaho, Inc.	Stibnite Gold Project
3. Brief Project Description:	Conventional open-pit mining and ore preparation and gold extraction processes.

APPLICABILITY DETERMINATION	
4. List all applicable subparts of the New Source Performance Standards (NSPS) (40 CFR part 60). List all non-applicable subparts of the NSPS which may appear to apply to the facility but do not. Examples of NSPS-affected emissions units include internal combustion engines, boilers, turbines, etc. Applicant must thoroughly review the list of affected emissions units.	List of all applicable subpart(s): 40 CFR 60.380, 40 CFR 60.670, 40 CFR 60.4200 List of all non-applicable subpart(s) which may appear to apply but do not: 40 CFR 60.40c, 40 CFR 60.340 ☐ Not Applicable
5. List applicable subpart(s) of the National Emission Standards for Hazardous Air Pollutants (NESHAPs) (40 CFR part 61 and 40 CFR part 63). List all non-applicable subparts of the NESHAP which may appear to apply to the facility but do not. Examples of affected emission units include solvent cleaning operations, industrial cooling towers, paint stripping and miscellaneous surface coating. Reference EPA's webpage on NESHAPs for more information.	List of all applicable subpart(s): 40 CFR 63.6580, 40 CFR 63.11110, 40 CFR List of all non-applicable subpart(s) which may appear to apply but do not: 40 CFR 63.7080 ☐ Not Applicable
6. For each subpart identified above, conduct a complete regulatory analysis using the instructions and referencing the example on the following pages. **Note**: Regulatory reviews must be submitted with sufficient detail so that DEQ can verify applicability and document in legal terms why the regulation does or does not apply. Regulatory reviews submitted with insufficient detail will be determined incomplete.	☒ A detailed regulatory review has been provided ☐ DEQ has already been provided a detailed regulatory review (please provide a reference)

IF YOU ARE UNSURE HOW TO ANSWER ANY OF THESE QUESTIONS, CALL THE AIR PERMIT HOTLINE AT 1-877-5PERMIT.

It is emphasized that it is the applicant's responsibility to satisfy all technical and regulatory requirements, and that DEQ will help the applicant understand those requirements prior to submittal of the application but that DEQ will not perform the required technical or regulatory analyses on the applicant's behalf.

NSPS, Subpart LL – Standards of Performance for Metallic Mineral Processing Plants

Subpart LL—Standards of Performance for Metallic Mineral Processing Plants

Contents

§60.380 Applicability and designation of affected facility.
§60.381 Definitions.
§60.382 Standard for particulate matter.
§60.383 Reconstruction.
§60.384 Monitoring of operations.
§60.385 Recordkeeping and reporting requirements.
§60.386 Test methods and procedures.

SOURCE: 49 FR 6464, Feb. 21, 1984, unless otherwise noted.

§60.380 Applicability and designation of affected facility.

(a) The provisions of this subpart are applicable to the following affected facilities in metallic mineral processing plants: ~~Each crusher and screen in open-pit mines;~~ each crusher, ~~screen, bucket elevator,~~ conveyor belt transfer point, ~~thermal dryer, product packaging station, storage bin, enclosed storage area, truck loading station,~~ truck unloading station, ~~railcar loading station, and railcar unloading station~~ at the mill ~~or concentrator with the following exceptions. All facilities located in underground mines are exempted from the provisions of this subpart. At uranium ore processing plants, all facilities subsequent to and including the beneficiation of uranium ore are exempted from the provisions of this subpart.~~

(b) An affected facility under paragraph (a) of this section that commences construction ~~or modification~~ after August 24, 1982, is subject to the requirements of this part.

Midas Gold is proposing to operate a metallic mineral processing plant at the Stibnite Gold Project, where they will operate a combination of equipment to produce gold and silver concentrates from ore. Therefore, the provisions of this subpart will be applicable per §60.380(a). The metallic mineral processing plant will include crushers, conveyor belt transfer points, and a truck unloading station. The proposed metallic mineral processing plant will be subject to the requirements of this subpart as it will commence construction after August 24, 1982, per §60.380(b).

§60.381 Definitions.

All terms used in this subpart, but not specifically defined in this section, shall have the meaning given them in the Act and in subpart A of this part.

~~*Bucket elevator* means a conveying device for metallic minerals consisting of a head and foot assembly that supports and drives an endless single or double strand chain or belt to which buckets are attached.~~

~~*Capture system* means the equipment used to capture and transport particulate matter generated by one or more affected facilities to a control device.~~

Control device means the air pollution control equipment used to reduce particulate matter emissions released to the atmosphere from one or more affected facilities at a metallic mineral processing plant.

Conveyor belt transfer point means a point in the conveying operation where the metallic mineral or metallic mineral concentrate is transferred to or from a conveyor belt except where the metallic mineral is being transferred to a stockpile.

Crusher means a machine used to crush any metallic mineral and includes feeders or conveyors located immediately below the crushing surfaces. Crushers include, but are not limited to, the following types: jaw, gyratory, cone, and hammermill.

~~*Enclosed storage area* means any area covered by a roof under which metallic minerals are stored prior to further processing or loading.~~

Metallic mineral concentrate means a material containing metallic compounds in concentrations higher than naturally occurring in ore but requiring additional processing if pure metal is to be isolated. A metallic mineral concentrate contains at least one of the following metals in any of its oxidation states and at a concentration that contributes to the concentrate's commercial value: ~~Aluminum, copper,~~ gold, ~~iron, lead, molybdenum~~, silver, ~~titanium, tungsten, uranium, zinc, and zirconium.~~ This definition shall not be construed as requiring that material containing metallic compounds be refined to a pure metal in order for the material to be considered a metallic mineral concentrate to be covered by the standards.

Metallic mineral processing plant means any combination of equipment that produces metallic mineral concentrates from ore. Metallic mineral processing commences with the mining of ore and includes all operations either up to and including the loading of wet or dry concentrates or solutions of metallic minerals for transfer to facilities at non-adjacent locations that will subsequently process metallic concentrates into purified metals (or other products), or up to and including all material transfer and storage operations that precede the operations that produce refined metals (or other products) from metallic mineral concentrates at facilities adjacent to the metallic mineral processing plant. This definition shall not be construed as requiring that mining of ore be conducted in order for the combination of equipment to be considered a metallic mineral processing plant. (See also the definition of *metallic mineral concentrate*.)

Process fugitive emissions means particulate matter emissions from an affected facility that are not collected by a capture system.

~~*Product packaging station* means the equipment used to fill containers with metallic compounds or metallic mineral concentrates.~~

~~*Railcar loading station* means that portion of a metallic mineral processing plant where metallic minerals or metallic mineral concentrates are loaded by a conveying system into railcars.~~

~~*Railcar unloading station* means that portion of a metallic mineral processing plant where metallic ore is unloaded from a railcar into a hopper, screen, or crusher.~~

~~*Screen* means a device for separating material according to size by passing undersize material through one or more mesh surfaces (screens) in series and retaining oversize material on the mesh surfaces (screens).~~

~~*Stack emissions* means the particulate matter captured and released to the atmosphere through a stack, chimney, or flue.~~

Storage bin means a facility for storage (including surge bins and hoppers) of metallic minerals prior to further processing or loading.

Surface moisture means water that is not chemically bound to a metallic mineral or metallic mineral concentrate.

~~*Thermal dryer* means a unit in which the surface moisture content of a metallic mineral or a metallic mineral concentrate is reduced by direct or indirect contact with a heated gas stream.~~

~~*Truck loading station* means that portion of a metallic mineral processing plant where metallic minerals or metallic mineral concentrates are loaded by a conveying system into trucks.~~

Truck unloading station means that portion of a metallic mineral processing plant where metallic ore is unloaded from a truck into a hopper, screen, or crusher.

[49 FR 6464, Feb. 21, 1984, as amended at 65 FR 61760, Oct. 17, 2000]

The highlighted definitions in §60.381 will apply to the Stibnite Gold Project affected facilities under this subpart.

§60.382 Standard for particulate matter.

~~(a) On and after the date on which the performance test required to be conducted by §60.8 is completed, no owner or operator subject to the provisions of this subpart shall cause to be discharged into the atmosphere from an affected facility any stack emissions that:~~

~~(1) Contain particulate matter in excess of 0.05 grams per dry standard cubic meter (0.05 g/dscm).~~

~~(2) Exhibit greater than 7 percent opacity, unless the stack emissions are discharged from an affected facility using a wet scrubbing emission control device.~~

(b) On and after the sixtieth day after achieving the maximum production rate at which the affected facility will be operated, but not later than 180 days after initial startup, no owner or operator subject to the provisions of this subpart shall cause to be discharged into the atmosphere from an affected facility any process fugitive emissions that exhibit greater than 10 percent opacity.

[49 FR 6464, Feb. 21, 1984, as amended at 65 FR 61760, Oct. 17, 2000; 79 FR 11250, Feb. 27, 2014]

§60.382(a) will not apply to the Stibnite Gold Project as it will not have any affected facilities subject to this subpart with stack emissions.

§60.382(b) will apply to the Stibnite Gold Project affected facilities subject to this subpart. The affected facilities' process fugitive emissions may not exhibit greater than 10 percent opacity.

§60.383 Reconstruction.

(a) The cost of replacement of ore-contact surfaces on processing equipment shall not be considered in calculating either the "fixed capital cost of the new components" or the "fixed capital cost that would be required to construct a comparable new facility" under §60.15. Ore-contact surfaces are: Crushing surfaces; screen meshes, bars, and plates; conveyor belts; elevator buckets; and pan feeders.

(b) Under §60.15, the "fixed capital cost of the new components" includes the fixed capital cost of all depreciable components (except components specified in paragraph (a) of this section) that are or will be replaced pursuant to all continuous programs of component replacement commenced within any 2-year period following August 24, 1982.

§60.383 will not apply as the Stibnite Gold Project affected facilities subject to this subpart are not being reconstructed.

§60.384 Monitoring of operations.

(a) The owner or operator subject to the provisions of this subpart shall install, calibrate, maintain, and operate a monitoring device for the continuous measurement of the change in pressure of the gas stream through the scrubber for any affected facility using a wet scrubbing emission control device. The monitoring device must be certified by the manufacturer to be accurate within ±250 pascals (±1 inch water) gauge pressure and must be calibrated on an annual basis in accordance with manufacturer's instructions.

(b) The owner or operator subject to the provisions of this subpart shall install, calibrate, maintain, and operate a monitoring device for the continuous measurement of the scrubbing liquid flow rate to a wet scrubber for any affected facility using any type of wet scrubbing emission control device. The monitoring device must be certified by the manufacturer to be accurate within ±5 percent of design scrubbing liquid flow rate and must be calibrated on at least an annual basis in accordance with manufacturer's instructions.

§60.384 will not apply as Midas Gold is not proposing to use a wet scrubbing emission control device on the affected facilities subject to this subpart.

§60.385 Recordkeeping and reporting requirements.
